About Wireless Personal Multimedia Communications (WPMC)

The Wireless Multimedia Personal Communications (WMPC) was inaugurated as a global platform which aims at enabling collaboration in the field of wireless information and multimedia communications. The Wireless Multimedia Personal Communications (WMPC) International Symposium was started way back in 1998, with about 200 participants and about accepted 100 papers. Thereafter, in four years span, the number of participants has reached and exceeded 400 and the number of papers more than 300 for each Symposium. In every WPMC International Symposium, high-quality technical sessions, workshops, tutorials as well as product exhibitions are organized. Since the first WPMC in YRP (Japan), seventeenth WPMCs were held through the world in Asia, Europe, North and South Americas.

In the year 2007, this event was held in Jaipur (India). The quality of the presentations is also very high. It is indisputable that WPMC has become one of the major international conferences in the field of wireless Communications. Some of the themes of earlier Symposia were (i) Communications, Networking and Applications for the Internet of Things, (ii) Autonomous Communication and Networking for Promoting Human Living, and (iii) Orchestrating Wireless Personal Multimedia Communications for Digital Services etc.

Every year is witnessing rapid change in the field of wireless communications with the development and deployment of new technologies and solutions in the field of wireless technologies. Every aspect of wireless communications right from physical layer, resource management including alternative methods of spectrum management, interference management, IoT & M2M, smart antenna, MIMO, multimedia QoS & traffic management, visible light communications, cloud computing, security & privacy, vehicular networks, radio propagation & channel modelling, cognitive radio & SDR, mobile multimedia & mobile TV, wellness & health care, ICT for energy efficiency etc. WPMC is becoming more and more important every year. Against such a backdrop, it was truly gratifying that the 18th International Symposium of WPMC was held in Hyderabad during December, 2015. This Symposium was supported by National Institute of Information and Communications Technology (Japan), and YRP (Japan).

About Global Wireless Summit

The Global Wireless Summit (GWS) had been conceptualized in bringing together wireless media communication/personal communication, etc. The First GWS was successfully held in Princeton (USA), in 2013, followed by the Second one in Aalborg (Denmark), in 2014. As has been the tradition for this Summit, it continues to feature a high-quality technical program across a wide range of research in the wireless communications and related areas. Under the theme "Democratizing Communications", the GWS-15 brought together academia, industry and standardization bodies working on green and secure communication. The conference explored activities, trends and future challenges towards ICT globalization including energy and security issues in existing and future wireless technologies. The Global Wireless Summit-15 presented high-level technical sessions; tutorials, and special sessions on advance topics; workshops; and panel discussions.

Under the theme of 'Democratizing Communications,' the 18th International Symposium on Wireless Personal Communications (WPMC), and the 3rd Global Wireless Summit (GWS) are jointly organized, encompassing the 5th International Conference on Wireless Communication, Vehicular Technology, Information Theory and Aerospace & Electronics Systems (WirelessVITAE), The 12th World Wide Security and Mobility Conference (WWSMC), and the 3rd International Conference on Communications, Convergence, Content and Cooperation (IC5).

About Wireless VITAE

The Wireless Vehicular Technology, Information Theory Aerospace & Electronics Systems (VITAE) is the only international conference broadly addressing the wireless developments in the world by merging the communities from four different IEEE societies. The 1st Conference was held in 2009 in Aalborg (Denmark) followed by 2nd in 2011 in Chennai (India). The 3rd was held in 2013 at Atlantic City, NJ, USA. The 4th was co-located with GWS-2014 in 2014 at Aalborg (Denmark). The primary event in Aerospace, Information Technologies and Databases & Information Systems category centerpieces to Aerospace, Wireless Communication, Information Theory, Vehicular Technology and Electronics Systems issues. Wireless VITAE joined hands with GISFI to provide a platform to gather the different facets of the wireless into a single event and to exchange ideas and knowledge among the different research communities that address the various aspects of the wireless theme. The International Wireless VITAE conference is Global one that addresses the trends, challenges and future roadmaps within a conglomerate of existing and novel wireless technologies, including cellular, short-¬range, sensor and embedded ones. Cognitive and self-¬organizing networks, nano-sensors, positioning and localization, Internet of Things (IoT), positioning and localization, recent advances in information theory and its applications, space technology for very high data rates, and techno-¬economic aspects of telecommunications are part of the scope, among others.

Committee Members

RAMJEE PRASAD,

- Steering Board Chair/Co-Chair of WPMC, GWS, and Wireless VITAE;
- Founder Director, CTIF Global Capsule (CGC), Aarhus University, Herning, Denmark;
- Founder Chairman, Global ICT Standardisation Forum for India (GISFI).

RATNAM VARADA RAJAKUMAR,
General Chair, Global Wireless Summit 2015
Director, Indian Institute of Technology,
Bhubaneswar, Odisha, India

ASHOK CHANDRA,
Executive Chair, TPC , Global Wireless Summit 2015
Former Wireless Adviser to the Government of India

Masao Sakauchi,
President, National Institute of Information and Communications Technology, Japan
WPMC Organizing Committee

Mitsutoshi Hatori,
Chairman, YRP R&D Promotion Committee, Japan
WPMC Organizing Committee

Shingo Ohmori
Co-chair of WPMC Steering Board
President, YRP International Alliance Institute, Japan
Vice President, YRP R&D Promotion Committee, Japan
WPMC Organizing Committee

NEELI R. PRASAD,
TPC Co-Chair, Global Wireless Summit 2015
International Technological University (ITU), USA

ERNESTINA CIANCA,
Publication Chair, Global Wireless Summit 2015
University of Rome Tor Vergata, Italy

AMBUJ KUMAR,
Web Co-chair, Global Wireless Summit 2015
Aarhus University, Denmark

Welcome Speeches

On behalf of the Steering Committee of the WPMC 2015, Global Wireless Summit (GWS) 2015, and Wireless VITAE 2015, it is my great pleasure to bid you all a warm welcome to these highly renowned events in the beautiful historic city of Hyderabad, India.

Under the theme of '**Democratizing Communications**,' the 18th International Symposium on Wireless Personal Communications (WPMC) and 3rd Global Wireless Summit (GWS) are jointly organized, encompassing the 5th International Conference on Wireless Communication, Vehicular Technology, Information Theory and Aerospace & Electronics Systems (Wireless VITAE), The 12th World Wide Security and Mobility Conference (WWSMC), and the 3rd International Conference on Communications, Convergence, Content and Cooperation (IC5).

Wireless communications have evolved over the years to open great potential for monetizing on multimedia data and diversified user-generated content, making them a ubiquitous means of connecting people and businesses. Democratization of hardware, software and connectivity is the necessary enabler to benefit all stakeholders and provide a stable platform for creating profits out of technology disruption.

The setting of WPMC 2015 jointly with GWS2015 was in the heart of the City of Pearls, as Hyderabad historically been known for its blooming pearl industry. Today, Hyderabad is also a major center for the technology industry. The WPMC and GWS2015 program featured an unusually distinguished group of keynote and invited speakers, as well as a strong technical program with novel research contributions from the relevant thematic areas from all over the world. In addition, an extensive list of social events were scheduled to allow for a break from the exciting technical sessions. Please, take the advantage of the many opportunities to network and expand your technical and cultural horizons.

I would like to extend my appreciation to my global colleagues for their dedication and effort to put together a strong event.

Ramjee Prasad,

Steering Board Chair/Co-Chair of WPMC, GWS, and Wireless VITAE

It is my great pleasure to host the 18th International Symposium on Wireless Personal Multimedia Communications (WPMC'15) in Hyderabad, India.

The WPMC symposia series first commenced in 1998, as a unique international conference dedicated to wireless multimedia communications aiming for global collaboration. In cooperation with YRP, we hold the symposium in a location in Asia, Europe, America or Australia each year.

This year's host country, India, has shown remarkable developments in the information and communications technology (ICT) field, in particular, in mobile phones, since the 10th WPMC Symposium held in Jaipur in 2007. During that time attention to wireless technology has also increased and a broad range of R&D activities have been advanced. Against such a backdrop, it is truly gratifying that the WPMC Symposium is being held here.

As Japan's sole national research institute in the field of ICT, the National Institute of Information and Communications Technology (NICT), promotes research and development in fundamental technologies in the fields of networks, including wireless communication, universal communication, advanced ICT, and electromagnetic sensing. Through these technologies, we aim to contribute to improving and resolving various challenges that society faces.

In particular, NICT positions big data of a public nature that helps to contribute to society as "Social Big Data." We focus on R&D of such Social Big Data, with the goal of having it used throughout society as social infrastructure, and ensuring that the knowledge and information gained from it is further disseminated. Additionally, efforts leading to the Internet of Things (IoT) and Internet of Everything (IoE), where all things and all data become connected, are advancing, and NICT is actively contributing to the IoT Acceleration Consortium, which represents Japan's efforts in this area, and its technology development working group, the Smart 'IoT Acceleration Forum'. Furthermore, learning from the response to the Great East Japan Earthquake that devastated Japan in March 2011, we are also engaging in research and development to swiftly deploy a wireless telecommunications network in the aftermath of a disaster.

For this symposium, NICT has set up a Wi-SUN workshop, 5G workshop, and Resilient Wireless Network Technologies workshop as themes related to such areas of research and development at this symposium. Currently, data gathering through networks using wireless technology is being conducted in various fields and industries across the globe. At the same time, the diversification of ICT had made wireless communications technology increasingly available to people. Given this situation, I believe that holding

this ICT workshop here in India will be extremely effective and holds great significance.

Lastly, I sincerely hope that WPMC'15 will be a significant forum that promotes extensive collaborations and interchanges among those engaged in the R&D of wireless communications, towards the realization of a society where people can live with a sense of security and comfort.

Masao Sakauchi,

President, National Institute of Information and Communications Technology, Japan

On behalf of YRP R&D Promotion Committee, one of the co-organizers of the 18th International Symposium on Wireless Personal Multimedia Communications (WPMC 2015), it is my great pleasure to welcome you in Hyderabad, India.

Since the first WPMC was held in our Yokosuka Research Park (YRP), Japan, in 1998, this symposium had been held in various cities in the world every year providing researchers of wireless communications with opportunities to gain new knowledge and information and also to exchange with each other. We are excited that this year the WPMC is held in India for the second time after the WPMC 2007 held in Jaipur owing to the great cooperation of Global ICT Standardization Forum in India (GISFI), Indian Institute of Technology Bhubaneswar and Kharagpur, Jawaharlal Nehru Technological University Hyderabad, and other Indian colleagues, and we truly appreciate hard work and great efforts of all people concerned. YRP has developed as an international R&D hub for radio and telecommunications technologies since its establishment in 1997. Currently, about 58 organizations with 5,200 researchers and engineers gather in YRP, and the member of our Committee, one of the promoting bodies of YRP, has reached to around 150. We have also concluded memorandums of understanding for research exchange with research parks and ICT institutions, totaling 51 organizations in 15 countries and one region.

Now, in YRP, in addition to the R&D of the 4th generation mobile communication systems, discussions and studies on the 5th generation mobile communication systems that are to be introduced in 2020 are under way. In Broadband Wireless Forum, which was established in our Committee in 2009, discussions on practical application of wireless power transmission technologies are going on, and last year in May, we also established a new Committee to promote application of Wireless Smart Utility Network, Wi-SUN. YRP intends to use the fruits of these activities as a foothold to lead the world's R&D in ICT and further enhance YRP's function. We also would like to further strengthen wide-ranging international collaboration encompassing Europe, America, Asia and Oceania, and other regions, and we expect WPMC to be the very important platform for international exchange.

I hope that this WPMC2015 will be fruitful and enjoyable to all participants.

Mitsutoshi Hatori,

Chairman, YRP R&D Promotion Committee, Japan

At the outset, as the Executive Chairman of the Technical Program Committee (TPC) of the third Global Wireless Summit (GWS-2015), it gives me an immense pleasure to heartily welcome you to this Summit being held in the City of Hyderabad, India during December 13-16, 2015.

The Global Wireless Summit (GWS) has been conceptualized in bringing together wireless media communication/personal communication, etc. The First GWS was successfully held in Princeton (USA), in 2013, followed by the Second one in Aalborg (Denmark), in 2014. Under the theme "Democratizing Communications", the GWS-15 brings together academia, industry and standardization bodies working on green and secure communication. The conference will explore activities, trends and future challenges towards ICT globalization including energy and security issues in existing and future wireless technologies.

Global Wireless Summit 2015 is hosting 18th International Symposium on Wireless Personal Multimedia Communications (WPMC); 5th International Conference on Wireless Communications, Vehicular Technology, Information Theory Aerospace & Electronics Systems (WirelessVITAE) 2015, IC5 and World Wide Security & Mobility Conference (WWSMC). The WPMC-15 and WirelessVITAE 2015 are the major events and both are held second time in India. The 1st International Symposium on WPMC was held in 1998, and since then it is held every year with an objective of providing a 'global platform' for discussions on the latest trends in the wireless multimedia communications. In the year 2007, this event was held in Jaipur (India). Wireless VITAE is the only international conference broadly addressing the wireless developments in the world by merging the communities from four different IEEE societies. The 1st Conference was held in 2009 in Aalborg (Denmark) followed by 2nd in 2011 in Chennai (India).

The Global Wireless Summit-15 presented high-level technical sessions; tutorials, and special sessions on advance topics; workshops; and panel discussions. All the submitted contributions received for technical and special sessions have been thoroughly reviewed by the TPC including other leading experts and only the best quality of papers have been accepted for presentations. It may be mentioned that each paper was reviewed by at least three experts. TPC of GWS-15 has 15 Co-chairs and over 70 members, from a wide variety of academic, industrial, and research organizations around the globe.

As has been the tradition for this Summit, it continues to feature a high-quality technical program across a wide range of research in the wireless communications and related areas.

I would like to take this opportunity to profoundly thanks the TPC Co-chairs; TPC members; Chairpersons of Special Sessions, Workshops; reviewers; and authors.

I request you all to take the advantage of this grand Summit and have thought provoking 4 days in the City of Hyderabad.

Ashok Chandra

Technical Program Committee (TPC) Executive Chair, WPMC 2015 and GWS 2015

Former Wireless Adviser to the Government of India

Welcome to Hyderabad, India to join WPMC2015.

On behalf of the Steering Board of WPMC, I would like to express my deep gratitude to all the delegates for coming from all over the world, and expect you will be having exciting experiences at WPMC2015 in Hyderabad.

The WPMC2015 is the 18th WPMC held for the second time in India, one of the most fantastic and attractive countries in the world.

The WPMC was inaugurated in 1998 to establish a global platform for mutual cooperation and discussions in the field of wireless multimedia communications with a strong financial supports by National Institute of Information and Communications Technology (NICT). The first WPMC was held at Yokosuka Research Park (YRP) in Japan in honor of the opening of YRP in 1997.

Since the first WPMC in YRP, seventeenth WPMCs were held through the world in Asia, Europe, North and South Americas.

With the continued and close support by numerous organizations and human relationships, the WPMC has grown into an international symposium widely recognized by industries and academic societies.

I wish to take this opportunity to thank all supporting committee members and staffs of WPMC2015, especially for General Chair, Prof. R.V Rajakumar, Director IIT Bhubaneswar, India, and TPC Chair, Dr. Ashok Chandra, Former Wireless Advisor, to the Government of India.

Shingo Ohmori

Co-chair of WPMC Steering Board

President, YRP International Alliance Institute, Japan

Vice President, YRP R&D Promotion Committee, Japan

Program at a Glance

Sunday, December 13

Day 1

"Tutorials"

Time Slot	Day1: Sunday, December 13| Tutorials	
08:30-19:00	Registration	
	Morning Tutorial Session	
09:00-13:30 Coffee Break 11:00-11:30	**WPMC Tutorial Session on "TV White Space for Affordable Broadband Access "** **Kentaro Ishizu**, *National Institute of Information and Communications Technology*, **Japan; Abhay Karandikar,** *Indian Institute of Technology Bombay*, **India; Takeshi Matsumura,** *National Institute of Information and Communications Technology*, **Japan**	**MR 2.01**
	WPMC Tutorial Session on "Optimal Filtering and Parameter Estimation Techniques for Statistical Models" **Laxminarayana Pillutla,** *Dhirubhai Ambani Institute of Information and Communication Technology*, **India**	**MR 2.02**
	WPMC Tutorial Session on " Antennas for Millimeter-wave Wireless Communications" **T Rama Rao,** *SRM University*, **India**	**MR 2.03**
	WVITAE Tutorial Session on "IoT and Low Voltage Analog Design for Wireless Applications" **Sudhanshu S. Jamuar,** *University Malaysia Perlis*, **Malaysia**	**MR 2.04**
	WVITAE Tutorial Session on "Energy-Spectral Efficiency in Cooperative Cognitive Radio Network with Challenges in Security" **Santi Prasad Maity,** *Indian Institute of Engineering Science and Technology, Shibpur*, **India**	**MR 2.05**
13:30-14:30	**LUNCH**	
	Afternoon Tutorial Session	
14:30-18:30 Coffee Break 16:30-17:00	**WPMC Tutorial Session on "Road to 5G Wireless Systems: Challenges Ahead vis-à-vis Progress Made "** **Amitava Mukherjee,** *IBM Pvt. Limited*, **India; Debashis Saha,** *Indian Institute of Management Calcutta*, **India**	**MR 2.01**
	WPMC Tutorial Session on "Wireless Channel Impairments Removal Techniques" **Sanjay Kumar,** *Birla Institute of Technology*, MESRA , **India**	**MR 2.02**
	WVITAE Tutorial Session on "Transmission Technologies for 5G" **Suvra Sekhar Das,** *Indian Institute of Technology, Kharagpur*, **India**	**MR 2.03**
	WVITAE Tutorial Session on "Visible Light Communication for Road Safety in the Intelligent Transportation Systems" **Navin Kumar,** *Amrita University & School of Engineering*, **India**	**MR 2.04**
	WVITAE Tutorial Session on "ICT for Health Care" **Vishwanath Sinha,** *M. N. National Institute of Technology, Jaipur,* **India**	**MR 2.05**
19:00-20:00	Welcome Reception in Foyer/ Pool Side Lawns	

Monday, December 14

Day 2

"Workshops, Special Sessions, Contributed Papers"

Time Slot	Day2: Monday, December 14 | Grand Opening Program		
08:30-19:00	**Registration**		
09:00-10:00	**GRAND OPENING**		**HALL 1**
	Ceremony	**Lighting of the Lamp Ceremony: Presided by B.N. Bhandari, Local Organizing Chair, WPMC/ GWS 2015**	
	Welcome Speech	**Ratnam Varada Rajakumar**, *General Chair*, WPMC/GWS 2015	
	Inaugural Speech	**Ramjee Prasad**, *Steering Board Chair/Co-Chair of WPMC, GWS and Wireless VITAE; Founder Chair, GISFI*	
	Introduction Speech	**Ashok Chandra, TPC Executive Chair, WPMC/ GWS 2015**	
	Opening Speech-1	**Fumihiko Tomita**, Vice President, *NICT*, **Japan**	
	Opening Speech-2	**Mitsutoshi Hatori**, Chairman, *YRP*, **Japan**,	
	Opening Speech-3	**Smriti Dagar**, *President, IETE*, **India**	
	Round Table Discussions: "India Knowledge Economy- Transformation through Digitization and Innovation"		
10:00-11:00	**Discussion**	Moderator:-**Sudhir Dixit**, WWRF, **USA**, **Anand R. Prasad**, NEC Corporation **Japan,** **Dina Simunic,** *University of Zagreb***, Croatia** **Ashok Chandra,** *TPC Executive Chair, WPMC/ GWS 2015*, **India** **Kiritkumar Lathia, GISFI/CTIF, Denmark,**	
	Vote of Thanks	**Sandip Inamdar**, Finance Chair, **WPMC/ GWS 2015**	
11:00-11:30	**Coffee Break**		
11:30-19:00		**Technical Sessions**	
19:30-22:30	END of DAY 2 || Cultural Program (Mridangam and Kuchipudi Group Dance Recital), GALA DINNER & Best Paper Award: HALL1		

Time Slot	Day2: Monday, December 14 || HALL 1.1 Activities || Workshops & Special Sessions (I-A)		
08:30-19:00	Registration		
09:00-11:00	**GRAND OPENING**		**HALL 1**
11:00-11:30	**COFFEE BREAK**		
11:30-13:30	**WPMC Special Session on "Mobile applications for Management of the Digital Business, Implications for the Infrastructures and Organisations"** **Session Organizer and Chair: Zoran Veljovic,** *University of Montenegro,* **Montenegro**		HALL 1.1
	Invited Talk	Manufacturing and Standardization in India**, Arun Golas**, *former DDG, Ministry of Communications, Government of India, New Delhi,* **India**	
	1570231052	Dynamic Pathloss Model for Future Mobile Communication Networks; **Ambuj Kumar, Albena Mihovska, Ramjee Prasad**; *CTIF, Aalborg University,* **Denmark**	
	1570228076	Challenges and Opportunities for Enhancing User Privacy and User Empowerment; **Prashant Dhotre, Samant Khajuria , Henning Olesen**; *Center for Communication, Media and Information Technologies (CMI),Aalborg University Copenhagen,* **Denmark (***)**	
	1570228069	Sensitive Association Rules Hiding Methods: A Survey; **Geeta Navale, Suresh Mali**; *Sinhgad Institute of Technology and Science, Pune,* **India**	
13:30-14:30	LUNCH		
14:30-16:30	**WPMC Workshop on "Vision and research activities toward the Fifth Generation Mobile Systems (5G)"** **Workshop Organizer and Chair: Kentaro Ishizu,** *Association of Radio Industries and Businesses (ARIB) & National Institute of Information and Communications Technology (NICT),* **Japan**		HALL 1.1
	Activities on 5th Generation Mobile Communications System in Japan ;**Kohei Sato;** *Association of Radio Industries and Businesses (ARIB),* **Japan**		
	5G Prospects in India; **VikramTiwathia**; *The Cellular Operators Association India (COAI),* **India**		
	5G research activities and key enabling technologies ;**Haesik Kim**; *VTT,* **Finland**		
	Small-cell Structured Wireless Networks for 5G: Centralized vs Decentralized Architecture ;**Fumiyuki Adachi**, *Tohoku University,* **Japan**		
	The Unified 5G Platform; **J. VinoshBabu James**, *Qualcomm,* **India**		
16:30-17:00	COFFEE BREAK		
17:00-19:00	**WPMC Special Session on "Combedded Systems"** **Session Organizer and Chair: Abhay Gandhi,** *Viswesarayya National Institute of Technology, Nagpur,* **India**		HALL 1.1
	1570227356	Artificial intelligence auto-mobility in material handling & fork-lift manufacturing; **Ajinkya Vasant Nichit①, Kedar S. Joshi①, Sachin B. Rao ②, Sushant S. Gaidhani ①, Shrinivas Vasantrao Shinde③**; ①*Sandip Institute Of Engg, & Management, Nashik,* ②*G.H. Sapat College Of Engg., Nashik,* ③*Jawahar Institute Of Technology, Nashik;* **India**	
	1570227801	Interference Analysis and Mitigation Techniques in Wireless Body Area Network; **Subhojit Moitra, P.H.Ghare, A.G. Kothari**; *VNIT, Nagpur,* **India**	
	1570227808	Implementation of Low Cost IoT Based Smart Home using Open Source Platform; **Varun Tiwari, Avinash Keskar** □; *Visvesvaraya National Institute of Technology, Nagpur,* **India**	
	1570227846	Performance Comparison of DCT based Entropy Coding Techniques; **Samruddhi Y. Kahu, Kishor M. Bhurchandi**; *Visvesvaraya National Institute of Technology, Nagpur,* **India**	
	1570227857	UWB Sensing antenna, Reconfigurable transceiver and antenna based Cognitive Radio Test bed; **S. Manoj, Sumin. D. Joseph**□, **Chetan. Waghmare, Nandakumar. K., Ashwin Kothari**; *Department of Electronics VNIT, Nagpur,* **India**	
	1570227987	Methods of Frequency Offset Estimation in OFDM Based System; **A. P. Rathkanthiwar①, A.S.Gandhi②**; ①*Priyadarshini College of Engineering Nagpur,* ②*Visvesvaraya National Institute of Technology, Nagpur* , **India**	
19:30-22:30	END of DAY 2 || Cultural Program (Mridangam and Kuchipudi Group Dance Recital), GALA DINNER & Best Paper Award: HALL1		

Time Slot	Day2: Monday, December 14 || HALL 1.2 Activities || Workshops & Special Sessions (I-B)		
08:30-19:00	Registration		
09:00-11:00	**GRAND OPENING**		**HALL 1**
11:00-11:30	**COFFEE BREAK**		
11:30-13:30	**WVITAE Special Session on " mHealth and Medical Informatics"** **Session Organizer and Chair: Albena Mihovska, Aalborg University, Denmark**		HALL 1.2
	Opening Talk	**Shyam Chakrabortty,** *Oy Trinnect Ltd.,* **Finland**	
	Invited Talk	Role of ICT for the Advancement of Dentistry **, Gianpaolo Sannino,** *University of Rome, Tor Vergata,* **Italy**	
	Invited Talk	Patient centered learning and Early clinical exposure of medical students to 'Diabetes and Metabolic syndrome**, Yogesh Sharma①, Ankur Joshi②, Dept of Medicine③, Rakesh Biswas;** *①LNMCH,②dept of Medicine, GMC,③dept of Medicine, LNMCH;* *Bhopal Madhya Pradesh*, **India**	
	Invited Talk	Review of telemedicine technologies in India**, Sumit Gautam***①***, Shyam Chakraborty②;** *① IIIT Hyderabad, India;* ***②****Trinnect Ltd.,* **Finland**	
13:30-14:30	LUNCH		
14:30-16:30	**WPMC Workshop on "Resilient Wireless Network Technologies" (I)** **Workshop Organizer and Chair: Ryu Miura,** *National Institute of Information and Communications Technology (NICT)*, **Japan**		HALL 1.2
	1570213366	On-going Field Experiment of NerveNet in Shirahama Town for Resilient Town Network; **Masugi Inoue, Yasunori Owada , Kiyoshi Hamaguchi** *; Resilient ICT Research Center,* *National Institute of Information and Communications Technology (NICT)*☐, **Japan**	
	1570213263	Pilot testing and demonstration of self-management network and applications by NerveNet; **Yasunori Owada , Kiyoshi Hamaguchi, Masugi Inoue;** *Resilient ICT Research Center,* *National Institute of Information and Communications Technology (NICT)*☐, **Japan**	
	1570213055	Development and Field Experiment of Distributed Peer Aware Communication Networks; **Lin Shan, Huan-Bang Li, Takashi Matsuda, Ryu Miura**; *Wireless Network Research Institute, National Institute of Information and Communications Technology (NICT)*☐, **Japan**	
	1570213332	A hybrid multi-hop network by small-unmanned aircraft and satellite telecommunication systems; **Fumie Ono①**; **Byeong-pyo Jeong②, Yasunori Owada②, Shan Lin ①, Ryu Miura①**; *①Wireless Network Research Institute,* ***②****Resilient ICT Research Center, National Institute of Information and Communications Technology (NICT)*☐; **Japan**	
16:30-17:00	COFFEE BREAK		

16:30-17:00	(Continued: Hall 1.2 Activities) COFFEE BREAK		
17:00-19:00	**WPMC Workshop on "Resilient Wireless Network Technologies" (II)** **Workshop Organizer and Chair: Ryu Miura,** *National Institute of Information and Communications Technology (NICT)***, Japan**		HALL 1.2
	1570213462	QZSS SS-CDMA Location and Short Message Communication System; **Noriharu Suematsu, Suguru Kameda, Yuji Miyake, Tomohide Takahashi , Akinori Taira, Tadashi Takagi, Kazuo Tsubouchi**; *Research Institute of Electrical Communication, Tohoku University*, **Japan**	
	1570213016	Disaster Countermeasure Experiments using WINDS; **Takashi Takahashi①, Kazuyoshi Kawasaki①, Akira Akaishi①, Toshio Asai①, Maki Akioka①, Tomoshige Kan①, Morio Toyoshima①, Byongpyo Jeong②, Hajime Susukita②, Shuji Murakami②**; ①*Wireless Network Research Institute,* ②*Resilient ICT Research Center; NICT,* **Japan**	
	1570195491	A Path Ordering and Reference Selection Method for the Differential Delay Tomography; **Takehiro Otsuka① , Shinsuke Hara①②, Takahiro Matsuda③②, Kenichi Takizawa③, Fumie Ono‡ , Ryu Miura‡**; ①*Graduate School of Engineering,* ②*Osaka City University,* ③ *Graduate School of Engineering, Osaka University*; **Japan**	
	1570205987	Experimental Evaluation on Wireless Tomography with Compressed Sensing in a Three-Dimensional Space**; Kengo Yokota; Kengo Yokota① , Shinsuke Hara① , Takahiro Matsuda②, Masaki Mukamoto②, Yuki Uemura②, Kenichi Takizawa③, Fumie Ono④, Ryu Miura④** □; ①*Graduate School of Engineering, Osaka City University ,Sugimoto, Sumiyoshi-ku, Osaka,* ②*Graduate School of Engineering, Osaka University 2-1 Yamadaoka, Suita, Osaka,* ③*Strategic Planning Office, National Institute of Information and Communications, Koganei, Tokyo ,* ④*Wireless Network Research Institute, National Institute of Information and Communications Technology ,Kanagawa*; **Japan**	
19:30-22:30	END of DAY 2 || Cultural Program (Mridangam and Kuchipudi Group Dance Recital), GALA DINNER & Best Paper Award: HALL1		

Time Slot	Day2: Monday, December 14 || MRG .01 Activities || Contributed Papers: Cognitive Radio Networks and Spectrum Management (I)		
08:30-19:00	Registration		
09:00-11:00	**GRAND OPENING**		**HALL 1**
11:00-11:30	COFFEE BREAK		
11:30-13:30	**Cognitive Radio Networks and Spectrum Sensing & Management (I-A) | CRN, Relay and Routing : WVITAE & WPMC || *Session Chair: K.T.V. Reddy, TPC Chair, IETE, India***		MRG .01
	1570213275	C2R2M: Cluster-based Cognitive Radio Routing Mechanism; **Shriram Kulkarni, Shriram Markande**; *University of Pune*, **India**	
	1570209919	Adaptive Cooperative Spectrum Sensing and Access in Cognitive Radio Networks; **Kayalvizhi G;** *SSN College of Engineering*, **India**	
	1570212756	Evaluation of Channel Assembling Strategies with Single-Class Users in Cognitive Radio Networks; **Ebenezer Esenogho, Tom Walingo**; *University of KwaZulu-Natal*, **South Africa**	
	1570188607	Evaluating the Effect of Selfishness on Flooding Based DTN Routing Algorithms; **C Sobin**, **Vaskar Raychoudhury**; *IIT Roorkee*, **India**	
	1570213104	**WPMC:** Throughput of Secondary User in Underlay Cognitive Relay Network with Energy Harvesting; **Binod Prasad, Sanjay Dhar Roy, Sumit Kundu**; *National Institute of Technology, Durgapur*, **India**	
	1570207535	**WPMC:** Quality of Service Enforcing Centrally Optimized Routing for Delay Tolerant Networks; **Abhishek Thakur, Chittaranjan Hota**; *BITS Pilani, Hyderabad Campus* , **India**	
13:30-14:30	LUNCH		
14:30-16:30	**Cognitive Radio Networks and Spectrum Sensing & Management (I-B): WPMC || *Session Chair: Masahiro Umehira, Ibaraki University, Japan***		MRG .01
	1570193943	A Compressive Sensing-based Channel Estimation via GAMP in FBMC/OQAM System; **Meng Lin, Yunzhou Li, Limin Xiao, Yan Zhang, Xibin Xu, Jing Wang**; *Tsinghua University*, **China**	
	1570206001	New Pricing Model for Dynamic Dual-operator Spectrum Sharing in GSM; **Meghan Saitwal, Yuva Kumar, Brij Mohan Baveja, Mohammed Zafar Ali Khan, Uday B Desai;** *Indian Institute of Technology, Hyderabad*, **India**	
	1570192957	Improved p-norm Energy Detector with Soft Combining in AWGN Channel for Spectrum Sensing; **Vaibhav Kumar, Deep Kandpal, Ranjan Gangopadhyay, Soumitra Debnath;** *L.N.Mittal Institute of Information Technology, Jaipur*, **India**	
	1570213925	Selective Sensing Framework for Opportunistic Mobile Phone Sensing Networks; **Thejaswini M, Pachamuthu Rajalakshmi, Uday B Desai**; *Indian Institute of Technology, Hyderabad*, **India**	
	1570193867	Investigation on Listen-Before-Talk Mechanism of Licensed-Assisted Access to Unlicensed Spectrum; **Yu Jiang①, Hiroki Harada②, Liu Liu①, Huiling Jiang① ,Satoshi Nagata††**; ① *DOCOMO Beijing Communications Laboratories Co., Ltd*, **China**, ② *NTT DOCOMO, INC*, **Japan**	
	1570213278	CDF Based Spectrum Occupancy Rate Measurement Using Least Square Estimation of Gaussian Noise Period; **Shota Rachi, Akira Saito, Masahiro Umehira, Shigeki Takeda;** *Ibaraki University*, **Japan**	
16:30-17:00	COFFEE BREAK		

16:30-17:00	(Continued: MRG .01 Activities) COFFEE BREAK		
17:00-19:00	**Cognitive Radio Networks and Spectrum Sensing & Management (I-C): WPMC** ***||Session Chair: Sumit Kondu, NIT DurgapurA Leti, France***		MRG .01
	1570208599	Detection Performance of Soft Data Fusion in Rician Fading Channel for Cognitive Radio Network; **Srinivas Nallagonda[1][2], V Chandra Sekhar[1], Aniruddha Chandra[3][4], Sanjay Dhar Roy[4], Sumit Kundu[4];** *[1]M V S R Engineering College ,[2]Osmania University,[3]Brno University of Technology, [4]National Institute of Technology, Durgapur, WB*;**[1][2][4]India, [3]Czech Republic**	
	1570213378	Evaluation of permutation entropy detection for cognitive radio networks; **Srinu Sesham, Amit Kumar Mishra**; *University of Cape Town, Cape Town*, **South Africa**	
	1570208853	Optimization of Cooperative Spectrum Sensing in Cognitive Radio over Erroneous Reporting Channel; **Narasimha Rao Banavathu, Mohammed Zafar Ali Khan**; *Indian Institute of Technology, Hyderabad*, **India**	
	1570213111	Distributed Token Based MAC for Multi-Channel Multi-Interface Cognitive Radio WMN; **Mohammed A R Quadri, Ramesh Babu Battula, Manoj Singh Gaur, Dinesh Gopalani, Meenakshi Tripathi**; *Malaviya National Institute of Technology Jaipur*, **India**	
	1570209789	Path and Load Aware Routing Algorithm for Cognitive Radio Wireless Mesh Network**; Ramesh Babu Battula, Manoj Singh Gaur, Dinesh Gopalani, Emmanuel Shubhakar Pilli**; *Malaviya National Institute of Technology, Jaipur*, **India**	
	1570213374	Fractal dimension of spectral estimates for spectrum sensing under noise variance uncertainty; **Srinu Sesham[1], Amit Kumar Mishra[1], Siba Kumar Udgata [2], Samrat Sabat[2]**; *[1]University of Cape Town, Cape Town* ,**South Africa,** *[2]University of Hyderabad, Hyderabad*, **India**	
19:30-22:30	END of DAY 2 || Cultural Program (Mridangam and Kuchipudi Group Dance Recital), GALA DINNER & Best Paper Award: HALL1		

Time Slot	Day2: Monday, December 14 || MRG .02 Activities || Contributed Papers: Next Generation Networks & Internet of Things (I)		
08:30-19:00	Registration		
09:00-11:00	**GRAND OPENING**		**HALL 1**
11:00-11:30	COFFEE BREAK		
11:30-13:30	**Next Generation Networks (I-A) | 5G and Device to Device Communications: WPMC || *Session Chair: Sri Ganesh Rao, Tata Consultancy Services, Bangalore, India***		MRG .02
	1570194953	The impact of Network Neutrality on the OTT Service of 5G WISDOM; **Yapeng Wang, Ramjee Prasad**; *Center of TeleInFrastrukur, Aalborg University,Aalborg*, **Denmark**	
	1570206855	Efficient Device-to-Device (D2D) Offloading Mechanism in LTE Networks; **Bighnaraj Panigrahi, Rashmi Ramamohan, Hemant Kumar Rath, Anantha Simha**; *Tata Consultancy Services*, **India**	
	1570208181	Survey of Device-to-Device Communications Infrastructure-less in IEEE 802.15.8 Task Group; **Marco Hernandez, Ryu Miura**; *NICT*, **Japan**	
	1570208909	Link Adaptation Strategies for Cellular Downlink with low-fixed-rate D2D Underlay; **Afonso Eduardo, Ivo Sousa, António J. Rodrigues**; *Instituto de Telecomunicações (IT) Instituto Superior Técnico (IST), Universidade de Lisboa Lisbon*, **Portugal**	
	1570210057	A Pattern Division Multiple Access Scheme for 5G wireless communication systems; **Zhang Kai, Jin Xu**; *Beijing University of Posts and Telecommunications*, **China**	
	1570213212	Coexistence of Systems with Different Multicarrier Waveforms in LSA Communications; **Mirza Golam Kibria, Gabriel Porto Villardi, Kentaro Ishizu , Fumihide Kojima**; *Wireless Network Research Institute, National Institute of Information and Communications Technology*, **Japan**	
13:30-14:30	LUNCH		
14:30-16:30	**Next Generation Networks (I -B) | Spectrum Issues and Intelligent Approach: WVITAE || *Session Chair: S.K. Agarwal, Former Director, DIETY, Government of India, India***		MRG .02
	1570213573	Spectrum Scarcity at the Extensive and Intensive Edges: From White Space to 5G; **Benoît Pierre Freyens**; *University of Canberra*, **Australia**	
	1570210051	Real Time Evaluation of Energy Detection and Covariance based Spectrum Sensing Algorithms; **Sunil Devanahalli, Samrat Sabat**; *University of Hyderabad*, **India**	
	1570213985	Self Configurable Intelligent Distributed Antenna System; **Ambuj Kumar, Albena Mihovska, Ramjee Prasad**; CTIF, *Aalborg University*, **Denmark**	
	1570209885	Distributed Forward-Backward Pursuit Algorithm for Distributed Compressive Sensing; **Suchithra Sudhakaran, Neelakantan PC**; *Adi Shankara College of Engineering and Technology*, **India**	
	1570210103	Spectrum for 5G Services; **Purnendu Shekhar Mani Tripathi①②, Ramjee Prasad②**; ①*Ministry of Communications* & IT, **India**, ②*Centre for TeleInFrastructure(CTiF),Aalborg University, Aalborg*, **Denmark**	
	1570209977	On Performance of Eigenvalue based Detectors for Spectrum Sensing under Different Fading Conditions; **Ashwini Deshmukh①, Madhukar Deshmukh②, Flemming Bjerge Frederiksen②, Ramjee Prasad②③**; ①*Trinity College of Engineering Research Pune*, **India**, ②*RATE, Department of Electronic Systems,* ③*CTIF; Aalborg University*, **Denmark**	
16:30-17:00	COFFEE BREAK		

16:30-17:00	(Continued: MRG .02 Activities) COFFEE BREAK		
17:00-19:00	**Next Generation Networks (I- C) | Future Vision and IoT: WVITAE & WPMC ||*Session Chair: Raja Rajeswari, IETE, India***		MRG .02
	1570213430	Access for Internet of Things using Smartphone as a Gateway utilizing LTE and WiFi; **Prateek Mathur[1], Rasmus Hjorth Nielsen[2], Neeli Rashmi Prasad[3], Ramjee Prasad[1]**; *[2]Cisco Systems* , **USA,** *[3]Center for TeleInFrastructure (CTIF)*, **USA**, *[1]Center for TeleInFrastructure (CTIF), Aalborg University*, **Denmark**	
	1570213454	Cognitive framework for flexible queuing strategy in Next Generation Networks; **Hanuma Chitti[1], Neeli Rashmi Prasad[2], Knut Ovsthus[3], Ramjee Prasad[1]**; *[2]Center for TeleInFrastructure (CTIF)*, **USA**, *[3]Bergen University College*, **Norway**, *[1]Center for TeleInFrastructure (CTIF), Aalborg University*, **Denmark**	
	1570215979	Service Interaction through Gateways for Inter-Cloud Collaboration within the Arrowhead Framework; **Pál Varga[1], Csaba Hegedus[2]**; *[1]Budapest University of Technology and Economics, [2] AITIA International Inc.*; **Hungary**	
	1570191635	Single Thing Sign On Identity Management for Internet of Things; **Vanya Zdravkova, Mihail Mihaylov, Albena Mihovska, Ramjee Prasad**; *Department of Electronic Systems, Center for TeleInfrastruktur, Aalborg University*, **Denmark**	
	1570191687	**WPMC:** Towards Internet of Services - SDN-enabled IMS Architecture for IoT Integration; **Anton Katov[1], Bayu Anggorojati[1], Sofoklis Kyriazakos[1], Albena Mihovska[1], Neeli Rashmi Prasad[2]**; *[1]Center for TeleInFrastructure (CTIF), Aalborg University*, **Denmark,** *[2]Center for TeleInFrastructure (CTIF), Aalborg University*, **USA**	
	1570195595	**WPMC:** Packet Scheduling Scheme to Guarantee QoS in Internet of Things; **Reema Sharma[1], Navin Kumar[2], Namratha Gowda[1,3], Srinivas Talabattula[4];** *[1]The Oxford College Of Engineering, [2]Amrita University & School of Engineering, [3]Visvesvaraya Technological University, Karanataka, [4]Indian Institute of Science, Bangalore*; **India**	
19:30-22:30	END of DAY 2 || Cultural Program (Mridangam and Kuchipudi Group Dance Recital), GALA DINNER & Best Paper Award: HALL1		

Time Slot	Day2: Monday, December 14 || MRG .03 Activities || Contributed Papers: Vehicular & Mobile Ad-hoc Networks (I)		
08:30-19:00	Registration		
09:00-11:00	GRAND OPENING		HALL 1
11:00-11:30	COFFEE BREAK		
11:30-13:30	**Vehicular & Mobile Ad-hoc Networks (I-A)| Aerial and Sensor Ad-Hoc Networks: WVITAE|| *Session Chair: Sanjay Kumar, Birla Institute of Technology, Ranchi, India***		MRG .03
	1570214001	Embedded Video Processing and Data Acquisition for Unmanned Aerial Vehicle; **Vrunal Mhatre, Akshay Patil, Siddhesh Chavan, Ashish Chittimilla, Aaron Samuel;** *Fr. Conceicao Rodrigues College of Engineering*, **India**	
	1570194189	HANET: Millimeter wave based intelligent radio architecture for serving place time capacity issue; **Purnima Lala Mehta[①②③④], Troels B. Sørensen[①③], Ramjee Prasad[①②③]**; *[②]Center for TeleInFrastructure (CTIF),* **Denmark**; *[③]Department of Electronic Systems, [①]Aalborg University,* **Denmark**; *[④]HMRITM, New Delhi,* **India**	
	1570195421	GSHMAC: Green and Secure Hybrid Medium Access Control for Wireless Sensor Network; **Pranav Pawar[①], Rasmus Hjorth Nielsen[②], Neeli Rashmi Prasad[③], Ramjee Prasad[①]**; [②]Cisco Systems , **USA**; [③]Center for TeleInFrastructure (CTIF), **USA**; [①]Center for TeleInFrastruktur, Aalborg University, Aalborg, **Denmark**	
	1570214751	Automatic Household Power Measurement & Control System based on Wireless Sensor Networks; **Jameel Ahamed;** *Aligarh Muslim University, Aligarh,* **India**	
	1570213872	Conducted EMI Analysis of Vehicle Positioning System and Strategies to Reduce Conducted EMI; **Shreenivas Ramesh Jog, Nidhi Chaturvedi**; *D. Y. Patil Institute of Engineering & Tech.*, **India**	
	1570213870	Study of Radiated Emission from Wireless Positioning System and the strategies to minimize it; **Shreenivas Ramesh Jog, Suvidha Chitnis**; *D. Y. Patil Institute of Engineering & Tech.*, **India**	
13:30-14:30	LUNCH		
14:30-16:30	**Vehicular & Mobile Ad-hoc Networks (I-B) |Wireless Sensor Networks: WPMC || *Session Chair: Vishwanath Sinha, M N National Institute of Technology, Jaipur, India***		MRG .03
	1570210123	An Interdependent Source-Channel Coding for Energy Efficient Communication in WSNs**; Resmi N C, Sonali Chouhan**; *Indian Institute of Technology Guwahati,* **India**	
	1570194199	Impact of Network Coding on Distributed Indoor Target Tracking using Wireless Sensor Networks; **Laxminarayana Pillutla, Shourya Gupta, Dushyant Singh**; *Dhirubhai Ambani Institute of Information and Communication Technology (DA-IICT)*, **India**	
	1570195119	Mobility-aware Hybrid Synchronization for Wireless Sensor Network; **Dnyaneshwar Mantri, Neeli Rashmi Prasad, Ramjee Prasad**; *Center for TeleInFrastructure (CTIF), Aalborg*, **Denmark**	
	1570195013	Characterization for Reporting Rate of Adaptive Sectoring Scheme to Improve Reliability in WSN; **Manohar S. Chaudhari [①], Vivek Shankar Deshpande[②], Ramjee Prasad[③]**; *[①]Sinhgad Institute of Technology, Pune University,* **India**; *[②]University of Poona & MIT College of Engineering,* **India**; *[③]Center for TeleInFrastructure (CTIF), Aalborg University,* **Denmark**	
	1570195063	Q-MOHRA:QoS Assured Multi-Objective Hybrid Routing Algorithm for Heterogeneous WSN; **Nandkumar Kulkarni[①], Neeli Rashmi Prasad[②], Ramjee Prasad[①]**;*[①]Center for TeleInFrastructure (CTIF),* ***Denmark****; [②]Center for TeleInFrastructure (CTIF),Aalborg University*, **USA**	
	1570213289	Performance Analysis of Total Power Consumption in Linear Multi-hop Networks; **Satoshi Yamazaki[①], Kouji Ohuchi[②]**; *[①]Numazu National College of Technology & Department of Control & Computer Engineering, Numazu, Shizuoka, [②]Shizuoka University Johoku, Hamamatsu, Shizuoka;* **Japan**	
16:30-17:00	COFFEE BREAK		

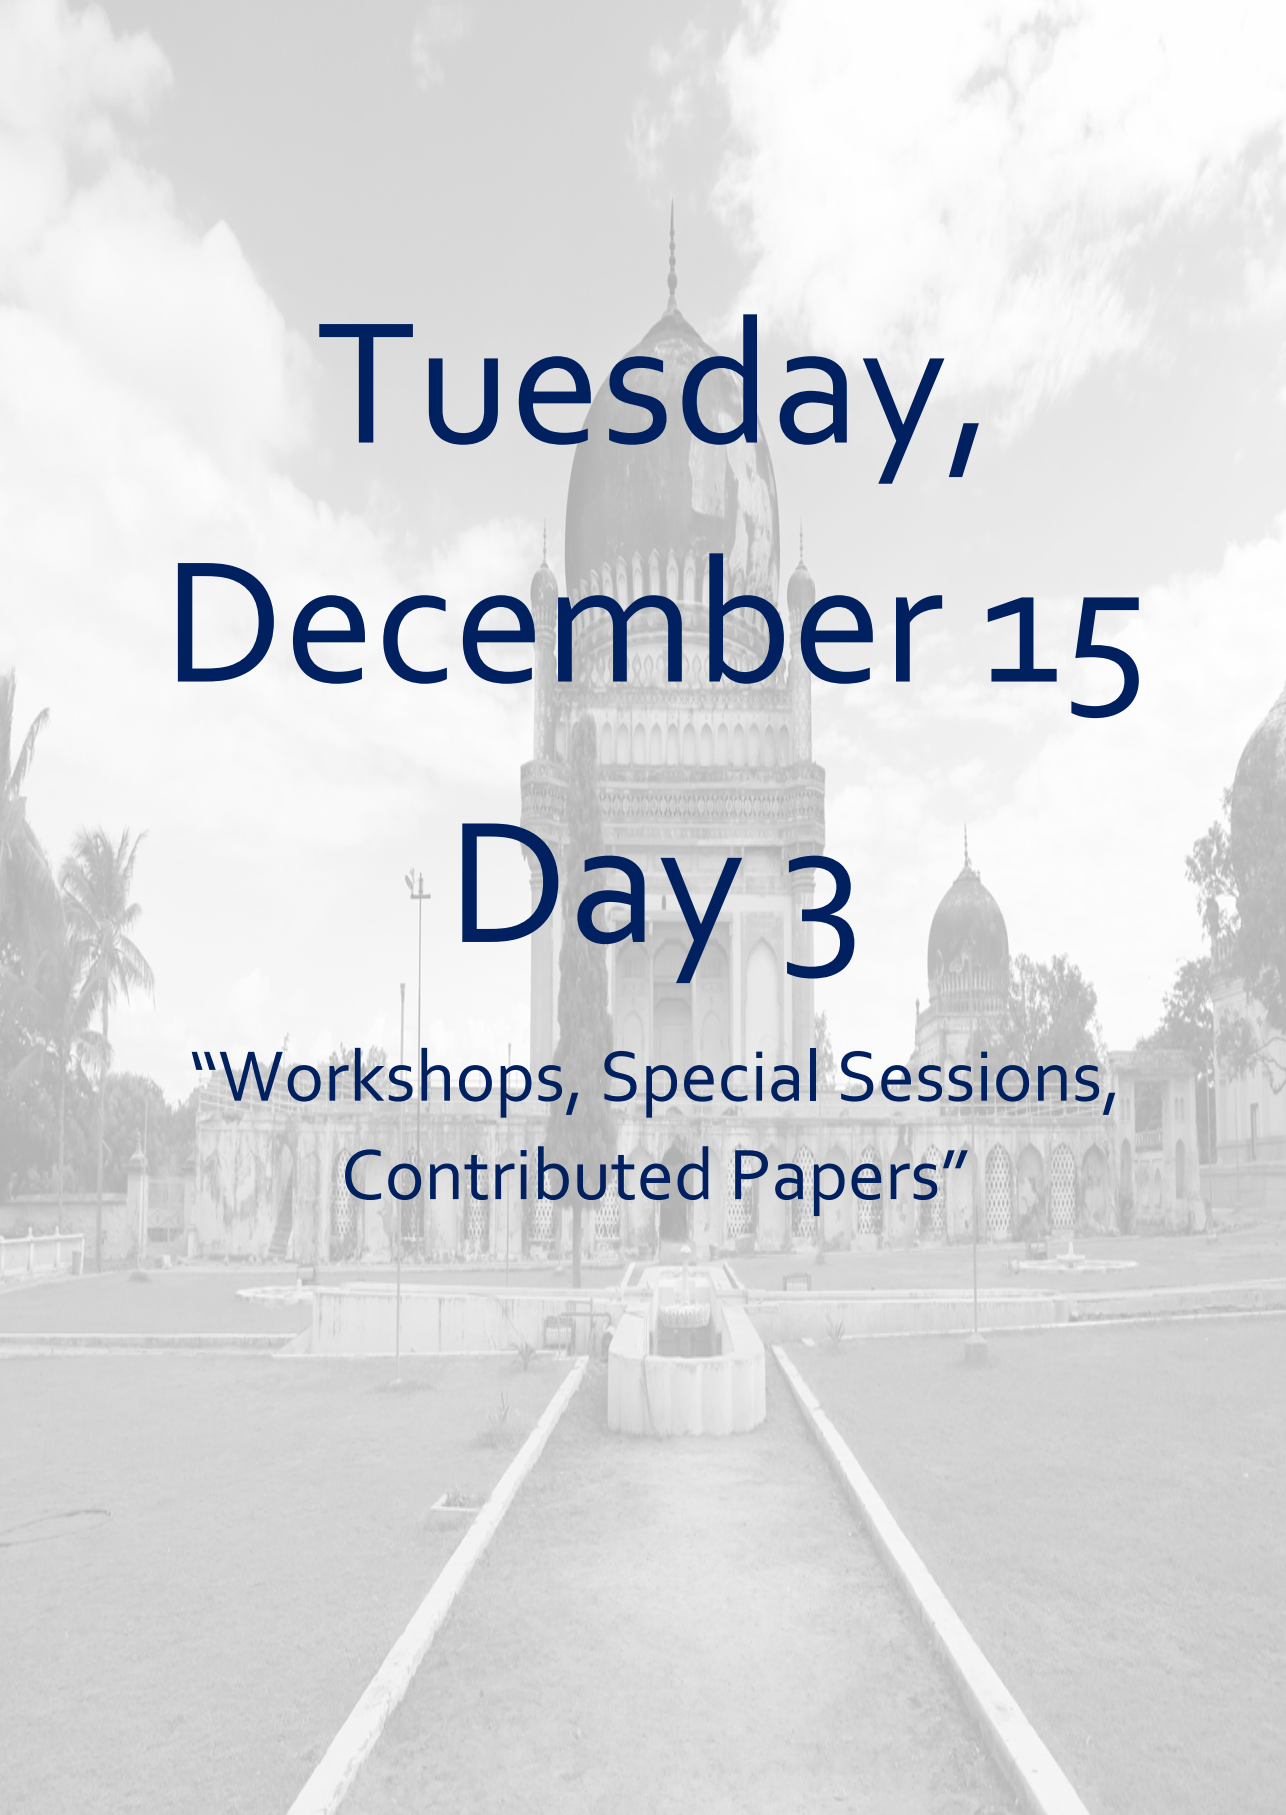
16:30-17:00	(Continued MRG .03 Activities) COFFEE BREAK		
17:00-19:00	**Vehicular & Mobile Ad-hoc Networks (I-C)|Vehicular and Mobile Ad-Hoc Networks: WPMC || *Session Chair: Vladimir Poulkov, Technical University of Sofia, Bulgaria***		MRG .03
	1570188641	Transmission Capacity Analysis for Linear Vehicular Ad Hoc Networks; **Xinxin He, Weisen Shi, Tao Luo;** *Beijing University of Posts and Telecommunications*, **China**	
	1570199753	Trust based Detection and Elimination of Packet Drop Attack in the Mobile Ad-hoc Networks; **Vishvas Kshirsagar[1][2], Ashok Kanthe[1][3], Dina Simunic[3]**; *[1]Sinhgad Institute of Technology, Lonavala,* **India**, *[2]Savitribai Phule Pune University,* **India,** *[3]Faculty of Electrical Engineering and Computing (FER), University of Zagreb*, **Croatia**	
	1570199757	The Behavioral Based Gray Hole Attack Detection in Mobile Ad-hoc Network (MANET); **Parineet Shukla[1][2], Ashok Kanthe[1][3], Dina Simunic[3]**; *[1]Sinhgad Institute of Technology, Lonavala,* **India**, *[2]Savitribai Phule Pune University*, **India**, *[3]Faculty of Electrical Engineering and Computing (FER), University of Zagreb*, **Croatia**	
	1570194567	On Supporting Integrated Multimedia Traffic in TDMA based Mobile Ad hoc Networks; **Mallesham Dasari[1], Himanshu Sindhwal[1], Naresh Vattikuti[1], Bheemarjuna Reddy Tamma[2]**;*[1]Uurmi Systems Pvt. Ltd. Hyderabad, [2]IIT Hyderabad, Hyderabad;* **India**	
	1570194813	Intrusion Detection System Against Colluding Misbehaviour in MANETs; **Pragya Mishra, Karm V Arya, Hardev singh Pal**; *ABV-Indian Institute of Information Technology & Management, Gwalior*, **India**	
	1570195073	Two-Party Key Agreement Protocol for MANETs based on Verifiable Secret Sharing Scheme; **Cheruku Asha Jyothi, Narsimha Gugulotu**; *Jawaharlal Nehru Technological University College of Engineering, Jagtial, Karimnagar, Telangana,* **India**	
19:30-22:30	END of DAY 2 || Cultural Program (Mridangam and Kuchipudi Group Dance Recital), GALA DINNER & Best Paper Award: HALL1		

Time Slot	Day2: Monday, December 14 || MRG .04 Activities || Contributed Papers: Technology Applications (I)		
08:30-19:00	Registration		
09:00-11:00	**GRAND OPENING**		**HALL 1**
11:00-11:30	COFFEE BREAK		
11:30-13:30	**Technology Applications (I-A) | Human Applications : WVITAE & WPMC || *Session Chair: Vladamir Poulkov, Technical University of Sofia, Bulgaria***		MRG .04
	1570213423	Behavior State Feature Extraction through Single Channel EEG Device for Medical Application; **Sravanth Kumar Ramakuri, Vivek Kumar, Bharat Gupta**; *Birla Institute of Technology Mesra, Ranchi*, **India**	
	1570206439	Real-time Detection of EEG Electrode Displacement for Brain-Computer Interface Applications; **Giulia Cisotto, Silvano Pupolin**; *University of Padua*, **Italy**	
	1570213165	Remote Heart Rate Evaluation by Variational Mode Decomposition**; Bogdan Gavriloaia[1], Octavian Fratu[1], Simona Halunga[1], Gheorghe Gavriloaia[2], Constantin Mara[2], Radu Vizireanu[1]**; [1]University Politehnica of Bucharest, [2]University of Pitesti; **Romania**	
	1570210205	Speech Feature Analysis and Selection for Emotion Classification; **Angel Manolov, Ognian Boumbarov, Agata Manolova, Vladimir K. Poulkov, Krasimir Tonchev**; *Technical University of Sofia*, **Bulgaria**	
	1570213386	Public Auditing and Data Dynamics in Cloud with Performance Assessment on Third Party Auditor; **Snehal Sawant[1,2], Aaradhana Arvind Deshmukh[1,2], Albena Mihovska[1], Ramjee Prasad[1];** [1]*CTIF, Aalborg University*, **Denmark,** [2]*Smt.Kashibai Navle College of Engineering, Vadgoan BK, Pune*, **India**	
	1570195309	**WPMC:** Non Audio-Video gesture recognition system; **Razvan Craciunescu[1,2], Cristian Ionut Dita[1], Albena Mihovska[1], Octavian Fratu[2], Sofoklis Kyriazakos[1], Ramjee Prasad[1]**; [1]*CTIF, Aalborg University*, **Denmark**, [2]*University Politehnica of Bucharest*, **Romania**	
13:30-14:30	LUNCH		
14:30-16:30	**Technology Applications (I-B) | Human Applications : WPMC || *Session Chair: fred Harris, San Diego State University, USA***		MRG .04
	1570207155	Fuzzy Logic based Human Detection in Video; **Manojkumar M Gawali, Dipti R. Pawar**; *Sinhgad College of Engineering, Pune*, **India**	
	1570207563	Improving Segmentation Accuracy for Motion Detection using Bidirectional Video Processing**; Abhishek Thakur, Ankesh Kumar**; *BITS Pilani , Hyderabad Campus*, **India**	
	1570194919	Automatic Speaker Detection and Recognition in a multi classroom E-Learning System; **Amitha Vijayan, Balaji Hariharan**; *AMRITA Vishwa Vidyapeetham Amritapuri, Kollam*, **India**	
	1570213262	Real-time EEG Monitoring and Transmission over Low Bandwidth Wireless Networks; **Kaushik Lahiri[1], Amitava Mukherjee[1], Mrinal Kanti Naskar[2]**; [1]*IBM India Pvt Ltd;* [2]*Jadavpur University*; **India**	
	1570194425	Adaptive priority based network bandwidth throttling for a Virtual Classroom System**; Jobina Varghese, Balaji Hariharan**; *AMRITA Vishwa Vidyapeetham Amritapuri, Kollam*, **India**	
	1570213445	Minimal Error IEEE 802.15.4 Communication Module for Heart Monitoring Data Transmission in IoT; **Subrahmanyam Vuddagiri, Mohammed Abdullah Zubair, Ajay Yadav, Pachamuthu Rajalakshmi**; *Indian Institute of Technology Hyderabad*, **India**	
16:30-17:00	COFFEE BREAK		

16:30-17:00	(Continued MRG .04 Activities) COFFEE BREAK		
17:00-19:00	**Technology Applications (I-C) | Multiple Areas: WVITAE || *Session Chair: Hiroshi Harada, Kyoto University, Kyoto, ICT, Koganei,* Japan**		MRG .04
	1570207041	Design of Amateur Radio Wireless Transceiver to Reduce the Impact of Natural Calamities; **Ashwini Shingate[1], Rushikesh Borse[2], Shubham Tiwari[3], Arvind Jawale[4]**; [1][2]*Savitribai Phule Pune University*, [2]*Savitribai Phule Pune University*, [2]*Shubhra Energy*, [4]*Scout Satara*; **India**	
	1570210199	Deep Sea Exploration Recovery and Transport [DESERT] Vehicle and its Modes of Communication; **Aileen Sengupta[1], Pavel Sengupta[2]**; [1]*Techno India College of Technology, Rajarhat,* [2]*Dr. Sudhir Chandra Sur Degree Engineering College, Dum Dum, Kolkata* □; **India**	
	1570208685	Energy Efficient Lighting System for Indoor Parking with Ubiquitous Communication; **Mahesh Jha[1], Navin Kumar[2]**; [1]CMRIT, VTU, [2]Amrita University & School of Engineering; **India**	
	1570210063	Recent Progress in Radioclimatological Modeling in Equatorial and Tropical Africa; **Thomas Afullo, Akintunde Alonge**; University of Kwazulu-Natal, Durban, **South Aftrica**	
	1570210261	Digital door lock using fingerprint, webcam and GSM - a novel approach for smart homes; **Ashish Patwari, Karuna Yepuganti, Arpit Omar, Shekhar Thakur, Kaushik Kumar**; *VIT University, Vellore*, **India**	
	1570209921	Marine Vessel Detection Comparing GPRS and Satellite Images for Security Applications; **Sajan Ambadiyil[1], Dintu Thomas[2], V P Mahadevan Pillai[3]**; [1]*Optical Image Processing Division, C-DIT,* [2]*SCMS School of Engineering and Technology,* [3]*University of Kerala, Thiruvanthapuram, Kerala*; **India**	
19:30-22:30	END of DAY 2 || Cultural Program (Mridangam and Kuchipudi Group Dance Recital), GALA DINNER & Best Paper Award: HALL1		

Time Slot	Day2: Monday, December 14 || MRG .05 Activities || Special Sessions on WWRF & GISFI and; Contributed Papers: Physical and Fundamentals (I)		
08:30-19:00	Registration		
09:00-11:00	**GRAND OPENING**		**HALL 1**
11:00-11:30	COFFEE BREAK		
11:30-13:30	**WPMC Special Session on "Selected Topics"** **Session Organizer and Chair: Shinsuke Hara,** *Osaka City University*, **Japan**		MRG .05
	Invited Talk	"Home neuro- rehabilitation: an ICT near Future Service", **Silvano Pupolin**, *University of Padua*, **Italy**	
	Invited Talk	" **Lakhshmi Mukunkutla**, *USA/Aalborg University*, **Denmark**	
	Invited Talk	"Convergence Techniques for Future Communications", **M. Jankiraman**, *Larsen & Toubro Ltd. (L&T), Bangalore*, **India**	
	Invited Talk	" Making a Safe and Secure 4 G World", **Debu Nayak**, *Huawei Telecommunications India Pvt. Ltd*, **India**	
13:30-14:30	LUNCH		
14:30-16:30	**Physical and Fundamentals (I-A) | LTE and Multiple Access Techniques (OFDMA/OFDM/SC-FDMA, MIMO, SISO): WPMC & WVIATE || *Session Chair:* ", M. Jankiraman, *Larsen & Toubro Ltd. (L&T), Bangalore, India***		MRG .05
	1570196365	Joint Transceiver Design for QoS-Constrained MIMO Two-Way Non-Regenerative Relaying; **Rohit Budhiraja, Bhaskar Ramamurthi**; *Department of Electrical Engineering, IIT Madras*, **India**	
	1570190883	New virtual 8x1 MISO scheme with QOSTBC; **Ugljesa Urosevic, Zoran Veljovic, Milica Pejanovic-Djurisic**; University of Montenegro, Podgorica, **Montenegro**	
	1570212700	Limited Feedback Scheduling For MIMO-OFDM Broadcast Network; **Prabina Pattanayak, Preetam Kumar;** *Indian Institute of Technology, Patna*, **India**	
	1570193823	An Efficient Deterministic Scheme for Blind CFO Estimation in SC-FDMA; **Vinay Kumar Trivedi, Vidya Sagar, Preetam Kumar**; *Indian Institute of Technology, Patna*, **India**	
	1570209997	**WVIATE:** Capacity Analysis of MIMO BC Channels in Presence of Spatial Correlation; **Ashok Panda①, Swadhin Kumar Mishra②, Ajit Kumar panda②**; ①IIIT Bhubaneswar,② *NIST Berhampur*; **India**	
	1570212704	**WVITAE:** Error Rate Performance for Multiuser scheduling in MIMO downlink system with imperfect CSI; **Prabina Pattanayak, Diwakar Pandey, Preetam Kumar;** *Indian Institute of Technology, Patna*, **India**	
16:30-17:00	COFFEE BREAK		
17:00-19:00	**WVITAE Special Session: Wireless World Research Forum (WWRF):** **Knud Erik Skouby,** Aalborg University **, Denmark and Sudhir Dixit,** WWRF**, USA**		MRG .05
	Theme : **Mobile History of India**		
	Opening Speech	**Knud Erik Skouby,** *Aalborg University* **, Denmark**	
	Keynote Speech	**Sudhir Dixit,** *WWRF*, **USA**	
	Invited Talk	**Krishna Sirohi,** *NIKSUN*, **India**	
19:30-22:30	END of DAY 2 || Cultural Program (Mridangam and Kuchipudi Group Dance Recital), GALA DINNER & Best Paper Award: HALL1		

Time Slot	Day2: Monday, December 14 || MRG .06 Activities || Second International Workshop on Innovation and Entrepreneurship(IWIE) (I)			
08:30-19:00	Registration			
09:00-11:00	**GRAND OPENING**			**HALL 1**
11:00-11:30	COFFEE BREAK			
11:30-13:30	**Second International Workshop on Innovation and Entrepreneurship(IWIE) :(I-A) || Entrepreneurship Contest** Second International Workshop on Innovation and Entrepreneurship(IWIE) | (I –A) Organizer and Chair: Sofoklis Kyriazakos, CTIF, Aalborg University, Denmark **Introduction to the Workshop and Entrepreneurship Contest**			MRG .06
	Mayank Kumar Mittal, **SaleYourBooks.com** Mayank Semwal , **Genralsorts** Shilpa Chaudhary, **Car security Systems** Meenakshi Gupta, **MNY PRO** Jafar Mapara, **Identity Management System** Akskay Radke, **Smart Indian railways**	Mayank Semwal, **App for professional Help** Deepak Sharma, **Instant Presentation and Converter** Mukesh Wadile, **SecureChip** Heramb Pawar, **Clear Vision** Naman Vashishth, **Find ME!!!!** Darshan Vyas, **CLOTH TESTER using IMAGE PROCESSING** Shashank Roy, **Electronic Refigerator**	Adarsh Mishra, **Virtual PPM-1** Utkarsh Trivedi, **Service Providers Support** Irram Patharwat, **Methane Extraction Digester** Manoj Radadiya, **Gesture and Voice based Television Control System** Nikhil Prabhu, **Smart Electric Car using AMR7** Jafar Mapara, **Connected Homes** Madhukesh Heggannavar, **Design and Development of Magnetron Power Source**	
13:30-14:30	LUNCH			
14:30-16:30	**Second International Workshop on Innovation and Entrepreneurship(IWIE) :(I-B) || Entrepreneurship Contest** Second International Workshop on Innovation and Entrepreneurship(IWIE) | (I –B) Organizer and Chair: Sofoklis Kyriazakos, CTIF, Aalborg University, Denmark IWIE Activities			MRG .06
16:30-17:00	COFFEE BREAK			
17:00-19:00	**Second International Workshop on Innovation and Entrepreneurship(IWIE) :(I-C) || Entrepreneurship Contest** Second International Workshop on Innovation and Entrepreneurship(IWIE) | (I –C) Organizer and Chair: Sofoklis Kyriazakos, CTIF, Aalborg University, Denmark **Results and Discussion of Entrepreneurship Contest of the IWIE Workshop Day -1**			MRG .06
19:30-22:30	END of DAY 2 || Cultural Program (Mridangam and Kuchipudi Group Dance Recital), GALA DINNER & Best Paper Award: HALL1			



Tuesday, December 15

Day 3

"Workshops, Special Sessions, Contributed Papers"

Time Slot	Day3: Tuesday, December 15 || HALL 1.1 & 1.2 Activities || Workshops & Special Sessions (II-A)			
08:30-19:00	Registration			
09:00-11:00	**Keynote Speech || Chair: Ashok Chandra, TPC Executive Chair, WPMC/ GWS-2015** **Lars Kiekegaard**, Teracom, **Denmark** **Ramesh Rao**, University of California, San Diego, **USA**			**HALL 1**
11:00-11:30	**COFFEE BREAK**			
11:30-13:30	**WPMC Special Session on "Smart Village 'Rural Model': Basic Unit for a Digital India" || Session Organizer and Chair: Mayur Dave,** *IETE*, **INDIA**			HALL 1.1
	1570227716	Demonstrating SWiFiIC - Sustainable WiFi for Rural Communication; **Abhishek Thakur, Aarthi J, Amit Chawla, Chittaranjan Hota**; *BITS Pilani, Hyderabad Campus,Hyderabad*, **India**		
	1570234273	"IoT" based Smart Village: An Indigenous step towards 'Digital India'; **Madhukant Patel①, Piyush Yadav②**; *①MD, Reve Automation LLP, ②Green Cloud iSoft P. Ltd., Dehradun*, **India**		
	1570234316	Rurbanisation of India; **Bipin Pradeep Kumar**, *Gaia Smart Cities*, **India**		
	WVITAE Special Session on "Persuasive Multi Business Model Innovation in a World of Persuasive Technologies" **Session Organizer and Chair: Peter Lindgren,** *Multi Business Model Innovation and Technology, Aarhus University*, **Denmark ||Session Co-organizers: Troels Christian, K. Andersen, Torben Bjerrum, Annabeth Aagaard, Ole Horn Rasmussen, Morten Karnøe Søndergaard** *Aarhus University*, **Denmark; Theodoor van Dongen,** *VDMBee, Veenendaal*, **The Netherlands**			HALL 1.2
	1570228216	Persuasive Technology and Business Models; **Morten Karnøe Søndergaard, Peter Lindgren, Niels Einar Veirum;** *Stanford Peace Innovation Lab, Department of Business Development and Technology, Aarhus University*, **Denmark**		
	1570228627	Service and Big Data business model in a world of persuasive technologies; **Troels Christian K. Andersen, Torben Cæsar Bisgaard Bjerrum**; *Aarhus University, Herning*, **Denmark**		
	1570228634	Secure Persuasive Business Models and Business Model Innovation in a World of 5G; **Peter Lindgren, Katharina Wuropulos**; *Aarhus University*, **Denmark (###)**		
13:30-14:30	LUNCH			
14:30-16:30	**WPMC Workshop on " Advanced Technologies and Promotion Strategies for Wi-SUN and the Wireless Grid Systems" || Workshop Organizer and Chair:** *Fumihide Kojima*, **Japan**			HALL 1.1
	Wi-SUN Alliance -Promoting open interoperable industry standards for smart utility networks; **Hiroshi Harada**, NICT, Japan		NICT's R&D, Standardization and Promotion Avtivities on Wi-SUN and the wireless grid systems; **Fumihide Kojima**, NICT, Japan	
	Wi-SUN RLMM Profile for Sensor Network Application; **Ryota Yamada**, Omron, Japan		Wi-SUN Alliance Activity in India; **Amarjeet Kumar**, Wi-SUN Alliance, India	
	WVITAE Workshop on "Wearable and Nearable Internet of Things (WaNIOT 2015)"|| Workshop Organizer and Chair: Balamuralidhar P, *Tata Consultancy Services (TCS)*, **Bangalore, India**			HALL 1.2
	Introduction by the workshop chair: Dr. Balamuralidhar P., TCS Innovation Lab, Bengaluru Wearables for Newborns": Prof. Bharadwaj Amrutur, Indian Institute of Science, Bengaluru Wearables for Safety: Mr. Ganesh Suryanarayanan, GTIO, Tata Group, Bengaluru		Data-driven Healthcare using Affordable Sensing", Dr. Arpan Pal, TCS Innovation Lab, Kolkata RF based Sensing of Cardiopulmonary Vital Signs": Mr. R.P.Pinto, SAMEER, Mumbai IoT in healthcare: Applications to neurology: Dr. Jayavardhana Gubbi, TCS Innovation Labs, Bengaluru	
16:30-17:00	COFFEE BREAK			

16:30-17:00	(Continued Hall 1.1 and 1.2 Activities) BREAK				
17:00-19:00	**Matchmaking session – Indian industry meets Global Industry || Organizer and Chair: Krishnal Sirohi,** *GISFI*, **India**				HALL 1.1
	Lars Kierkegaard, *Teracom*, **Denmark**	**Srinivasa Gutta, INVECAS,** *Hyderabad,* **India**	**Sivabalan Arumugam,** *NEC* **, Japan**	**Kiritkumar Lathia, GISFI/CTIF, Denmark**	
	Sandip Inamdar, *WISDOM Pvt. LTD.*, **India**	**Balaji Kanigicherla,** *Ineda Systems, Hyderabad,* **India**	**Gangadhar Gude, SoCtronics,** *Hyderabad,* **India**	**Subbarangaiah,** *VEDA IIT, Hyderabad*, **India**	
	WVITAE Special Session on " Fiber-Wireless Convergence for broadband Connectivity in 5G perspective" || **Session Organizer and Chair: Jayashree Ratnam,** International Institute of Information Technology, *Hyderabad*, **India**				HALL 1.2
	Invited Talk	Journey to World Wide Wireless and its Deployment Challenges**, D.S. Rao**, Tata Communications Ltd, Hyderabad, India			
	1570228022	Participation of Optical Backbone Network in Successful Advancement of Wireless Network; **Rajarshi Mahapatra**; *CVR College of Engineering*, **India**			
	1570228026	On 5G Cellular Backhaul Networks; **Mahima Mehta**, *Intel Mobile Communications India Pvt. Ltd., Bangalore*, **India**			
	1570228029	Telecom Regulatory Issues in Converged Era; **G. Muralidhar , Robert Ravi**; *Telecom Regulatory Authority of India*, India **(***)**			
19:30-22:30	END of DAY 3 || NETWORKING DINNER: FOYER				

Time Slot	Day3: Tuesday, December 15 || MRG .01 Activities || Workshops & Special Sessions (II-B)		
08:30-19:00	Registration		
09:00-11:00	**Keynote Speech**		HALL 1
11:00-11:30	COFFEE BREAK		
11:30-13:30	**WVITAE Special Session on" Internet of Things (IoT)"** **Session Organizers: Birger Andersen①, Knud Erik Skouby②, ② Samant Khajuria,** ①*Technical University of Denmark, Copenhagen*, ②*Aalborg University, Copenhagen*, **Denmark** **Session Chair: Birger Andersen,** *Technical University of Denmark, Copenhagen*, **Denmark**		MR G.01
	Keynote Talk	IoT in Theory and Practice**, Birger Andersen,** *Technical University of Denmark, Copenhagen*, **Denmark**	
	1570227404	Heuristic Trust in IoT; **Bipjeet Kaur①, Henrik Tange②;** ①*Denmark Technical University* , ②*Wireless Center CTIF Copenhagen*; **Denmark (###)**	
	1570228109	Cyber security for M2M Smart Grid; **Sarmistha De Dutta①, Prof. Ramjee Prasad②**; ①*NIKSUN, Inc.*, **USA** ②*Center For TeleInFrastruktur , Aalborg University*, **Denmark**	
	1570228247	GET IoT- Green Computing and Energy Harvesting technology in Internet of Things (IoT); **Jetendra Joshi, Anshumali Singh, Lakshya Gourav Moitra , Manash Jyoti Deka**; *NIIT University, Neemrana, Alwar, Rajasthan*, **India**	
	1570228361	An Energy Efficient Adaptive Wireless Link for Farms based on IoT technologies**; T. Blaszczyk①, P. Lynggaard②**; ①*Technical University of Denmark,* ②*CMI, Aalborg University Copenhagen*; **Denmark**	
	1570231008	Implementation Of Internet Of Things Using Near Field Communication For Parking Automation; **Aishwarya Sanjay Ikhe, Sagar Jayant More, Priyanka Sanjay Suranglikar, Prashant S Dhotre;** *Sinhgad Institute of Technology and Science, Pune*, **India**	
13:30-14:30	LUNCH		
14:30-16:30	**WVIATE Special Session on "Spectrum Management and Networking for Multi-link Satellite and Terrestrial Communication Systems"** **Session Organizers and Chairs: Preetam Kumar, Vinay Kumar Trivedi, Akash Agarwal;** *Indian Institute of Technology Patna*, **India**		MR G.01
	Invited Talk	Vimal Bhatia, *Associate Professor, IIT Indore*, **India**	
	Invited Talk	Preetam Kumar, *Assistant professor, IIT Patna*, **India**	
	1570221151	Cancellation of Inter-Cell Interference in Downlink with No Backhaul Information Exchange; **Shuvabrata Bandopadhaya①, Jibendu Sekhar Roy②**; ①*Silicon Institute of Technology, Bhubaneswar, Odisha,* ②*School of Electronics Engineering, KIIT University, Bhubaneswar, Odisha*.; **India**	
	1570226980	Performance Analysis Of Interference Cancellation In MIMO-FBMC; **V.Padmapriya , N.Venkateswaran**; *SSN College of Engineering, Chennai*,**India**	
	1570227724	Measurement and Identification of White Space using Low Cost SDR for Rural Wireless Broadband; **Vinit Sharswat, Pradeep Godara, Abhijeet Bishnu, Vimal Bhatia;** *Indian Institute of Technology Indore*, **India**	
16:30-17:00	COFFEE BREAK		

16:30-17:00	(Continued MRG .01 Activities) COFFEE BREAK		
17:00-19:00	**WVITAE Special Session on " eWALL"** **Session Organizer and Chair: Sofoklis Kyriazakos, CTIF,** *Aalborg University***,** *Aalborg,* **Denmark**		MR G.01
	1570224200	Improving the Trustworthiness of Ambient Assisted Living Applications; **Elias Z. Tragos①, Pavlos Charalampidis①, Alexandros Fragkiadakis①, George Lambropoulos②, Sofoklis Kyriazakos②;** ①FORTH-ICS,② Converge SA**; Greece**	
	1570224206	Requirements and Challenges in Evaluation of Systems for Independent Living of Senior Citizens; **Antun Kerner, Antonija Marinčić, Ana Koren, Dina Šimunić ,Ramjee Prasad**; *Faculty of Electrical Engineering and Computing, University of Zagreb,* **Croatia**	
	1570224166	Virtual sensing environment for care at home; **Aristodemos Pnevmatikakis;** *Athens Information Technology, IRIS Laboratory, Athens,* **Greece**	
	1570224167	Expression recognition using graph based feature selection; **Krasimir Tonchev, Nikolay Neshov, Agata Manolova ,Vladimir Poulkov**; Technical University of Sofia, **Bulgaria**	
	1570213206	Participatory Heuristic Evaluation of the First Iteration of the eWALL Interface Application**; Clara Schaarup①, Louise Bilenberg Pape-Haugaard①, Stine Veje Hangaard①, Albena Mihovska② ,Ole Hejlesen①; ①Department of Health Science and Technology, ②Center for TeleInfrastruktur □;** *Aalborg University, Aalborg,* **Denmark**	
	1570195309	Non Audio-Video gesture recognition system; **Razvan Craciunescu, A. Mihovska ; Center for TeleInfrastruktur □;** *Aalborg University, Aalborg,* **Denmark**	
19:30-22:30	END of DAY 3 || NETWORKING DINNER: FOYER		

Time Slot	Day3: Tuesday, December 15 || MRG .02 Activities || Workshops & Special Sessions (II-C)		
08:30-19:00	Registration		
09:00-11:00	**Keynote Speech**		HALL 1
11:00-11:30	COFFEE BREAK		
11:30-13:30	**WPMC Special Session on "Manufacturing Engineering"** **Session Organizer and Chair: Dnyandeo Dattatray Shinde,** *Sandip Foundation, Sandip Institute of Engineering & Management, Nashik, Maharashtra*, **India**		MR G.02
	Invited Talk	Total Productive Maintenance (TPM) an overview; **Rajendra G. Tated**; *Sandip Foundations, Sandip Institute of Engineering and Management, Nashik*, **India**	
	Invited Talk	Application of KK pillar of TPM – An Industrial Case study; **J. P Yavalkar;** *TPM-Learning center, Bajaj auto ltd. Waluj Aurangabad*, **India**	
	Invited Talk	Lean Six Sigma - Success Story of Kavach; **Jadhav Ganesh A.;** *Gabriel India Ltd. Pune*, **India**	
13:30-14:30	LUNCH		
14:30-16:30	**WPMC Special Session on "Manufacturing Engineering" (Contd.)** **Session Organizer and Chair: Dnyandeo Dattatray Shinde,** *Sandip Foundation, Sandip Institute of Engineering & Management, Nashik, Maharashtra*, **India**		MR G.02
	1570226974	Identifying Root Causes for Students Problems in Technical Education using Fishbone Diagram; **Dnyandeo Dattatraya Shinde①, Shwetambari Sanjay Ahirrao①, Prachi Dilip Shinde①, Rajendra G. Tated①, Morten Falch②**; ①*Sandip Foundations, SIEM, Nashik, India,* ②*Center for Communication, Media and Information Technologies (CMI), Aalborg University Copenhagen*, **Denmark**	
	1570226994	Effect of Newly Designed Burnishing Tool on Surface Micro hardness of AA6351; A. S. Maheshwari①, Dr. R. R. Gawande②; ①*Sandip Institute of Technology & Research Centre, Nashik. (Maharashtra),* ②*Bapurao Deshmukh College of Engineering, Wardha (Maharashtra)*; **India**	
	1570228066	Application of Principal Component Analysis to Magnetic Abrasive Finishing**; Sandip B. Gunjal, P. J. Pawar**; *K.K.W.I.E.E. & R, Nasik*, **India**	
	1570227495	Metric Based Efficiency Analysis Of Educational ERP System Usability - Using Fuzzy Model; **Anil Kumar, Reza Tadayoni, Lene Tolstrup Sorensen**; *Department of Electronic Systems, Aalborg University*, **Denmark**	
	1570227534	A Brief Review on Process Parameter Optimization of GMAW Process and Grey-based Taguchi Method; **U. V. Patil, G. R. Naik**; *KIT's College of Engineering, Shivaji University, Kolhapur*, **India**	
	1570227977	Vehicle Monitoring and controlling system using CAN protocol; Mosam Sangole□, **Vicky Chaudhary, Vishakha Nighute, Priyanka Satpute;** *Sandip Foundation Nashik, Maharashtra*,**India**	
16:30-17:00	COFFEE BREAK		

16:30-17:00	(Continued MRG .02 Activities) COFFEE BREAK		
17:00-19:00	**WPMC Special Session on "Manufacturing Engineering" (Contd.)** **Session Organizer and Chair: Dnyandeo Dattatray Shinde,** *Sandip Foundation Sandip Institute of Engineering & Management, Nashik, Maharashtra,* **India**		MR G.02
	1570227004	Application of Real Coded Genetic Algorithm to Dynamic Layout Benchmark Problem; **Kailas V. Chandratre, P.J. Pawar**; *, K.K.W.I.E.E. & R, Nasik*, **India**	
	1570227011	Model Development for Preventive Maintenance and Replacement Policy; **Anand S. Relkar, Keshav N. Nandurkar**; *S. I.T.R.C., Nashik, K.K.W.I.E.E.R, Nashik*; **India**	
	1570227290	Vacuum Gripper Design For An Industrial Handling System; **Ajinkya Vasant Nichit, Suraj Ramesh Jadhav, Anirudh Arun Desai, Vishal Eknath Patil,Vishal Sonowane**; *Sandip Institute Of Engg. & Mangt. Nashik*, **India**	
	1570228555	Automatic Ration Distribution System-A Review; **Swapnil R. Kurkute, Dipak P. Patil, Chetan Medhe, Ashwini Kshirsagar, Ashlesha Revgade** □; *SIEM Nasik*, **India**	
	1570227469	Self -Balancing Platform for Personal Transport; **Yogesh Risodkar , Ganesh Shirsath, Monali Holkar, Mayur Amle**; *SIEM, Sandip Fondation, Nashik*, **India**	
	1570228052	Decommissioning of Nuclear Facilities and Dose Rate Calculations for Nuclear Power Plant Staff; **Pushkar Prashant Lachake, Dnyandeo Dattatraya Shinde**; *Sandip Institute of Engineering and Management, Nashik*, **India**	
19:30-22:30	END of DAY 3 || NETWORKING DINNER: FOYER		

Time Slot	Day3: Tuesday, December 15 || MRG .03 Activities || Contributed Papers: Physical and Fundamentals (II-A)		
08:30-19:00	Registration		
09:00-11:00	**Keynote Speech**		**HALL 1**
11:00-11:30	COFFEE BREAK		
11:30-13:30	**Physical and Fundamentals (II-A-1) | Antenna & Circuit Design, Analysis and Investigation: WPMC || *Session Chair: Laxminarayana Pillutla; Dhirubhai Ambani Institute of Information and Communication Technology, India*** 1570213114	Design Optimization and SAR Evaluation of SS-UWB Patch Antenna for WBAN; **Vivek Kumar, Sravanth Kumar Ramakuri**; **Bharat Gupta**; *Birla Institute of Technology Mesra, Ranchi,* **India**	MRG .03
	1570210207	Radar Range and Range Resolution Enhancements; **Uma S Jha, Erik Chowdhury**; *Space & Airborne Systems, Raytheon Co, El Segundo, California,* **USA**	
	1570209793	SIW based Antipodal Linear Tapered Slot Antenna for Inter-Satellite Communication Links at 60 GHz; **Nishesh Tiwari, T Rama Rao, Purva Shrivastava**; *SRM University,Chennai,* **India**	
	1570192429	SAR and Thermal effects of a Body Wearable Microstrip Antenna at UHF and UWB frequencies; **Varshini Karthik, T Rama Rao**; *SRM University,Chennai,* **India**	
	1570213460	Antenna Radiation Pattern Based 3D Localization Technique; **Amarlingam Madapu[1], Pachamuthu Rajalakshmi[1], Vinod Kumar Netad[1], Masaya Yoshida[2], Kiyohito Yoshihara**; [1]Indian Institute of Technology Hyderabad, Hyderabad, **India,** [2]*KDDI R&D Laboratories Inc., Green and M2M Application Laboratory Iidabashi,* **Japan**	
13:30-14:30	LUNCH		
14:30-16:30	**Physical and Fundamentals (II-A-2) | LTE & Multiple Access Techniques (OFDMA/OFDM/SC-FDMA, MIMO, SISO): WPMC || *Session Chair: Uma S. Jha, Raytheon Co., California, USA*** 1570213429	Distributed Spatial Modulation-OFDM in Uplink Relay-assisted Cellular Network; **Kunal Sankhe, Rama Garimella**; *International Institute of Information Technology, Hyderabad,* **India (***)**	MRG .03
	1570213444	Simultaneous Transmission of Information and Energy in OFDM Systems; **Sumit Gautam, P. Ubaidulla**; *International Institute of Information Technology-Hyderabad,* **India**	
	1570210151	Blind Channel Length Estimation for OFDM Systems using Cumulant Features; **Ajay Kambhampati, Udit Satija, Baratram Ramkumar, M Sabarimalai Manikandan**; *IIT-Bhubaneswar,* **India**	
	1570213302	A Feasibility Analysis of LTE-CommSense; **Amit K. Mishra[1], Mohammed Zafar Ali Khan[2], Santu Sardar[3]**; [1]*Department of Electrical Engineering, University of Cape Town,* **South Africa**, [2]*Department of Electrical Engineering, IIT Hyderabad,* **India,** [3] *ANURAG, Defence Research & Development Organization*, **India**	
	1570167111	An Efficient Resource Block Allocation Algorithm in LTE-Based Systems with User Rate Constraints; **Vijay Gutta, AmruthMuddana, T K Ramesh**; *Amrita VishwaVidyapeetham,* **India**	
	1570213529	LTE-Advanced Radio and Network Optimization: Basic Coverage and Interference Constraints; **Fernando J. Velez, Sofia Sousa, Jessica Acevedo ,Daniel Robalo**; *Instituto das Telecomunicações - DEM Universidade da Beira Interior,Faculdade de Engenharia, Covilhã,* **Portugal**	
16:30-17:00	COFFEE BREAK		

16:30-17:00	(Continued MRG .03 Activities) COFFEE BREAK		
17:00-19:00	**WPMC Special Session on " Selected Topics in Physical & Fundamentals-1"** **Session Organizer and Chair** : **T Rama Rao,** SRM University, **India**		MRG .03
	1570160791	Performance of MIMO Detection Techniques with Spatial Multiplexing**; Soma Umamaheshwar①, Tipparti Anil Kumar②, K Srinivas Rao③**; ①*SR Engineering College,* ②*SVS Group of Institutions,* ③*TRR College of Engineering, Telangana*, **India (###)**	
	1570213390	Reducing memory consumption with a lossless image compression algorithm based on predictive coding; **Rupali S. Vairagade**; *Sinhgad Institute of Technology and Science, Pune*, **India (***)**	
	1570209839	Enhancement in Spectral Efficiency using Circular Convolution in MIMO FBMC towards Wireless Network 5G; **Payal P. Tayade, Vandana M. Rohokale**, *SKNSITS, Lonavala*, **India (###)**	
	1570209843	Performance Analysis of Group based Cooperative Sensing Schemes; **K Jyostana①, N. Vandana②, Swathi Roja②, B. N. Bhandari②**; ①*VNR Vigana Jyothi Institute of Engineering and Technology,* ②*Jawaharlal Nehru Technological University*; Hyderabad, **India (###)**	
	1570238199	A Comparative Study of Channel Estimation for MIMO-OFDM system; **G Surendher**, Sree Chaitanya *Institute of Technological Sciences, Karimnagar,* **India (###)**	
19:30-22:30	END of DAY 3 || NETWORKING DINNER: FOYER		

Time Slot	Day3: Tuesday, December 15 || MRG .04 Activities || Contributed Papers: Physical and Fundamentals (II-B)		
08:30-19:00	Registration		
09:00-11:00	**Keynote Speech**		**HALL 1**
11:00-11:30	COFFEE BREAK		
11:30-13:30	**Physical and Fundamentals (II-B-1) | Channel Fading and Selection :WVIATE || *Session Chair-Ernesthina Cianca, University of Rome, Tor Vergata, Italy***		MRG .04
	1570208291	Joint Channel Estimation and CCI Cancellation for STBC-OFDM System in Fast Fading Channel; **Jyoti P Patra, Prasanta Kumar Pradhan,, Poonam Singh, Sarat Kumar Patra**; *National Institute of Technology Rourkela*, **India**	
	1570210195	Rate Independent Multicarrier Variable Rate Scheme over Frequency Selective Channel; **Akash Agarwal**, **Vijay Mukati**, **Preetam Kumar**; *Indian Institute of Technology, Patna*, **India**	
	1570210219	Performance of Amplify-and-Forward Cooperative Diversity under Ricean Fading; **Maja Delibasic, Milica Pejanovic-Djurisic, Zoran Veljovic**; *University of Montenegro*, **Montenegro**	
	1570213163	Performance of a space-time coded MC-CDMA system in a Rayleigh fading channel; **Olanrewaju B Wojuola**, **Stanley H. Mneney**, **Viranjay M Srivastava**; *University of KwaZul-Natal*, **South Africa**	
	1570194569	A new shaping code for PAPR Reduction in Single-Carrier Modulation; **Yonathan Tate, Dan Raphaeli;** *Tel Aviv University*, **Israel**	
	1570207637	PAPR Reduction Comparison of the MC-CDMA System with Various Companding Techniques; **Sarala Beeram①, Bhagya sree Vonguru②, BN Bhandari③, Dronam Raju Venketeswarlu③**; *①M V S R Engineering College, Hyderabad & Osmania University*; *②B E & Osmania University, Hyderabad*; *③JNT University Hyderabad;* **India**	
13:30-14:30	LUNCH		
14:30-16:30	**Physical and Fundamentals (II-B-2) | Physical Channel: WPMC || *Session Chair-Thomas J. O. Afullo, University of KwaZullu-Natal, South Africa***		MRG .04
	1570213381	On Detection Improvement in MC-CDMA Image Watermarking on Fading Channel; **Santi Prasad Maity①, Seba Maity②**; ①Indian Institute of Engineering Science and Technology, Shibpur, ②CEMK, Kolaghat, **India**	
	1570213387	On the Backhaul Reduction in Joint Transmission Network with Channel Uncertainty; **Zhangxing Liu, Hui Tian, Cheng Qin** ; *Beijing University of Posts and Telecommunications*, **China**	
	1570212327	Variable Encoding and Sequencing Pattern Driven Multiple Image Bit Watermarking for Wireless Domain; Soumit Chowdhury①, Nabin Ghoshal ②; ①Govt. College of Engineering & Ceramic Technology, Kolkata, ② University of Kalyani, India	
	1570177831	Improving Performance of Impulsive Noise Canceller Under Class A Impulsive PLC Channel; **Hirotomo Yasui, Akira Nakamura, Makoto Itami**; *Tokyo University of Science*, **Japan**	
	1570211271	A Generic and Compatible Implementation for 2D and 3D Geometry-based Stochastic Channel Models; **Zhenzi Liu, Tian Lei, Yuming Bi, Pan Tang, Wei Chen, Jianhua Zhang**; *Beijing University of Posts and Telecommunications*, **China**	
	1570209407	Low Rate Common Control Channels with Distributed Cross-Layer Optimization via Genetic Algorithm; **Pranoti Balki, Kishor P. Patil**; *Sinhgad Academy of Engineering, Pune*, **India**	
16:30-17:00	COFFEE BREAK		

16:30-17:00	(Continued MRG .04 Activities) COFFEE BREAK		
17:00-19:00	**Physical and Fundamentals (II-B-3) Performance, Analysis and Ranking: WPMC || *Session Chair- Mqhele Dlodlo, University of Cape Town, South Africa***		MRG .04
	1570194241	Analysis of Data Transmission Management through Software Defined POX Controller; **Vaishnavi Moorthy, Revathi Venkatraman**; *SRM University, Chennai*, **India**	
	1570193591	Design and Performance Analysis of a Penta-band Spiral Antenna for Vehicular Communications; **Ramya R, T Rama Rao;** *SRM University, Chennai*, India	
	1570194537	Performance Analysis of Energy Detector in Correlated Log-normal Fading Channels for IR-UWB Systems; **S. Josephine, Anil Mahanta, P. R. Sahu**; *IIT Guwahati*, **India**	
	1570208727	Performance Comparision of Various Detection Methods for QO-STBC over Time Selective Channel; **Jyoti Patra, Poonam Singh**; *National Institute of Technology Rourkela*, **India**	
	1570211595	Design and Data Analysis of a Signal Measurement System Based on Variable Signature Sequences; **Ji-Hyun Moon, Jeong-Ho Kim, Na-Hyung Kim, and Bing Yuan Chen**; *Ewha Womans University*, **Republic of Korea**	
	1570191499	Ranking of Total Productive Maintenence pillars using Analytical Hierarchy Process; **Dnyandeo Shinde[1][2][3], Morten Falch[2], Rajendra Tated[3], Ramjee Prasad[4];** [1]*Center for Communication, Media and Information Technologies (CMI), Aalborg University Copenhagen,* **Denmark**, [2]*Aalborg University Copenhagen,* **Denmark,** [3] *Sandip Foundations, Nashik***, India,** [4]*CTIF, Aalborg University*, **Denmark**	
19:30-22:30	END of DAY 3 || NETWORKING DINNER: FOYER		

Time Slot	Day3: Tuesday, December 15 || MRG .05 Activities || Contributed Papers: Efficient Wireless Communications		
08:30-19:00	Registration		
09:00-11:00	**Keynote Speech**		**HALL 1**
11:00-11:30	COFFEE BREAK		
11:30-13:30	**Efficient Wireless Communications (A) | Energy Harvesting: WPMC || *Session Chair- Sudhanshu S. Jamuar, University of Malaysia Perlis*, Malaysia**		MRG .05
	1570213231	Energy-Efficient Resource Allocation for Hybrid Services with QoS Requirements in Cellular Network*;* **Yuhao Zhang, Ning Wang, Baoling Liu***; Beijing University of Posts and Telecommunications*, **China**	
	1570192925	DEAR: An Energy-centric Adaptive Region of Interest Mechanism for Wireless Mobile Devices; **Hrishikesh Venkataraman①, Ting Bi②, Ting Wu②, Gabriel-Miro Muntean②;** ①*Center for Smart Cities, Indian Institute of Information Technology (IIIT), Chittoor, Sricity, AP,* **India,** ②*Performance Engineering Laboratory, Dublin City University (DCU), Glasnevin, Dublin 9,* **Ireland**	
	1570192965	EDAS- Energy-Efficient Device-based Adaptive Cross-Layer Scheme for Wireless Multimedia Transmission; **Hrishikesh Venkataraman①, Shen Wang②, Gabriel-Miro Muntean②;** ①*Center for Smart Cities, Indian Institute of Information Technology (IIIT), Chittoor, Sricity, AP,* **India,** ②*Performance Engineering Laboratory, Dublin City University (DCU), Glasnevin, Dublin 9,* **Ireland**	
	1570194465	Energy Efficient Scheduling Algorithm for the Real-time Multicast and Unicast Services; **Min Wang①, Qiaoyun Sun①, Shuguang Zhang①, Yinlong Liu②, Yu Zhang②;** ①*Information School, Beijing City University;* ②*Institute of Information Engineering Chinese Academy of Sciences, Beijing;* **China**	
	1570213117	Secrecy Outage of a Cognitive Relay Network with Energy Harvesting and Imperfect CSI; **Pranabesh Maji, Binod Prasad, Sanjay Dhar Roy, Sumit Kundu;** National Institute of Technology, Durgapur, **India**	
	1570213446	Analytical Model of Relay Node Integrating IEEE 802.15.4 MAC and Energy Conserving State Behaviour; **Rajavaraprasad Yerra, Malyala Pavana Ravi Sai Kiran, Pachamuthu Rajalakshmi**; Indian Institute of Technology Hyderabad, **India**	
13:30-14:30	LUNCH		
14:30-16:30	**Efficient Wireless Communications (B) | Security, Trust, Privacy and Authentication: WPMC || *Session Chair- Vandana Rohokale , SIT, Lonavala, India***		MRG .05
	1570194123	Elliptic Curve Cryptography based Key Management for the M2M Local Cloud Platform; **Bayu Anggorojati①, Neeli Rashmi Prasad②, Ramjee Prasad①;** ①*Center For TeleInFrastruktur , Aalborg University*, **Denmark**; ②*Center For TeleInFrastruktur*, **USA (***)**	
	1570210161	Privacy-Preserving Friend Matching Protocol approach for Pre-match in Social Networks; **Shubhangi S.Ople①, Aaradhana A. Deshmukh②, Albena Mihovska②, Ramjee Prasad②;** *Savitribai Phule Pune University*, **India,** ②*CTIF, Department of Electronics Systems Aalborg University, Aalborg*, **Denmark**	
	1570195039	A certificate-driven Approach to Access Control in Future Internet; **Nancy Ambritta①, Poonam Railkar②, Parikshit Narendra Mahalle①;** ①*Sinhgad Institute of Technology and Sciences & Smt. Kashibai Navale College of Engineering,* ②*Smt. Kashibai Navale College of Engineering of Engineerin, Pune University*; **India (***)**	
	1570195141	A Modified RFID Authentication Protocol Using Elliptic Curve Cryptography; **Rajesh Dochania, Nirmal Roberts, Karm V Arya***; ABV-Indian Institute of Information Technology and Management, Gwalior*, **India**	
	1570213335	Secure and Privacy Enabled Anonymous Computing for Heterogeneous (SPEACH) IoT; **Meena Singh, Rajan M A, Shivraj Vl , P. Balamuralidhar**; *Tata Consultancy Sevices Limited*, **India**	
16:30-17:00	COFFEE BREAK		

16:30-17:00	COFFEE BREAK		
17:00-19:00	**Efficient Wireless Communications (C)	Security, Trust, Privacy and Authentication: WVITAE || *Session Chair-K.V. Arya, AVIIITM, Gwalior, India***		MR5 .05
	1570213434	Architectural Integration for Security in Advanced Metering Infrastructure; **Priyanka D.Halle[1], Vandana Rohokale[1], Ramjee Prasad[2]**; [1]E&TC SKNSITS, Lonavala, **India** [2] *Center For TeleInFrastruktur , Aalborg University*, **Denmark**	
	1570194669	Trustbook: A Trust-based access control in Online Social Networks; **Vedashree Takalkar, Parikshit Narendra Mahalle**; Savitribai Phule Pune University, STES, Pune, **India**	
	1570210113	Daubechies Wavelet based Effective Data Authentication in Wireless Domain; **Anirban Goswami[1], Nabin Ghoshal[2]**; [1]*Techno India*, [2]*University of Kalyani*; **India**	
	1570211897	Mesh IP Video Surveillance Systems Model Design and Performance Evaluation; **Smart Lubobya[1], Mqhele E. Dlodlo[1], De Jager Gerhard[1], Ackim Zulu[2]**; [1]*University of Cape Town*, **South Africa**; [2]*University of Zambia*, **Zambia**	
	1570210201	Secret Transmission through Audio Signal with Reduced Distortion for Wireless Communication (STASRD); **Dipnkar Pal[1], Nabin Ghoshal[2]**; [1]*Techno India*, [2]*University of Kalyani*; **India**	
	1570209931	Secure E- Voting System with integration of NFC, Biometrics and Cloud Computing; **Amol Potgantwar[1], Tejas Upasani[2]**; [1] *Sandip Foundation*, [2]*Savitribai Phule*,[1][2]*Pune University*; **India**	
19:30-22:30	END of DAY 3 || NETWORKING DINNER: FOYER		

Time Slot	Day3: Tuesday, December 15 || MRG .06 Activities || 23rd GISFI Standardization Series Meeting Meeting on Security and Privacy/ WWSMC	
08:30-19:00	Registration	
09:00-10:30	**23rd GISFI Standardisation Meeting on Security and Privacy/ WWSMC:** *Session Chair:* ***Anand R. Prasad****, NEC Corporation* ***Japan****; Session Organiser:* ***Anand R. Prasad,*** *NEC Corporation* ***Japan****;* ***Krishna Sirohi****, NIKSUN,* ***USA;*** ***Sivabalan Arumugam,*** *NEC Mobile Network Excellence Centre(NMEC), NEC India Pvt Ltd,* ***India*** Opening by Co-Chairs: **Anand R. Prasad**, Chief Advanced Technologist, Executive Specialist, NEC Corporation ; **Krishna Sirohi**, Senior Advisor, Niksun **Session 1: Cyber Security ||** Moderator**: Krishna Sirohi**, NIKSUN Topic: Cyber Security**, Ramamurthy Gemini,** *Chairman , Cyber security & privacy foundation***, India** **Session 2: IoT Security ||** Moderator: **Krishna Sirohi**, NIKSUN Topic: Internet of Things – Security**; Sivabalan Arumugam,** NEC Mobile Network Excellence Centre(NMEC), NEC India Pvt Ltd	MRG .06
10:30-11:00	COFFEE BREAK	
11:00-13:00	**GISFI Special Session on Security and Privacy/ WWSMC-1** **Session 3: Communication System Security ||** Moderator: Anand R. Prasad, NEC Corporation Topic: Telecom Security **; Vijay Madan,** Chief Mentor - IT & Technology, Network Operation, Tata Teleservices Limited Topic: Telecom Security **; Alf Zugenmaier,** Professor, Munich University of Applied Sciences Topic: Mobile PKI , **Zia Saquib**, Scientist, CDAC, Hyderabad Topic: Wired & Wireless Security **G.K. Satyanarana;** Head, Telecom, ECIL, Hyderabad	MRG .06
13:00-14:00	LUNCH	
14:00-16:00	**GISFI Special Session on Security and Privacy/ WWSMC-1** **Session 4: Cloud & Platform Security ||** Moderator: Sivabalan Arumugam, NEC India Pvt Ltd Topic: Information Security - Cloud Environment ; **Gopala Rao Jammi**, Professor , MEC (A Group of TechM), Hyderabad Topic: Personal Safety: Next Frontier in Mobile Security ; **Kulkarni Dattatraya**, Intel Security Group, Bangalore Topic: NFV Security**; Prabhu T**, NEC India, Chennai, **India** Topic: Monitoring Aspects**; Krishna Sirohi,** Senior Advisor, NIKSUN	MRG .06
16:00-16:15	COFFEE BREAK	
16:15-17:15	**GISFI Special Session on Security and Privacy/ WWSMC-2** **Session 5: Panel Discussion "What are the pains? What is needed?" ||** Moderator: **Anand R. Prasad**, NEC Corporation, **Japan** **Vijay Madan,** Chief Mentor - IT & Technology, Network Operation, Tata Teleservices Limited **G.K. Satyanarana,** Head, Telecom, ECIL, Hyderabad **Krishna Sirohi,** Senior Advisor, NIKSUN **Alf Zugenmaier,** Professor, Munich University of Applied Sciences	MRG .06
19:30-22:30	END of DAY 3 || NETWORKING DINNER: FOYER	

Wednesday, December 16

Day 4

"Workshops, Special Sessions, Contributed Papers"

Time Slot	Day4: Wednesday, December 16 || HALL 1.1 & 1.2 Activities || Workshops & Special Sessions (III-A)		
08:30-19:00	Registration		
09:00-11:00	**Keynote Speech || Session Chair : Ramjee Prasad, Center for TeleInFrastructure , Aalborg University, Denmark** **fred Harris**, San Diego State University, **USA** **Harish Mysore**, *IEEE*, **India** **Dinesh Chand Sharma,** *SESEI*, **India**		HALL 1
11:00-11:30	COFFEE BREAK		
11:30-13:30	**Second International Workshop on Innovation and Entrepreneurship(IWIE)- III** **Workshop Organizer and Chair: Sofoklis Kyriazakos,** CTIF, Aalborg University, **Denmark**		HALL 1.1
	WVITAE Special Session on "Communication, Navigation, Sensing and Services (CONASENSE)" - I **Session Organizers and Chairs: *Leo Ligthart, Tu-Delft, the Netherlands; Ernestina Cianca, University of Rome Tor Vergata, Italy***		HALL 1.2
	1570227732	Modified RAR and PLSR-based artifact removal for stroke detection in UWB radar imaging; **E. Ricci, A. Colucciello, S. Di Domenico, E. Cianca, T. Rossi**; University of Rome "Tor Vergata",Rome, **Italy**	
	1570228263	Communication Framework for Tele-rehabilitation Systems with QoS Guarantee; Plamen Semov, **Nikolay Dandanov, Georgi Balabanov, Krasimir Tonchev and Vladimir Poulkov**; *Technical University of Sofia*, **Bulgaria**	
	1570230189	vNet Zero Energy for Radio Base Stations- Balearic Scenario①; Pere Sabater Frau①, Albena Mihovska①, Ramjee Prasad①, Andreu Moia Pol② ,Angel Igelmo Ganzo②, Xavier Canals Solé③, Jaume Ochogavia Colom④; *Center for TeleInFrastruktur (CTIF) Aalborg University, **Denmark**; ②Universitat Illes Balears (UIB), ③Telefonica España S.A., ④Balearic Islands Government*, **Spain**	
	1570236132	Reliable Frame Selection for Speaker Identification under Voice Disguise Scenario; **Swati Prasad, Ramjee Prasad**; *Centre for TeleInfrastruktur (CTIF), Aalborg University, Aalborg*, **Denmark**	
	1570228151	Performance Analysis of SOFDM Transmission Scheme over Integrated Satellite/Terrestrial Network; **Akash Agarwal□①, B. M. Bhaveja②, Preetam Kumar①**; ①*Indian Institute of Technology Patna□*, ②*Department of Electronics & Information Technology (DeitY) New Delhi*, **India (***)**	
13:30-14:30	LUNCH		
14:30-16:30	**Second International Workshop on Innovation and Entrepreneurship(IWIE)- III (Contd)** **Workshop Organizer and Chair: Sofoklis Kyriazakos,** CTIF, Aalborg University, **Denmark**		HALL 1.1
	WVITAE Special Session on "Communication, Navigation, Sensing and Services (CONASENSE)" -II **Session Organizers and Chairs: *Leo Ligthart, Tu-Delft, the Netherlands; Ernestina Cianca,** University of Rome Tor Vergata, **Italy***		HALL 1.2
	1570226963	Efficient Filtering Technique for Chronic Wound Image Processing under Tele-Wound Network; **Chinmay Chakraborty, Bharat Gupta**; *Birla Institute of Technology Jharkhand*, **India**	
	1570227100	End-to-End Delay Analysis of IEEE 802.15.6 Standard for WBAN Medical Paradigm; **Vivek Kumar, Bharat Gupta**; *Birla Institute of Technology Jharkhand*, **India**	
	1570227212	Relevance of signal processing of the voice in diagnosing human tuberculosis; **Giovanni Saggio①, Santosh Bothe②**; ①University of Rome "Tor Vergata",Rome, **Italy, ②***Bharati Vidyapeeth University , Pune*, **India**	
	1570227247	A P2P architecture for Mobile Assisted Logistic Operations; **Pierpaolo Loreti* , Lorenzo Bracciale* , Francesco Zampognaro* , Massimo Povia† , Gianluca Gargiulo‡;** **NITEL - University of Rome Tor Vergata, †Technosky Via del Casale Cavallari, §NAIS Via Andrea Noale; Rome*, **Italy**	
	1570238200	GeoLocation Aware Dynamic Spectrum Sensing in Cognitive Radio Networks; **Usha Kurumaddali,** *GGS Indraprastha University*, **India**	
17:30	END OF WPMC-2015 & GWS-2015		

Time Slot	Day 4: Wednesday, December 16 || MRG .01 Activities || Contributed Papers: Wireless Communications		
08:30-19:00	Registration		
09:00-11:00	**Keynote Speech**		**HALL 1**
11:00-11:30	COFFEE BREAK		
11:30-13:30	**Wireless Communications (A) | Spectrum for Future Radio Networks: WPMC || *Session Chair: Albena Mihovska, CTIF, Aalborg University, Denmark***		MRG .01
	1570235616	Preliminary performance evaluation of the FBMC based future IEEE 1900.7 Standard; **D. Noguet, J.-B. Doré and B. Miscopein**; *Minatec Campus CEA Leti 17, rue des Martyrs – 38054 Grenoble Cedex 9*, **France**	
	1570213121	Long-haul Communication Trial in London TV White-space with IEEE 802.11af-based High Power Prototype; **Takeshi Matsumura[1] , Kentaro Ishizu[1] , Keiichi Mizutani[2], Tran Ha Nguyen[1], Homare Murakami[1][3], Fumihide Kojima[1][3], Hiroshi Harada[2][3]**; *[1]NICT, Yokosuka, [2]Kyoto University, [3]Kyoto, ICT, Koganei*, **Japan**	
	1570192849	Outage Analysis of Cellular Two-Way Relaying with Spectrum Sharing in Nakagami-m Fading; **Ronshee Chawla, M. Mounika Reddy, Prabhat Kumar Upadhyay**; *IIT Indore*, **India**	
	1570213448	Field Experiments for Broadband Mesh Network Operating in TV White Space; **Kentaro Ishizu, Fumihide Kojima**; *National Institute of Information and Communications Technology*, **Japan**	
	1570210145	TVWS Regulations and the first IEEE 802.11af indoor experiments in Singapore; Dien Vinh Hoang[1], Takeshi Matsumura[2], Kentaro Ishizu[2], Homare Murakami[2], Fumihide Kojima[2]; [1]*Singapore Smart Wireless Lab, National Institute of Information and Communications Technology* (NICT), **Singapore**, [2]*NICT*, **Japan**	
	1570194697	Novel Closed form Expression for Multi Cell Cooperation using MHCP to Reduce Interference; **Suman Yadav, S Pratap Singh**; *Galgotia College of Engineering and Techolongy*, **India**	
13:30-14:30	LUNCH		
14:30-16:30	**Wireless Communications (B) | Algorithms and Innovative Approach: WVITAE || *Session Chair: Sri Chandrasekaran, IETE, India***		MRG .01
	1570210211	Classification Based Automatic Assessment for Web Based Learning; Wacharawan Intayoad, Punnarumol Temdee; Mae Fah Luang University, **Thailand**	
	1570188921	Comparative analysis of load balancing algorithms for LTE/LTE-A Hetnets; **Diego Castro-Hernandez**, **Raman Paranjape**; *University of Regina*, **Canada**	
	1570208745	Fuzzy based Moving Object Detection and Classification in Video; **Manojkumar M Gawali**, *Sinhgad College of Engineering*, Pune, **India**	
	1570213914	Swarm Optimization Based on Genetic Algorithm & Relevance Feedback Technique for Data Clustering; **Gandamalla Malini, M.Seetha, K.V.N.Sunitha**; *GNITS, Hyderabad*, **India**	
	1570212950	Downlink Joint Processing for Non Orthogonal Multiple Access; **Islam Atef, Essam Sourour;** *Alexandria University, Alexandria*, **Egypt**	
	1570197177	The Studies of Millimeter Waves at the frequencies of 60 GHz in Outdoor Environments- A Survey; **Hitesh Singh**; *HMRITM, Delhi*, **India**	
16:30-17:00	COFFEE BREAK		
	Networking		
	END OF WPMC-2015 & GWS-2015		

Time Slot	Day 4: Wednesday, December 16 || MRG .02 Activities || Contributed Papers: Physical and Fundamentals (III)		
08:30-19:00	Registration		
09:00-11:00	**Keynote Speech**		**HALL 1**
11:00-11:30	COFFEE BREAK		
11:30-13:30	**Physical and Fundamentals (III–A) | Signal Processing-1: WPMC & WVITAE || *Session Chair: Navin Kumar, Amrita University, Bangalore, India***		**MRG .02**
	1570194245	Blind Image Quality Assessment Based on Phase Congruency and Spatial-spectral Entropies; **Maozheng Zhao, Yanping Lu, Cuiwei Li, Ran Gao, Qin Tu, Bo Yang, Aidong Men**; *Beijing University of Posts and Telecommunications*, **China**	
	1570195699	Opinion-unaware blind image quality assessment based on sparse representation; **Maozheng Zhao[1], Xiaoqiang Guo[2], Ran Gao[1], Bo Yang[1], Aidong Men[1]**; [1]*Beijing University of Posts and Telecommunications*, [2]*Academy of Broadcasting Science*, **China**	
	1570208027	QoE Based Pseudo Heartbeat Message Compression Mechanism for Wireless Networks; **Zhiqun Hu, Xiangming Wen, Zhaoming Lu, Zhaoxing Li**; *Beijing University of Posts and Telecommunications*, **China**	
	1570213506	**WVITAE**: On CS Reconstruction Images using LDPC code over Radio Mobile channel; **Ankita Pramanik, Santi Prasad Maity**; *Indian Institute of Engineering Science and Technology, Shibpur*, **India**	
	1570210061	Modeling of Modified Erlang-k Distribution for Raindrop Size Distribution over South Africa; **Akintunde Alonge, Thomas Afullo**; *University of KwaZulu-Natal, Durban*, **South Africa**	
	1570192393	Enhanced Turbo Equalizer Using 2 Dimensional Iterative Soft Decision Interference Cancellation; **Doron Shinbox, Dan Raphaeli**; *Tel-Aviv University*, **Israel**	
13:30-14:30	LUNCH		
14:30-16:30	**Physical and Fundamentals (III –B) | Design and Development: WPMC & WVITAE || *Session Chair: Venkatapathy Prithviraj, Rajalakshmi Institute of Technology, Chennai, India***		**MRG .02**
	1570209863	Modeling & Simulation for complex System of systems design, test, and verification; **Uma Jha, Jon Wada**; *Space & Airborne Systems, Raytheon CoEl Segundo, California* , **USA**	
	1570213885	Design Of Low Voltage Bandgap Reference Circuit Using Subthreshold MOSFET; Sushma Sangolli, Rohini Hongal; *B.V.B College of Engineering and Technology, Hubli*, **India**	
	1570194201	Eight-Path Harmonic Rejection Mixer for Full Band Mobile TV; **Kiran B, Roy P Paily**; *Indian Institute of Technology Guwahati*, **India**	
	1570209947	Database Assisted Automatic Modulation Classification Using Sequential Minimal Optimization; **K. Pavan Kumar Reddy, Lakhan Shiva, Kadiri Abhilash, Yoganandam Yeleswarapu**; *Birla Institute of Technology and Science, Hyderabad Campus*, **India**	
	1570212671	Design and Development of a Mobile Wireless Video Streaming Mote; **Bhuvanesh D, Manjunath Hegde, Manikandan J**; *PES Institute of Technology*, **India**	
	1570213484	Design of BiCMOS based low temperature coefficient bandgap reference; **Deepa Talewad, Anilkumar Nandi, Ramesh Karmungi**; *B.V.B College of Engineering and Technology, Hubli*, **India**	
16:30-17:00	COFFEE BREAK		
	Networking		
	END OF WPMC-2015 & GWS-2015		

Time Slot	Day 4: Wednesday, December 16 || MRG .03 Activities || Contributed Papers: Wireless Networks		
08:30-19:00	Registration		
09:00-11:00	**Keynote Speech**		**HALL 1**
11:00-11:30	COFFEE BREAK		
11:30-13:30	**Wireless Networks | WPMC & WVITAE || *Session Chair: G S Tomar, MIR Labs, Gwalior, India***		MRG .03
	1570184143	A Fine Grained Position for Modular Core NoC; B. **Naresh Kumar Reddy, M.H.Vasantha, Y.B.Nithin Kumar, Dheeraj Sharma**; *National Institute of Technology, Goa*, India **(***)**
	1570191965	Analytical Evaluation of Frequency Reuse For Hybrid Full-/Half-Duplex Cellular System; Wenping Bi, Limin Xiao, Xin Su, Shidong Zhou; *Tsinghua University*, **China**
	1570192715	A New Approach for Crossed Sector Detection in Live Mobile Networks based on Radio Measurements; David Duarte①②, Pedro Vieira①②, António J. Rodrigues③, André Martins, Nuno Silva③; ①*Instituto Superior de Engenharia de Lisboa (ISEL),* ②*Instituto de Telecomunicac¸˜oes (IT), Lisbon,* ③*Instituto Superior T´ecnico (IST), Lisbon,* **Portugal**
	1570213280	A Revolutionary Rural Agricultural Participatory Sensing Approach Using Delay Tolerant Networks; **Prateek Gupta, Bhushan Gurmukhdas Jagyasi, Bighnaraj Panigrahi, Hemant Kumar Rath, Srinivasu Pappula, Anantha Simha**; *Tata Consultancy Services*, **India**
	1570213277	**WVITAE:** Performance Analysis of EPC with IMS Network Architecture; **A Bagubali①, Prithiviraj Venkatapathy②, Pathak Mallik①**; ①*VIT University, Vellore,* ②*Rajalakshmi Institute of Technology , Chennai,India,* **India**
	Invited Talk	Role of Cyber Security for Digital Business; **T. R. Dua**, *GISFI*, **India**
13:30-14:30	LUNCH		
14:30-16:30	**Wireless Networks | WPMC || *Session Chair: Hrishikesh Vankataraman, Indian Institute of Information Technology, Chittoor, India***		MRG .03
	1570213596	IEEE802.15.4g based Wide Area and Mobile Wi-SUN Communication Systems; **Hiroshi Harada, Keiichi Mizutani, Kentaro Mochizuki, Kentaro Obata**; *Kyoto University*, **Japan**
	1570207517	Hierarchical Mesh Based Energy Efficient Multicast Routing on IEEE 802.15.4 based networks; **Verotiana Rabarijaona①, Fumihide Kojima①, Hiroshi Harada②**; ①*National Institute of Information and Communication Technology,* ②*Kyoto University & Graduate School of Informatics,* **Japan**
	1570192635	Efficient Visibility Modeling for Free-Space Optical Systems Design; **Ivo Sousa①③, António J. Rodrigues②, Maria Paula Queluz②**, ①*Instituto de Telecomunicac¸˜oes (IT), Lisbon,* ②*Instituto Superior T´ecnico (IST), Lisbon,* **Portugal**
	1570187749	Reliable Link Layer Packet Reconstruction for Rotating Polarization Based Radio Communication; **Ritesh Kumar Kalle**, *HITACHI*, **India**
	1570213414	SUN-RAN Orchestrating Resource Management using Superframe Division Data Aggregation Technology; **Fumihide Kojima, Chang-Woo Pyo, Masayuki Oodo**; *National Institute of Information and Communications Technology(NICT),* **Japan**
	1570176791	Green Indoor Network In A Passive Way; Yu Liu, *Jiangsu Automation Research Institute*, **China**
16:30-17:00	COFFEE BREAK		
	Networking		
	END OF WPMC-2015 & GWS-2015		

Time Slot	Day 4: Wednesday, December 16 || MRG .04 Activities || Workshops & Special Sessions (III-B); IC5		
08:30-19:00	Registration		
09:00-11:00	**Keynote Speech**		**HALL 1**
11:00-11:30	COFFEE BREAK		
11:30-13:30	23rd GISFI Standardization Meeting- 5 G Innovation in India **Session Chair: Ashutosh Dutt**		
	Presentation1	5G Framework for a Personalised Network; **Nitish Mittal**, *5G Company, Vishawaniketan*, **India**	
	Presentation2	5G Model in WISDOM; **Sounak Moulik**, *5G Company, Vishawaniketan*, **India**	
	Presentation3	Security Challenges in a 5G Network; **Nidhi** , *5G Company, Vishawaniketan*, **India**	
	Presentation4	5G Concept; **Sandeep Mukherjee**, *,5G Company, Vishawaniketan*, **India**	
13:30-14:30	LUNCH		
14:30-16:30	**IC5: Third International Conference on Communications, Connectivity, Convergence, Content and Cooperation** **Session Chair: Swrana Ravindra Babu, IETE, India**		MRG .04
	1570213308	Survey on Service Discovery Mechanisms; **Gitanjali Shinde Henning Olesen**; *Center for Communication, Media and Information Technologies (CMI) Aalborg University Copenhagen*, **Denmark**	
	1570191301	Multislotted Microstrip Patch Antenna for Dual Band and UWB Applications; **Shailendra Kumar Dhakad, Dr. Neeraj Kumar, Keshav Kumar, Swapnil Mengade, Rohit Gupta**; *Birla Institute Of Technology and Science Pilani, Goa*, **India (***)**	
	1570194207	An application of Internet of Things in Transportation System; **Ganesh Balaraman, Harisudha Kuresan**; *SRM University*, **India (***)**	
	1570195047	Analysis of Audio Watermarking Techniques for Cyber Security in Copyright Infringement; **Sushma Ambekar① □, Vandana Rohokale①, Ramjee Prasad②;** ①SKNSITS, Lonavala, **India**, ②CTIF, Aalborg University, **Denmark**	
	1570208707	30-Second Integration Time Power Law Conversion Model for Rainfall Attenuation in South Africa; **Mary N. Ahuna,, Thomas J. Afullo, , Akintunde A. Alonge**; *University of KwaZulu Natal Durban*, **South Africa**	
	1570209327	Illumination, Indoor Localization and Very High Speed Data Communication using VLC; **Anusha Addanki, Navin Kumar**; *Amrita Vishwa Vidyapeetham (University) Bangalore*, India	
16:30-17:00	COFFEE BREAK		
	Networking		
	END OF WPMC-2015 & GWS-2015		

Time Slot	Day 4: Wednesday, December 16 || MRG .05 Activities || Workshops & Special Sessions (III-C)		
08:30-19:00	Registration		
09:00-11:00	**Keynote Speech**		**HALL 1**
11:00-11:30	COFFEE BREAK		
11:30-13:30	**WVITAE Special Session on " Wireless Communications"** **Session Organizer and Chair** : *Mqhele Dlodlo, University of Cape Town, South Africa*		MRG .05
	1570227491	Hard-combined Cooperative spectrum sensing using Time-frequency method; **S M Hiremath①, Sarat Kumar Patra①, Amit Kumar Mishra②;** ①*National Institute of Technology Rourkela, Odisha,* **Indiadlodlo,** ②*University of Cape Town*, **South Africa**	
	1570228229	The Implementation of the Modified AODV Routing Protocol in Mobile Ad-Hoc Networks; **Vekani Reviet Baloyi, Lesiba Kola**; *University of Limpopo*; **South Africa (###)**	
	1570228530	Enlarged QR-LRL Based Massive MIMO Detector for Soft Output Generation; **Sukriti Garg, Krati Mittal, Divyang Rawal**; *LNM Institute of Information Technology, Jaipur*, **India**	
	1570230967	Interference Management in Heterogeneous and Small Cell NetwPerorks; **M. Bala Krishna, Puneet Bansal**; *Guru Gobind Singh Indraprastha University , New Delhi,* **India**	
	1570233114	Mesh IP Video Surveillance System - A System Perspective and Performance Evaluation; **M .E. Dlodlo, C. S. Lubobya, S Lubobya, O Osanaiye, E Okumu, H Ohize,** *University of Cape Town*, **South Africa**	
13:30-14:30	LUNCH		
14:30-16:30	**WPMC Special Session on " Selected Topics in Physical & Fundamentals -2"** **Session Organizer and Chair** : ***Bharat Gupta, Birla Institute of Technology, Ranchi, India***		MRG .05
	1570210153	An ingenious framework for solving cold start problem in recommender system; **Pankaj Chaudhary① , A. A. Deshmukh②**; ①*Smt. Kashibai Navale College of Engineering, Pune* **India**, ②*Department of Electronics Systems, Aalborg University*, **Denmark (***)**	
		Area-Power Analysis of Carry Selected Adder using Transmission Gates; **Ch. Rajendra Prasad①, T. Anil Kumar②**; ①*SVS Institute of Technology*, ②*SR Engineering College*; Warangal, **India (###)**	
		Privacy Preserving Friend Matching Protocol for Pre match in Social Networks; **Shubhangi Ople, Aradhna Deshmukh**; *Smt. Kashibai Navale College of Engineering, Pune* **India (###)**	
		Self-Programmable Variable Digital Filter (VDF) Design Based of FPGA; **T. Anil Kumar;** *SR Engineering College,* Warangal, **India (###)**	
		Design of High Performance Phase Locked Loop for Clock Synchronization; A. Rajesh①, B.L. Raju①, K. Chenna Kesava Reddy②; ①ACE, Engineering College, ②*Jawaharlal Nehru Technological University College of Engineering*; Hyderabad, **India** (###)	
	1570237867	Object Detection, Passive tracking and Active Tracking; **Shreeya Shevade**, *Government College of Engineering, Aurangabad, Maharashtra,* **India (***)**	
16:30-17:00	COFFEE BREAK		
	Networking		
	END OF WPMC-2015 & GWS-2015		

Time Slot	Day 4: Wednesday, December 16 || MRG .06 Activities || Workshops & Special Sessions (III-C)

***Abstract*—Delay Tolerant Networks (DTNs) are sparse mobile networks in which a complete end-to-end path may not exist. Routing is challenging in such networks, because of the frequent network disconnections, which will result in frequent change in network topology. Most of the existing DTN routing algorithms consider that all the nodes are honestly participating in message delivery. But in many real scenarios, nodes are selfish, and not willing to forward the message further in the network. We observed that in many real scenarios, neither all nodes are altruistic nor selfish, and classified the selfishness present in the network into individual selfishness and social selfishness. In case of individual selfishness, a node may behave selfishly because of some external reason, such as limited buffer space, limited power, etc. A node will forward the message only to nodes, who are friends, or having similar interests, or belongs to same community, etc., in case of social selfishness, In this paper, we have analyzed the impact of both individual and social selfishness on exiting flooding based routing algorithms such as Epidemic routing and Spray and Wait routing and proposed a method to detect and resolve selfishness to improve their routing performance.**

I. Introduction

Delay Tolerant Networks (DTNs) are sparse wireless networks where mobile nodes work in an ad-hoc manner and forward data opportunistically upon contacts. DTNs allow communication between nodes in the absence of network infrastructure and continuous network connectivity. Therefore, they are widely used in many applications like social networking [1] [2], wildlife tracking [3] [4], remote village networks [5] [6], vehicular communication [7] [8] and underwater networks [9], etc.

In DTNs, different types of user behavior will result in different network conditions. DTN based short message service has become very popular these days because it offers a more convenient way to exchange information in a mobile way. DTNs are marked by their mobile nodes with their contact sequences in order to exchange the packets. DTN Routing can be divided into opportunistic routing, social based routing and incentive based routing. In opportunistic routing, the relay node is selected based on its opportunity of meeting the destination node. In social based routing, the relay is selected based on social relationship with the destination node. In incentive based routing, credits are given to the relay node for forwarding the message.

A node in a DTN is considered as selfish when that node is not willing to forward the packet further in the network. There can be various scenarios present in which few nodes in a network can act selfishly. The nodes in DTN can act individually or socially selfish. Nodes show individual selfishness because of the small buffer space and less battery power and they act socially selfish because they do not want to act as a relay for the nodes with which it does not have social ties with it or does not belong to same communities, etc. For successful working of DTNs there is a need that all nodes in the network communicate honestly, but in reality nodes are not willing to participate in the network which hinders the performance of the network.

In this paper, we have discussed two types of selfishness, individual and social, that can be present in the network. We then analyze the effects of these two types of selfishness on flooding based DTN routing algorithms such as Epidemic routing and Spray and Wait routing, and proposes a technique to improve the packet delivery ratio of the existing algorithms by mitigating the selfishness involved.

II. Related Works

The routing in DTN can be done with the help of the social characteristics of the nodes, like friendship, community, etc.; or by forcing the nodes to participate in the routing process by giving credit to them; or it can be done just by mere exchanging the packets when encountered with other nodes. Selfishness can be divided as individual selfishness and social selfishness. In individual selfishness the nodes behave selfishly because of its own interest, the nodes in this category are only interested in forwarding their own packets. In the social selfishness, the nodes do they not forward the packet to the nodes with which they do not have any social connection.

Three types of individual selfishness are considered in the previous works. In the first category, non-participation, there are two types of nodes present in the network, the one who explicitly do not take part in the routing process and the other one, who after accepting the packet drops it from the network. In the second category, energy-preservation, the nodes do not participate to save their device energy. In the last category, storage-preservation, the nodes act selfishly even when the storage space is available to save their buffer space for their own use.

Chen, et al. [10] proposed a trust management protocol in which, not only the quality of service is considered, but, also considers the social properties of the network. The social properties include the honesty and unselfishness of the nodes.

They propose two models, equal weight QoS and also the social trust management protocol. When compared with epidemic routing, the trust based protocol gave a higher delivery ratio than epidemic routing.

Wu, et al. [11] uses a theoretical framework to analyze the effect of the social selfishness. A social graph is considered as an overlay above the actual physical graph. A social graph is a graph in which two nodes are connected if they are friends with each other. It is then assessed that the links of a node in the social graph follow a power law distribution. A relation between nodes can be of strong link and weak link as nodes are more willing to help their friends. The system is modeled as a Markov process. The results of the analysis show that the different degree of social selfishness has different performance of the routing algorithm.

Miao, et al. [12] calculates the effect of binary Spray and Wait protocol when selfish nodes present in the network. Two types of nodes are assumed to be present in the network, the nodes which specifies explicitly for non participation and the nodes which drops the packet after receiving the same. They calculated that the delivery probability of the routing algorithm reduced to 40 % when all the nodes are selfish with the help of Random Way Point Model.

Wu, et.al. [13] gives a theoretical model to simulate the presence of individual and social selfishness in Epidemic Routing. The model was based on Markov process. Their simulation results show that the presence of selfish nodes reduces the performance of epidemic routing significantly, also, if there are nodes which are present in two or more communities which in turn improves the delivery performance of the same.

III. Epidemic Routing

Vahdat, et al. [14] have proposed a flooding based forwarding approach, called as Epidemic routing with an aim to maximize the delivery rate while minimizing the delivery delay. For reducing the total network resources consumed while routing the message from source to destination, they suggest to put a limit on either the message hop count or the buffer space allocated at each node. Therefore, the message will be dropped after its TTL (Time-To-Live) expires or if the buffer at the peer is full. This scheme is based on the idea that the message will eventually find its destination through transitive exchanges between nodes, if they are spread in the connected portion of the network.

The primary goal of epidemic routing is to deliver messages with high delivery probability to the destination node. As it can be seen from figure 1, that the source of the message floods the message to C_1 and C_2, which are in its range; C_2 then stores the message till it meets another node C_3. Then C_3 stores the message and finally deliver it to the destination D. So, the overall goal of epidemic routing is to escalate the delivery rate and minimize the delivery latency.

All nodes are assigned a unique node identifier. Every node stores a summary of the messages it has cached locally in a summary vector. Whenever some node *A* comes in the communication range of node *B*, the node with smaller identifier, say node *A*, starts an anti-entropy session with the

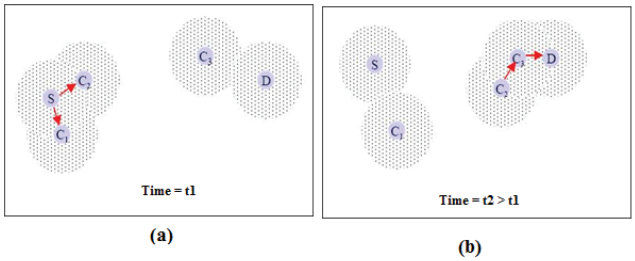

Fig. 1. Epidemic Routing

node *B*, as shown in figure 2. During this, *A*, provides its summary vector to *B*. Node *B*, finds which messages present in *A*s cache are not present locally and makes a request for them. Then, the initiator of the anti-entropy session, here node A, provides the requested messages to node *B*. Some messages may find their destination in this step only (i.e., messages destined to *B*), while others have to be similarly relayed across the network.

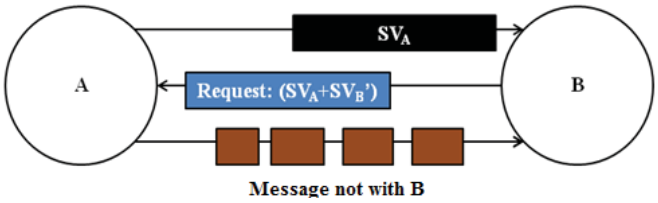

Fig. 2. Summary vector exchange in Epidemic Routing

Flooding results in high resource consumption in terms of both power and storage. Hop count can be set to lower values to avoid this. By setting a low value of hop count, the delivery ratio will decrease and average delivery time will increase. On the other hand, if hop count is high, messages will be dispersed in the network more quickly, resulting in a higher delivery ratio and lower average delivery time. Bounding the buffer space at every node is another trick to reduce resource consumption. Epidemic routing can have a delivery rate of 100% in partitioned networks where ad-hoc routing protocols fail entirely.

A. Epidemic Routing With Selfishness

Epidemic routing is the flooding based algorithm, no decision making scheme is required while choosing the relay, to decrease the resource consumption. Whenever node *A*, meets a peer *B*, all the messages which node *A*, have, are forwarded to node *B*. As the contact time is small in these types of networks and when the nodes in the network are showing the selfish behaviors, the packets should be sent to those nodes first who does not show the selfishness property. Every node in the network maintains a table *R*, which is used to store history of receipt of messages from its neighbors. Suppose, a source node *S*, wants to send a message to destination node *D*. Let *X*, be the set of neighbors of the node *S*, then the node *S*, sorts the list its neighbors in increasing order with respect to

the value of corresponding *R*, as shown in equation 1. Then a node sends the messages to the connections in order according with the sorted list.

$$\underset{i \in X, i \neq S}{\forall} Sort_{ascending}(X, R) \tag{1}$$

IV. Spray and Wait Routing

Spray and Wait is a limited flooding-based approach [15], a betterment of Epidemic Routing. It is also a multi-copy scheme where the message is replicated with encountered nodes for routing to the destination. The strength of this scheme is that it is simple, does not require any knowledge about the network and does not even use the past encounter records.

Whenever a node has a message to send to some other node, it replicates the message into *L* different nodes. This is called as the spray phase, because the source node, without any network information, copies its message to other nodes. If the destination of the message is not met during the spraying process, these *L* nodes transmit a single copy directly to the destination node. Transmitting the message directly means that the nodes will buffer the message till they see its destination or its TTL expires. This is the wait phase of the algorithm.

There may be different variations of the algorithms based on the distribution of initial *L* copies on the network. In the simplest form, *L* copies can be distributed to first *L* distinct nodes the source encounters. Another variation of the algorithm, called Binary Spray and Wait, is to distribute half of the copies to the encountered node and keeping the remaining half at every step of relaying. This means, if a node A has *n* copies of the message and encounters a node B, it sprays *n/2* copies to B and keeps the remaining *n/2* copies with itself and repeats this until it is left with just a single copy when it switches to direct transmission. Spray and Wait is a ticket-based forwarding scheme, in which, every message is assigned logical tickets. Tickets depict the number of relays the message is to be forwarded.

We have worked on Binary Spray and Wait algorithm, in which, if a node have multiple copies of a packet and if it has a connection with node B, then the former node gives half of the copies to the later node and keeps half of it. And when a node is left with one instance of the packet, it can do only transmission to the destination node.

We can see an example, in figure 3, in which node *S*, sprays, 3 copies to node 1, 2 and 3 respectively. Node 7 sprays 2 copies to node 11 and 8 and is left with half of the copies. Nodes 11 and 8 send their copies to node 10 and so on. Node 14 and 16 is the nodes who were finally left with only one copy and they send it directly to the destination, *D*.

The advantages of this algorithm are :

• It has less number of transmissions when compared with other flooding-based schemes

• When the load is high in the network, it gives less delivery delay

• It is scalable, as the number of nodes in the network increases, the number of transmissions per node decreases

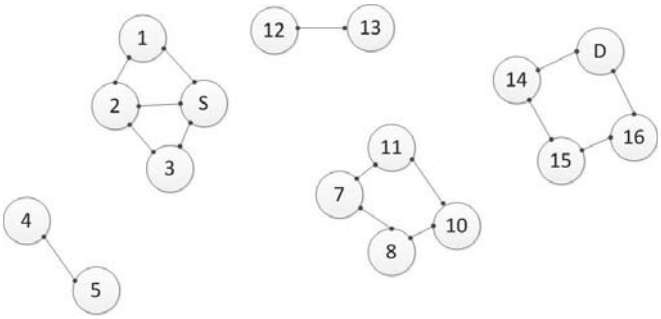

Fig. 3. Spray and Wait Routing

• It is a very simple algorithm and requires no knowledge of the network

A. Spray and Wait With Selfishness

As Spray and Wait routing is the modified version of epidemic routing, it is also a type of flooding based technique. The only difference lies in the fact that instead of disseminating the message to all the connections, it sprays or sends only L copies to all the active connections it has. Similar to epidemic routing, the method sort all its neighbors, *X*, in the increasing order of table *R* as in equation 1, where *S* is the node who is seeking the next relay.

V. Results

Evaluating the various DTN protocols requires some proper tool and the ONE simulator [16] is one such tool. The ONE simulator is mainly used for the modeling of the nodal movement, inter node contacts, message handling and routing. We have done the empirical analysis for Epidemic Routing and Spray and Wait with the help of ONE Simulator.

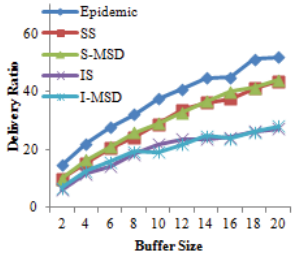
We have considered that there are three types of nodes present in the network, vehicular nodes, pedestrian nodes and tram nodes. The simulation time is the total number of time span which have considered for node communication. The transmission speed of the node is the data rate at which the packets are transmitted from one node to another. Time to live is the total number of seconds after which the packet will get dropped from the network. A message creation interval is the time range in which the nodes creates packet for each other. Wait time is the time for which each node waits before moving to the next location.

TABLE I. Simulation Settings

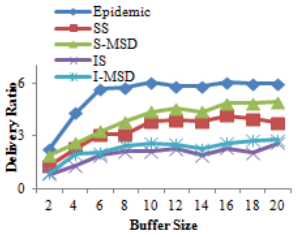
Parameters	Values
Simulation time	43200s=12h
Transmission Speed of nodes	250kBps
Number of nodes	125
Time To Live (TTL) of a message	300 minutes
Message Creations Interval	25-30 Seconds
Wait Time	10-30 seconds
Interface	Bluetooth and high speed interface

To model the real-world mobility, we have used two types of map based mobility and random movement models for simulation.

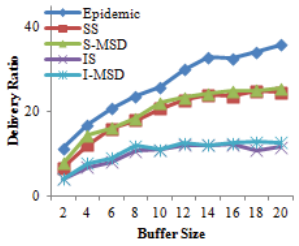
TABLE II. EPIDEMIC ROUTING RESULTS



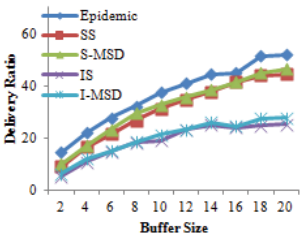
(a) SPMBM, pnc =0.9, pnf =0.1



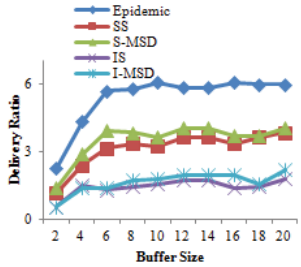
(b) RWPM, pnc =0.9, pnf =0.1



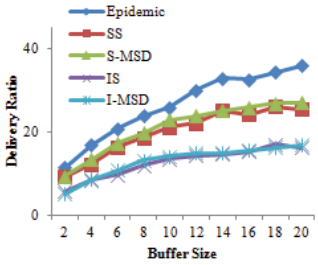
(c) MBM, pnc = 0.9, pnf = 0.1



(d) SPBM, pnc =0.5, pnf =0.5

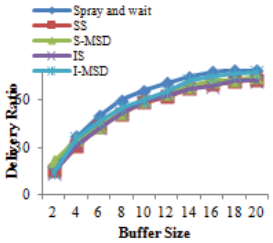


(e) RWPM, pnc =0.5, pnf =0.5

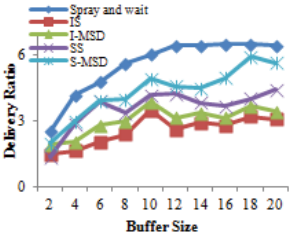


(f) MBM, pnc =0.5, pnf =0.5

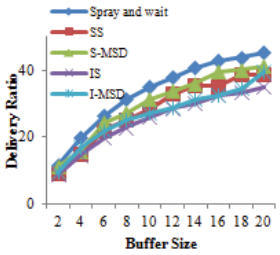
TABLE III. SPRAY AND WAIT ROUTING RESULTS



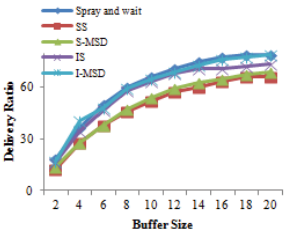
(a) SPBM, pnc=0.9, pnf=0.1



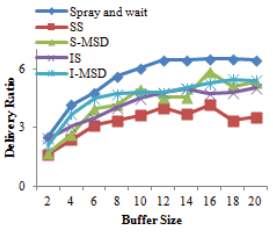
(b) RWPM, pnc=0.9, pnf =0.1



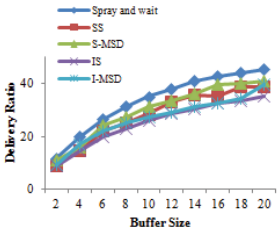
(c) MBM, pnc =0.9, pnf =0.1



(d) SPMBM, pnc = 0.5, pnf =0.5



(e) RWPM, pnc =05, pnf =0.5



(f) MBM, pnc =0.5, pnf =0.5

• Random Movement Mobility Model: In this type of models the nodes move randomly and freely without restrictions, and their location, velocity and acceleration changes with time. It is a famous model because of its simplicity. The destination for a node, its speed and direction are all chosen randomly. The drawback with this type of model is that, it is not close to the real world movement.

• Map-Based Movement Mobility Model: This mobility model is different from the random movement model in a way that all the node movement is confined to the underlined paths of the graph. We have used Helsinki downtown area, both roads and pedestrian walkways.

Figure (a) to (c) in Table II shows the performance of Epidemic Routing when the buffer threshold is 30% and the value of pnc=0.9 and pnf=0.1 with ShortestPathMapBased Movement (SPMBM), Random Waypoint Movement (RWPM) and MapBasedMovement (MBM). Figure (d)-(f) shows the same but with variation with probabilities, pnc=0.5 and pnf=0.5.

It can be concluded from the above results that the effect of social and individual selfishness is different on the delivery probabilities of the Epidemic routing. I-MSD and S-MSD gives good performance with SPMBM and RWPM model and, I-MSD does not gives good results with MBM model, as this mobility model does not follow any path property and the relations between the nodes could not be created. Whereas S-MSD gives better results with MBM because the friends of a node does not change and is irrespective of the node mobility.

Figure (a)-(c)in Table III shows the performance of Spray and Wait Routing when the buffer threshold is 30% and the value of pnc=0.9 and pnf=0.1 with ShortestPathMap-Based Movement (SPMBM), Random Waypoint Movement (RWPM) and MapBasedMovement (MBM). Figure (d)-(f) shows the same but with variation with probabilities, pnc=0.5 and pnf=0.5.

It can be seen from the above results that the effect of social and individual selfishness is different on the delivery probabilities of the Spray and Wait routing. The effect of social selfishness on the delivery performance is more than individual selfishness which is not the case in epidemic routing. I-MSD and S-MSD gives good performance with SPMBM and RWPM model and, I-MSD does not gives good results with MBM model as this mobility model does not follow any path property and the relations between the nodes could not be created. Whereas S-MSD gives good results with MBM, because no matter the mobility, the friend in the network does not change.

VI. CONCLUSION

In many real scenarios of DTN applications, selfishness may be present in the network. In such cases, a node will not forward the packet to ray node or to the destination. There can be various scenarios present in which few nodes in a network can act selfishly such as individual selfishness and

node selfishness. Individual selfishness is when selfish nodes do not want to store messages of other nodes because of their limited buffer space. Social selfishness is when a node acts selfishly towards another node only if the latter is not a friend of the former. In this paper, we have evaluated the impact of both individual selfishness and social selfishness on flooding based DTN routing algorithms such as Epidemic routing and Spray and Wait and proposed a technique to improve the packet delivery ratio of the existing algorithms by mitigating the selfishness involved. As part of future work, we would like to conduct the empirical and real test bed analysis of the proposed method.

***Abstract*—The performance of load balancing algorithms in HetNets is investigated in this paper. We performed a comparative analysis of three load balancing algorithms, including our previously proposed algorithm based on local optimization. We evaluated the offloading capabilities, fairness of the distribution of the load among base stations and downlink data rate gains. We also evaluated the practicality of these algorithms in terms of the required amount of coordination and exchange of information among base stations (e.g. handover triggering). An excessive exchange of signaling messages is undesired and leads to an increase in power consumption, this type of analysis has usually been overlooked in past studies. We tested these algorithms in a typical HetNet deployment in a university campus, subject to realistic traffic and load distribution. Our results show that all three algorithms were able to provide significant data rate gains. However, our load balancing algorithm was substantially superior in terms of practicality due to a minimum level of coordination and exchange of information among base stations.**

I. Introduction

Heterogeneous networks (HetNets) are becoming the preferred choice of network operators to meet the ever increasing demand of mobile data traffic in LTE/LTE-A networks. HetNets are particularly useful and a cost-effective solution to provide high quality service to traffic hotspots. One of the main objectives of HetNets is to offload users from the already congested macrocells.

In conventional mobile networks, users are associated with the base station that provides the strongest received signal or the highest signal-to-interference-plus-noise ratio (SINR). These types of user association mechanisms tend to overload macrocells, due to their high transmission power compared to microcells or picocells. This situation leads to unbalanced load distributions, causing congestion in macrocells and under-utilization of the resources provided by small cells. Several authors have studied the load balancing problem in HetNets. Different strategies based on *traffic transfer* have been proposed, e.g. cell breathing techniques and cell biasing methods. A detailed description of these strategies can be found in [1]. In recent years, authors in [1] and [2] have proposed approaching the load balancing issue as a convex optimization problem. A utility function is formulated, typically in terms of the user's achievable data rate and the user association that maximizes the network-wide sum of the utility is found. Iterative algorithms that can be implemented in a distributed manner were proposed in [1], [2]. In [3], we proposed a distributed load balancing algorithm based on the local optimization of the sum of the utility values, such maximization is performed by each base station (BS) considering only local information regarding its currently associated users.

In this paper, we performed a comparative analysis of the performance of three load balancing algorithms. The algorithms considered in this study are the one proposed by Ye *et al.* in [1], by Shen and Yu in [2] and our load balancing algorithm proposed in [3]. The evaluation scenario consisted of a typical HetNet deployment in a university campus venue under realistic traffic and load conditions. Our results confirmed the benefits of balancing the load in HetNets. Significant data rate gains were achieved by all the algorithms. However, our load balancing algorithm is substantially superior in terms of practicality due to the minimum amount of exchange of information among eNBs, a situation that leads to lower power consumption compared to the other two algorithms.

II. System model

In this paper, we are interested in the evaluation of the performance of load balancing algorithms subject to typical conditions in a two-tier LTE/LTE-A HetNet deployment. Our analysis focuses on downlink transmissions. The implications of load balancing in the uplink are not considered in this study. Furthermore, in this paper we do not consider inter-layer interference since we have selected a HetNet deployment with dedicated spectrum per layer, i.e. non-cochannel deployment.

Effective load balancing in HetNets is directly related to the user association scheme being applied. User association is the process of selecting the serving BS for a mobile user (UE). An indicator variable x_{ij} has been typically used to describe the association of the UE i to eNB j [1]–[3]. The variable x_{ij} takes the value of 1 when user i is associated to eNB j, otherwise it takes the value of 0 .

We denote as $\mathcal{I}$ the set of all active users in the network, and as $\mathcal{J}$ the set of all base stations. The total number of active users is denoted as N_U, while the total number of BSs is denoted as N_B. The set of users associated with base station j can be expressed as $\mathcal{I}_j = \{i | x_{ij} = 1, i \in \mathcal{I}\}$.

We now define the instantaneous downlink data rate offered by the j^{th} eNB to the i^{th} user as [3]:

$$r_{ij}(k) = \omega^o_{ij}(k) \cdot b_{ij}(k) \tag{1}$$

Where $\omega^o_{ij}(k)$ is the bandwidth in Hz scheduled (offered) for downlink transmissions to the i^{th} UE during the k^{th} subframe. The term $b_{ij}(k)$ corresponds to the normalized rate of the UE in b/s/Hz and is, in general, a function of the SINR$_{ij}$. Where SINR$_{ij}$ is the ratio of the received power from the j^{th} eNB and the total power of the received interference from neighbouring cells belonging to the same tier plus noise. The value $b_{ij}(k)$ has been typically calculated with the well-knwon Shannon Hartley theorem [1], [2]. However, in our analysis we follow the approach proposed in [3]. Where the value of b_{ij} is determined by the *Channel Quality Indicator* (CQI) periodically reported by each UE to its serving BS. Our simulator uses a SINR-to-CQI mapping for a 10% block error rate (BLER) [3].

A. Load of eNBs

In a LTE/LTE-A network, all active UEs that connect to an eNB have to share the available bandwidth. Each one of the UEs demands a specific quality of service depending on the running application. The task of the scheduler is to distribute the available bandwidth such that the demanded quality of service of each user is satisfied, while keeping a sense of fairness. The load of an eNB can be quantified in terms of the demanded load index L^D_j calculated as [3]:

$$L^D_j = \frac{\sum_{i \in \mathcal{I}_j} \bar{\omega}^D_{ij}}{W_j} \tag{2}$$

Where $\bar{\omega}^D_{ij}$ is the average demanded bandwidth of user i and W_j corresponds to the total bandwidth of the j^{th} eNB. A demanded load index higher than 1 indicates that the total demanded bandwidth is higher than the available bandwidth, i.e. the base station is overloaded.

III. Problem formulation

The load balancing problem has been typically defined in terms of an optimization problem. Such problem consists of the maximization of a network-wide aggregate of a utility function $U(\cdot)$, usually such function is defined in terms of the long-term data rate R_{ij} as in [3] or in terms of the achievable data rate as in [1], [2]. The optimal user association $\hat{\mathbf{X}} = \{x_{ij} | i \in \mathcal{I}, j \in \mathcal{J}\}$ is then the solution to:

$$\begin{aligned} \hat{\mathbf{X}} = \arg\max_{X} \quad & \sum_{i \in \mathcal{I}} \sum_{j \in \mathcal{J}} x_{ij} \cdot U_i(R_{ij}) \\ \text{s.t.} \quad & \sum_{j \in \mathcal{J}} x_{ij} = 1, \forall i \in \mathcal{I} \\ & x_{ij} \in \{0,1\}, \forall i \in \mathcal{I}, \forall j \in \mathcal{J} \end{aligned} \tag{3}$$

The optimal user association $\hat{\mathbf{X}}$ is the one that maximizes the network-wide sum of the utilities, with the constraint that each user must be associated to only one eNB. This optimization problem is a combinatorial problem whose computation has been shown to be intractable for real-size networks [1].

IV. Load balancing algorithms

We start this section with a description of the two load balancing algorithms based on convex optimization. These algorithms were proposed by Ye *et al.* in [1] and by Shen and Yu in [2]. Both these algorithms approximate the solution to the problem formulated in (3) by applying Lagrangian dual decomposition analysis. The algorithm proposed in [1] is based on the subgradient method, the one proposed in [2] is based on the dual coordinate descend method. We finish this section with a description of our load balancing algorithm based on local optimization, proposed in [3].

A. Algorithm based on the Subgradient Method (SGM)

The use of Langrangian dual decomposition to solve the load balancing problem formulated in (3) was initially proposed in [1]. Two dual variables are defined: $\boldsymbol{\mu} = [\mu_1, \ldots, \mu_{N_B}]^T$ (which can be interpreted as BS-specific prices), and ν. The maximization of the Lagrangian function in the dual domain is achieved with the following user association rule: [1]:

$$j^{(i)} = \arg\max_{j'} (a_{ij'} - \mu_{j'}), \ \forall \ j' \in \mathcal{J} \tag{4}$$

With a_{ij} being the achievable utility that user i would obtain if it is associated with eNB j. It is given by:

$$a_{ij} = \log\left(W_j \log\left(1 + \text{SINR}_{ij}\right)\right) \tag{5}$$

According to (4), UE selects as its serving cell the eNB that provides the highest value of its utility minus the BS-specific price. The values in $\boldsymbol{\mu}$ should be calculated in such a way that the load among eNBs is balanced. This pricing interpretation of the dual variable $\boldsymbol{\mu}$ is further discussed in [1], [2]. In [1], the subgradient method is proposed to calculate the values of the dual variables in an iterative manner. During the $(t+1)^{th}$ iteration of the algorithm, the BS-specific prices are updated according to [2]:

$$\mu^{(t+1)}_j = \mu^{(t)}_j - \beta^{(t)} \left(e^{\mu^{(t)}_j - \nu^{(t)} - 1} - \sum_i x^{*(t)}_{ij} \right) \tag{6}$$

The variable $\beta^{(t)}$ is a step size that can be calculated with a self-adapted scheme as proposed in [1]. Such scheme depends on many parameters whose selection greatly affects the speed of converge as shown in [2]. The other dual variable $\nu^{(t+1)}$ is given by:

$$\nu^{(t+1)} = \log\left(\frac{\sum_j e^{\mu^{(t)}_j - 1}}{N_U} \right) \tag{7}$$

For the algorithm to converge, all BS-specific prices μ_j have to be calculated with the same value of the step size, hence tight synchronization between eNBs is needed. Finally, the primal variable $\hat{\mathbf{X}}$ is obtained from the dual variables by applying (4).For a more detailed description of this method we refer the reader to [1].

B. Algorithm based on Dual Coordinate Descend (DCD)

Similarly as in [1], authors in [2] also apply a Lagrangian dual analysis to obtain the network-wide user association that approximates the solution to (3). However, the use of a dual coordinate descend approach is proposed as the mechanism to update the BS-specific prices μ_j. The values of the BS-specific prices are updated according to [2]:

$$\mu_j^{(t+1)} = \sup\left\{\mu_j \mid f_2^{(t)}(\mu_j) - f_1^{(t)} \leq 0\right\} \tag{8}$$

With $f_1^{(t)}$ being the number of UEs currently associated to eNB j and $f_2^{(t)} = e^{\mu_j^{(t)} - \nu^{(t)} - 1}$.

The resulting algorithm for load balancing is then identical to the SGM method, with the exception that (8) must be used to update the BS-specific prices as opposed to (6) used by the SGM method. A key advantage of the dual coordinate descent method is the fact that it does not depend on a step size and convergence is faster. However, as stated in [2], this is in general a suboptimal approach and a tight duality gap can exists. Additional details about this method as well as an upper bound of the duality gap can be found in [2].

C. Load balancing algorithm based on local optimization (LOM)

Our proposed load balancing algorithm is based on the observation that the network-wide optimization problem described in (3) can be simplified by letting the overloaded base stations determine their own local optimal user association. Where such local user association is constrained by a desired level of demanded load. The simplified version of the optimization problem can be expressed in terms of a local indicator variable $\tilde{x}_i$ as [3]:

$$\begin{aligned} \hat{\mathbf{X}}_j = \underset{\tilde{X}_j}{\arg\max} \quad & \sum_{i \in \mathcal{I}_j} \tilde{x}_i \cdot U_i(R_{ij}) \\ \text{s.t.} \quad & \sum_{i \in \mathcal{I}_j} \tilde{x}_i \cdot \bar{\omega}_{ij}^D < \alpha W_j \\ & \tilde{x}_i \in \{0,1\}, \forall i \in \mathcal{I}_j, \alpha \geq 1 \end{aligned} \tag{9}$$

Where R_{ij} is the long-term rate and $\tilde{\mathbf{X}}_\mathbf{j} = \{\tilde{x}_i | i \in \mathcal{I}_j\}$. The local optimal user association $\hat{\mathbf{X}}_\mathbf{j}$ can be calculated by each overloaded base station considering the demand of the UEs currently associated to it. The main objective of the optimization problem in (9), is to allow an overloaded BS to select which users would maximize its sum of the utility while keeping its total demanded load under a desired level, i.e. the total demanded load of the selected users must not exceed the value αW_j. The parameter α can take a value higher or equal than 1. A value of α closer to unity will provide a stricter selection of UEs. Such parameter can be setup by the network operator.

Based on the set $\hat{\mathbf{X}}_j$, an overloaded eNB classifies its currently associated users in two sets $\mathcal{S}_j$ and $\mathcal{T}_j$. With $\mathcal{S}_j = \left\{i | \tilde{x}_i = 1, \tilde{x}_i \in \hat{\mathbf{X}}_j\right\}$ and $\mathcal{T}_j = \left\{i | \tilde{x}_i = 0, \tilde{x}_i \in \hat{\mathbf{X}}_j\right\}$. The set $\mathcal{S}_j$ contains the subset of users that will continue to be associated with eNB j after such eNB has estimated $\hat{\mathbf{X}}_j$. The set $\mathcal{T}_j$ contains the subset of users that the base station will attempt to transfer to other underloaded eNBs via handover operation.

Similarly as in [1] and [2], we have selected a logarithmic utility function. A logarithmic function has the advantage that it yields high increase in utility values if more resources are provided to users with low rates (cell-edge users), as opposed to providing the same amount of resources to users already with good rates. This encourages cell-edge user associated with overloaded eNBs to be transferred to underloaded base stations where they can receive more spectrum resources, hence improving the balance of the load among eNBs. In our case we define the logarithmic utility function as:

$$U_j(R_{ij}, \bar{\omega}_{ij}^o) = \log\left(\frac{R_{ij}}{\bar{\omega}_{ij}^o}\right) \tag{10}$$

The quantity $R_{ij}/\bar{\omega}_{ij}^o$ represents the average normalized long-term rate for the i^{th} UE in b/s/Hz. We approximate the solution of the problem formulated in (9) with an approach based on greedy heuristics as described in [3]. The pseudocode of this process is presented in Algorithm 1.

Algorithm 1 Get $\hat{\mathbf{X}}_j$

Require: $\mathcal{U} = \{U_i | i \in \mathcal{I}_j\}, \mathcal{W}^D = \{\bar{\omega}_{ij}^D | i \in \mathcal{I}_j\}, \alpha$
1: $demanded_load \leftarrow 0$
2: Sort($\mathcal{U}$) in descending order
3: **for** $n = 1$ to $|\mathcal{I}_j|$ **do**
4: $\quad UE_n \leftarrow Get_UE(\mathcal{U})$
5: $\quad$ **if** $demanded_load + \bar{\omega}_{nj}^D < \alpha W_j$ **then**
6: $\quad\quad \tilde{x}_n = 1$
7: $\quad\quad demanded_load = demanded_load + \bar{\omega}_{nj}^D$
8: $\quad$ **else**
9: $\quad\quad \tilde{x}_n = 0$
10: $\quad$ **end if**
11: **end for**
12: $\hat{\mathbf{X}}_j \leftarrow \{\tilde{x}_n\}$

After executing Algorithm 1, an overloaded BS can determine the sets $\mathcal{S}_j$ and $\mathcal{T}_j$. Then, the base station must submit handover requests for each UE in $\mathcal{T}_j$ to neighboring cells with spare capacity and whose RSRP (Reference Signal Receive Power) and SINR satisfy the cell selection criteria defined by the operator. In order to identify a base station with spare capacity, all base stations must periodically broadcast their demanded load index. The

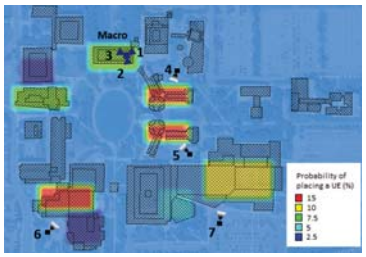

Fig. 1. Traffic map and location of base stations

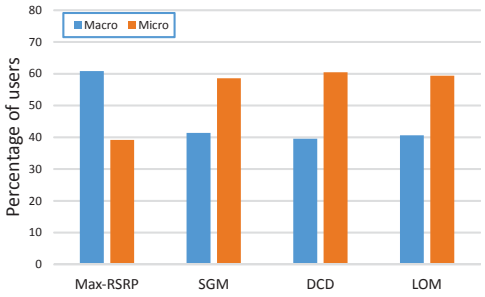

Fig. 2. Distribution of users between macrocell and microcell layers

exchange of this information is a functionality expected to be part of Self-Optimizing Networks (SON) [3].

V. Performance Evaluation

The performance evaluation of the three load balancing algorithms described in Sect. IV was carried out considering a two-tier HetNet deployment in the University of Regina campus, in Saskatchewan, Canada. This university campus corresponds to a urban environment with irregular distribution of buildings over a flat terrain. A 3D model of the environment, including 18 buildings, was created with a resolution of 1 m. The area under study has dimensions 600 m by 700 m. The distribution of the buildings is shown in Fig. 1.

The two-tier HetNet considered in this paper consists of one three-sector macrocell (cells 1,2 and 3) and four outdoor microcells (cells 4,5,6,7) as shown in Fig. 1. The macrocell is located on the rooftop of a building at a height of 36 m, its transmission power was set at 47 dBm and it operates at 2.1 GHz. All microcells are mounted on lamposts with a height of 6 m, their transmission power was set at 30 dBm and their carrier frequency is 2.6 GHz. Users were distributed spatially according to a traffic map derived from network statistics and knowledge of the users' distribution. The traffic map is presented in Fig. 1. A proportional scheduler was applied in our simulations.

The propagation model applied in this study corresponded to a site-specific path loss model based on the Uniform Theory of Diffraction and geometrical optics, this model is similar to the one proposed in [4]. A total of 350 runs were simulated, 130 users were considered in every run. The baseline of our analysis was provided by the Max-RSRP user association scheme, i.e. UEs associate to the eNB with strongest RSRP. The demanded downlink rate for each user was randomly generated between 0.5 Mbps and 10 Mbps.

A. Distribution of users

Fig. 2 shows the distribution of users between the macrocell and the microcell layers. The Max-RSRP rule clearly shows an unbalanced distribution of users, where the macrocell tends to be overloaded and the microcells are under-utilized. For the Max-RSRP rule, most of the users were associated to the macrocell, only 40% were associated to the microcells. The three load balancing algorithms were able to revert this situation, they were capable of offloading the macrocell by approximately 20%. The DCD method showed a slightly better offloading percentage, around 1% higher than the SGM and LOM methods. Therefore, regarding the offloading of the macrocell, all three load balancing algorithms perform equally good.

TABLE I
Fairness Indexes

	Max-RSRP	SGM	DCD	LOM
Fairness index	0.6	0.87	0.82	0.86

B. Distribution of the load among eNBs

The distribution of users per layer in a HetNet is not enough to measure the effectiveness of the load distribution among eNBs, especially in the case where the demand of all users is not assumed constant. It is important to quantify how fair is the sharing of the load between base stations. This can be done with the calculation of the Jain's fairness index $F(\mathbf{L})$. Where $\mathbf{L} = [L_1^D, \ldots, L_{N_B}^D]^T$ is a vector containing the load indexes of the N_B base stations in the network. The fairness index is calculated according to:

$$F(\mathbf{L}) = \frac{\left(\sum_{j\in\mathcal{J}} L_j^D\right)^2}{N_B \cdot \sum_{j\in\mathcal{J}} \left(L_j^D\right)^2} \tag{11}$$

The fairness index $F(\mathbf{L})$ takes the maximum value of 1, under the idealistic situation where the total load is equally shared by all base stations.

Table I shows the results. The Max-RSRP rule showed the lowest value of the fairness index, reaching only 0.6, this indicates a poor distribution of the load. On the other hand, the load balancing algorithms achieved a fairer load sharing among base stations since the value of the fairness index was increased above 0.8. In particular, the SGM method achieved the highest value of the fairness index, reaching 0.87. The other two load balancing methods achieved slightly lower fairness indexes.

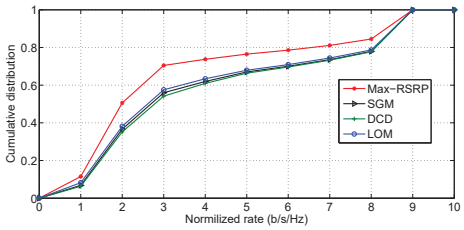

Fig. 3. Cumulative distribution of the normalized long-term rate

C. Cumulative distribution of the normalized long-term rate

As an additional performance metric, we were interested in quantifying the overall data rate gain after balancing the load. In Fig. 3 we provide the cumulative distribution of the normalized long-term data rate for the overall HetNet. It can be observed that the CDFs obtained by the load balancing algorithms show a significant improvement in the normalized data rate. This means that a higher spectral efficiency was achieved. Therefore, a more efficient use of spectrum resources was possible compared to the case when the user association was defined by the max-RSRP scheme. The three load balancing algorithms showed a similar improvement of the normalized rate. All percentiles experienced a gain, this is specially important for the low percentiles, since they represent users receiving the worst downlink rates in the network (i.e. cell-edge users).The rate gain for the 10^{th} percentile reached a value between 1.22x to 1.3x. This means data rates were improved by 22% to 30% due to a more balanced load distribution among base stations. The data rate was almost doubled for the 70^{th} percentile.

These results show that our load balancing algorithm (LOM) provide data rate gains that are very close to the ones provided by the other two methods SGM and DCD, however our algorithm is significantly less complex. It is important to mention that these two methods SGM and DCD are very close to optimality as shown in [1], [2].

D. Evaluation of the practicality of the algorithms

In this final subsection of the performance evaluation of the load balancing methods, we focus our attention on the complexity and practicality of the algorithms considered in this study.

The SGM and DCD methods require the exchange of at least $m(N_B + N_U)$ messages where m is the number of iterations [1]. On the other hand, our load balancing algorithm only requires each base station to broadcast its demanded load index. An overloaded base station would proceed to execute Algorithm 1 and select the UEs that would be transfered to lightly loaded base stations (i.e. set $\mathcal{T}_j$), at this point only UEs currently associated with overloaded base stations would be handed over, there is no need to update the network-wide user association as it is done in every iteration of the SGM and DCD methods. Therefore, our load balance algorithm requires the exchange of $N_B + \sum_{j\in\mathcal{J}} |\mathcal{T}_j|$.

TABLE II
AVERAGE EXCHANGE OF MESSAGES

	SGM	DCD	LOM
Number of messages	7065	785	36

Table II shows the average number of additional exchanged messages due to the application of the load balancing algorithms. The SGM method requires an extraordinary amount of exchanged messages due to the fact that its convergence is slow, as opposed to the DCD method. Our load balancing algorithm requires a minimal amount of exchange of messages among base stations, this leads to lower levels of required coordination and lower impact on the signaling load of the network. Furthermore, our algorithm would have a reduced impact on power consumption as opposed to the DCD and SGM methods. Therefore, it is evident that in terms of practicality as well as impact on power consumption, our algorithm is superior.

VI. Conclusion

In this paper, we performed a comparative analysis of the performance of three load balancing algorithms. We evaluated the effectiveness of these algorithms considering a typical two-tier HetNet deployment subject to a realistic traffic distribution. The load balancing algorithms were able to offload up to 20% of the users from the macrocell layer, this led to a fairer distribution of the demanded load among base stations. The three algorithms provided significant data rate gains for all percentiles, reaching a value up to 2x gain for the 70^{th} percentile. Particularly important is the evaluation of the number of exchanged messages and triggered handovers, since this factor is related to the practicality of the algorithms. Our load balancing algorithm is substantially superior since it requires a minimal amount of exchange of messages among base stations, this leads to lower levels of coordination and lower impact on the signaling load of the network.

***Abstract*—Significant developments in automotive industries ensures safety and entertaining journey by sharing information among the vehicles and inside vehicles utilizing wireless networks available. A new printed single arm spiral antenna with tapered feed is proposed to cover the navigational wireless frequencies viz., 1.2 GHz, 1.5 GHz (Indian Regional Navigation Satellite System and Global Positioning System) and Wireless Communication frequencies viz., 2.45 GHz, 3.3 GHz (Wi-Fi & WiMAX) and Dedicated Short Range Communication (DSRC) frequency, 5.8 GHz for vehicular communications. To achieve better impedance matching and multiple frequencies, tapered feed is introduced at the edge of single arm spiral. Antenna is designed using 3D Electromagnetic (EM) software tool and validated using RF equipment. Compact size, omnidirectional radiation pattern and improved circular polarization make this antenna an appropriate candidate for vehicular wireless communications.**

Keywords—Multiband antenna;tapered feed;spiral antenna; circular polarization;impedance matching;Vehicular wireless communications.

I. INTRODUCTION

The remarkable growth in the present communication technologies increases the usage of communication systems for automotive applications. The intelligent transport system (ITS) ensures better quality travel by providing vehicle safety information through broad communication technologies. In addition, ITS expects multimedia data exchange through internet connection among the moving vehicles [1]. ITS includes short-range and long-range communication to allow a vehicle to interact with the outside world for information exchange. Nowadays, the vehicles upcoming with GPS, GSM, Wi-Fi, Bluetooth, WiMAX, DSRC and more. These services which functions at different frequency necessitate a number of dedicated antennas to be integrated in the vehicle. Hence, the vehicle antennas are likely to be of compact, low cost and with multiband operations.

Researcher around the globe explored different methods of resonating multiband with single radiator. This includes slot antennas [2], inverted F antennas [3, 4]. In [5 - 7] author proposed stacked antennas to resonate in multiband for vehicular applications that occupies more space in roof of the vehicle. In [8], two separate radiator shared aperture to reduce the space occupation by proposing PIFA antenna integrated with 'Y' shaped monopole. In [9], author proposed a fractal multiband antenna for vehicular radar and imaging system.

Now a days, printed monopole antenna became prevalent for automotive systems because it could meet the benefits of omnidirectional pattern, compact in size, low cost, ease to fabricate and achieve ITS requirements [10]. In [11], coplanar monopole (cactus shaped) antenna is proposed to resonate at 2.4 GHz and 5.8 GHz. In [12], two – hook facing opposite side in one plane and cross shaped monopole at the back plane is introduced to operate at 2.4 GHZ, 5.2 GHz and 5.8 GHz. The antennas observed in literature does contain omnidirectional pattern with linear polarization. The European standard EN 12253 [13] provides the requirement for vehicular communication antenna. As per EN 12253, omnidirectional radiation pattern with circular polarization helps to maintain better communication between moving vehicles.

A key to miniaturize the antenna is maximizing the current flow in the conducting element. Hence we have chosen the spiral structure in our proposal. Added to that one of the characteristics of spiral antenna is circular polarization which satisfies the requirements of vehicular communication antenna. Several spiral monopole antenna are proposed to achieve multi band, circular polarization and omnidirectional radiation pattern [14 - 17]. In spiral antennas impedance matching is not uniform at all bands especially at lower bands. A tapered feed helps to improve the impedance matching [18]. This paper gives solution for the mentioned issues of multiband, circular polarized and omni directional radiation pattern with better impedance matching.

In this paper, we propose a printed spiral antenna with tapered feed which supports wireless communication services along with navigation services operates at IRNSS (1.2 GHz), GPS (1.5 GHz), Wi-Fi (2.4 GHz), WiMax (3.3 GHz) and DSRC (5.8 GHz). IRNSS is a regional navigation satellite system being developed by India to offer precise position information service to users [19]. Further the paper is organized as, in Section II defines the design of the

proposed antenna and the effects of tapered feed on impedance matching followed by Section III, the discussion on performance of the antenna.

II. ANTENNA DESIGN

A. Construction of the Proposed Antenna

The proposed printed spiral antenna with tapered feed is shown in Fig. 1. The size of the proposed antenna is 51 x 35 x 1.574 mm3 with ground plane size of 4.5 x 35 mm2 designed on the Rogers's RT Duroid 5880 substrate with permittivity(ε_r) of 2.2 and loss tangent(δ) of 0.0009. The dimensions of the dielectric substrate is obtained using (4) and (5) [20].

$$W_p = \frac{c}{2f_r}\sqrt{\frac{2}{\varepsilon_r+1}} \quad (1)$$

$$L_p = \frac{c}{2f_r\sqrt{\varepsilon_{reff}}} - 2\Delta \quad (2)$$

$$\Delta L = \frac{h(0.412)(\varepsilon_{reff}+0.3)(\frac{W_p}{h}+0.264)}{(\varepsilon_{reff}-0.3)(\frac{W_p}{h}+0.8)} \quad (3)$$

$$L = L_p + 6h \quad (4)$$

$$W = W_p + 6h \quad (5)$$

For our desired multiband operation, we have considered circumference of the inner and outer circle of the planar spiral as $\lambda/4$ with respect to the lower and upper frequencies. The inner and outer radius of the circles are obtained using (6) and (7). The Table 1. gives the dimensions of the antenna.

$$r_1 = \frac{c}{8\pi f_{high}} \quad (6)$$

$$r_2 = \frac{c}{8\pi f_{low}} \quad (7)$$

$$s = w = \frac{r_2 - r_1}{4N} \quad (8)$$

B. Effects of Tapperd Feed

In spiral antennas the impedance matching is not uniform at all bands. In order to achieve better impedance matching we introduced taper feed. Fig 2 and Fig. 3 shows the effects on impedance due to taper feed at lower and higher frequency band.

In Fig.2. , the slope 1 defines without tapering. We could observe that there is less effect of tapper feed on impedance at lower frequency bands and significant variation at higher frequency bands. As the slope increases there is a decrement in impedance value. In our proposed design we have chosen taper slope of 1.6.

TABLE I. DIMENSIONS OF THE PROPOSED ANTENNA

Label	Dimensions (mm)
L	51
W	35
L1	18.1
L2	4.5
S	1.25

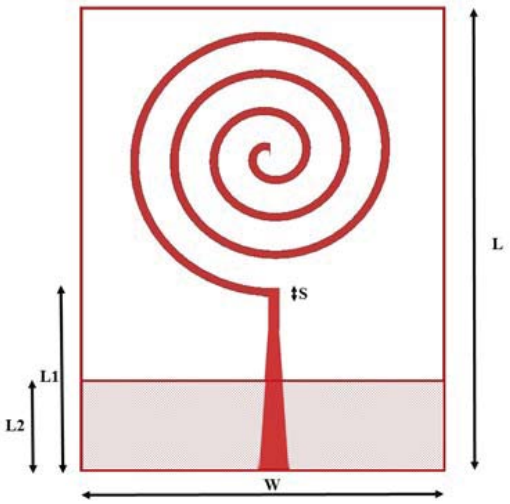

Fig. 1. Geometry of the proposed antenna

III. RESULTS AND DISCUSSIONS

The proposed antenna is designed and simulated using the 3D Electromagnetic tool HFSS. Keysight's N9925A Vector Network Analyzer is used to validate the antenna performance. The comparison of simulated and measured return loss of the proposed antenna is shown in Fig. 4. It shows, there is good agreement between measured and simulated results.

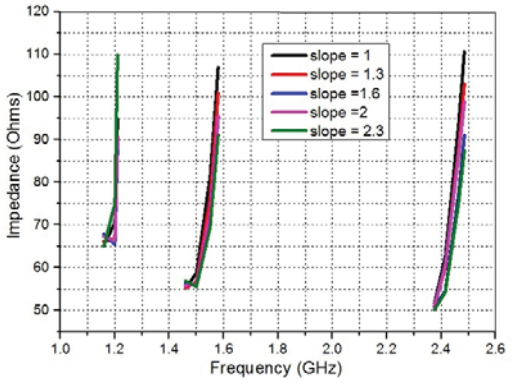

Fig. 2. Impedance variation based on slopes at lower frequency bands

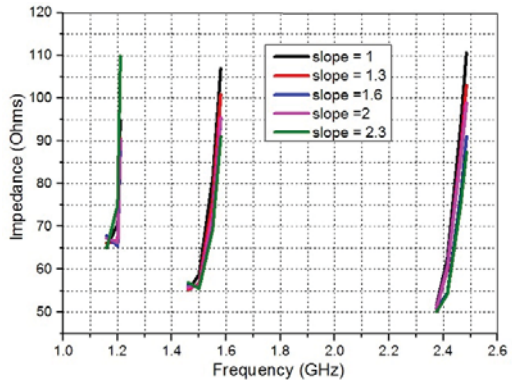

Fig. 3. Impedance variation based on slopes at lower frequency bands.

Fig. 5 shows 2D plot of the axial ratio verses frequency of the proposed antenna. It can be observed that, axial ratio is less than 3dB at all desired frequency bands implies that the proposed antenna is circularly polarized. Axial ratio bandwidth of 50 MHz, 60 MHz, 110 MHz, 170 MHz, and 370 MHz at 1.2 GHz, 1.5 GHz, 2.4 GHz, 3.3 GHZ and 5.8 GHz are achieved.

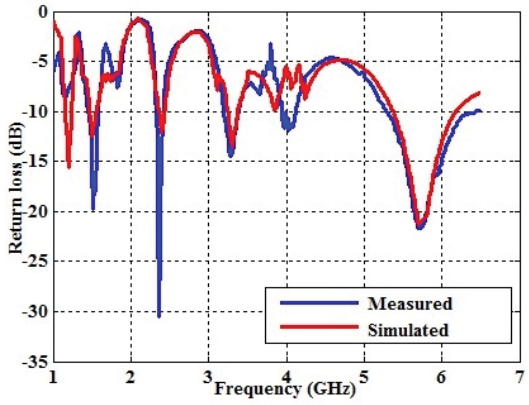

Fig. 4. Return loss versus frequency of the proposed antenna.

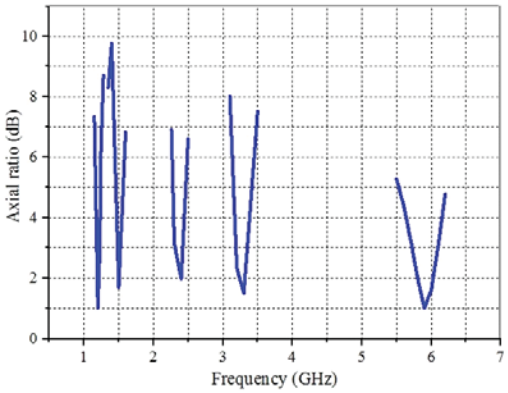

Fig. 5. Axial ratio versus frequency of the proposed antenna

Fig. 6 shows the radiation pattern at lower frequency bands (1.2 GHz, 1.5 GHZ and 2.4 GHZ) of the proposed antenna. At all three desired bands, antenna radiates in omnidirectional. Gain is found to be 1.07 dB, 1.75dB, 1.88 dB, 1.52 dB and 5.48 dB at 1.2 GHz, 1.5 GHz, 2.4 GHz, 3.3 GHZ and 5.8 GHz respectively.

The near omnidirectional radiation pattern at higher frequency bands (3.3 GHz and 5.8 GHz) of the prosed antenna is shown in Fig. 7.Table. 2 lists the performance comparison of simulated and measured antenna. It can be inferred from the table that the measured and simulated results are with good agreement. Prototype of the proposed antenna is shown in Fig.8.

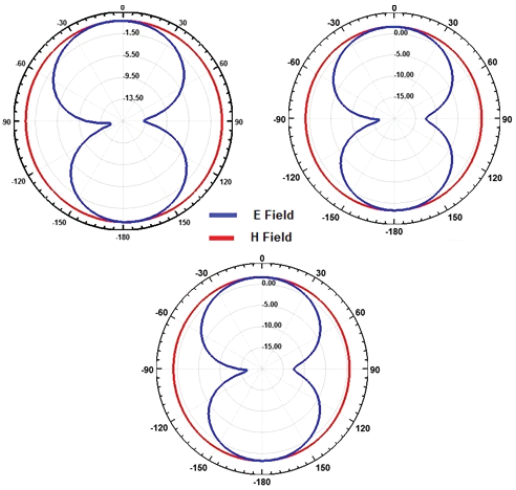

Fig. 6. Radiation pattern of the proposed antenna at lower frequency bands.

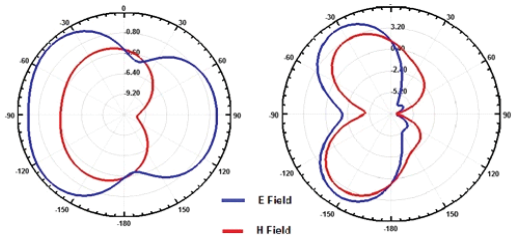

Fig. 7. Radiation pattern of the proposed antenna at higher frequency bands.

Fig. 8. Prototype of the proposed antenna.

TABLE II. ANTENNA PERFORMANCE

Parameters M –MEASURED S – SIMULATED		**Frequency in GHz**				
		1.2	***1.5***	***2.4***	***3.3***	***5.8***
Impedance BW (GHz)	M	0.05	0.11	0.09	0.19	1.10
	S	0.07	0.08	0.07	0.13	0.81
Return loss (dB)	M	10.80	15.43	13.85	14.2	20.4
	S	15.6	12.50	12.30	13.6	20.5
Gain (dB)	S	-1.30	0.17	1.20	1.61	5.32
AR BW (%)	S	4.16	4.00	4.58	5.15	6.37
Radiation Efficiency (%)	S	82.1	89.7	89.8	85.0	94.7

IV. CONCLUSIONS

The design of penta-band based circularly polarized, single arm spiral antenna is presented with a compact size of size 51 x 35 x 1.574 mm3 to address Vehicular Wireless Applications for Navigational Communications and Terrestrial Wireless Network Communications. By the introduction of tapering in the feed line, better impedance matching is achieved at all desired bands. It is inferred that there is a healthier agreement between measured and simulated results. Further, it is observed efficiency with the multiband spiral antenna varied from 82.13 ~ 94.74%. Thus the multiband, omnidirectional pattern and circular polarization at all desired frequency makes the proposed antenna an appropriate applicant for the various applications of Vehicular Wireless Communications.

Single Thing Sign On Identity Management for Internet of Things

Vanya Zdravkova, Mihail Mihaylov, Albena Mihovka, Ramjee Prasad
Department of Electronic Systems, Center for TeleInfrastruktur
Aalborg University
Aalborg, Denmark
{vzdrav,mrm,albena,prasad}@es.aau.dk

Abstract*—Within the context of heterogeneous Internet of Things (IoT) network driven by Machine-to-Machine (M2M) communications there is a need for a proper user identification and Identity Management (IdM) mechanisms which to involve all of the objects in the IoT. The paper addresses user identification by proposing Single Thing Sign On (STSO) IdM architecture for IoT, where the end-user is in the middle of a user-centered services ecosystem. The proposed scheme enables user recognition and services access only by identification of one of the "things" related to the user such as personal computing devices, sensors etc. The authors propose a novel user identification method driven by computing device recognition algorithm (CDR algorithm). To better illustrate the use case of the STSO IdM and CDR algorithms they are analyzed in context of the eHealth platform for Ambient Assisted Living – eWALL.*

Keywords—IoT, STSO, IdM, CDR, user identification, eWALL(or eHealth platform)

I. INTRODUCTION

Internet of things (IoT) represents a unique interconnected system, which enables devices to communicate globally using set of standard protocols and connecting various heterogeneous networks. By means of a unique identifier (ID) IoT objects are able to communicate directly with each other [1]. In the context of IoT, the concept of identity extends to things. Identities can be considered as end points so that it is easy to ensure access to that thing endpoint independently [2].

The user identification process can be explained as an interaction whereby the user identity is provided to the security system. The identification provides access to and the modification of data by a certain personal, and enables services and communications to be customized [3]. In IoT context, identification can be explained as an association of attributes which represents identifiers. To make the communication within IoT more efficient, one common device and object identifier would be beneficial [2] [3].

Various methods for user identification and attractive Identity Management (IdM) mechanisms, such as Single Sign On (SSO) have been proposed [2] [4]whereby the user effort of remembering passwords is simplified on a web level. L. Some early solutions to IoT IdM [5] are now being implemented but they still need improvement and standardization [4][6]. TIdM for M2M is represented by authentication of multiple user's devices where the user can access a particular single service with all of his/her devices after performing initial authentication only on one device. The scenario adopted here assumes that the user will be able to access multiple services on a number of different devices by authenticating only to one of those devices. The access to connected shared devices, will enable gathering contextual metadata and sensors data and will enable user centered responsive services. The enabling IdM feature is introduced in this paper as Single Thing Sign On (STSO), which addresses challenges, such as heterogeneous networks with minimum human interaction, how to enable successful communication among personalized devices, and privacy.

Based on the published research [6] [7] [8], a number of generic system requirements of relevance to the STSO integrated IdM system were summarized in Table I.

TABLE 1. GENERIC SYSTEM REQUIREMENTS

Goal	Description
Flexibility	To enable support of various network devices
Scalability	To scale easily to envisioned use-cases and provides global communication through discoverable identifiers which are unique within various domains
Extensibility	To provide integrity and proper APIs for integration of novel for the system devices
Reliability	To provide reliable communication on-time reaction.
Privacy	To keep and protect the personal user information from unauthorized access.

To address the identity issues related with the proposed STSO IdM in IoT Computing Device Recognition (CDR) algorithm for automated and secured user and device identification.

This paper is organized as follows: Section II proposes the IdM system model for IoT. Section III proposes a Computing Device Recognition algorithm for automated user identification. Section IV discuss about the implementation of the STSO IdM in eHealth platform scenario. Section V summarizes the improvements and finally Section VI concludes the paper.

II. STSO IDM SYSTEM MODEL

A. IdM system Architecture

The proposed idea is to enable IdM for the identification of the user across multiple domains. The STSO IdM is based on

the federated IdM system model proposed in [2]. The high-level system architecture is shown in Fig.1

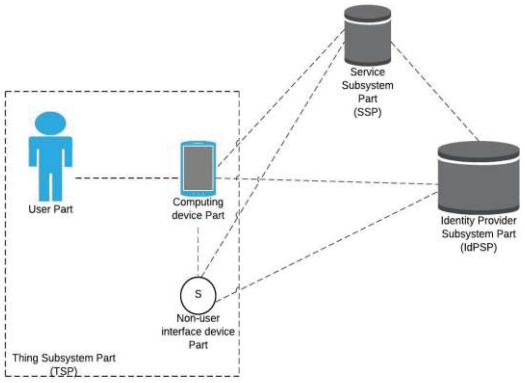

Fig. 1. High - level IdM system structure

The main physical entities of the system in Fig. 1 are the following:

1) Thing Subsystem Part (TSP) - it represents the "things" in IoT such as users, smart computing devices, sensors and actuators. All of these take an important role in the user identity process by providing identities to the Identity Provider Subsystem Part (IdPSP). TSP is divided into three separate subsystems as follows:

a). User as a Part (UP) - in the proposed IdM system, the user is an actor, being a part of the system, who access multiple services by using his/her device(s). User identity data is obtained and provided by IdPSP.

b*). Computing Device Part (CDP)* - it is a functional layer residing in a user device and serve for providing middleware functionalities for the system. From security point of view, this part is needed to prevent unauthorized data modification and corruption.

c*). Non-user interface Device Part (Non-userIntDP)* - this part is responsible for collecting accurate information from personal and/or shared non-user interface devices regarding users' needs. In that way, it supports SSP to provide always on time responsive services to the users.

2) Identity Provider Subsystem Part (IdPSP) - the responsibility of the IdPSP is to store all the identity data. In addition, it is also responsible for the user, device and service authentication. Also, access to the non-user interface devices is managed by IdPSP. It can be remotely or locally located and one of the main benefits is that the IdPSP can provide communication and different functionalities automatically.

3) Service Subsystem Part (SSP) - is a part of the proposed IdM service layer that enables authentication of a user or "things" both for local or remote services.

The design of the proposed IdM system allows multiple IdPSs management by multiple IdPs. The IdPSPs provides identity storage information, features for searching and discovering from a device perspective in an easier way and thus the latter is able to establish dynamic connections.

The regular user can create a private subsystem of identifiers for his devices and established identities, which can be further provided to an IdPSP to manage them.

B. STSO Connection Procedure

The general STSO connection procedure is shown in Fig. 2.

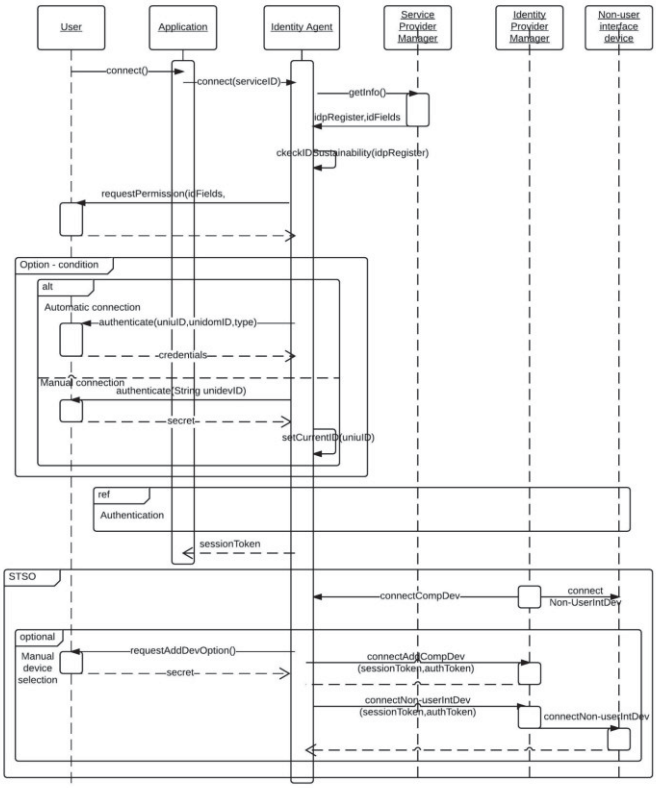

Fig 2. STSO connection sequence diagram

Let us consider a case where a given computing device is utilized by a human user and the latter intends to connect locally or remotely to an available service through a certain application. The user may use beforehand applications, which require an automatic connection to the service, independently of the user's intentions. The sequence flow is as follows:

1) *Application* sends connect request to *IdentityAgent* providing service ID or alternative information related to requested service.

2) *IdentityAgent* uses the provided service information in order to establish communication with related *ServiceManager* and learn about IdPs relationships with the service and the required identity fields.

3) *IdentityAgent* obtains certain information associated to desired service from *ServiceProviderManager*.

4) *IdentityAgent* checks whether the provided computing device identity is active (if there is any) and appropriate for the service by using IdP list related to the service.

5) Subsequently, *IdentityAgent* notifies the user about the required identity data fields and gives an option for identity switch based on service requirements.

There are two possible alternative login mechanisms as shown in Fig. 2 The first one is an optional automated connection where all of the devices related to the user are automatically connected based on only one thing identification. If certain computing device(s) is (are) recognized by IdPs regarding user's preferences, STSO is activated.

The second is a manual connection procedure, whereby the user may manually confirm the identity and choose a device. Then, the provided thing's credentials should be checked by the *IdentityAgent* or IdP, which are required parties in the authentication procedure

Once the authentication is successfully completed, *sessionToken* is being set from *IdentityProviderManager* and send to the *IdentityAgent*. The latter sends a received *sessionToken* to the *Application,* which needs that token in order to establish its own communication to the service without elaborating with *IdentityAgent*.

The connection procedure includes an STSO feature where the *IdentityProviderManager* sends the connection device a request to, both, the computing and non-user interface devices groups related to the current user profile. That allows the automatic connection to the other user-related devices, after one of the things (user or computing device) is identified and connected. The procedure is enabled by a recorded connection in the *ConnMsg* class managed by the *IdentityManagerProvider*.

As an optional step, the user can choose manually devices, which he/she would like to utilize. In this case, either the *IdentityAgent* would ask whether they would like to access the service by means of the personal devices, or the user might agree and choose some additional devices and specify a secret key derived as an *authToken.* The latter will be used in the message send to the *IdentityProviderManager* afterwards.

When the *ServiceManagerProvider* requests authentication from the *IdentityProviderManager*, then:

1) The *IdentityAgent* sends a message to the *IdentityProviderManager* to request a connection to the additional computing devices and non-user interface devices as per the user's preferences. The message contains the *authToken* and *sessionToken*.

2) The *IdentityManagerProvider* receives the message for connecting to the additional devices, performs the authentication and sends a connection message to the targeted devices, if the authentication is successful.

III. COMPUTING DEVICE RECOGNITION ALGORITHM

In order to support STSO IdM, we propose a Computing Device Recognition (CDR) algorithm for user identification. The CDR algorithm does not exclude the most commonly adopted method for identification - *username* and *password*. It can be considered as an additional feature that simplifies the authentication (automatic and less user intervention) but manual authentication can still optionally be used.

The CDR algorithm is given in Fig. 3.

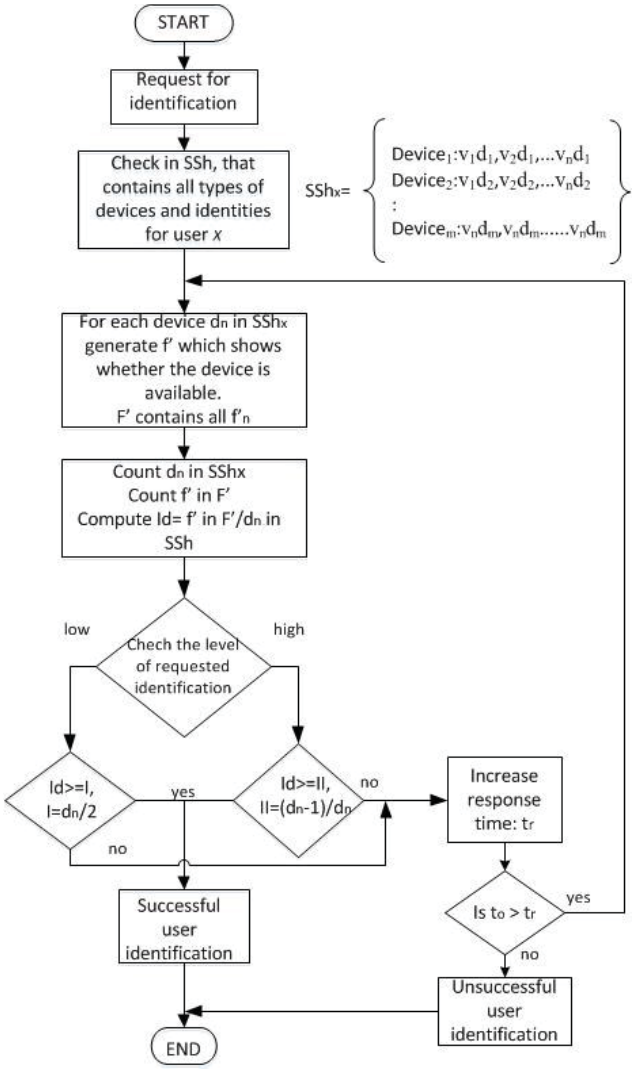

Fig. 3 CDR identification algorithm

The user's types of device identities (v_nd_m) are stored in a Smart Sheet (*SSh*). SSh_x is unique list of devices pointing to user *x*. Each device *d* is recorded to the SSh_x list with a reference number within the interval *[1-m]*. For each device in the *SSh* list, there is a set of different types of identifiers *v*, with a reference number within the interval *[1-n]*, which is assigned to the particular device d_m. If a request for identification from one of the listed and registered devices in a certain domain is received, the register automatically starts to search if there are other user devices and how many of them are available in the local domain. The user is able to define the level of security by manipulating the number of the devices needed for a proof of user identity. For example a certain user may create a policy for 3 out of 5 personal devices simultaneous recognition for automatic user identity recognition. The user is a part of the Internet of people whereby he/she plays the role of manager of

the rules in the system, regarding his/her preferences and wishes.

The available user's computing devices are counted and written in *F'sheet*. After that, the algorithm computes the *Id* index which shows the ratio between the entire devices stored in the SSh and those which are available in the *F' sheet* at a certain moment. Then, the level of required identification is checked. Here, two scenarios are available – for high and low level of identification depending on the user's or services' rules. If the level is low, the algorithm compares whether *Id* is bigger or equal to *I*. In that case, the ratio *I* is equal to at least half of the declared devices in *SSh* which must be discovered and recognized.

If that expectation is true, the identification of the user is successful. If not, the response time t_r is increased and compared with the timeout t_o for the service so the the process is started again until $t_o > t_r$. If the level is high – that the *Id* should be compared to *II index* which allows only one of the user computing device to be unavailable. If that expectation is true, the identification of the user is successful. If not, the process is started again until the timeout t_o for the service expires.

A coefficient which defines the identification rate of the computing device is proposed in order to be used for the identification assessment within the CDR algorithm, $\boldsymbol{Ir_{cd}} = \boldsymbol{N_{cd}/M_{cd}}$, where Ir_{cd} is an identification rate coefficient of the computing device N_{cd} is a number of identified computing devices *(cd)* related to the particular user M_{cd} is a total number of predefined computing devices *(cd)* required for the identification

Ircd is equal to the number of identified computing devices related to the particular user over the total required number of predefined computing devices necessary for the identification procedure.

The identification rate of the CDR algorithm depends on the number of correctly identified computer devices, related to a particular user and it must be equal or close to '1' in order to recognize the user itself.

IV. STSO IDM EHEALTH SCENARIO

This section proposes an implementation and use of STSO IdM in an eHealth scenario. The key requirements for enabling a sustainable eHealth system, are the personalization and adaptation to specific needs and preferences, the efficient data and context sharing between the different required services and artefacts, including the handling of multiuser identification, auto configuration and calibration systems [9]. Typically, a myriad of wireless and wired communication and data processing technologies and networked devices need to interoperate in order to provide highly personalized services.

The funded under the European Union's Framework Program Seven (FP7) project eWALL[1] (eWall for Active Long Living, 2013) has proposed a system platform able to sense and "learn the needs of the user who in order to provide personalized support to healthcare and unobtrusive daily activities [10]. In the context of eWALL, IdM would allow for real-time user and device recognition regardless of the presence of other users around. IdM would allow for more efficient use of resources and would eliminate the need to deploy personal sensor nodes specifically to cater for the needs of the user under observation.

The eWALL system is composed of two main subsystems: the eWALL Sensing Environment and the eWALL Cloud.*The eWALL Sensing Environment* - is deployed over a physical space and interacts with the primary user. A Home Sensing Environment, operates in the domestic surroundings of the user. It monitors the status of environmental parameter such as humidity, temperature, luminosity, motion etc. A Mobile Sensing Environment would operate around the user and collect data from wearable devices. The data would be transferred to the home device gateway wirelessly when the user is within the communication range of it. Such wearables could be smartphones, pulse and blood oxygen saturation sensors, body temperature sensors, ect.

The eWALL Cloud would handle the data processing and storage whereby the eWALL Cloud is connected to the home environment of each user. Based on actions performed within the Cloud environment, personalized services and applications will be offered to the corresponding user.

A. Implementation of STSO IdM in eWALL

The implementation of STSO IdM is proposed as subsystems components to be included in the eWALL architecture shown in Fig. 4 with the benefits of improved eWALL user identification, better mobility and more responsive eWALL applications

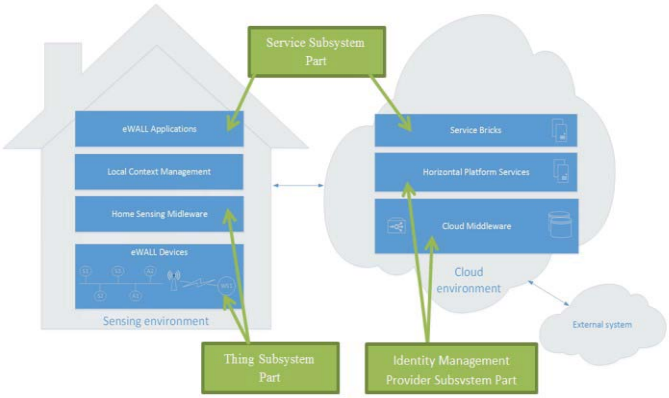

Fig. 4. Implementation of STSO IdM subsystem parts in eWALL

TSP resides on the eWALL devices and Home Sensing Middleware components of eWALL where the eWALL users, sensors and computing devices could be assumed as part of the infrastructure, when referring to IoT and IdM. The Identity

[1] EU FP7 Project eWALL http://ewallproject.eu/

Agent should be installed on the eWALL primary user's computing devices, in order to enable the STSO feature.

IdPSP should be deployed as part of the Cloud Middleware and as a part of the Horizontal Platform Services where the user profile information is stored and managed at a cloud level. The IdentityManagerProvider should be implemented on a cloud middleware level to enable identity functionalities such as thing identity creation, management and deletion. What is missing for the eWALL system on a cloud level is a device identity management related to a certain user.

SSP is already represented in eWALL by User profiling functionalities the respective applications and services assignment to a certain user.

It is proposed to include the implementation of the STSO IdM within eWALL as a part of the holistic architecture of the platform, rather than as a single component or plug in. This would affect the overall architecture and would require dedicated C++ components to be implemented on a DeviceGateway level while other Java software artefacts should be deployed on a cloud level. The implementation may also cause changes in the JSON data format used for the sensors and actuators data representation and exchange, as well as it will require storing of additional device identity data both on the homePC (CouchDB) and eWALL cloud (MongoDB) databases.

V. IMPROVEMETS

By introducing and implementing the IdentityAgent and IdentityProvider, eWALL will be able to extend further with adoption of the CDR algorithm where the user input efforts will be minimized. The password retyping and remembering will be substituted by the algorithm, which will contribute for simplifying the system and improving the privacy and security.

A number of advantages should be summarized as follows:

- CDR algorithm will improve the eWALL system in terms of usability and ease of use. It also is a way of performing better user experience, improved personalization and minimizing the need of user input which is important from senior or cognitive impaired users' point of view.
- STSO IdM will improve the eWALL system in terms of mobility and inner system sites roaming – by ensuring user identification and eWALL application access.
- STSO will add value to the eWALL system by providing Service orientation and ensuring always responsive services
- Personalization and privacy of services by improved ability for the user to create the rules for identification within the eWALL system.
- STSO IdM and CDR algorithm will improve the security by reducing the possibility for personal data abuse or unwanted system intrusion.

With introducing the STSO IdM in eWALL both the users and the business parties will benefit from better utilized sensing infrastructure, seamless roaming between eWALL sensing environments, improved personalization and security of the services and better monitoring of the patients.

Another advantage is that based on only one profile for STSO IdM, the user could be identified and be able to utilize various services by using myriad of devices. Furthermore, the user will be able to define and manage his/her own rules in the stage of profile creation such as: device connectivity type (automatically or manually), services access permissions, number of computing devices as an input data for CDR procedure.

VI. CONCLUSION

Referring to proper and meaningful scenarios for implementation of STSO IdM, good examples are the e-Health and, in particular, the Ambient Assisted Living (AAL) services The introduced STSO IdM system is a novel solution addressing the communication and interactions between all of the things involved in IoT in automated, time- and efford-saving manner. The STSO feature enables access to services through only one thing sign on without need of separate identification on web level or any additional manual actions. The proposed CDR identification algorithm ensures automated user identification. Privacy and security supportive technologies like the proposed from the author STSO IdM and CDR algorithm have the potential to fill in this gap for proper technology solutions.

Enhanced Turbo Equalizer Using 2 Dimensional Iterative Soft Decision Interference Cancellation

Doron Shinbox and Dan Raphaeli
Dept. EE-Systems, Tel-Aviv University, Israel

***Abstract*—In this paper, a novel iterative equalizer applying soft feedback is introduced, the 2 dimensional ISDIC (2D ISDIC) equalizer. The 2D ISDIC is the first equalizer that bridges the gap between the low complexity ISDIC equalizer which has poor performance, to the high complexity inverse channel equalizing methods, such as the LMMSE and the MMSE ISDIC equalizers, which has better performances. The 2D ISDIC will be incorporated into the turbo equalization scheme, resulting in an enhanced turbo equalizer, that performs better than the conventional, state of the art, linear turbo equalizer, with lower complexity and lower amount of iterations.**

I. Introduction

Inter symbol interference (ISI) is a well known phenomena affecting single carrier (SC) communication system, requiring the need on an equalizer. Various solutions to the ISI problem were widely investigated in literature throughout the years, from the maximum likelihood sequence estimator (MLSE) through different linear equalizers and to decision feed back (DFE) equalizers. One of latest class of equalizers are the iterative equalizers applying soft decision feedback. This type of equalizers consist of a two parts, linear part and a soft decision calculation part, which in not linear. The soft decision symbols are fed back to the linear equalization part and thus adding a non linear information for the symbol estimation which improves the equalizer's performance. This scheme is done in an iterative manner until it converges.

The optimal, in the sense of minimum mean square error (MMSE), iterative equalizer applying soft feedback is the MMSE ISDIC equalizer [1]. The MMSE ISDIC uses the information of the soft decision symbols in order to compute the LMMSE filter. Then a soft decision is made on the LMMSE output. The computation of an LMMSE filter of minimum twice the channel size every symbol estimation, makes it to be high complexity equalizer, and not practical to implement. On the other hand, the ISDIC equalizer [2], is a low complexity iterative equalizer applying soft feedback. The ISDIC equalizer uses a matched filter as a feed forward filter in order to concentrate the overall impulse response at one sample. Then, an ISI cancellation is made on that sample, followed by a soft decision. The application of a matched filter, instead of a channel inverse filter, makes it a very low complexity equalizer. However, it was shown that this equalizer performs well only on long random channels, with impulse like auto correlation functions.

In 1993, the novel turbo code scheme was introduced [3] and the concept of passing information between two decoders gave rise to the turbo equalization scheme [4]. In the turbo scheme an iterative receiver repeat the equalization and decoding on the same set of received data, where the feedback information from the decoder is incorporated into the equalizer in an iterative manner. The first turbo equalizer scheme was presented using a maximum a posteriori (MAP) equalizer. However the MAP equalizer suffers from high computational load for channels with long memory or large constellation size. Replacing the MAP equalizer with an LMMSE equalizer was proposed in [5], [6], and is widely known as the linear turbo equalizer. This approach performs almost as well as turbo equalizer based MAP algorithm, only requiring more iterations to achieve similar BER results.

In this paper, we introduce the novel 2 dimensional ISDIC (2D ISDIC) equalizer. The 2D ISDIC is based on a patent from 2005 [7] which was never published as a paper, and was implemented as an ASIC for use in power line communications. In the 2D ISDIC equalizer, we use a matched filter, in order to concentrate the overall impulse response at two samples, hence 2D. Then a partial ISI cancellation is made on the two matched filter's output samples, leaving two symbols uncanceled. A minimal 2 length LMMSE filter is then used to cancel the ISI left. Finally, a soft decision is made on the LMMSE output. The use an LMMSE filter improves the performance on much more difficult channels, with minimal increase in complexity. The main reason for the performance improvement of the 2D ISDIC is that the errors in the fed back symbols are less amplified in return to some increase in noise enhancement. If we take $D = 1$, we get the ISDIC equalizer, and if we take D to be the block length, we get the LMMSE equalizer. Therefore, the 2D ISDIC, may be considered as the bridge between both equalizers.

The 2D ISDIC will be then incorporated into the turbo scheme, resulting in an enhanced turbo equalizer. The enhanced turbo equalizer has two feedback. The feedback from the inner 2D ISDIC equalizer and from the decoder. The results show that the performance of the resulting 2D ISDIC turbo equalizer is better than the conventional, state of the art, linear turbo equalizer, with lower complexity and lower amount of iterations.

Before proceeding, Some frequently used notation is introduced. Vector are written in bold letters and are considered to be column vectors. Matrices are specified by capital letters. The vector $H_{(m,:)}$ represent the m^{th} row vector of the matrix H . The LLR operator $L_{obsevation}(x)$ is given by:

$$L_{observation}(x) \triangleq ln\left[\frac{P(x=1/observation)}{P(x=-1/observation)}\right] \quad (1)$$

The observation represents either the equalizer output which will be denoted by $L_e(x)$ or the decoder output denoted by $L_c(x)$. The soft decision of a symbol x_n will be defined as $s \triangleq E[x/observation]$. In this paper we will use a very simplified approximate model for the observations as $observation = x + z$ where z is a white Gaussian noise with zero mean and variance σ_z^2. Then, the relation between $L_{observation}(x)$ and the soft decision which is also the MMSE of x given an observation: $E[x/observation]$, is

$$s = tanh\left(\frac{L_{observation}(x)}{2}\right) = tanh\left(\frac{observation}{\sigma_z^2}\right) \quad (2)$$

II. System model

Fig 1, depicts the transmitter structure of our model. First the data bits are passing through a convolutional encoder and then through an interleaver, followed by a modulator. In this paper, for simplicity, e consider a real, discrete, time invariant impulse channel response $\mathbf{h} = [h_0, ..., h_{L-1}]$, perfectly known to the receiver. We will use the matrix notation for the received sequence $\mathbf{r}$

$$\mathbf{r} = H\mathbf{x} + \mathbf{w} \quad (3)$$

where H is an $N + L - 1 \times N$ size toeplitz matrix, describing the channel h. $\mathbf{x}$ is a length N transmitted coded data sequence $\mathbf{x} = [x_0, ..., x_{N-1}]$ taken from a BPSK alphabet $x_n \in \{+1, -1\}$ and $\mathbf{w}$ is a $N + L - 1$ length i.i.d Gaussian noise vector with zero mean and σ^2 variance. In order to develop the equations for the 2D ISDIC equalizer, we will define the matched filter output $\mathbf{u}$

$$\mathbf{u} = C\mathbf{x} + H^T\mathbf{n} \quad (4)$$

where$C$ is the channel's auto-correlation matrix $C = H^T H$.

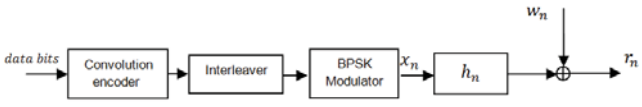

Figure 1. Transmitter and channel configuration

III. 2 Dimensional ISDIC Equalizer (2D ISDIC)

The 2D ISDIC equalizer is a combination of the ISDIC equalizer and a 2 size LMMSE filter. Like the ISDIC operation, the received signal is passing through a matched filter followed by an ISI cancellation. However, in the 2D ISDIC we choose two matched filter's outputs to perform a partial ISI cancellation on. For the estimation of x_n we will choose the outputs u_n and u_{n+d} , where d is chosen according to the channel characteristics. The number of matched filter's outputs selected, will be denoted by D, and will be referred as the dimension of the ISDIC equalizer. In this scheme, the ISI is not tempted to by fully canceled like in the ISDIC equalizer. Instead a number of symbols are left uncanceled and therefore we refer it as a partial ISI cancellation. The number of uncanceled symbols will be equal to the dimension of the equalizer D. Next, an LMMSE equalizer of length D is used to estimate the current symbol since the ISI of the uncanceled symbols remains. Finally, a soft decision is made on the LMMSE output. The parameter D is a trade-off between the ISI cancellation part and the LMMSE part, where $D = 1$ leads to the conventional full cancellation ISDIC equalizer, will be referred from now on as the 1D ISDIC, and $D = N$ leads to the conventional LE. The LE suffers from noise enhancement, and the conventional ISDIC suffers from error propagation (feeding wrong estimations), so some value in between can give best performance. We analyzed the trade-off, and found out that the value $D = 2$ gives good performance in most of the channels tested, and is also leads to the lowest complexity.

Every estimation of the symbol x_n , the partial ISI cancellation is done using the soft decision symbols vector $\mathbf{s}_n^\mu$, defined as

$$\mathbf{s}_n^\mu = \quad (5)$$

$$\left[\ s_0^\mu, \quad ... \quad s_{n-1}^\mu, 0, s_{n+1}^{\mu-1}, ..., 0, s_{n+d+1}^{\mu-1} \quad , ... \quad s_{N-1}^{\mu-1}\ \right]^T$$

where s_k^μ is the soft decision of the symbol x_k at the μ^{th} iteration, $\mu \in \{0, ..., \mu_{max}\}$, with initial conditions $s_k^0 = 0, \forall k$. Note that we exclude the soft symbols $s_n^{\mu-1}$ and $s_{n+d}^{\mu-1}$, where for the 1D ISDIC equalizer this vector excludes only $s_n^{\mu-1}$. The choice of d is done according to next highest peak (in absolute value) of the channel's auto correlation function defined as

$$\rho_n = \sum_{k=0}^{L-1} h_k h_{n+k} \quad (6)$$

Since $\rho_n = \rho_{-n}$ we can take d to be either positive or negative. For example, in both channels auto correlation functions, depicted in Fig 5, we can choose d to be ± 1. Furthermore, we know that the soft decision symbols vector $\mathbf{s}_n^\mu$ is updated sequentially, meaning that the pre soft symbols $\mathbf{s}_k^\mu, \forall k < n$ passed one more iteration than the post soft symbols $\mathbf{s}_k^{\mu-1}, \forall k > n$, and probably more accurate. Therefore, we choose d to be positive in order to use the soft symbol $\mathbf{s}_{n-d}^\mu$ instead of $\mathbf{s}_{n+d}^{\mu-1}$ for the partial ISI cancellation part, and leave the ISI from the symbol x_{n+d} to be treated by the LMMSE filter.

After choosing the two matched filter's $u_n$and u_{n+d} we perform a partial ISI cancellation according to

$$q_0 = u_n - C_{(n,:)}\mathbf{s}_n^\mu \quad (7)$$

$$q_1 = u_{n+d} - C_{(n+d,:)}\mathbf{s}_n^\mu \quad (8)$$

Assuming normalized channel, i.e. $\rho_0 = 1$, the matrix notation for the partial ISI cancellation output $\mathbf{q}$ is

$$\mathbf{q} = G\mathbf{x}_n + \mathbf{e} \quad (9)$$

where

$$\mathbf{q} = \begin{bmatrix} q_0 \\ q_1 \end{bmatrix} \quad G = \begin{bmatrix} 1 & \rho_d \\ \rho_d & 1 \end{bmatrix}$$

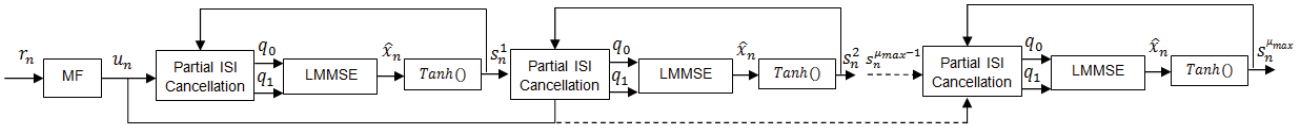

Figure 2. 2D ISDIC Equalizer

$$\mathbf{x}_n = \begin{bmatrix} x_n \\ x_{n+d} \end{bmatrix} \quad \mathbf{e} = \begin{bmatrix} e_0 \\ e_1 \end{bmatrix}$$

and $\mathbf{e}$ is the error term due to Gaussian noise and estimation errors.

The way we chose to compute the LMMSE coefficients follow the basic idea which was presented in [1], and states that the computation of the coefficients should be done given the past soft decisions and should be carried out on every symbol i.e new LMMSE coefficients are calculated for each symbol. The LMMSE solution for estimating x_n from the vector $\mathbf{q}$ is

$$\mathbf{w}^T = E[x_n \cdot \mathbf{q}^T / \mathbf{s}_n^\mu] \cdot \left(E[\mathbf{q} \cdot \mathbf{q}^T / \mathbf{s}_n^\mu]\right)^{-1} \tag{10}$$

Neglecting the conditional (given the vector $\mathbf{s}_n^\mu$) statistical dependencies between $x_i, x_k \forall k \neq l$ and between $x_k, n_l \forall k, l$ and using the following relations:

$$E[x_n / \mathbf{s}_n^\mu] = E[x_n] = 0 \tag{11}$$

$$E[x_{n+d} / \mathbf{s}_n^\mu] = E[x_{n+d}] = 0 \tag{12}$$

and

$$E[x_k / \mathbf{s}_n^\mu] = s_k^\mu, \forall k < n \tag{13}$$

$$E[x_k / \mathbf{s}_n^\mu] = s_k^{\mu-1}, \forall k > n,\ k \neq n+d \tag{14}$$

$$E[x_k^2 / \mathbf{s}_n^\mu] = 1, \forall k \tag{15}$$

we can derive the LMMSE coefficients

$$\mathbf{w}^T = G_{(1,:)} \left(GG^T + \Sigma_e\right)^{-1} \tag{16}$$

where Σ_e is the covariance matrix of the error term vector $\mathbf{e}$. (the covariance matrix elements will be presented in the journal paper). The biased LMMSE output is

$$\hat{x}_n = \mathbf{w}^T \mathbf{q} \tag{17}$$

We now approximate $\hat{x}_n$ as white Gaussian noise added to the symbol and the soft decision is computed according to

$$s_n^\mu = tanh\left(\frac{\hat{x}_n}{1-\alpha}\right) \tag{18}$$

where $\alpha = \mathbf{w}^T G_{(:,1)}$ is the LMMSE biased term. Note that in the 1D ISDIC $1-\alpha$ is replaced with the variance of the error signal after the ISI cancellation $\widehat{\sigma}_\mu^2[n]$, given in [2]. The scheme of the 2D ISDIC is presented in Fig 2.

IV. The Enhanced Turbo Equalizer Architecture

The conventional turbo equalizer scheme is depicted in Fig.3. and will be used here as the basis for the development of the new enhanced algorithm. $L_e(x_n)$ and $L_c(x_n)$ represents the LLR of the symbols at the output of the equalizer and at the output of the decoder, respectively. $L_p(x_n)$ represents the prior information of the symbols from the decoder (independent of the channel observations for a sufficient long block length) and is equal to

$$L_p^i(x_n) = L_c^i(x_n) - (L_e^i(x_n) - L_p^{i-1}(x_n))$$

where the superscript i represents the outer iteration number. The iterations begin with initial conditions of $L_p^0(x_n) = 0, \forall n$.

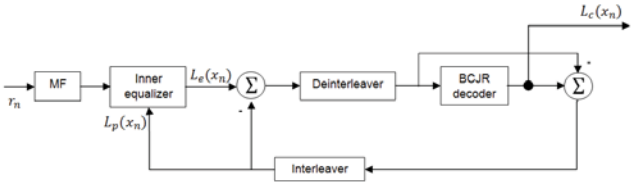

Figure 3. Turbo equalizer receiver

In the enhanced turbo equalizer scheme we use the ISDIC algorithm as a inner equalizer (1D or 2D). When using the ISDIC algorithm in the turbo scheme, we have two sources of feedback for each symbol. The feedback from the equalizer iteration (inner iterations) and from the decoder (outer iterations). We use the information from the decoder to update the soft symbols vector every outer iteration. Furthermore we use the information from the decoder when computing the soft symbol $s_n^{\mu,i}$ which is the soft symbol in i^{th} outer iteration and in the μ^{th} inner iteration where $i \in \{1, ..., i_{max}\}$. We also use the information from the decoder for the a priori information on the x_{n+d} symbol in the 2D ISDIC algorithm as will be explained. The enhanced turbo equalizer scheme is depicted in Fig .4.

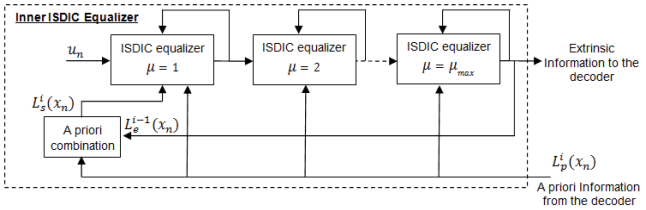

Figure 4. Enhanced Turbo equalizer receiver

where we have two observations for each symbol: $L_e^{i-1}(x_n)$ and $L_p^i(x_n)$, assuming that$L_e^{i-1}(x_n)$ and $L_p^i(x_n)$ are independent for a sufficient long block length, we simply combine the two sources

$$L_s^i(x_n) = L_e^{i-1}(x_n) + L_p^i(x_n) \tag{19}$$

where $L_s^i(x_n)$ is the combined prior to be used in the inner equalizer.

A. 1D ISDIC Turbo Equalizer

In order to incorporate the ISDIC into the turbo scheme we need to make the following modifications. After each outer iteration, new prior information $L_p^i(x_n)$ is given from the decoder. The soft symbols are initialized every outer iteration according to

$$s_n^{0,i} = tanh\left(\frac{L_e^{i-1}(x_n) + L_p^i(x_n)}{2}\right) = \tag{20}$$

$$= \frac{s_n^{\mu_{max},i-1} + tanh\left(\frac{L_p^i(x_n)}{2}\right)}{1 + s_n^{\mu_{max},i-1} tanh\left(\frac{L_p^i(x_n)}{2}\right)}, \forall n$$

with initial conditions $s_n^{0,1} = 0, \forall n$. The a prior information from the decoder is in addition used in the soft decision calculation, and the soft decision calculation of the 1D ISDIC becomes

$$s_n^{\mu,i} = tanh\left(\frac{y_n^{\mu,i}}{\widehat{\sigma}_\mu^2[n]} + \frac{L_p^i(x_n)}{2}\right) \tag{21}$$

B. 2D ISDIC Turbo Equalizer

In order to incorporate the 2D ISDIC to the turbo scheme we need to make the following modifications. First we need to update the soft symbols vector (5) which is done in the same way as in (20). Second we need to modify the LMMSE coefficients. Recall that the 2D-ISDIC principle is not to use the soft symbol of the symbol $n+d$ in the ISI cancellation, however, when incorporating the 2D ISDIC into the turbo scheme we wish to use the a prior information from the outer iteration available for this symbol and therefore equation (12) is modified to

$$E[x_{n+d}/\mathbf{s}_n^{\mu,i}] = E[x_{n+d}] \triangleq m_{n+d} \tag{22}$$

, where

$$m_{n+d} = tanh\left(\frac{L_p^i(x_{n+d})}{2}\right) \tag{23}$$

and the LMMSE solution is now

$$\mathbf{w}^T = G_{(1,:)}\left(G\begin{pmatrix} 1 & 0 \\ 0 & 1 - m_{n+d}^2 \end{pmatrix} G^T + \Sigma_e\right)^{-1} \tag{24}$$

$$b = -m_{n+d} \cdot \mathbf{w}^T G_{(:,2)} \tag{25}$$

Finally the soft decision equation (18) is modified according to

$$s_n^{\mu,i} = tanh\left(\frac{\hat{x}_n}{1-\alpha_n} + \frac{L_p^i(x_n)}{2}\right) \tag{26}$$

V. Complexity Comparison

An important aspect of the ISDIC equalizers is their low computational complexity. We will compare the computational complexity per received symbol of the ISDIC Equalizers to the Linear Equalizer. For our comparison we do not consider the computation of the LLRs and the soft decision (the $tanh()$ operator) which can be done with a lookup and it is 1 operation.

The number of multiplications and additions for the Linear Equalizer was given in [6] and is $O(M^2)$ where M is the length of the LMMSE filter and is usually twice the channel size. For both 1D and 2D ISDIC Equalizers the matched filter operation the ISI cancellation part and the calculation of σ_n^μ and Σ_e consist of $O(M)$ multiplications and additions. Furthermore the 2 size LMMSE filter in 2D ISDIC scheme requires a constant number of multiplications and additions and therefore the overall computational complexity of the 1D and 2D ISDIC Equalizers is $O(M)$.

VI. Results

We present the BER performance results by simulating data transmission using the system introduced in section 2. We examine the performances of the different schemes on two channels examples. The first channel was taken from [8] and was used in [5]. We took this channel for comparison reasons. The second channel is twice the size of the first channel and was randomly chosen from a Gaussian fading distribution.

$$h_1 = [0.407, 0.815, 0.407] \tag{27}$$

$$h_2 = [0.65, -0.56, 0.08, -0.36, 0.34, -0.1] \tag{28}$$

The absolute value of the auto-correlation function of the two channel is shown in Fig.5.

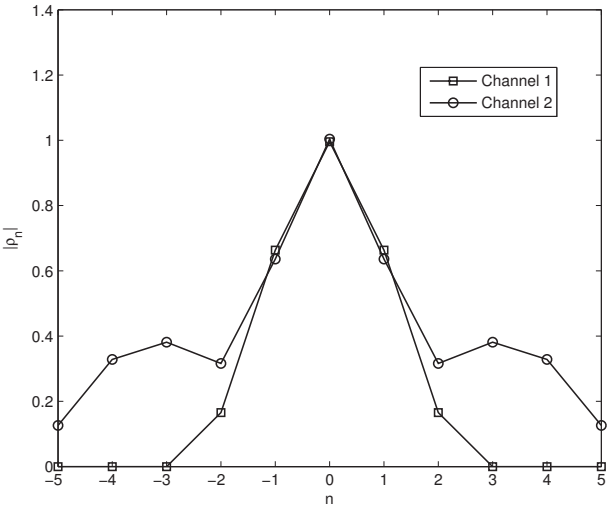

Figure 5. Channels auto correlation functions

The decoder and the interleaver/deinterleaver are identical to all methods. They differ only in the inner equalizer, which is either LMMSE, 1D-ISDIC, 2D-ISDIC or MAP Equalizer. For the LMMSE in the first channel we took a filter of 5 taps and for the second channel we used a 12 taps filter. The Linear Turbo Equalizer is the state of the art Turbo Equalizer [6] and [5]. The performance of the equalizers is lower bounded by the coded AWGN channel BER and by the MAP Turbo Equalizer [4] and they serve as a reference for evaluating the performance of our algorithm. We used a recursive, systematic encoder for the rate 0.5 code G=[7 5] where the first polynomial is used for the feedback and the second for the output bit. This code was chosen for comparison with other papers that used the same code[6] and [5]. For the interleaver we used the S-Random permutation [9] with S=20 and we took the block length to be 1024 ($N = 2048$) . We present our results after 2 outer iterations (1 iteration of separate equalization and code and one iteration with feedback from the code) and 1 inner iteration per outer iteration.

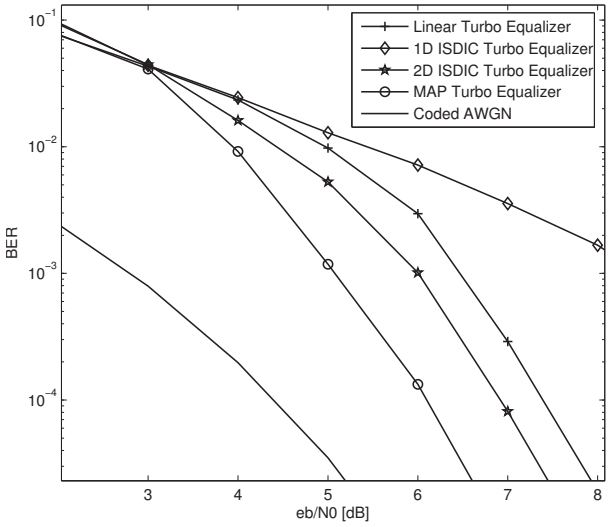

Figure 6. First channel BER Performance

Fig .6. shows the BER results of the 3 different equalizers on the first channel. The 2D ISDIC Turbo Equalizer perform better than the Linear Turbo Equalizer while the 1D ISDIC Equalizer performs poorly. There is less than 1dB gap from the MAP Turbo Equalizer.

Fig .7. shows the BER results of the second channel. Again the 2D ISDIC Turbo Equalizer performs better than the Linear Turbo Equalizer and it has 1dB gain over it. The gap from the MAP Turbo Equalizer is still about 1dB. The 1D ISDIC still performs poorly.

VII. Conclusions and Further research

A new approach for iterative soft decision feedback equalizers with a 2 coefficients length LMMSE estimation was proposed. This type of equalization is suitable for a inexpensive systems working with a single carrier but suffer from strong ISI. Due to the high performance after only few iterations we can suggest it for even for a latency limited applications. We have shown that our method improves the BER performance drastically with only few iterations made. Further optimizations that we will present in later publications will include optimization of the cancellation part, other than using only two symbols as shown in this paper, and in the case for two symbols we will present an optimization on the selection of the symbol $n + d$. An adjustments to spectrum efficient constellations such as high rate QAM will be also presented. One more interesting point that will be elaborated in the journal paper is the convergence of those iterative equalizers and their analysis using EXIT charts.

***Abstract*— Small Unmanned Aerial Vehicles (UAVs) are advancing their scope beyond military applications. Most of the work has been concentrated in adopting multi-UAV systems in providing cellular services to enhance the network coverage. However, little or no attention has been considered in serving moving hotspot conditions aka Place Time Capacity (PTC). In this paper, we explore a disparate way of employing multi-UAV systems by proposing a concept of Hovering Ad-Hoc Network (HANET) distinctively to solve PTC congestion using millimeter wave communication. We present a suitable architecture based on airborne HANET members as load balancing assistance to the primary network to offload user traffic to the nearby base station. The paper also presents a conceptual physical design of a HANET member to endorse further the proposed architecture.**

Keywords*— *WISDOM; Place Time Capacity; UAVs; HANET; Millimeter waves

I. BACKGROUND

Wireless Innovative System for Dynamic Operating Megacommunications (WISDOM) concept as asserted by Dr. Ramjee Prasad in [1], predicted the need for design and development of wireless infrastructure to serve the massive capacity with high data rates as high as 1 Tbps for the future 5G networks. However, a key challenge for telecom operators has always been serving hotspot areas that are densely packed by potential subscribers. Large subscriber base trying to access the radio resources at the same time is a major cause of network congestion leading to connection failures. Nonetheless, when such subscribers move in a group attempting to use mobile internet concurrently at events like festivals, carnivals, etc., they tend to create capacity demand at every position they traverse. Ambuj et al. have termed this condition of moving hotspot, even more precisely capacity-in-motion with respect to time as Place Time Capacity (PTC) [2].

As reviewed in [3] and [4], adding low power Pico nodes have been proposed to be a promising proposal in enhancing network coverage and capacity to meet the high user traffic and data rate demand. However, under PTC situations, deploying small pico base stations does not seem to be an appropriate solution as capacity in demand is erratic and tend to cease with time. Moreover, the number of handovers might increase posing a burden to the pico base stations. PTC congestion does not occur all-round the year and adding permanent base stations will be under-utilized at all other times.

Recent trends in UAV based applications indicate in employing autonomous small aerial based radio nodes as a solution to assist the existing fixed infrastructure to provide cellular services to the ground users [5][6]. Exploiting the current advances in compact physical structures, mountable small radio equipment along with small antenna array and accurate sensors are making it feasible for the aerial cells to communicate reliably with the ground nodes. We believe that deploying such multi-UAV radio devices working in teams can greatly solve PTC congestion in countries with potentially dense subscribers, e.g. India.

In this paper, we propose Hovering Ad-Hoc Network (HANET) as a solution to serve PTC. This swarm based architecture employs multi-layered communication paradigm including Millimeter-Wave Communication (MMWC). Emphasizing on MMWC, first is the MMWC between aerial radio nodes and ground-based existing infrastructure. And, second is a millimeter wave (MMW) assisted communication link between radio nodes and users on the ground for traffic offloading assistance to ground-based infrastructure. Also, the conceptual physical design of the flying HANET member is proposed to endorse the proposed concept.

This paper is organized as follows: The related work is given in Section II. In Section III, we present the HANET concept architecture. Finally, we conclude the paper and indicate future work in section IV.

II. RELATED WORK

Recent years have seen increasing growth in research and implementation of UAV based deployments for a number of applications. Ongoing industrial projects like Facebook Drone [7] and Google Loon [8] are in development to lay high altitude platforms to extend web access and internet connectivity to the ground users. Also, low altitude platforms are being scrutinized for emergency operations and

communication services. In [9], a quadcopter based prototype was implemented to bridge two end systems using small single-UAV and multi-UAV relays depending upon the distance between them. The authors have also discussed the positioning of such UAVs forming a Wireless Mesh Network. The work presented in [10] describes a power efficient radio resource allocation mechanism based on game theory approach using Low-Medium Altitude Aerial Platforms (LMAPs) for Aerial LTE uplink and downlink. Low Altitude 3G Small UAVs (SUAVs) functioning as mobile relays have also been investigated for urban and rural areas. In [11], the authors have compared existing load balancing and static relaying techniques with the performance of 3G SUAVs and a significant improvement in throughput and QOS was observed when deployed with multi SUAVs in target areas. Tom et al. [12], have presented Octocopter based GSM infrastructure for establishing field communications in the absence of commercial services and argued upon improvised cost, power and, spectral efficiency in comparison to existing GSM radio interface.

There are only a couple of studies that have considered moving subscriber hotspots. One of them has tested a set of adaptive base stations deployed on a rail at the ceiling of an airport building to service the moving user hotspot at the arrival of an airplane [13]. Authors proposed stigmergy based distributed algorithms to identify the need for changes in position and configuration of the railing base stations autonomously according to the dynamic user demand. A Swarm of UAVs equipped with LTE-4G to offload traffic into neighboring cells for cell outage compensation was suggested in [6]. Their proposed work incorporated aerial UAV relays to reduce the downlink system loss for a given outage scenario and suggested that it can also be applied to moving traffic overload situations (parade, etc.). A similar implication was made in [14] for natural disaster recovery management and user traffic offloading during massive moving of crowds using Low Altitude Platforms (LAPs). Wherein, a statistical propagation model for predicting the air-to-ground path loss between a low altitude platform and a terrestrial terminal was proposed, however, no specific case in handling moving crowd situations was outlined.

Some other related projects like AVIGLE [15], SMAVNET [16], ABSOLUTE [17], etc. are also dealing with UAV/Drone based implementation in the areas of surveillance, disaster management, civil security and cellular communication services. Further, the AIRBEAM project [5] have proposed a role based connectivity management to maintain reliable communication between UAV swarms for emergency operations and ground user services. However, none of the work has been propounded distinctly for servicing moving hotspot situations using aerial devices. In this paper, we propose the applicability of UAV-MM wave based cellular communication service through a concept of HANET exclusively to serve the Place Time Capacity problem.

III. PROPOSED HANET ARCHITECTURE

A. Hovering Ad-Hoc Network (HANET)

We coin HANETs as *a team of self-itinerant, intelligent and adaptive hovering radios to serve the dynamic traffic need of moving subscriber hotspots by optimally positioning themselves at the Area of Event (AoE). We consider Area of Event as an area where a moving crowd accumulation is potentially high.*

In comparison to other classes of ad-hoc networks, namely Mobile Ad-hoc Networks (MANETs) and Flying Ad-Hoc Networks (FANETs), HANETs mainly differ by having lower mobility, LOS connectivity between the devices in the HANET, and ability to provide cellular services to the ground mobile users. We will assume cellular services in the International Mobile Telecommunications (IMT) communication bands currently defined, as well as the possible future use of the millimeter wave bands. Table 1 summarizes a comparison of HANETs from MANETs and FANETs [18].

Table I

Parameter	MANETs	FANETs	HANETs
Node Mobility	Low	Very high	Low
Mobility Model	Random	Regular (predetermined paths) /Special (autonomous multi-UAV systems)	Nomadic (mobility follows PTC)
Node Density	Low	Very low	Low
Topology Change	Slow	Fast	Quasi-constant
Radio Propagation (node altitude)	Close to ground, NLOS for most cases	High above ground, LOS for most cases	Both above and close to ground (LOS)
Mobility type	Quasi-Stationary, ground	Flying	Hovering (ground & flying)
Inter-member distance	Short	Long	Shorter
Communication Band	On-demand, Unlicensed	Unlicensed/ Cellular	IMT and Millimeter-wave
Application type	Specific user scenario	Multi-UAV applications	PTC load dispersion

B. HANET Network Architecture

A Hovering Ad-hoc Network (HANET) is a network of aerial radio nodes that collaborate and coordinate to serve accumulated PTC situations at the AoE. To understand the working of HANET, fig. 1 depicts a conventional network architecture with an AoE served by two conventional base stations (following a PTC congestion and overloading), BS1 and BS2. The modified architecture will comprise additional elements that are:

1) HANET Members
2) HANET Gateway Base Station (HGBS)

The flying HANET members that include HANET Serving Members (HSM) and/or HANET Relay Members (HRM) is defined under HANET Base Station Subsystem (HBS) and is a separate network subsystem other than conventional Base Station Subsystem (BSS) involving the overloaded Base Stations BS1 & BS2. A team of HRM that are connected to a HGBS form a HANET Relay Subsystem (HRS). The role of HSM is to provide service to the mobile users underneath and the HRM are used to relay user data from HSM to HGBS. Each HANET member is capable of being a part of either HSM or HRM or both.

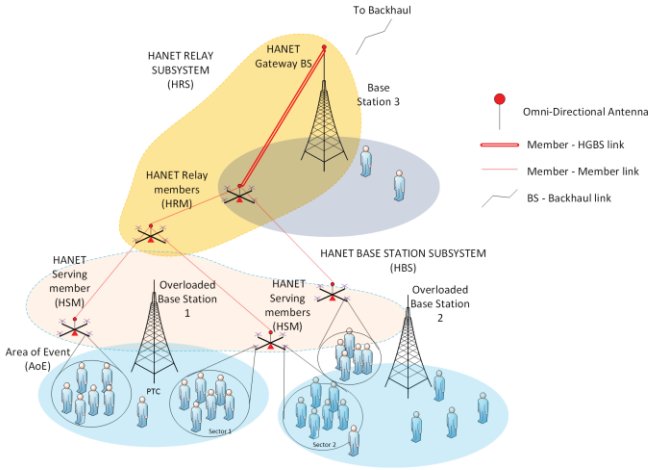

Fig 1. HANET complementing Primary Network

Each HANET member will service the subscribers using four sectors comprising of directional antennas. As we can see from fig. 3, the four sectors are mainly taking advantage of the proposed HANET design with a quadcopter base with four arms. Covering these arms with aerodynamic carbon based casing will provide sufficient room for sticking metallic wafers to form a directional antenna and therefore, we can have four directional antennas for each of the technology (IMT and MM). Further, having more sectors per 360-degree span will provide better control on the dynamic subscriber movements in the HANET member's vicinity. Also, the higher number of sectors will provide the opportunity to increase the antenna gain by narrowing the beamwidth without losing coverage at the sector boundaries. Depending on many propagation related factors, more sectors will likely also give us better confinement of interference in the system.

In dense urban, urban and suburban scenarios, it is inevitable to face severe propagation loss due to shadowing, diffraction, reflection, etc. Therefore direct backhaul from HSM may lead to loss of communication. In this case, the HRM can relay the user data to the nearby base station (HGBS). The communication in the HBS requires member to user communication that will be provided through IMT channels and possible future millimeter wave cellular channels by the HSM. User data will be relayed by the HRM to service the moving crowd continuously. By making HANET follow the moving subscribers, the number of handovers that could have possibly occurred in the network otherwise would eventually reduce thereby potentially relieving the bulk handover issues within the overloaded network. Further, the backhauling will be done through millimeter wave channels only. The member to member control information containing their placement coordinates, IDs, etc. for maneuvering control and optimal positioning of each member will also be communicated through millimeter wave channels.

For our research, we particularly delve into laying mm-waves for a member to member/HGBS and member to mm-user devices as an overlay to traditional IMT layer. This is because i) no interference with any of the IMT channels, ii) higher bandwidth to serve mm-user devices and for relaying user data to the nearest base station (both IMT and mm data), and, iii) member to user communication likely to be in LOS at all times as HSM will be closer to the users underneath. The HSM might not be necessarily in LOS with the HGBS, which is why HRM forming a network chain will come into play to relay the user data from HSM to HGBS.

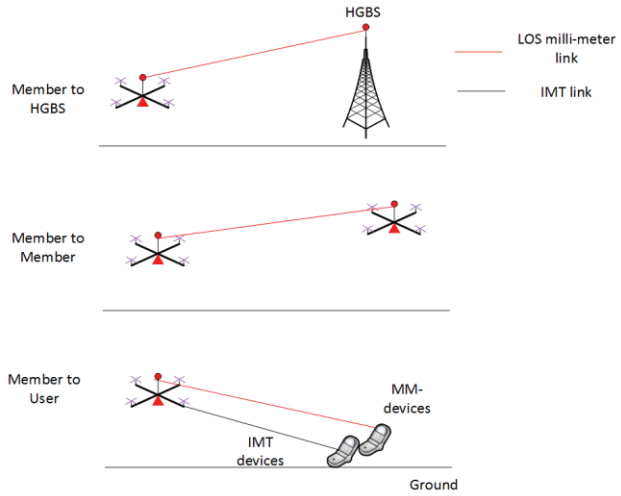

Fig 2. HANET Communication Links

There is one challenge that needs consideration when HANET members are airborne using mm-waves. Mm-waves need more power due to short aperture antennas and higher transmission losses. Advancement in using arrays of multiple antennas producing highly coherent and directional beams can overcome this challenge [19]. However, this comes at the cost of more intelligence required by the HSM to keep the beams highly directional and focused. Even for HRM to communicate, an LOS is important to maintain. Further, Rappaport et.al have further concluded that significant non-line-of-sight (NLOS) outdoor, street-level coverage is possible up to approximately 200 m from small base stations at 28 & 73 GHz [20]. In addition to this, it has been estimated that there will be 50 billion devices including mm-future phones, which would be connected to mobile networks with multi-gigabit data rates by 2020 [19]. The millimeter wave

communication is surely paving its way onto serving cellular communication in 5G and hence a separate layer of mm-waves has been proposed with the architecture.

Fig.2 summarizes the connecting links between HANET members and with the user devices and HGBS. As it is possible to know the time and place of events where PTC might arise, base stations nearby the subscriber hotspots can be strategically exploited to service the overloaded user traffic. We propose an additional transceiver architecture that will reside on such base stations to act as HANET Gateway Base Stations (HGBS) thereby exclusively communicating with the HANET members. A HANET member closest to the HGBS will be the Point of Interconnect (PoI) and will act as HRM and further relay the user data to the backbone network. Although the HGBSs can be placed at uniform locations across the city/region but doing so will put an extra load on the Capital Expenditure (CAPEX) to the service operators. The events that trigger PTC problems occur at some particular areas or, at open spaces hence the base stations around only those areas only can be put to function as HGBSs.

The HANET will be a formation of Wireless Mesh Network (WMN) that uses multi-hop communication. Routing plays a fundamental role, and selecting a routing protocol is a challenge for the HANET to ensure which is needed for reliability in routing the data and control information between the members. The configuration of the members might change in lieu of dynamically changing mobility patterns of the subscriber hotspots. The inter-member communication protocol will focus on sustaining a temporary itinerant hovering network in dynamic weather conditions to deliver high data rate to the PTC. For the proposed architecture, the communication protocol will address a reliable and efficient, power aware, time synchronized network topologies like star or mesh.

Furthermore, the idea of employing HANET to serve PTC requires some form of intelligence to be assimilated into such devices to sense the network environment and the PTC region. The intelligence would assist them to decide their network footprint by electronically/mechanically steering their antennas. The HANET members must aim to i) maximally cover the AoE with required QOS to users, ii) establish continuous connectivity among themselves such that no voids/overlaps are created, and iii) maintain network dynamics while moving with respect to subscriber hotspot movements.

C. Physical Framework

A robust, reliable and compact physical structure is important to design and build to be executed as a complement to fixed base stations, with the purpose of delivering adequate Quality of Service (QOS) to a real-time moving hotspot event. Here we present a thought generated physical design of HANET structure shown in fig. 3. Apart from the basic components of a UAV-quadcopter structure, Table II elaborates the radio communication equipment in HRS/HBS for a HANET device required to serve PTC-driven network conditions.

Table II

System members	Component Usage	Description
	Communication Equipment	
HBS	Panel Antenna	Directional antenna for Member-User communication in IMT band
HBS	Patch Antenna	MM-wave antenna for Member to MM-based user device communication
HRS, HBS	Omni-Antenna	MM-wave antenna for Member-Member communication
HRS	Omni-Antenna	MM-wave antenna for Member-HGBS communication
Morphologic & Subscriber Sensing		
Real Time Image Analysis using cameras & sensors to identify physical environment and human clusters		

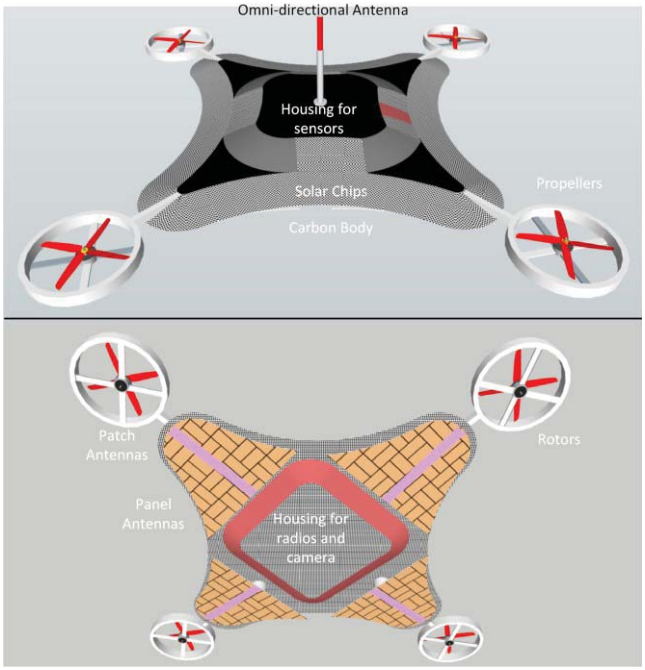

Fig 3. HANET member proposed physical design

As depicted in the fig. 3, we have proposed a quadcopter based HANET device design consisting of four brushless rotors with propellers wide in diameter for better stability and low power consumption. The contour of the propeller chassis extrudes a carbon fiber panel that will consist of both panel (IMT devices) and patch (mm devices) antenna's metallic wafers to provide coverage underneath the hovering altitude. The wings of the quadcopter will affix four such assemblage of panel and patch antennas to cater four sectors with four distinct carriers to serve different clusters of subscribers. The coverage area to be served by each of the panel antennas can be steered depending upon the cluster of users within the

communication range of the quadcopter. Furthermore, the top surface of the frame will mount the omni-directional millimeter wave antenna for the member to member/HGBS communication. As the lower surface of the wing frame is utilized for serving antennas, consequently the upper surface of the frame can be used to mount solar panels that will keep charging the Lithium Polymer (LiPo) batteries thereby increasing the longevity of device service per period of operation.

The lower part of HANET device structure will encapsulate all the radios (IMT & MM) and the Inertial Measurement Unit (IMU) consisting of sensors along with GPS and cameras. The IMT radio will be connected to the port of panel antennas, and similarly millimeter wave radio will be connected to the port of patch antennas on each of the quadcopter wings. The carriers of the HANET member can be distributed among its four sectors thus improvising frequency re-use at the local level.

The members have a Control and Maneuvering Unit (CMU) that is connected to the rotors and propellers for adjustment of angular velocity to perform operations like turn, hold, hover, etc. The IMU will be composed of sensors to measure the physical parameters like direction, speed, and coordinates of the HANET device structure. The CPU of the member will account for all the information from radios and IMU to instruct CMU to move the mechanical parts of the device and to control further the physical parameters of the radios.The power requirements of quadcopter based aerial devices need to be addressed to increase the flight hours during its single operation. We propose adding multiple solar chips over its upper body to charge the quadcopters continually. The weight of the device should be sufficient to carry communication equipment and sensors for its operation during PTC situation and still bearing high-level endurance.

IV. Conclusion

This paper proposed a concept of Hovering Ad-Hoc Network (HANET) as a different prospect of using small multi-UAV based network deployment to deal with Place Time Capacity (PTC) problems. User capacity is not static but in motion and varies dynamically at events like carnivals, festivals, etc. and therefore, providing service with HANET as an assistance to the primary base stations can be useful to balance heavy traffic conditions. A physical framework based on quadcopter structure forming a suitable network architecture is also presented. Further, the paper proposed an adoption to millimeter wave mobile service delivery by HANET members keeping in view the future 5G networks incorporating millimeter wave devices by 2020. The HANET concept introduced in this paper can be extended to devise artificial intelligence based HANET for decision making in hovering control and positioning. Furthermore, the swarm of such hovering members can be utilized in specific scenarios like defense applications and disaster management.

***Abstract*—A novel PAPR shaping technique for single carrier transmission with high spectral efficiency is presented. This technique applies puncturing of error correction redundancy bits to achieve a desired Markovian symbol transmission probability distribution, which avoids symbol sequences with high peak values. To measure the overall gain of a peak reduction transmission, a link-gain metric, which takes into account both PAPR reduction and average energy loss, is presented. For a 16-QAM system with transmission rate of 3 bits/symbol and a SRRC pulse shape with roll-off factor 0.1 and duration of 4 symbols, a link gain of 1.87 dB is demonstrated using a pragmatic binary Turbo code for error correction. The technique can be used to improve any single carrier communication link limited by the PA peak power. It is in particular attractive to satellite communications by maximizing the rate of a given transponder, or given terminal hardware.**

I. Introduction

In practical communication systems power amplifiers (PA) are commonly used to enable wireless transmission over long distances. When using such a PA, it is crucial to keep the input signal's power within the PA's linear region in order to avoid saturation of the transmitted signal, which leads to both in-band and out-band disturbances. Transmission signals at the PA input are therefore backed-off (BO) so that instantaneous high peak power values will not cause saturation. The cost of the BO is that the average power of the signal is lower, thus compromising the transmission rate. This effect is especially severe in transmission signals with wide dynamic range, such as OFDM. However, in band limited single carrier transmission, which is common in satellite communication systems, high Peak to Average Power Ratio (PAPR) is also common. The PAPR problem in satellite communication is significant due to the high cost of PA, and due to the limited satellite resources even 1dB loss is critical.

Since the length of the pulse shape exceeds the symbol duration, high instantaneous peak power values are the result of certain symbol sequences. A possible approach to reduce the PAPR is therefore to try to avoid such sequences.

The method of Trellis shaping (TS), first suggested by Forney to reduce the average transmission power in high orders constellation signaling [1], has been shown to be useful for the purpose of PAPR reduction as well [2]. Originally, TS was shown to work well with Trellis Coded Modulation (TCM) [1]. Several attempts have been made to combine TS with other ECC schemes [3] [4]. In [4], LDPC code as inner code was combined with TS for power reduction. In [3] TS for PAPR reduction was combined with convolutional ECC. The reported gain in [3] was 1.8 dB PAR gain with 1.5 dB loss in SNR, resulting in an overall link gain of 0.3 dB. However, the SNR loss was calculated theoretically and may be higher in practical schemes. Additionally, the information rate was 1 bit/symbol, and higher rates were not investigated.

TS is based on adding shaping bits, usually one bit per symbol, to create redundancy in the possible symbol sequences representing a given information word, and a Viterbi decoder which is used to select the symbol sequence with the minimal PAPR cost. Although PAPR gain can be achieved in this way, several issues are not fully addressed by PAPR reduction using TS. First, TS adds an integer number of bits per symbol, which does not allow a complete rate/shaping trade-off. Second, it is not clear whether the PAPR reduction achieved by TS for a given rate is optimal. And third, the combination of TS with modern error correcting codes (ECC) such as Turbo codes or LDPC, which is crucial for enabling a reliable communication system, has not been optimized, leading to lower gain.

This paper addresses all three issues by proposing a novel PAPR shaping technique, which is based on puncturing of ECC redundancy bits to achieve a non-uniform Markovian symbol distribution which completely avoids symbol sequences with high peak values, but allows transmission of all other symbol sequences and thus

maximizes the information rate for a given peak constraint. Also, this technique is shown to perform well when applied with pragmatic Turbo codes, compared to a non-shaped system. The method can be regarded as a generalization of a previous work by the authors [8], obtaining a power reduction gain in a similar way.

We obtained encouraging results. For a turbo coded 16-QAM system with transmission rate of 3 bits/symbol and a SRRC pulse shape with roll-off factor 0.1 and duration of 4 symbols, a shaping gain of 2.81 dB is demonstrated by simulation. Since the scheme had also loss of 0.94 dB in Eb/N0, the resulting link gain is 2.81-0.94=1.87 dB. We also compared shaped 16-QAM to unshaped APSK and even 8PSK, and achieved gain, though lower than compared to unshaped QAM.

The rest of the paper is organized as follows: In section 2 some background and notations are given. In section 3 the process of deriving a practical symbol distribution with peak constraint is presented. In section 4, the combination of TCM with the shaping process is defined, both for the Tx and Rx parts. Section 5 presents simulation results of the shaped system, compared to a non-shaped reference system. In section 6 conclusion remarks are given.

II. System Model

Let C be a 2-dimensional constellation with cardinality $|C| = M$. Let $\boldsymbol{c} = (c_0, ..., c_{n-1})$ where $c_i \in C$ be a frame of n symbols transmitted over an AWGN channel. The transmission sequence $\boldsymbol{c}$ is passed through an over-sampled Square Root Raised Cosine (SRRC) pulse shape filter $h[n]$ with effective duration spanning over K_s symbols. The resulting transmission signal $x[n]$ is given by

$$x[n] = \sum_{k=\lfloor n/N_s \rfloor}^{\lfloor n/N_s \rfloor + K_s - 1} c_k \cdot h\big(T(n/N_s - k)\big) \qquad (1)$$

Where T is the duration of a symbol and N_s is the number of samples taken in a symbol period.

The instantaneous power of the signal is given by $p[n] = |x[n]|^2$. The PAPR is the ratio between the peak and the average values of $p[n]$, where the peak value is defined as the value of $p[n]$ which is exceeded with probability P_{peak}. In this paper we use the value $P_{peak} = 10^{-4}$.

Generally, when applying shaping for PAPR reduction both PAPR and average power of the transmitted waveform are affected. Since any reduction in PAPR allows for an equivalent increase of average power, the overall gain of a shaped system is the sum of the PAPR and average power gains. This gain is denoted from here on as "link gain".

III. Markovian Symbol Distribution With Peak Constraint

A. Optimal Symbol Distribution

A *channel state* at time k, denoted s_k, is defined as the length $K_s - 1$ symbol sequence $(c_{k-K_s+1}, .., c_{k-1})$. The combination of a channel state and a symbol c_k determines N_s samples of $p[n]$. Consider a peak constraint $p[n] < p_{peak}$ on the signal's power samples. Let $\mathcal{C}$ be a codebook of length n frames, which consists of all the frames which do not include a sequence exceeding p_{peak}. $\mathcal{C}$ is a one-to-one mapping function which associates information words of length $\log_2(M) n R_s$ bits to frames of n symbols, where R_s is the shaping rate. Taking $n \to \infty$ and calculating the marginal distribution $P^* \triangleq \Pr(s_k|s_{k-1})$ gives the maximal entropy symbol distribution given the peak constraint. P^* can be derived analytically using the conditional limit theorem [5]. Specifically, if $W(s_k|s_{k-1})$ is the Markov representation of the uniform transmission, then according to theorem 4 remark 2 in [5] the desired Markov I-projection P^* is given by

$$P^*(x,y) = \begin{cases} \lambda^{-1} u(x) W(y|x) v(y) & \text{if } (x,y) \in E \\ 0 & \text{if } (x,y) \notin E \end{cases} \qquad (2)$$

Where E is the set of all (s_{k-1}, s_k) combinations of consecutive channel states for which the resulting samples of $p[n]$ do not exceed p_{peak}, λ is the largest eigenvalue of the matrix obtained from W by replacing the entries $(s_{k-1}, s_k) \notin E$ by zeros, and u and v are the corresponding left and right eigenvectors.

In general, an additional constraint on the average power of the distribution may be considered to attempt an increase in shaping gain. However, previous work by the authors has shown that given a peak constraint, the optimal distribution is achieved when no further constrains are applied [6].

To simplify the following notations, from here on any stationary distribution $P(s_k|s_{k-1})$ is denoted by $P(c|s)$ instead, since given s the next channel state is uniquely defined by the symbol c.

B. Practical Symbol Distribution

To apply the theoretical distribution on a practical scheme, first it is required that the symbol transition probabilities will be of the form 2^{-k}. Since the maximal entropy distribution P^* in general does not hold this property, a quantized version of P^*, denoted as $\bar{P}^*$, is used instead. Specifically, for a conditional distribution

$\Pr(c|s)$ the quantized probability $\bar{\Pr}(c|s)$ is obtained by rounding $\Pr(c|s)$ to the closest 2^{-k}. If required, the lowest probabilities are manipulated to ensure that the sum of the quantized distributions equals 1.

Since a 0 probability is rounded to 0, it is ensured that no illegal symbol transition occurs when applying $\bar{P}^*$. The only effect of the quantization process is therefore a reduction of the transmission entropy, and thus it's rate. This reduction however was found to be negligible in most cases.

C. Theoretical Gain

The channel capacity of transmission with Markovian constraint generally cannot be found analytically. Instead, it can be derived by monte-carlo simulation as described in [7]. In our case the state depends on the input sequence only, therefore the recursion of $\mu_k(s_k)$ reduces to

$$\mu_k(s_k) = \sum_{s_{k-1}} \sum_{c_k} \Pr(y_k|c_k) \Pr(c_k|s_{k-1}) \delta(s_k, s_{k-1}, c_k) \mu_{k-1}(s_{k-1}) \quad (3)$$

Applying this method on the distributions $\bar{P}^*$ for various peak constraints, and comparing to the capacity of uniform un-shaped transmission, yields the theoretical SNR gain of each $\bar{P}^*$. In addition, the PAPR gain can also be found analytically, as both p_{peak} and p_{avg} are known for each $\bar{P}^*$, and can be compared to the PAPR of the uniform transmission. Such comparison is presented in figure 1 for the case of transmission in rate of 3 bits/symbol over a 16-QAM constellation, with an SRRC filter with roll-off factor 0.1, $K_s = 4$ and $N_s = 8$. The constellation is normalized such that the average (uniform) symbol energy is 1. It can be seen that the maximal link gain in this case is expected for peak constraint of 2.2. Note that comparing to a different constellation would not change the optimal peak constraint, as only the reference PAPR and SNR would differ.

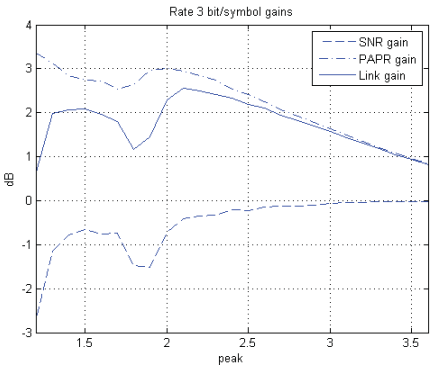

Fig. 1: Theoretical SNR gain, PAPR gain and link gain for different peak constraints of 3 bits/symbol transmission over a 16-QAM constellation, with an SRRC filter with roll-off factor 0.1, $K_s = 4$ and $N_s = 8$.

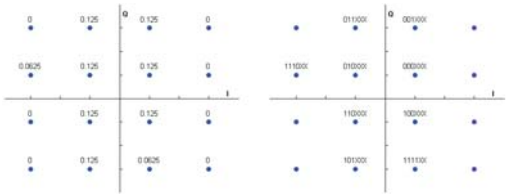

Fig. 2: Example of a 16-QAM bit-mapping. On the left are quantized probabilities, on the right are bit values assigned to each symbol. 'X' marks a don't-care value, which translates to an erased bit.

IV. Applying with Pragmatic Binary TCM

A. General Method

The nonequiprobable signaling is now applied in the following way. After adding error correction redundancy bits to the information sequence, the resulting bit sequence is divided into m-tuples, where the first d bits of each tuple are information bits and the last $m-d$ bits are redundancy bits. The m-tuples are then sequentially mapped into symbols using a channel-state dependent mapping table. The table contains for each state the quantized values of $P(c|s)$. The channel state is updated with the new symbol and the process is repeated with the next m-tuple. An example of a mapping table is illustrated in figure 2.

B. Bit Labeling

For a given channel state, each symbol is transmitted with a different probability. The method to apply different symbol probabilities is adopted from [8]. A larger probability is obtained by assigning to that symbol a bit sequence with smaller number of bits, while taking the rest of the bits of the label as "dont care. For example assuming the number of bits used for bit labeling is $m = 6$. A symbol with assigned bits of 11xxxx will have a probability of 0.25 since all the words 110000-111111 will be assigned to it. An example of a mapping table is illustrated in figure 2.

The bit labeling problem is not trivial. A straight forward Gray bit labeling is not well defined. Additionally, the bit-mapping is different for each state, which implies that the bit labeling of a symbol depends on the channel state. On the receiver side, a Trellis decoder must be used to keep track of the channel state. Consider a scenario in which a symbol error occurred at the receiver; because the channel state is the sequence of the last $K_s - 1$ symbols, a single symbol error results in an error in the evaluation of $K_s - 1$ consecutive states.

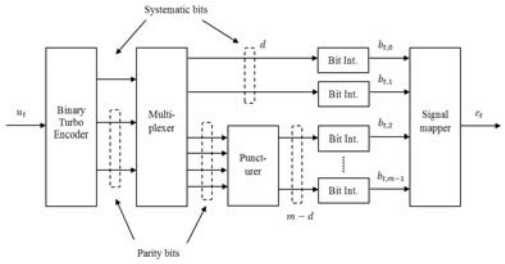

Fig. 3: Pragmatic turbo encoder. In the shaped case, the signal mapper saves the current channel state and applies additional puncturing to achieve non-uniform signalling.

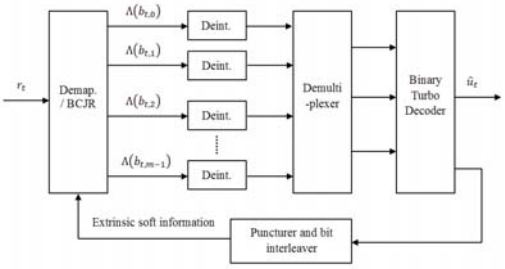

Fig. 4: Pragmatic turbo decoder. In the shaped case, the de-mapper is replaced by a BCJR decoder which runs over the channel state progression.

Since each state holds a different bit labeling, even if all other symbols are evaluated correctly their bits might be in error due to their state dependent labeling.

Following these observations, when constructing the symbol bit-maps two objectives are to be taken under consideration: first, that for each state the labeling of the symbols would be as close to Gray as possible and second, that for "close states", which differ by one symbol, the labeling would be as close as possible, to minimize the bit error probability in the correct-symbol incorrect-state scenario.

C. Combining with Pragmatic TCM

The nonequiprobable signalling is now applied to TCM. In pragmatic binary TCM [10], a single binary turbo code of rate 1/3 is used as the component code. The encoder outputs are multiplexed and punctured to obtain m bits per symbol, with d systematic information bits and $m-d$ parity bits, as shown in figure 3. The signal mapper then maps each m-tuple into a symbol from C. In the non-shaped system $m = \log_2(M)$ and the mapping is a constant Gray code. In the shaped system $m > \log_2(M)$ and the mapping depends on the channel state. Due to "X" mapping digits the mapping itself applies an additional puncturing, therefore this scheme is in fact a variable-rate turbo code, since the number of parity bits given to each information bit varies as a function of the input combination.

At the receiver side, shown in figure 4, the noisy symbols are received by a demapper module in the non-shaped case, or a BCJR module in the shaped case. In both cases, the LLR values $\Lambda(b_t)$ are produced for each encoded bit. The LLR values are used, after appropriate bit de-interleaving, as an a-priory input to a binary turbo decoder. In each iteration, the turbo decoder produces extrinsic LLRs which are used as an a-priory input to the demapper/BCJR module, which in turn calculates new extrinsic LLRs which are sent back to the turbo decoder. After a pre-determined number of iterations has been reached, the bit estimations $\hat{u}_t$ are determined by performing hard decision on the turbo decoder's a-posterior LLRs.

V. Simulation Results

The pulse shape tested in all our simulations is an SRRC filter with effective duration $K_s = 4$, roll-off factor 0.1 and an over-sampling factor $N_s = 8$. The shaping was applied on a 16-QAM constellation. This setup results in a Trellis with 4096 states. To reduce the complexity of the channel state BCJR decoder, states with alpha value smaller than 1e-6 were disregarded. This approximation was found to have negligible effect on performance. In addition, all constellations were normalized such that the average (uniform) symbol energy is 1. In the shaped transmission, power samples caused by inter-frame symbol sequences were ignored. In practice, peak samples caused by such sequences can be avoided in several ways, such as using tail-biting on the BCJR, applying proper termination with small rate cost or extending the frame length so that these peaks become negligible.

The code used with all schemes is a standard rate 1/3 turbo encoder [11], made up of two elementary encoders with memory size 4 and the same generator polynomial 37-23 (octal number 37 represents the feed-forward connections and 23 the feedback connections). This code is known to be an optimal code with memory size 4 for various turbo-code rates [12]. The Turbo decoding was ran for 18 iterations on block length of 4096 information bits with pseudorandom interleaving.

As was shown in section III-C in the case of rate 3 bits/symbol the maximal gain is expected at peak constraint of 2.2. This peak constraint was indeed found to achieve the highest link gain also in simulations. The shaped transmission is compared to non shaped 16-QAM and 16-APSK transmissions with the same pulse shape. The resulting FER curves and PAPR distribution are presented in figures 5, 6 respectively. The SNR at which FER 10^{-2} is reached and the PAPR corresponding to cross-over probability of 10^{-4} are summarized

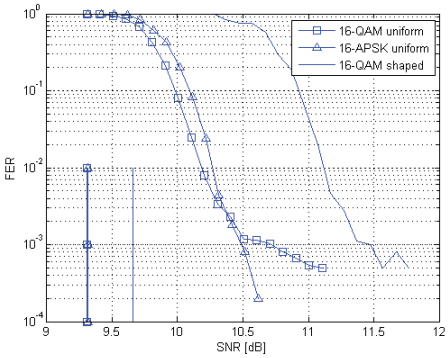

Fig. 5: FER to SNR performance comparison for rate 3 bits/symbol. All schemes used the same pragmatic binary TCM code with data length = 4096 bits. The loss of the 16-QAM shaped transmission is 0.943 dB and 0.845 dB compared to uniform 16-QAM and 16-APSK respectively.

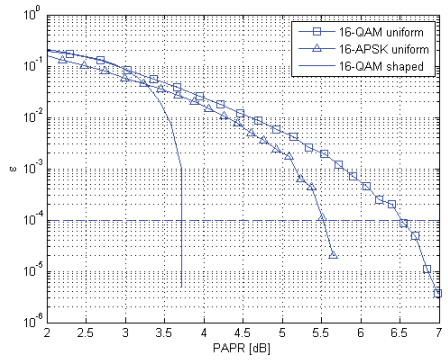

Fig. 6: PAPR comparison for rate 3 bits/symbol. For each scheme the CCDF of the peak power is presented, where the x-axis are normalized by p_{avg} to reflect the PAPR. At crossover probability of 10^{-4} the shaped transmission has a gain of 2.81 dB and 1.84 dB over uniform 16-QAM and 16-APSK respectively.

in table I. It can be seen that the shaped transmission achieves an overall link gain of 0.99 dB compared to uniform 16-APSK transmission and 1.87 dB compared to uniform 16-QAM transmission. Comparing the 10^{-2} SNR to the capacity, it can be seen that the uniform transmission distance from capacity is 0.89 dB and 0.97 dB for uniform 16-QAM and 16-APSK respectively, while the shaped transmission is 1.48 dB from capacity. This indicates that a loss of about 0.5 dB is suffered due to the proposed practical scheme.

System	Capacity	SNR 10^{-2}	PAPR 10^{-4}
16 QAM shaped	9.65 dB	11.13 dB	3.71 dB
16 QAM uniform	9.3 dB	10.19 dB	6.53 dB
16 APSK uniform	9.32 dB	10.28 dB	5.56 dB

TABLE I: Rate 3 bits/symbol FER and PAPR summary

VI. Conclusion

In this letter we have presented a novel technique for reducing the PAPR of single carrier transmission with high spectral efficiency. The main cost of this technique is loss of SNR and an additional BCJR decoder which replaces a simpler de-mapper module. However, this technique was shown to operate well with modern ECC scheme, namely turbo codes, and reduce the PAPR of the transmission signal such that an overall gain is achieved compared to uniform transmission. In the rate of 3 bits/symbol when using a 16-QAM constellation, this gain was demonstrated to be up to 1.87 dB compared to uniform transmission. This technique also allows for SNR loss to PAPR gain tradeoff by choosing different peak power values to be avoided.

Abstract*—In recent years Online Social Networks (OSNs) like Facebook, Twitter have become very popular. As a result, lot of data is uploaded and generated. The privacy settings that are offered are very cumbersome for user. Hence, the data that is uploaded should be imposed with certain access control policies. This paper discusses the trust-based approach for OSN. Also, it discusses the novel model for calculating the Trust value. Further it discusses the performance of the 'Trustbook' showing that the system is scalable. This paper solves the problem of data confidentiality in OSN by building a user friendly application where more of the task is shifted from user to system.

***Index Terms*— Access control, Data confidentiality, Social network, Trust**

I. INTRODUCTION

Online Social Networks (OSNs) are becoming popular day by day. The popularity is tremendously increasing as social networks help to establish the relationships between different people around the globe. As mentioned in [1], the architecture of OSN puts light on the various components of OSN. Fig 1 [1] shows the architecture of OSN. It includes applications at the top which are developed by third party and use the OSN services. OSN is primarily made of users who are identified by their profiles. All the users are connected to each other through the relationships like friends, close friends. OSN service provider [1] is finally responsible to provide all the OSN specific functionalities and data management. As per the study [3] there are 3.14 billion users who actively use Facebook which is one of the popular OSN and this number continues to grow exponentially. Thus, data uploaded by them also grows and hence should be given a secured access. A Facebook survey of 325 users [4] was conducted and it was found that 69.2% keeps their posts public giving no privacy to it. This may be because of cumbersome privacy settings. Also only 19.4% users are concerned about the privacy policies on Facebook. Hence, the survey shows that people are not much concerned about the data confidentiality attack that may happen due to weak privacy settings. In real world, all the relations are based on trust between the people. Same trust is now proposed to be used in the access control of the data in OSN. Hence, a trust-based access control strategy is formulated so as to make the access control more efficient and user friendly. Various attributes are used to decide a trust value between the user and his each friend.

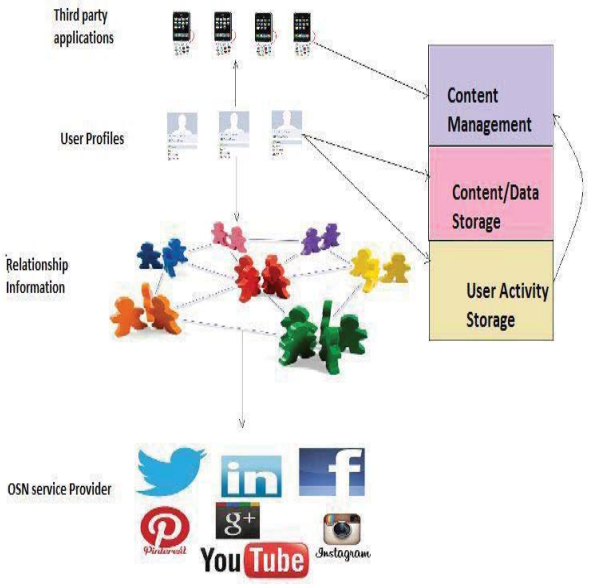

Fig.1 Generalized OSN Architecture [1]

In current scenario, whenever data is uploaded it can be viewed by all the friends. However, it may happen that some data is highly secured and the user may not want it to be seen or accessed by all the friends in the friend list. In the current OSN scenario like in Facebook, it lets you to take a binary decision about whether to keep your data public or private [5]. Also to customize the privacy settings is a cumbersome and time consuming job for the user. Hence, it is very important to develop an access control mechanism that will automate the access control decision effectively and also be user-friendly.

II. RELATED WORKS AND EVALUATION

Table I discusses the various literatures that have been studied and surveyed from the perspective of trust. Few literatures used

the trust but did not use it for data access control. In [5] multiparty access control was proposed which was used to achieve data confidentiality. However, trust between the user and friends were not considered for the formulating the access control policies. [6] uses the concept of trust in OSN by calculating credibility which is dependent on the interactions between the user and his friends. However, the interaction cannot be a sole attribute to decide the trust between the users. [7] takes into consideration the distance metric to decide the trust. This trust is used to filter out the content. It uses the clustering techniques to compute trust value. [8] mentions the different propagation models and classification schemes for trust metrics .[7] discusses different techniques to evaluate trust such as behavioral, machine-based ,statistical and heuristic techniques. In [9] Appleseed is used to compute trust in a local group. [10] uses the hop distance to calculate the trust. New algorithm is proposed in [11] for trust-based inference in social network. To find optimal trust path, [12] mentions the heuristic based approach which otherwise is a difficult task. The user's

Facebook usage patterns were studied in [15]. Thus the literature was specifically studied from the required point of view of trust. It has been observed from the study that there is less application of trust in OSN. Even if it is used, it is not applied for data access control. Hence, a novel approach for Trust value calculation is proposed to be applied in the field of OSNs.[13] – [19] were studied to understand the current work in security in OSN.

IV PROPOSED WORK

In order to reduce the user efforts and also to achieve automated and efficient access control mechanism, trust-based access control has been used. The notable contribution of the work lies in establishing an access control mechanism which is effective as well as simple from the user's point of view. Trust-based access control involves the design of the system that involves the access of the user's data to be given only to the trusted friends in the friend list. The three attributes are taken into consideration for calculating the trust value. They are Experience (EX), Context information (CI), and interaction (I). The reason for considering these three attributes is the surveys that were studied. According to [2] almost 82% users give importance to experience while accepting the friend request. Also [15] mentions that the user unfriend those users who are not active on OSN as every OSN has a limit upto which the friends can be added. Hence, another parameter CI was considered. [6] considers the interaction for establishing the trust between the users. The importance given by the user for every factor while accepting the friend request was studied. This means that these are the factors that are important from the user's perspective when it comes for showing the trust.

The Trust value is calculated using the derived formula from the survey results. Hence, trust value is calculated from every user to every friend. More the Trust value more secured data can be shared. Now, the decision of denying or allowing the access to a particular data is defined by a Trust Rule. While uploading any data like a photo as mentioned in [4], security level is attached to every data that is uploaded. The Trust Rule compares the trust value and the security level of each data that is given as an input by the user. If the trust value is greater than or equal to the security level then access to the data is allowed else the access is denied. Permission to access the data means that the data like photos, videos, posts can be seen on the home page of the friend. Thus Trust Rule works with the security level of the data and the Trust value that is calculated by the formula.

Table 1. Specific Evaluation of Related Work

Reference	Technique used to achieve trust	Is Trust used for Access control ?	User opinion considered?	Consideration of Characteristics of friends in OSN
Multiparty Access Control for Online Social Model and Mechanisms [5]	Trust is not considered	No	No	No

Operators for Propagating Trust and their Evaluation in Social Networks[9]	Trust metrics	No	No	No
Trust based approach for protecting user data in social networks[10]	Hop based technique	Yes	No	No
Proposed Scheme	Using EX,CI and I	Yes	Yes	Yes

There are different components of the architecture.

A. Activity Tracker

Activity Tracker is required to track how much the user is active on the OSN. It considers various parameters like frequency of logins, number of posts posted by the user. This tells that how much the user is active on the OSN. Thus this is defined as the context information. The Activity Tracker mainly computes the activity of the user in the OSN.

B. Trust Manager

The Trust Manager is responsible for the calculation of the trust value of every user. Also it executes the formulated equation to calculate the Trust value. As and when the CI changes, the Trust value also changes. This work of modification and calculation of Trust value is done by the Trust Manager.

C. Decision Maker

The Decision Maker is responsible for taking the decision of permission to grant or deny the access to the data.

This component executes the Trust Rule. Trust Rule works as follows:

If Trust_Value > = security_level of the data then access is allowed
Else
Access Denied.

This is the mathematical representation of the Trust Rule which includes a simple comparison between the security level and the trust value of the friend. The Trust Rule is designed based on the concept of data confidentiality. In real life we like to share our confidential data with the trusted people. Hence, mathematically a direct variation exists between the trust value and the security level.

D. Data Center

The data center is responsible for storing data that has been uploaded by the user as well as the relationship information. The access to the data is controlled by decision maker from the data center. It consists of all the details such as the frequency of logins, number of posts, photos uploaded by the user. Also, it stores all the user activities like comments, likes given by the users. All these information is helpful to calculate the context information and hence further calculation of the Trust value.

II. MATHEMATICAL MODEL

Mathematically, system can be represented as a trust function. Let T(X) be the trust value of friend X of user U. Hence, T(X) depends on three values EX, CI and I. Thus,

T(X)=F(EX, CI, I) (1) The survey of Facebook users [21] was studied and few literatures were studied to understand the parameters that users consider while accepting a friend request. Those parameters were considered while calculating the Trust value. The percentages were used to calculate the weights for each parameter. These weights show the effect on the action of accepting a friend request. Hence, the weights depict the importance given by every user for trusting someone as a friend. The Trust value is calculated as follows:

T_{val}=0.614EX+0.277CI+0.109I (2) All the parameters have been given a fuzzy value and which has a crisp value which is put into (2) to get the trust value.

VI RESULTS AND DISCUSSION

The proposed system named ‘Trustbook’ is implemented in JSP, PHP and at the backend MySql is used. The aim of the system is to make the access control of the data on the social network simpler and less tedious to the user. The developed system only accepts the EX from the user while accepting the friend request of a new friend. The rest of the parameters are calculated by the values stored in the database. The database has tables to store the photos uploaded by the user, likes, comments, posts of the users. Also online-offline details, login details are maintained. All these counts were maintained for the calculation of CI. To the best of our knowledge, this is the first system that is developed which calculates and implements the CI for the Trust value calculation.

The Trust Rule is implemented as a join query and depending upon which the access control is decided. Trustbook is designed in such a manner that it bestows less efforts for the user for the access control. User chooses the EX by selecting one of the three categories for the friend while accepting a friend request. Also, the user while uploading a photo selects a security level for the photo and then the trust Rule is executed.

Following are the modules that play an important role in the efficient execution of ‘Trustbook’.

A User Interface

OSNs provide lot of functionalities starting from the basic to the advanced like third party applications and different games. However, Trustbook has only implemented the required functionalities of OSN like sending and accepting a friend request, uploading photos, posts, liking, commenting on the data. The User interface is kept simple to increase usability of the application. A mechanism to input EX is just a matter of click. Also to add a security level to a photo before it is being uploaded, a slider is provided which makes user easy to change the security level.

B Trust Value Calculation

The database holds tables to store I and CI of the user. Also the response of a user while accepting a friend request is stored in the database as EX. This fuzzy value is matched with the corresponding crisp value and then stored in the database. This is done for rest of the parameters and using (2) the final trust value is calculated.

The Trust Rule is applied as a query that implements this rule. The rule is implemented on the Home page of every user because all the photos, videos are seen at the home page. The security level is also stored in the database along with the data for which that security level is submitted by the user.

Thus the user has only 2 inputs to the system as far as trust calculation is required. First is EX which is an experience of the user while accepting the friend request and second one is the security level that is attached with every photo that has been uploaded by every user.

The results of the system have been studied with only photos but the Trust rule and sensitivity level is not dependent on the type of data for which it is put to use. It defines an approach to implement stricter and simpler access control mechanism.

The system was implemented and then checked for the performance with the current system. The implemented system outstands in following aspects:

- User friendliness
- Scalability
- Design of Dynamic Access Policies

The current scenario expects the user to frame the access policies mentioning the names of the friends who can view a particular data. It becomes cumbersome for the user if he has many friends in the friend list. Also even if the user has made groups of friends, some of the photos can be expected to be viewed by the intersection of friends from those groups. Hence, it makes the task more cumbersome and tiring for the user. The implemented scenario makes this task easier. The access control is defined using Trust Rule. Hence using only two input values of EX and security level the Trust policies are implemented. Other job is not the responsibility of the user.

The other performance measure is the scalability. The system was checked for the performance of different number of users. The observations stated that the time remains almost constant with the growing number of users. The time was recorded for calculating Trust value through the database.

.

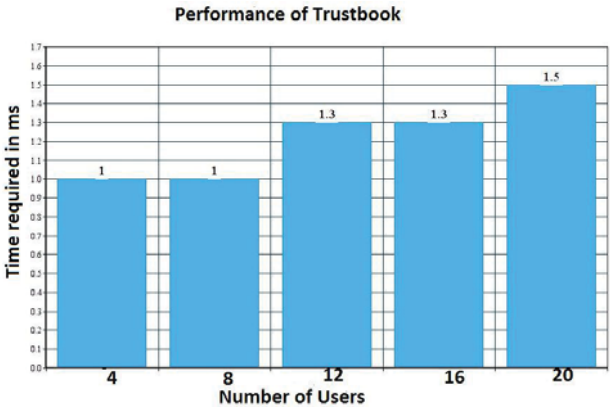

Fig 2.System Performance to calculate Trust Value

Fig 2 depicts the performance of the system. X axis mentions the number of users considered for every experiment. For every turn of an experiment, the required numbers of user profiles were created. After that, their profiles were built and then the actual OSN activities such as sending and accepting friend requests, commenting, liking, uploading photos etc was initiated.

This made the entries in database regarding the CI and I. EX was made to be inserted in the database when the owner of the profile accepts friend request. Thus through the time readings given by the MySql to execute the query that finds the CI,EX and I values, the total time was calculated by the summation of the time required to get EX,CI and I from database. These values retrieved from the database are further used in (2) to calculate the Trust Value.

Ti(Tr_Val) = Ti(CI)+Ti(I)+Ti(EX) (3) In (3), Ti is the function to calculate time. Since, the Trust value depends on the specified three parameters, the time required to calculate trust will also depend on the time required to calculate the three parameters.

Additionally there were some observations made in the system. The Trust Value is the dynamic parameter which keeps on changing. The system takes EX as the input only once. However, it can be made updatable anytime is a future work. However, CI measures the dynamicity of the user. As long as he is dynamic the Trust value will be positively affected. But if he is not active on OSN for some days or month, the CI will be dropped adversely affecting the Trust value. Hence Trust value is dynamic in nature. The system has also implemented the Trust value dynamically. Whenever, the related sub parameters (dynamicity, number of friends of CI change) change so does change the Trust value. This gives rise to the dynamic access control policies where user's involvement and effort is reduced giving more accurate and efficient results than it would have been done in the current scenario (manually).

VIII CONCLUSIONS AND FUTURE WORK

Trustbook performs the access control by adding a flavor of Trust to it. Trust-based access control with the specified parameters is a novel approach. It solves the problem of defining the access control policies in the current OSN. The users spend lot of time to design the access control policies making the task tedious. To solve this problem, 'Trustbook' is developed which generates the access control policies depending on the Trust Rule that is defined. Every time the system generates the new access control policies depending on the user's input for EX and security level for the data. However, the access control policies are governed by the Trust Rule only. The system has been proved to be more user-friendly and efficient as far as access control is concerned.

'Trustbook' has efficiently achieved the data confidentiality in OSN through efficient Trust-based access control.

The future work aims at implementing a data confidentiality attack as mentioned in [20]. The data can be leaked due to data dissemination. To avoid this [20] has proposed the threat

handling mechanism using Trust. This threat handling mechanism will be implemented in the future work. Also, the results regarding the efficiency of the threat handling mechanism need to be found out and validated for efficiency. Moreover, the current system can be improved in terms of security of maintaining the trust values at the data center. Some stringent encryption techniques can be used for the same.

***Abstract* — With the enormous intensification in the development of internet technology and rapid growth in usage of digital multimedia, the problem such as copyright infringement has emerged. Copyright infringement occurs when someone other than the copyright holder or copyright owner use or distribute information without permission. In recent times, due to great developments in computer and internet technology, multimedia data i.e. audio, video, images have found wide applications. Digital watermarking has been considered as a powerful technique for copyright protection of multimedia data. As compared to the image and video watermarking, less research attention is given to audio watermarking techniques. As audio watermarking has not been investigated in details, this paper performs a comparative analysis of different audio watermarking techniques for copyright protection.**

Keywords— Copyright infringement, Audio watermarking, Robustness, Security, complexity, imperceptibility. Copyright infringement, Audio watermarking, Robustness, Security, complexity, imperceptibility.

I. INTRODUCTION

In today's world, the number of internet users has vastly increased with the parallel growth of information and digital technology. With the internet development and rapid growth in usage of digital multimedia, it has become very easy to generate unauthorized copies of digital data. In many areas this has become very problematic. Therefore it has created new challenges to protect intellectual property rights (IPR). Nowadays, protecting the electronic documents from unauthorized copying is an important issue. Due to the rapid growth of evolving technologies, there is an increase in the risk of different cyber-crime attacks. The problems such as copyright infringement and intellectual property rights (IPR) violation have emerged due to the growth of information and digital technology.

Copyright infringement occurs when someone other than the copyright holder or copyright owner use or distribute information without permission. For example illegally downloading music, image or cartoon on website or in a document. It is not easy to avoid copyright infringement. By using new technologies, virtually anything can be copied easily and nearly perfectly. Digital watermarking is one of the best solutions to prevent illegal copying, modifying and redistributing multimedia data. Security is the degree of protection from loss, damages, criminal activity and resistance to harm. Nowadays, it's very important to provide security for the electronic documents. It is common for many people to share and transfer the multimedia data due to rapid growth of Internet and networks technique. This multimedia data is easily copied and modified due to which necessity for copyright protection is increased.

Digital Watermarking has been proposed as technique for copyright protection of multimedia data. Digital Watermarking is a process of embedding digital signals or pattern into a multimedia object without affecting in any way the quality of the original file. While sending a message to destination, it should be watermarked to protect this message from illegal copying and it also provides the security. In digital watermark mechanism, information is invisibly inserted into audio or video, image. Digital Watermarking is nothing but hiding digital signal message such as image, audio (song), video within the signal itself. The hiding process has to be robust in such a way that the modifications of the media are hardly possible. Digital Watermarking is used to prevent or avoid illegal copying, redistributing and modifying multimedia data. By using digital watermarking, we can provide the copyright protection, covert communication, content identification and data authentication.

.

II. CLASSIFICATION OF DIGITAL WATERMARKING TECHNIQUES

Digital watermarking techniques classification is based on type of document. Using this criterion, techniques can be classified into three types:

- Image watermarking
- Video watermarking
- Audio watermarking

Several digital watermarking techniques are proposed which include watermarking for images, audio and video.

1) *Image Watermarking*: This adds watermark to image. It is used to hide the information into image and this information is later detected and extracted for author's ownership.
2) *Video Watermarking*: Here watermark is applied to individual frames of a video. Video Watermarking is nothing but the extension of image watermarking. Video watermarking imposes real or near real-time watermarking system.

3) *Audio Watermarking*: Digital audio watermarking is used for protecting audio files against illegal copying. It embeds the watermark to audio files such as music, MP3, etc.

Primarily, the research of image watermarking was started, and then the watermarking techniques were developed for audio. There is less research on the development of audio watermarking techniques. Less watermarking techniques are proposed for audio compared to the image/video. As Human Auditory System (HAS) is more sensitive than the Human Visual system (HVS), it is very difficult to add watermark data in audio file as compared to the image file. The audio watermarking algorithms are not easy. Also the available studies on audio watermarking are far less than that of video watermarking or image watermarking. Applying watermarks on audio data by using various algorithms is known as audio watermarking.

III. PROPERTIES OF DIGITAL WATERMARKING

Properties of digital watermark are as listed below:

1) Robustness: Robustness is nothing but the watermark embedded in data has the ability to withstand non-malicious distortions. Watermark data should be robust so that it should not be eliminated by unauthorized distributors and watermark data should resist many attacks such as filtering, compression and filtering with compression, noise addition, cropping, resampling, Re - quantization.
2) Imperceptibility: The watermark should be invisible, inaudible to human eyes/ears, only be detected by an authorized person. Imperceptibility is nothing but hiding a watermark so that the watermark should not affect the quality of the original signal.
3) Capacity and data payload: Capacity is nothing but the number of bits that can be embedded in one second of the host signal. If multiple watermarks are embedded into an data, then watermarking capacity of the image is the sum of all individual watermarks data payload.
4) Security: Security of a watermark is the ability that watermark should only be extracted by authorized person. Security resists malicious attacks. Security provides watermark access only to the authorized parties and thus able to achieve the purpose of copyright protection. If we provide security then hacker cannot remove the watermark without having knowledge of detector, composition of watermark and embedding algorithm.
5) Computational cost: If the watermarking method is less complex then the computational cost of the watermark should reduce. If computing resources such as hardware and software required for watermarking method are with high complexity algorithms then it incurs more computational cost. If the watermarking method is simple then limited resource will be required and also computational cost should be less. Thus the computational cost and complexity of watermark methods are directly proportional to each other and vice-versa.

We need to make a trade-off between all these requirements/ properties because they are often contradictory with each other.

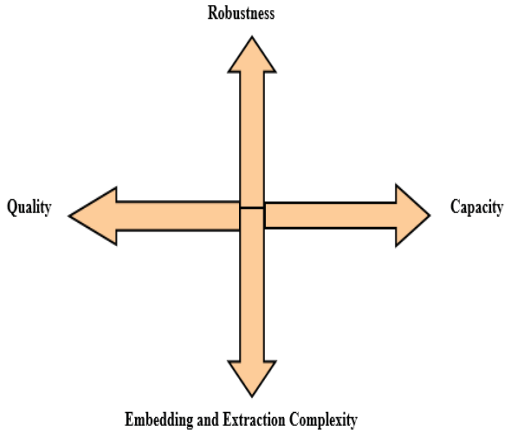

Figure 1 - Properties tradeoff

For example increasing data rate or capacity in watermark system results in reduces the robustness against attacks and also degradation of quality of the watermarked signal.

IV. STATE OF THE ART

The audio watermarking method by using Generalized Spread Spectrum Watermarking scheme (GSSW) was proposed in one. The big advantage of this scheme is that it is having large maximum capacity as compare to the Traditional Spread Spectrum method [1]. Audio watermarking using lifting wavelet transform (LWT) and QR decomposition method (QRD) has high data payload and good imperceptible and also this method is highly robust against various attacks. Here in this method first audio signal is divided into non-overlapping frames. Then watermark information is embedded in each frame of audio signal. From low frequency LWT coefficients of frame we can obtain upper triangular matrix. The largest or highest element of the upper triangular matrix watermark data can embed. Also this method has high robustness [2].

Time-spread Echo based audio watermarking for audio signal provides good imperceptibility but for this method there is need to further enhance the robustness against de-synchronization attacks. In this method robustness optimization and imperceptibility optimization has been performed simultaneously. Also here coefficients of echo filter are obtained by using finite-impulse-response (FIR) filter design [3]. Blind audio watermarking method based on DWT-SVD also provides the robustness. Audio watermarking is providing for the copyright protection [4]. In Audio watermarking using DWT and SVD method, two secret keys are used for encryption and description. Therefore this method can provides better security. In this method initially original audio signal is segmented by Discrete Wavelet Transform (DWT).

Table 1- State of the art in digital watermarking techniques for Audio Signals

Sr. No.	Paper Title	Publication year	Method used	Features
1	Channel Capacity Analysis of the Generalized Spread Spectrum Watermarking in Audio Signals	2015	Generalized spread spectrum watermarking (GSSW) scheme	maximum capacity of the GSSW scheme is larger than that of the traditional spread spectrum scheme
2	A Blind Audio Watermarking Method Based on Lifting Wavelet Transform and QR Decomposition	2014	lifting wavelet transform (LWT) and QR decomposition (QRD)	highly robust, high data payload and provides good imperceptible
3	Time-Spread Echo-Based Audio Watermarking With Optimized Imperceptibility and Robustness	2015	FIR with HAS	provides imperceptibility but need to enhance robustness
4	DWT-SVD Based Blind Audio Watermarking Scheme For Copyright Protection	2014	DWT-SVD	Robust
5	A Blind LWT-Based Audio Watermarking Using Fast Walsh Hadamard Transform and Singular Value Decomposition	2014	LWT using FWHT and SVD	robust, high perceptual quality audio, high imperceptibility, high data payload
6	Digital watermarking in audio for copyright protection	2014	DWT and SVD	high robustness, provides security by using 2 secret keys
7	Patchwork-Based Audio Watermarking Method Robust to De-synchronization Attacks	2014	discrete cosine transform(DCT)	higher embedding capacity, robust
8	An Improved Patchwork-Based Digital Audio Watermarking In CQT Domain	2014	CQT, ICQT, frame pairs, patchwork	better signal quality and robust
9	Fast and low-complexity Audio watermarking	2014	FFT	high capacity, robustness, low-complexity
10	A High Capacity Quantization-Based Audio Watermarking Technique Using the DWPT	2014	QIM (Quantization Index Modulation) technique on the DWPT (Discrete Wavelet Packet Transform) coefficients.	high embedding capacity, robustness
11	An Audio Watermarking Method Using Pitch-Transformed Sound of Original Music	2014	phase coding phase coding	sound quality increased
12	A Novel Audio Watermarking Algorithm Based On Neighboring Samples	2014	Time domain and Neighboring Samples	robustness, imperceptibility
13	Robustness Enhancement of Quantization Based Audio watermarking Method Using Adaptive Safe-band	2014	Adaptive safe-band based method	enhance robustness
14	A High Payload Audio Watermarking Algorithm Robust against Mp3 Compression	2014	Discrete wavelet transform (DWT)	Very good robustness, high embedding capacity, High Payload, good imperceptibility, high perceptual transparency
15	Spread Spectrum Audio Watermarking: Enhancement of Detection and Watermarking Capacity	2014	spread spectrum; LPC	high capacity and less robust
16	Audio watermarking system based on Frequency Hopping modulation	2014	Frequency hopping modulation, spread spectrum.	reliability increases

Then singular value decomposition (SVD) is applied on non--overlapping blocks and then in each block of singular values watermark information or watermark data is embedded. The advantage of this method is it having high robustness [6]. The audio watermarking based on Patchwork is robust to de-synchronization attacks. Initially in this method watermark Information is embedded in audio signal in Discrete Cosine Transform domain (DCT) and then in watermark signal synchronization bits are added in logarithmic DCT (LDCT) domain. The embedding capacity of this scheme is high [7]. In the research of audio watermarking in CQT domain includes improved patchwork method. This watermarking technique

provides the better signal quality and robustness is enhanced in this technique. Also this scheme ensures the imperceptibility [8].

Fast and low complexity audio watermarking based on Fast Fourier Transform (FFT) algorithm initially the FFT spectrums are segmented into short frames and then by using Fibonacci numbers the magnitude of the FFT samples changed. This scheme provides the high embedding capacity. The main advantage of this method is it's having low complexity. Also this scheme provides the high capacity. This method has good robustness [9]. Audio watermarking scheme based on high capacity quantization in Discrete Wavelet Packet Transform (DWPT) provides robustness and it's having high embedding capacity. Here in this method the audio signal is segmented into number of sub bands using Discrete Wavelet Packet Transform (DWPT). This method ensures the transparency [10].

Table 2 – Various Research Parameters for Audio Watermarking Techniques with Different Algorithms

Paper No	Method used	Robustness	Imperceptibility	Security	Capacity and data payload	Low complexity	Reliability	Quality
[1]	Generalized spread spectrum watermarking (GSSW) scheme			Not Addressed till now	Yes	Not Addressed till now		
[2]	Lifting wavelet transform (LWT) and QR decomposition (QRD)	Yes	Yes		Yes			
[3]	FIR with HAS		Yes					
[4]	DWT-SVD	Yes						
[5]	LWT using FWHT and SVD	Yes	Yes		Yes			Yes
[6]	DWT and SVD	Yes		Yes				
[7]	Discrete cosine transform(DCT)	Yes		Not Addressed till now	Yes			
[8]	CQT, ICQT, frame pairs, patchwork	Yes						Yes
[9]	FFT	Yes			Yes	Yes		Yes
[10]	QIM (Quantization Index Modulation) technique on the DWPT (Discrete Wavelet Packet Transform) coefficients.	Yes			Yes	Not Addressed till now		
[11]	Phase coding phase coding							Yes
[12]	Time domain and Neighboring Samples	Yes	Yes					
[13]	Adaptive safe-band based method	Yes						
[14]	Discrete wavelet transform (DWT)	Yes	Yes		Yes			
[15]	Spread spectrum; LPC				Yes			
[16]	Frequency hopping modulation, spread spectrum.						Yes	

Audio watermarking using the Pitch-Transformed sound of music improves the quality of sound. The key idea is use of phase coding and processed sound for audio watermarking for copyright protection [11]. Audio watermarking using Neighboring samples method was proposed. It uses the watermarking in time domain. This method provides the robustness and imperceptibility characteristics of watermarking. In this method the frame with three samples is used. These samples define the amount of distortion to be added. If middle sample is distorted then the middle sample of frame is made equal to '1' of the neighboring samples. This scheme provides the good signal quality [12].

The adaptive safe band based method is also used for audio watermarking. This scheme enhances the robustness. In this

paper fixed size safe-band is used between two quantization steps. Just by changing the size of safe band the robustness of watermarking can be improved [13].

Audio watermarking scheme using Discrete Wavelet Transform (DWT) gives very good robustness. Also it enhances the embedding capacity of watermarking. It improves the imperceptibility. Also it has high perceptual transparency and high payload. In this scheme the non-overlapping frames uses in Discrete Wavelet Transform [14].The research in audio watermarking performs by using spread spectrum and linear predictive coding algorithm (LPC). This method provides the high capacity of watermarking. But this scheme is less robust against various attacks. In this method at the receiver the linear predictive coding (LPC) and high pass filtering is used to reconstruct the embedding signal [15]. Audio watermarking using frequency hopping modulation technique and spread spectrum increased reliability is studied in [16].

V. PROPOSED WORK

Table 2 lists various research parameters for Audio Watermarking Techniques with Different Algorithms. It reveals from the table that lot of research work is done in the audio watermarking techniques with consideration of parameters such as robustness, imperceptibility, capacity, data payload and quality. But the security, complexity reduction and reliability are the least attended issues which are very important for the safety from various cyber attacks. This research work proposes the combination of Discrete Wavelet Transform (DWT) and singular value decomposition (SVD) with Fast Fourier Transform (FFT) using Frequency Hopping Spread Spectrum mechanism which will be able to provide security with low complexity and reliability with good quality of audio watermarking.

VI. CONCLUSIONS AND FUTURE SCOPE

Cyber Security is very critical issue for the forthcoming fifth generation mobile communication where huge data will be generated. To save that data from various cyber attacks is the real challenge. Negligible amount of attention has been given towards the security and reliability of the audio data which contains very important information. Development of robust and secure audio watermarking techniques is the need of the forthcoming converged internet age. This research work aimimg towards Analysis of Audio Watermarking Techniques for Cyber Security in Copyright Infringement will be further extended in the direction of the combination of Discrete Wavelet Transform (DWT) and singular value decomposition (SVD) with Fast Fourier Transform (FFT) using Frequency Hopping Spread Spectrum mechanism which will be able to provide security with low complexity and reliability with good quality of audio watermarking.

Abstract— **The cost efficiency of wireless platforms and their easy deployment enable the applicability of it in widespread application domains. Wireless sensor networks (WSNs) are not excluded from it. Their application domains vary from industrial monitoring to military applications. A WSN is a resource-constrained network and energy of the WSN node is a valuable resource. Like every other network, WSNs are also vulnerable to security attacks. A security attack can results in networks consuming more resources, leading to earlier depletion of node energy. A significant part of the resource consumption in a WSN is controlled by the medium access control (MAC) mechanism. This paper focuses on WSN MAC mechanisms and countermeasures for attacks targeting the MAC layer in a WSN. Denial of sleep attacks are the most relevant for WSN MAC as these types of attacks have shattered effects, which bring down the sensor lifetime from years to days. This paper proposes a secure hybrid MAC mechanism, Green and Secure Hybrid Medium Access Control (GSHMAC) to overcome the devastating effect of WSN MAC attacks. The proposed mechanism provides features such as collision threshold-based MAC mode control and countermeasures on WSN MAC using internal MAC mechanisms. GSHMAC shows improved energy-efficiency, delay, and throughput in the presence of attacks, as compared with state-of-art secure MAC mechanisms.**

Keywords- Wireless sensor network (WSN), medium access control (MAC), cluster, hybrid-MAC, security, denial of sleep attack, energy efficiency, throughput, delay.

I. INTRODUCTION

WSN applications in areas related to everyday life are speedily increasing and at the same time, the use of WSNs in industrial use cases is becoming still more widespread. Every application of sensors can significantly improve aspects of living and help to increase productivity and efficiency of the domains in which they are deployed [1]. However, as applications of WSNs are becoming still more widespread and broader, and their demands are increasing, the chances of the network to be attacked or compromised by malicious users are also increasing. Proper security measures while deploying WSNs are, therefore, a necessity to take full advantage of the deployment of new applications [2].

WSNs are subject to many different attacks at different layers of the communication stacks. Attacks on the medium access control (MAC) layer are some of the most severe as the MAC layer allocates resources for communications, which accounts for a significant part of the overall energy consumption of the system. Therefore, it is necessary to implement countermeasures to protect the MAC layer from security attacks. The literature suggests different security solutions for MAC layer attacks, a majority of which are cryptographic solutions. However, such solutions are computational heavy for a resource constrained WSN system. More lightweight solutions for the WSN MAC layer security can be achieved by organizing the internal MAC mechanisms of a WSN [3, 4].

This paper proposes a novel MAC layer mechanism, Green and Secure Hybrid Medium Access Control (GSHMAC), to countermeasure different attacks, specifically the collision attack, replay attack, and full domination attack [3]. The proposed mechanism is a cluster-based [4] hybrid MAC mechanism [5], which uses a mix of time division multiple access (TDMA) and carrier sense multiple access (CSMA) mode for intra-cluster communication and TDMA mode only for inter-cluster communication. During intra-cluster communication, MAC mechanism shifts the mode according to a collision threshold value. GSHMAC is inherently secure; as it implements cluster-based networking, where an attack in one cluster will not easily penetrate into another cluster. The other security perspective in GSHMAC is the use of TDMA mode for inter-cluster communication and mixed TDMA and CSMA mode for intra-cluster communication. If a node shifts to TDMA mode, it will communicate only during consigned slots and an attack will, therefore, only be successful if malicious nodes succeed in stealing those slots.

In addition, GSHMAC modifies the internal MAC mechanism (Mode shift mechanism of hybrid MACs according to traffic conditions and cluster-based topology used) further to enhance the security. In this respect, use of collision threshold value [6] is introduced to detect collision attacks along with the maintenance and analysis of a replay counter to detect replay attacks. In addition, the security relating to a full domination attack is improved by combining the two countermeasures. The proposed secure mechanism shows better performance in the presence of different kinds of denial of sleep attacks as compared with state-of-art secure MAC solutions. It shows improved energy efficiency, delay, and throughput.

The remainder of the paper is organized as follows. Section 2 presents the related work in secure MAC mechanisms and different countermeasures for MAC layer security attacks. Section 3 describes the assumptions and system model. Section 4 gives a detailed background of GSHMAC with the mechanism used. Section 5 gives insight of the security countermeasures used in GSHMAC. Section 6 discusses the

simulation details and comparative results of GSHMAC. Last section concludes the paper with future work.

II. Related Work

Qingchun Ren et al. [7] presented a secure MAC mechanism using a soft decision theory approach. It is developed by considering a request to send (RTS)/clear to send (CTS) based MAC mechanism. The proposed mechanism works for defending against collision, unfairness, and exhaustion attacks. A disadvantage of the proposed work is that it considers too many parameters for attack decision that leads to increased computational complexity. Brownfield et al. [8] studied energy resource vulnerabilities of WSNs and led WSN MAC mechanisms and proposed a new MAC mechanism, Gateway-MAC (G-MAC), for alleviating the effects of denial of sleep attacks. G-MAC uses centralized cluster management to defend against denial of sleep attacks, and the gateway node is responsible for relaying all inter- and intra-network traffic. G-MAC shows good energy savings in the presence of denial of sleep attacks as compared to other MAC mechanisms. The mechanism shows increased computational and communication overheads because of continuous transfer of gateway responsibilities and authentication of the packet at gateway. David R. Raymond et al. [9] developed a cluster adaptive rate limiting (CARL) approach to defending against denial of sleep attacks. It considers the denial of sleep attack involving unauthenticated and replay packets. It improves the defense against attacks by limiting active periods of high rate malicious traffic. The disadvantages of CARL are that the network designer has to set the various threshold values to control the rate-limiting behavior and an increase in control traffic. David R. Raymond et al. [10] made a significant contribution in the area of denial of sleep attacks for WSN MAC mechanisms. They proposed the denial of sleep attacks classification method according to the attacker's knowledge of the MAC mechanism and the capabilities to evade authentication and encryption mechanisms. Raghavendra V. Kulkarni et al. [11] proposed a secure MAC mechanism based on generalized neurons. The proposed solution is applicable to denial of service attacks on CSMA-based MAC mechanism. Here, the neurons are trained by using particle swarm optimization mechanism. The algorithm shows improved network lifetime in the presence of an attack. The algorithm is complex and requires the extensive training of neurons for attack detection. Chen Chen et al. [12] proposed a defense mechanism for S-MAC. It mainly considers defense against those attacks, which are having information of the victims such as collision attack, unfairness attack, exhaustion attack, and broadcast attack. The mechanism shows decreased packet drops in an attack situation. The disadvantage is that the solution increases the energy consumption and transmission delay because of fake schedule switch scheme. P. Sankara Rao et al. [13] presented a multi-layer perception based mechanism for securing CSMA-based MAC. It increases the security of the MAC by continuously monitoring for attack situations. The mechanism assures for improved performance in the presence of an attack, but the author had not given any experimental proofs for it. Ching-Tsung Hsueh et al. [14] proposed the two-tier receiver-initiated secure MAC (TE2S) for WSNs denial of sleep attacks. It presents a simplified authenticating process for improving the performance of MAC countermeasures. The proposed scheme is considered as a cross-layer receiver-initiated secure scheme. The proposed scheme shows improved defense against attacks, and it shows reduced energy consumption. The mechanism increases the computation overheads because of the used cryptographic solutions. Tapalina Bhattasali et al. [15] presented a distributed collaborative mechanism for detecting sleep deprivation torture in WSNs. The proposed solution uses a hierarchical network framework for heterogeneous sensor field. The mechanism promises for improved energy efficiency but has not provided any experimental evidences for it.

The review of related work illustrates that currently available secure MAC mechanisms are based on neural networks, fuzzy, and cryptographic approaches. These approaches countermeasure the denial of sleep attack but increase the computational complexity, which raises the overheads on resource constrained WSNs. These proposed solutions are also not tested by considering multiple malicious nodes in the network. Therefore, the motivation of the proposed work is to develop less computational intensive, energy, delay, and throughput efficient, secure MAC mechanism by considering internal features of hybrid MAC mechanisms.

III. Prerequisites

A. System Model

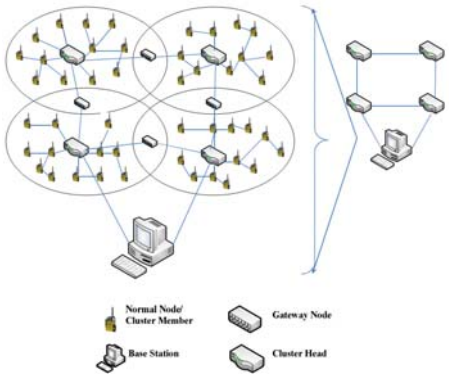

Figure 1. System model for GHMAC

The system model for the proposed mechanism is as shown in Figure 1. The proposed mechanism considers a cluster-based network, which is an effective way to improve the scalability and energy efficiency of WSNs. The clusters are collection of the cluster node (or cluster member) and cluster head (CH). Every node in the cluster has an equal amount of initial energy. Each cluster consists of a CH. The CH maintains the data counter and collision threshold value. The data counter will be incremented when the CH will receive a sensed information (or data) with different packet-id. The collision threshold value is the average amount of collisions allowed in the cluster. Every node in the network sends sensed information to the CH that aggregates it and sends it towards BS.

B. Assumptions

The secure and energy efficient MAC is developed by considering common network and node assumptions for WSNs. The considered assumptions for proposed MAC mechanism are described as above. All nodes have similar competencies and identical significance. Nodes are location un-aware without any global positioning system (GPS) capabilities. Every node has a unique identification (ID). The network is divided into clusters; every cluster has a CH and cluster members. BS, CH, and cluster members are assumed

static. There is a single BS in the network. The clusters are considered as multi-hop clusters, to achieve better energy efficiency and scalability in the clustered environment. The system considers the multi-hop communication for inter- and intra- cluster communication. There are mixed uni- and bi-directional links. The nodes in the network periodically elect the CHs. The nodes will transmit a message to the network after some particular interval of time.

IV. Green and Secure Hybrid Medium Access Control (GSHMAC)

GSHMAC is a green and secure hybrid MAC mechanism, which uses both TDMA and CSMA mode of communication according to the requirement of the network. The different blocks in GSHMAC are,

- ✓ Cluster-based topology
- ✓ GCF scheduling algorithm
- ✓ Hybrid synchronization mechanism
- ✓ MAC mode control
- ✓ Countermeasures on WSN MAC attack

- Cluster-based topology: Cluster-based topology helps to improve the scalability, energy efficiency, and contributes to reducing the effect of security attacks because of its inherent security. GSHMAC uses the Enhanced Multihop Clustering Algorithm (EMCA) [16] for forming the cluster-based topology.
- Green Conflict Free (GCF) scheduling algorithm: Scheduling algorithm is the essential part of the hybrid MAC mechanism, which helps to decide the particular conflict free slot for communication. The hybrid MAC mechanism proposed here uses GCF [17] as a scheduling algorithm. GCF is a three-hop conflict-free scheduling algorithm for WSN.
- Hybrid Synchronization Algorithm: Synchronization is necessary to achieve the timing accuracy during the node communication and slot assignment. GSHMAC uses hybrid synchronization for achieving it efficiently. The hybrid synchronization algorithm uses approximate diffusion-based synchronization for intra-cluster communication and tight sender-receiver synchronization for inter-cluster communication [18].
- MAC mode control: GSHMAC uses TDMA mode for inter-cluster communication and TDMA or CSMA mode for intra-cluster communication. It considers that initially all clusters are using a CSMA mode. The MAC mode control is responsible for shifting of mode from TDMA to CSMA and vice versa. The shifting of MAC mode depends on a collision threshold value. If the amount of collision inside the cluster goes beyond the collision threshold value, then the cluster will shift the node from CSMA to TDMA. Every time a node will experience a collision, it will send a CSE message to the CH.
- Countermeasures on WSN MAC attack: The proposed secure hybrid MAC mechanism includes the countermeasure against WSN MAC layer attack. The solution gives countermeasure for collision-, replay-, and full-domination- attacks. The proposed solution uses the internal characteristics of the hybrid MAC mechanism such as the collision threshold value for the counter measuring the collision attack and data counter value for the counter measuring the replay attack.

V. Security Countermeasures for WSN MAC Attacks

A. *Countermeasure for Collision Attack*

The proposed countermeasure is developed by considering the hybrid MAC layer mechanism, which changes its mode from CSMA to TDMA and vice-versa. The mode changes according to the amount of traffic in the network. If the number of collision in the cluster goes beyond the collision threshold value, the cluster shifts the mode from CSMA to TDMA. The typical collision threshold considered here is 5% [6], which is the normal collision rate considered in the literature. If the collision experience by a node is above the collision threshold, the node shifts the mode. An attack on a network increases the malicious traffic, which leads to increased collisions. The large amount of collisions in a network shifts the mode from CSMA to TDMA. In TDMA mode, every node will communicate only in consigning slots, and it is expected that collisions in the network should reduce. However, as the malicious users have knowledge of the MAC layer mechanism used. Therefore, a malicious user will not be stop and introduces collisions into the network. Hence, if a collision is introduced in TDMA mode and it is going beyond the collision threshold value, then a collision attack will be held on the network, and the network will take necessary care of it. Figure 2 shows the mechanism to countermeasure the collision attack. The proposed GSHMAC mechanism considers that if nodes in a cluster experience a collision, it will inform the CH using a CSE message. If the amount of collisions goes beyond the collision threshold value, the cluster will shift the mode from CSMA to TDMA, and otherwise the cluster will work in CSMA mode. Once the mode will be shifted to TDMA, nodes will start to transmit in TDMA mode. If nodes experience the collision in TDMA mode, that will inform it to the CHs. If the amount of collisions goes beyond the collision threshold value in TDMA mode, the collision attack on the network, otherwise no attack in the network and network shifts to CSMA mode. The CSE message transmitted from a node contains node ID and information about the collision. Once the collision attack in a network, the system will analyze the CSE message and the node that sent highest number of CSE messages to the CH is declared as a malicious node and isolate it from the network. The malicious node is isolated from the network by removing all incoming and outgoing links from node and updating the routing table of the network.

The other situation is when collisions are introduced due to misconfiguration of nodes or interference by some other sources. The proposed countermeasure considers such situations as malicious if the collision is caused due to crossing of collision threshold value. The same previously described mechanism will be used to detect misconfigured or interfering node. The proposed countermeasure is not using any cryptographic mechanism to detect the attack. It detects the attack by using the internal MAC mechanism considered the hybrid MAC mechanism.

B. *Countermeasure for Replay Attack*

The countermeasure for replay attack on the WSN MAC layer is built up by considering that data generated by the node have a unique ID. Every data packet considered here consist of the node ID, data ID, and information. If a node will receives the data with same data ID and node ID, it is not in sequence and not following the packet interval gap set in the network; then

the network will detect the replay attack. Here, two conditions are checked for node being malicious i.e. packet interval gap and data ID and node ID of the current packet.

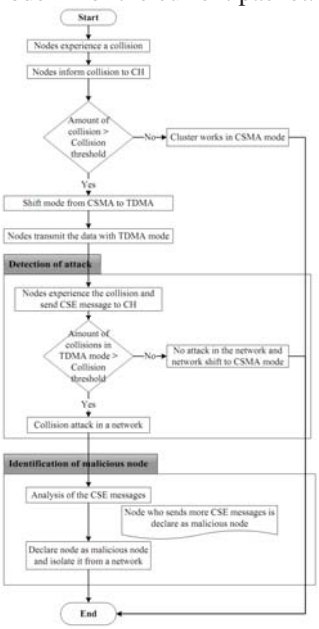

Figure 2. Countermeasure for collision attack

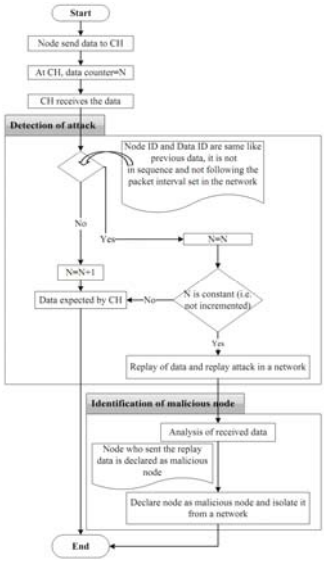

Figure 3. Countermeasure for replay attack

Here, the CH of each cluster maintains a data counter. The initial value of data counter is *N*, whenever the network is initialized. The data counter will be incremented by one when the event is not a replay event. The mechanism for detecting the replay attack is as shown in Figure 3. Here, the node sends a packet to the CH, and if the received packet on CH have the same node ID and data ID, like previously received packet, it is not in expected sequence and not following the packet interval set in the network then data counter will not be incremented. If the data counter is not incremented, it means there is the replay of the same event inside the cluster. Replay event is one of the signs of replay attack. Once the replay event is detected, the system will analyze the replayed packets. The node who replayed maximum number of packets is declared as a malicious and isolates it from the network.

C. *Countermeasure for Full Domination Attack*

The full domination attack will be detected on the network by combining countermeasure of collision attack and replay attack. Full domination attack dominates the network by introducing collisions and replays of a large number of events in the network.

VI. SIMULATION RESULTS AND DISCUSSIONS

A. *Simulation Details*

The simulation of the algorithm is performed using Network Simulator-2 (NS-2) and the parameters considered for the simulation are presented in Table I. The simulation considers that WSN nodes are deployed uniform randomly in an area of 100m by 100m. The simulations are carried out under the assumption that the attacker can initiate an attack from multiple nodes randomly from 1 to 20 malicious nodes in the network. The simulation considers the packet interval as 0.1s.

TABLE I. SIMULATION PARAMETERS

Parameter Name	Setting Used
Network Interface Type	Wireless Physical
Radio Propagation Model	Two-Ray Ground
Antenna Type	Omni-directional Antenna
Channel Type	Wireless Channel
Interface Queue	Priority Queue
Buffer size of IFq	50
MAC	GSHMAC, GMAC, TE2S
Routing Protocol	Ad-hoc Routing
Initial Energy (Joule)	100
Idle Power (mW) [3,5]	14.4
Receiving Power (mW) [3,5]	14.4
Transmission Power (mW) [3,5]	36.0
Number of Nodes	100
Number of sources	99
Number of BS	1
Placement of nodes and BS	Nodes are placed uniform randomly in a given area, and the BS is placed at the center of the area.
Clustering Algorithm	EMCA
Number of simulation runs	50

B. *Results and Discussions*

Figures 4, 5, and 6 show the average energy consumption, delay, and throughput of GSHMAC, TE2S, and GMAC under different attack situations respectively. Here, the experimentation considers the interference on the same slot. The graph shows that the performance of GSHMAC is better than the other two mechanisms in attack situations because GSHMAC countermeasure the attacks by using the internal MAC mechanism. GSHMAC shows 31.80% and 38.87% of improvement in average energy consumption as compared with state-of-the-art mechanism TE2S and GMAC respectively. It also improves delay by 18.41% and 22.61%, and throughput by 30.28% and 43.39% as compared with TE2S and GMAC respectively. Here, the GSHMAC shows better improvement in energy consumption and throughput but not significant improvements in delay. The reason for such tradeoff is time required for mode shifting and TDMA scheduling in hybrid MAC mechanisms. GSHMAC detects the attacks using collision threshold- and data counter value and mitigates the attack by isolating the malicious node. TE2S is receiver-initiated secure MAC mechanism. It also countermeasures the different kinds of denial of sleep attack, but its performance is less than GSHMAC as it uses cryptographic mechanism.. The cryptographic approaches use by the TE2S increases the communication and key maintenance overheads, which reduces the overall performance of MAC mechanism. TE2S shows better

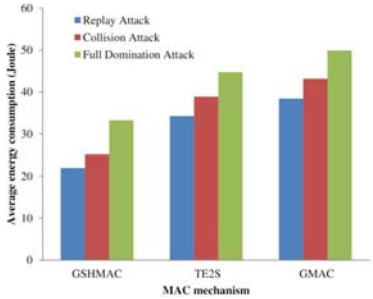

Figure 4. Average energy consumption of MAC mechanisms under attacks

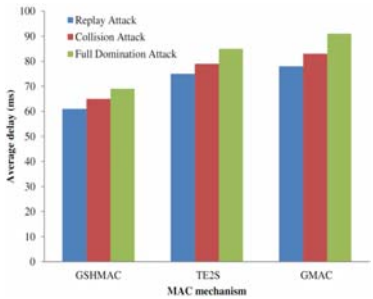

Figure 5. Average delay of MAC mechanisms under attacks

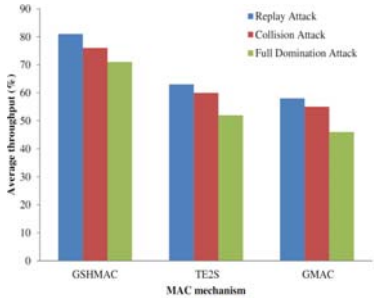

Figure 6. Average throughput of MAC mechanisms under attacks

performance than GMAC as TE2S is LPL (Low Power Listening MAC), where it overcomes GMAC. GMAC is a cluster-based approach, which shows good performance in the presence of attacks because of its frame architecture and cluster-based approach used.

The cluster-based approach helps to bring down the penetration of an attack by maintaining a hierarchy of nodes for communication. The MAC mode control mechanism used in GSHMAC also helps to countermeasure a collision attack at extent because as collisions are increasing in the network it shifts to TDMA mode. Another reason that GSHMAC is better than the other two mechanisms is that GSHMAC is more accurate to detect a collision- and domination attack. GSHMAC detects a collision- and domination attack if a collision is present in TDMA mode too. The primary reason for its enhancing throughput is counter-measuring of an attack at the required time, which leads to better throughput. The communication delay of the system is also better than attack situations, as it countermeasure the attack by internal MAC mechanisms and stops the attack.

CONCLUSIONS AND FUTURE WORK

The great extent of WSN research had concentrated towards the security issues of WSN as vast numbers of malicious attacks are making devastating effect on to the performance of WSN. The performance of WSN is majorly depended on to the amount of available resources and mechanisms for allocating or using the resources. MAC layer plays a significant role in it, and WSN MAC layer attacks (denial of sleep) are the most devastating one as they attack on resource allocation mechanisms of WSN. Hence, the paper makes a contribution in the area of the secure MAC mechanism for WSN. First, the paper studies the different kinds of secure MAC mechanism and WSN MAC attack countermeasures. The study shows that state-of-art available mechanisms are providing efficient security, but the amount of overheads introduced by them are larger. Second, the paper proposes the secure hybrid MAC mechanism GSHMAC to improve the performance of WSN in existence of WSN MAC attacks. GSHMAC provides the lightweight solution by using internal MAC mechanisms. The comparative evaluation of mechanism with the state-of-art work shows reduced energy consumption, and delay, with improved throughput in different attack situations. The future work includes exploring the solutions for other WSN layer attacks using the internal working mechanism of a particular layer-protocol. The work can also be extended to propose the secure framework for WSN, which helps to spread the horizon of WSN applications.

***Abstract*—With the tremendous growth of commercial mobile communication networks world over, the radio frequency becomes more valuable natural resources. The Radio spectrum is an essential tool for economic and social growth of a country. The shortage of bandwidth forces researchers for the exploration of the underutilized millimeter wave spectrum for designing the communication broadband networks. Very little research has been done in the areas of cellular mm-wave propagation in densely populated indoor and outdoor environments. For the design of future 5G network it is very necessary to obtain vital information regarding mm-wave propagation characteristics and its behavior in various environmental conditions. This paper describes the various studies carried out earlier in the field of radio wave propagation at 60 GHz in outdoor environment.**

***Index terms*: Millimeter waves, Wireless Propagation, 5 G, 60 GHz**

I. Introduction

Advancement in wireless technology has driven the demand for more radio spectrum bandwidth from every sector of the wireless applications. It is further accelerating day by day, and we are heading towards greater mobility with ever-increasing demand of higher data rates. The growth of internet has further fueled the demand for wireless services, due to which the available radio spectrum is becoming a scare and congested. Various studies have shown that the increasing demand for spectrum is due to the regulatory schemes introduced by authorities to protect rapid increase of spectrum users [2]. Various researchers are working hard on devising a methodology for resolving forthcoming spectrum crisis. Recently various regulators have shown interest in sponsoring free radio channels to allow access for unlicensed devices. For example Industrial, Scientific and Medical (ISM) radio band in 2.4 GHz frequency are allocated freely for public usage. This was very successful in short range low powered radio communications in wireless local area network.

Most of the terrestrial commercial applications are below 3GHz and have already been assigned to different radio communications services which are working with non-spectrum efficient, technologies. Lower spectrum bands provide better coverage, simpler hardware and good mobility. If we go to higher spectrum bands , situation would be just reversed, i.e. it provide less coverage, complexity in hardware and less mobility. Currently, no vacant spectrum especially below 3 GHz is available for newer wireless technologies. Radio spectrum, being natural resource, cannot be created. Therefore, its efficient use is inevitable.

The 5th generation wireless systems denote the next major phase of mobile telecommunications standards beyond the current 3G/4G/IMT-Advanced standards.

II. Concept of WISDOM

Today presence of various devices incorporates productivity and quality of life of human beings, in all technological domains. In most cases these devise work in isolation or with very little cooperation among each other, and serve a well-defined single purpose for which they have been designed.[5] The recent innovation of device manufacturing and communication technologies have enabled personalized and mobile connectivity of various devices, making them smart and their penetration is expected to grow exponentially in the next years such a huge growth is already creating an unprecedented opportunity for novel applications and services that grow far beyond the mere purpose of each user, but are based on interconnectivity and interworking. Users are benefiting from services in the public or private sphere, while more and more personalized digital content is being generated. This novel concept of connectivity and mobility is called WISDOM [1]. The Wireless Innovative System for Dynamically Operating Mega Communications, which is proposed to provide ubiquitous terabit wireless connectivity enabling human- centric mega-communication applications over a dynamic, interoperable and secure network.

WISDOM is developed to enable the growth of an interconnected society, bridge the physical and virtual worlds by offering a seamless personalized rich digital experience for the end users, while creating the optimal conditions for capitalizing on future internet innovations [4].

The three founding pillars of WISDOM are:

- An information theoretic performance/ capacity estimation of different types of networking paradigms.
- Design of protocols based on end-to-end, cross-network-domainperformance optimization
- Cognitive radio network based self organizing networks for management of possible usage scenarios and to minimize the spectrum and energy requirements [1,6]

WISDOM aims to design and develop technologies, system that could globally integrate, interconnect and communicate into a flexible and dynamic system for the human centric and machine centric communications in 2020 and beyond [1,11].

III. Importance of 60 GHz

With the increase in the demand of higher frequencies various researchers have shown their interest in millimeter wave mainly in 60GHz. The 60 GHz frequency band has many advantages over lower frequency bands. One of the reasons for increasing craze in the availability of huge bandwidth. The 60 GHz provides continuous and less restricted bandwidth in terms of power limit. With the huge potentials of capacity and flexibility 60 GHz bandwidth became a good candidate for high transmission rate future communication systems [13].

The regulations allows high transmission power for 60 GHz as compared to other less frequency bands in order to overcome high power losses due to oxygen and rain. As due to limited range of network in 60 GHz, it is confined to very limited areas which in turn provide higher frequency reuse which allows high throughput network. The form factor of 60 GHz systems is 140 times smaller than the systems which use lower frequencies.

With various advantages provided by 60 GHz bands it also has some of the limitations which need to be resolved. The IEEE 802.15.3c has provided various applications in the millimeter wave technology with various data rates and ranges. It is very challenging task for 60 GHz systems to provide sufficient power margins for reliable and efficient communication link. Another challenge for 60 GHz is the delay spread of the channel. Larger delay spread increases the complexity of the system which makes its practical implementation difficult.

IV. Studies done so far in outdoor Environment

Various researches have carried out studies in the areas of millimeter wave propagation in outdoor environment, but are limited especially for 60GHz. As in outdoor environments these waves faces various challenges like rate of rain drop size, dust and snow particles causing attenuation, de-polarization and noise. There are various types of outdoor environments and have different effects on propagation of radio waves. Different types of environments are:

URBAN ENVIRONMENTS

1) Less Dense
2) Highly Dense

The less dense areas consist of city streets with less population, road tunnels, empty parking area, grass fields etc. where as in highly dense urban areas consist of pedestrian walkway in densely populated city, Multistoried buildings etc. in the rainy conditions various factors affects the propagation like drop size, rain intensity etc. vegetation also plays an important role as size and types of trees, shape of leaves, trunk size etc. affect the radio wave propagation.

A. URBAN OUTDOOR ENVIRONMENTS

The urban environments consist of a city which, contain buildings, streets, lampposts, vehicles and people. There are also variations in urban environments which includes less dense and highly dense urban environments. Researchers had done various studies in these types of environments. Less dense urban environments consist of cities which are moderately populated. Their streets are not over crowded. Few high rise buildings are there with considerable distance between them. Roads are broader and lots of open spaces are available. Highly dense urban area consists of overcrowded cities. Their streets are full of traffic and lots of people are moving in pedestrian walkways. Considerable amount of high rise buildings are presents.

B. LESS DENSE URBAN ENVIRONMENTS

Various researchers have done propagation studies in this type of environments. Mostly include university campus, grasslands, empty parking area etc.

The outdoor 60GHz frequency measurements done by Duscan M. Matic, Ramjee Prasad et al [7] in the outdoor environments of Delft University, Netherlands. They had chosen grass fields outside the building and empty parking area. Here there were no obstacles. They present the results of frequency fading over 100 MHz bandwidth centered around 59.9 GHz. from the experimental results they obtained the k factor of the Rice distribution and path loss coefficients. By fixing the position of TX and moving the RX different spatially distributed locations throughout the test area was used. The experiment setup used in [13] consists of synthesizes signal generator named Marconi 2024, 60 GHz TX and RX and spectrum analyzer named Anritsu MS2651A. From spectrum analyzer to PC, data was transferred by general purpose information bus. The frequency response consists of 500 amplitudes samples at a frequency sampling of 0.2MHz. [13]. The TX consists of 120 degrees flat omnidirectional antenna and RX consists of 120 degree omnidirectional and 15 degree patch directional antenna was used.

The measurements are carried out outside building in open grassland. The receiver antenna was moved away in a straight line from 27 m distance apart from the receiver. The receiver was moved away from the TX and measurements were taken at the intervals of every one minutes. So we get 27 different measurements. The height of antenna was 1.59 meters.

Another measurement was done in an open empty parking area which includes some trees. The antenna height was 1.59 m the experiment was conducted with both type of antennas on distance of 3 to 25 meter with 25 points of observations in a straight line and 12 on the side of the parking.

From all the experimental results the average value of k and standard deviation s of rice factor k are calculated. For experiment done on grass field the value of k was 84.25 and s was 87.94. for parking area value of k was 80.71 for omnidirectional antenna and 423.85 for directional antenna. The value of s was 79.87 for omnidirectional antenna and 165.35 for directional antenna.

It was observed from the experiment that the average decay with distance is small. This is because of many reflections and they sum up together. Although this leads to small k factor and to the fact that the modeling is not so good.

Smulders. et.al. [12] has performed both narrowband and wideband measurements at outdoor environments for 60 GHz. The experimental results which they obtained are compared with deterministic model which they developed. They had conducted different experiments in different outdoor environments like airport fields, urban streets and city tunnels.

They had used a channel sounder which was based on correlation. The RF frequency was centered around 59.0 GHz with bandwidth of 200 MHz, corresponding to a resolution of 5 ns. For transmitter 90 degree horn antenna was used and 20 degree biconical horn used as a receiver. The height of TXwas kept at 4m and RX was 2.2m. The different parameters which was considered during measurements was mean delay (MD), RMS delay spread (RDS), delay interval (DI), delay window (DW) and sliding delay window (SDW).

The observation made in city streets do not represent multipath situation. Values of RDS and 90% SDW was lower than 20ns and 50ns respectively. In the case of city square the 90% SDW may be 150 ns or more. A read tunnel had many similarities to the city streets environments. A bad multipath situation was observed by parking garage because of the large dimensions and the relatively smooth surfaces creating strong reflections.

For the simulation purpose, a ray tracing tool was developed. It includes the features like direct and reflected rays which are up to the third order and diffuse reflections and diffractions are neglected. Rays are interpreted by non-reflected objects such as foliage. A dielectric canyon having a rough surface type of scenario was described. For both transmitter and receiver antennas polarization and radiation patterns are taken into account. This simulation tool was developed in order to understand the behavior of outdoor environments more specifically in urban streets, and allow the estimation of both narrowband and wideband channel characteristics. The results obtained were good except 90% SDW. This is because sensitivity of this parameter toward reflected rays with low amplitude, therefore yielding large differences between simulation and real results.

C. HIGHLY DENSE URBAN ENVIRONMENTS

Eshar Ben Dor. Et .al in [14] described 60 GHz wideband propagation measurements in cellular peer to peer outdoor environments. They presented a channel sounder which was operated at 38 and 60 GHz with a pass band bandwidth of 1.9 GHz. The channel sounder provides RMS delay spread measurements resolutions and angle-of-arrival (AoA). [14].

They have developed 750 mega chips per second spread spectrum sliding correlator channel sounder for 38 and 60 GHz. This has a 1.5 GHz null to null bandwidth and uses a 1.9 GHz RF pass band centered at 59.4 GHz carrier frequency in order to provide 1.3 ns multipath time resolution.

The experiment was performed in outdoor courtyard with pedestrian in University of Texas campus. The campus is consisting of various buildings and some trees. Another experiment was conducted for the investigation effect of vehicular communications. It was conducted in a parking area which includes various vehicles, several lampposts and surrounded by tall multistoried buildings with few vegetation. The TX and RX were placed 1.5 m above ground.

The experiment done in the courtyard showed that the path loss exponents are slightly greater than free space for LOS paths. For NLOS paths when exited for particular antenna orientation they produce a link which was 15 40 dB weaker than LOS. It was also observed that for all outdoor locations some of NLOS antenna pointing scenarios could make a link. For NLOS scenarios, the RMS delay spread was observed as 36.6 ns. In courtyard the mean RMS delay for both LOS and NLOS scenarios was 6.02 ns. For the experiments done in parking area, where transmitter was fixed on a ground and receiver was fixed inside a car and moving in a confined parking area. The mean RMS delay was observed as 2.73 ns and maximum of 12.3 ns for 17 measured LOS and NLOS scenarios in parking area. It was observed that in a free space path loss LOS pointing scenarios offered less than 1 ns RMS delay spread. On the other hand NLOS antenna pointing scenarios produce much higher multipath delay spread and path loss.

Rappaport.et.al. [15] has carried out propagation measurements at 38 GHz and 60GHz frequencies at various outdoor environments. Their measurements show time delay spread and path loss as a function of separation distance and antenna pointing angles.

They use channel sounder which has variable rate PN sequence generator. For 38 GHZ they had 400 Mcps and for 60 GHz they had 750 Mcps. The millimeter wave up down convertor get the input of IF frequency of 5.4 GHz. These convertors contain mixer and LO frequency multipliers which give output of 37.625 GHz and 59.4 GHz. The 38 GHz Tx and Rx used vertically polarized horn antennas with gain of 25 dB and half power beam width of 7 degree. The 60 GHz Tx and Rx used vertically polarized antenna whose gain is 25dB and contain beamwidth of 7.3 degrees.

In this work two different types of experiments are done. In the first type TX and RX was placed at the same level. There was single TX and 10 RX was placed at different locations. The area was surrounded by various buildings which are of 1 to 10 stories long. The receiver moved away from the transmitter to about 19 to 129 meters. There are various obstacles presented in the scenarios like automobiles, brick and aluminum sided buildings, foliage, lamppost, handrails and signs.

The second type of experiment was done in scenario where TX was placed on a roof top and receiver are placed at ground level. Rests of the situations were similar as described in first experiment.

The experimental results obtained for LOS link was free path loss with no RMS delay spread. In NLOS there was

higher RMS delay spread of 122 ns for first experiment and 107 ns for second experiment. It was also observed that as if the azimuth pointing angels increased from the bore sight the RMS delay spread is also increases in NLOS.

In [16] Jonathan S. Lu. et. al. has performed experimentation on diffraction and scattering on 60 GHz radio wave. Diffraction was measured at building corners whereas scattering was observed at car, lamppost and buildings. Human obstruction was also measured.

The TX used in this was consisting of SMF100A microwave signal generator of 10 GHz frequency which was attached to frequency multiplier SMZ90 which multiplies by 6. Then it was connected to V-Band horn antenna of 24dBi gain and 11 degree beam width. The Rx system consists of same antenna system used in TX. It was then connected to low noise amplifier NIZ 3387. The signal was then sentto harmonic mixer FS Z90. Then signal was down converted and sent to vector signal analyzer FSQ26.

For the conduction of outdoor measurements on cars, lamppost and buildings the TX and RX are placed on a moving cart and then moved according to some fixed angles. The height of antennas was kept at 1.33m.

The diffraction measurements were done for building corners. For this purpose two different sites were chosen one was the corner made up of concrete while another was made up of concrete and windows. In the first experiment TX cart was placed at a distance of 3.75 meter from the corner and the angle inclination was 18 degree. The Rx was placed at a distance of 2.8 meters in the shadow region and moved in an arc. The movement was done on angles between 200 and 260 degrees and recording was made at every 10 degree intervals. In the second experiment the TX was placed at a distance of 6.1 meters from the corner with inclination of 10 degree. The RX was placed at a distance of 4 meter in a shadow region and again moves in an arc with an angle of 200 to 260 degrees with an interval of 15 degrees.

The scattering measurements were done for a car in an empty parking area. The transmitter was placed at a distance of 23 meters from car. The transmitter bore sight was centered on the side of car and normal to the surface of car. The receiver was moved in an arc of 23 meters and scattering angles relative to the normal of car surface in ranges from 14 to 75 degrees.

For the study of human blocking two scenarios was taken. In the first scenario it was assumed that the TX and RX were at same height which was 1 meter and moving from one place to another. The observation was made within the LOS distance of TX and RX of 7 meters. In another scenario the TX was at roof top with height of 2.65 meters and RX at ground at the height of 0.9 meters. They are moving within the radius of 7 meters.

It was observed that scattering measurements done from cars and lampposts was higher near the specular direction. The diffraction results suggest that the scattering from lamppost and cars are higher than diffraction from corners of buildings.

It was observed from scattering measurements of buildings that received power was higher when TX and RX were placed in horizontal plane and in specular direction. In case of non-specular direction best results was found in case of ridges and columns.

The results of human blockings suggests that the absorbing screen models used in the work was quite accurate with the actual results obtained with standard deviation of prediction error not more than 5 dB.

V. CONCLUSION

This work had explored various studies done in radio wave propagation at 60 GHz. It had concluded that the higher frequencies specially 60 GHz are the very sensitive in nature for propagation in various outdoor environments. It was observed that results are different for different environmental conditions. In order to develop new technologies a thorough propagation studies are required in Indian environments.

Real-time Detection of EEG Electrode Displacement for Brain-Computer Interface Applications

Giulia Cisotto and Silvano Pupolin
Department of Information Engineering
University of Padua
{giulia.cisotto & silvano.pupolin}@dei.unipd.it

***Abstract* – Electroencephalography (EEG) has a relatively old history since Hans Berger in 1929 recorded the human brain activity for the very first time. Since then, a number of experiments had led to a strengthened employment of this technology both in the clinical practice and in the most advanced research platforms. Although amazing developments have already been achieved, no gold standards are available for the processing of EEG signals. However, EEG signal processing used in several applications of Brain-Computer Interface (BCI) has already promised unbelievable progresses. In the context of a specific BCI application, this paper deals with a particular kind of artifact due to electrode-pops that can degrade the EEG recordings and, consequently, make BCI give wrong outputs to patients operating it for their benefit in recovery or in daily life.**

Keywords – EEG, BCI, electrode-pop artifact, online algorithm.

I. Introduction

Electroencephalography (EEG) [1] has a relatively old history and nowadays all Hospitals, clinical Institutes and even Universities have an EEG system to perform daily clinical assessments of several kinds of patients or to study the cerebral activity of healthy and impaired people in a relaxation status or during a task execution. Although its widespread availability, no gold standards for the analysis of the EEG traces are recognized all over the world. Instead most clinicians analyze by-eye only the cerebral activity of their patients being satisfied to observe macroscopic changes like epileptic seizures or alternating phases of more or less reactive awareness represented by larger or smaller oscillations in the frequency band around 10 Hz, the so-called α band. However research has already shown, in many years of study, that an amount of information is hidden in this complex combination of waves that EEG is.

One of the most amazing fields of EEG employment is the Brain-Computer Interface (BCI): after a training period, a subject can learn to operate a computer to communicate in an alternative way with the external world or to move again by controlling a wheelchair or a robotic arm [2].

This paper deals with a specific kind of EEG artifact that can arise from the displacement of an electrode during recordings. This event can cause the subject to fail in operating a BCI – at least for a limited period of time - because of the artefactual analysis of the correspondent EEG signal affected by the huge abnormal peak and oscillations following the displacement.

II. Electrode-pop artifact in EEG recordings

EEG recordings at the scalp of a subject are a combination of useful signal and disturbance. To be precise, the former is constituted by the neural response of the subject to an experimental task or, simply, it carries the information about the status of the individual, and the latter is the sum of all the other components of the EEG traces. As mentioned before, there can be several causes of disturbance but, generally, they are classified as follows:

a) external interferences. The main element of this set is the power line noise that usually corrupts the EEG recordings. For this reason, a notch filter around 50 Hz or 60 Hz is implemented to remove this considerable interference during EEG evaluations or experimental sessions.

b) *physiological interferences*. They can be further divided into two subclasses: muscular and neural noises. Eye-blinks, eye-gaze changes, chewing, gnashing, swallowing and head slight movements are muscles activations that can compromise the whole recordings. Skin sweat can be also a relevant phenomenon to cope with sometimes. Finally, distractions, habituation and other collateral cognitive phenomena can elicitate neural populations of different cortical regions to spike and, at the scalp level, to show interfering waveforms. The latter are considered disturbance and are usually removed on the basis of their spatial and/or frequency occurrence.

Then artifacts can occur either accidentally or along the whole recording. For instance, artefactual activity due to mains is usually present along the entire registration while muscular contraction is in the most cases a very short phenomenon that can seriously corrupt a relatively short-lasting recording segment. One of the most impacting causes of artifact is the so-called *electrode-pop*: although quite rare, this kind of noise can be completely superimposed over the low amplitude useful signal and make the identification procedure of the EEG characteristics almost impossible for a long time (tens of seconds). A typical example of its shape is captured by Fig.1 where the usual abrupt negative fall, overshoot and slow-oscillating return to baseline values are clearly visible.

It can be easily expected that such an artefactual activity compromises any kind of automatic features identification.

Cautions in order to avoid this kind of artifacts can be taken during the recording preparation: clinical technicians are trained to pay attention on this type of occurrence. Nevertheless electrode-pops can sometimes happen anyway. A hardware solution to cancel out this artifact has been proposed in [3] although without any quantification of its performance.

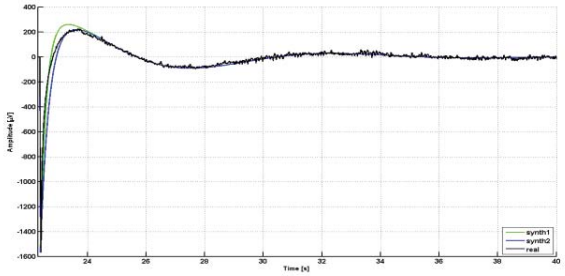

Fig. 1 Signal with electrode-pop artifact. A detail.

Several software solutions to remove artifacts have appeared in the past years [4-9]. The main objective of these solutions was to obtain a clear EEG signal for clinician eye-analysis. Our objective is somewhat different because we want to extract from EEG some real-time features to be used as feedback in BCI applications.

Hereafter a new real-time signal processing algorithm is presented with the aim to identify and remove this electrode-pop artifact before to estimate the EEG features required to assess the patient's status or to operate an EEG-based external device in a BCI fashion scheme.

III. Real-time algorithm for electrode-pop artifact

We consider the BCI treatment for motor recovery of the upper limb in stroke survivors described in [10], where the signal processing unit runs the world-spread software BCI2000 [11] which does not care about the electrode-pop artifact. Unfortunately, some recorded sessions of the whole BCI treatment were affected by this electrode displacement. We remark that feedback to the patient should be given in real-time based on *Movement-Related Desynchronization* (*MRD*) [12] of EEG signal. The presence of artifact prevents us to properly detect the MRD for several seconds. A new algorithm was designed and implemented with the goal to be performed in real-time during the BCI experiment and to reduce the time where MRD cannot be detected as short as we can. This algorithm has to be little time-consuming to allow the BCI system to process the remaining on-line analysis and provide the robotic feedback to the subject performing the experiment before he/she starts to execute the movement task.

In order to quantify the algorithm performance, the signal-to-disturbance-ratio (SDR) has to be computed. This would be possible only if a version of the same signal with and without the disturbance is available. To this purpose, a synthetic electrode-pop artifact was constructed and then added to a real EEG signal where no disturbance affected the trace. Then, the SDR is computed.

The artifact shown in Fig.1 is typical for each class of EEG amplifiers. Indeed, the first part, spanning few tens of milliseconds, is directly related to the amplifier bandwidth, while the second part, which shows a damped oscillation, is due to the AC coupling of the electrode to the amplifier.

Two different shapes of synthetic artifacts, similar to the real one, have been chosen for the following analysis and are displayed in Fig. 2 with a detail in Fig. 3.

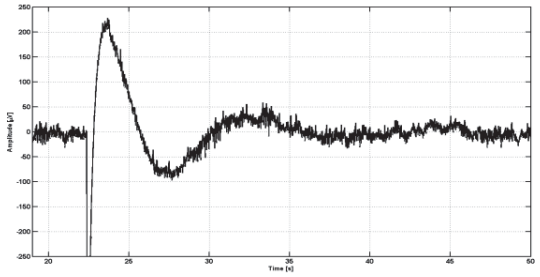

Fig. 2 Raw signal (black) and two different examples of synthetic artifacts.

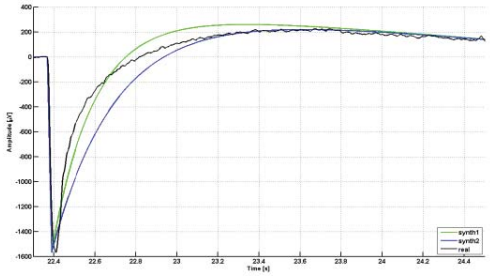

Fig. 3 Detail of Fig.2.

We remark that the artifact has an amplitude two order of magnitude larger than the EEG signal. To cancel the effects of this large disturbance only a nonlinear procedure works. We considered two different algorithms: i) estimate the main pulse and canceling it or ii) detect the time instant when the main pulse starts and set the signal to zero until it returns to zero. The first solution would be more precise but it would require a bunch of computations and an accurate model of the artifact to estimate the main pulse with enough precision. On the contrary the second algorithm has two main steps: 1) compute the first derivative of EEG signal as the difference between each sample and the previous one, and 2) determines where the absolute value of the derivative is higher than a threshold for N consecutive samples. Indeed, the electrode-pop could be represented as the impulse response of the amplifier filter. The rise-time t_r is related to the 3dB bandwidth B_s of the filter by the approximated relationship $t_r \approx 1/(3B_s)$. Hence, the rise-time span over $N=F_c t_r$ consecutive samples, where F_c is the sampling rate of the EEG. As an example, if F_c is set to 512 Hz and B_s is 20 Hz, N is about 8. The beginning of the artefact is given by the first sample where the derivative is higher than the threshold and the end by the sample where the EEG signal returns to zero. Then, the EEG samples between these points are replaced by zeros and discarded from the MRD detection. The zeros substitution between the two zero-crossing points is justified by the concern that filtering can give rise to transient signals due to possible abrupt signal discontinuities at the artefactual interval edges. During the interval of time where artifact is removed no feedback is intended to be provided to the subject but the system is thought to be waiting for new reliable values. An example of application of this method is reported in Fig.4 where the sum of an original artifact-free signal (recorded from the FZ site on the scalp) and a synthetic electrode-pop (black curve) is displayed along with its first

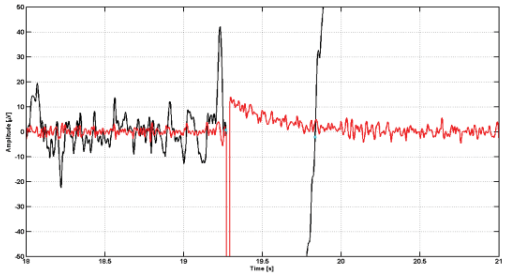

Fig. 4 Artifact-addicted EEG signal (black), its derivative (red) and the artefactual interval edges (cyan dots).

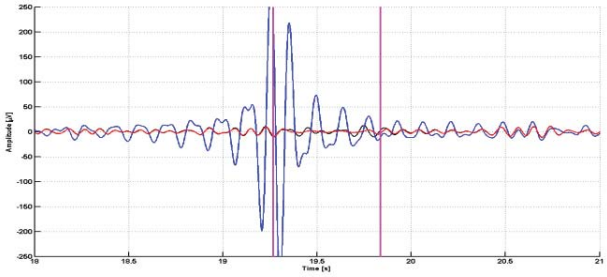

Fig. 5. The original raw signal filtered in the (7,14) Hz band (black curve), the filter output after the application of the proposed algorithm (red curve), the filter output without any artifact detection algorithm (blue curve) and the artefactual interval (magenta vertical lines).

derivative (red curve), and the two time instants labeled as the edges of the artefactual period are highlighted with cyan dots.

After these two first steps, the standard BCI2000 or another procedure involving a high-pass filtering above 1 Hz can be run as usual. The latter leads to the cancellation of the large remaining slow oscillation following the huge negative abrupt fall just removed, bringing back the signal to fluctuate around reliable values again. The zeros-fulfilled artefactual interval is filtered too and small oscillations arise at the filter output: however this does not represent an issue since this period of time is completely discarded from the following analysis. The difference between the (7,14) Hz band filter output with a previous step of artifact detection and removal and the same output without that preliminary operation is plotted in Fig.5. The (7,14) Hz band filtered version of the original raw signal without the synthetic artifact is also reported in both figures as a comparison. Moreover, two magenta vertical lines define the artefactual interval that is discarded from the following analysis.

Fig.5 shows that ideally-filtering a signal with an electrode-pop artifact causes an evident non-causal response that compromises the following analysis. Moreover, a real case filter would also introduce a significant delay that must be limited to make the BCI feedback reliable. On the contrary, filtering the EEG signal with the artifact removed does not cause any significant disturbance. The latter considerations are confirmed by the analysis of the performance presented later on.

Let us denote the original EEG signal filtered in the (7,14) Hz band as x while the filter output without the algorithm application as y_1 and the same quantity with the artifact previously detected and removed as y_2. Then e_1 and e_2 are defined as the following differences:

$$e_1 = y_1 - x \quad \text{and} \quad e_2 = y_2 - x$$

represent the errors between the filter output and the original artifact-free signal.

In order to quantify the algorithm performance, the error energy M_e, the signal energy M_x and the SDR (computed as the ratio between M_x and M_e) at the filter output was computed over 256 samples-wide time windows. Such a window width was chosen to be the same as that used by the BCI2000 software currently operating in the online procedure during the BCI experiment.

Then the new algorithm was employed in an offline analysis to assess its effectiveness. The goal of this analysis was to detect the presence of MRD during the BCI experiment described in [10].

III. Results

Let s be the original raw EEG signal and a the synthetic artifact. The latter was implemented as the formula below:

$$a(t) = A_1 \exp(-t/\tau_1) + A_2 \exp(-t/\tau_2)\cos(2\pi f_0 t + \varphi_0),\ t>0$$

where the constants A_1, A_2, τ_1, τ_2, f_0 and φ_0 are reported in Table I for the two synthetic artifacts shown in Figs.2 and 3 as an example.

In both the cases the synthetic artifact shapes are pretty close to that of the real one, but the "blue" artifact was selected to perform the following computations.

Then the linearly combination of signal s with signal a (s+a) drives the filter in the (7,14) Hz band. If the signal s+a has been previously processed by the algorithm for the electrode-pop artifact detection and removal, the filter output is y_2, otherwise y_1 is obtained. The above mentioned signal x is the filter output when the raw signal s drives the filter. The energy of the two errors e_1 and e_2, and the correspondent SDR_1 and SDR_2 were computed on the limited time intervals of 256 samples and compared to assess the advantage of the application of the new algorithm. Fig.6 shows indeed the energy of the two different errors computed within the above defined windows shifting by 8 samples at time.

The correspondent SDRs behaviors are displayed in Fig.7 where the ratio between the signal energy M_x and the error (either e_1 or e_2) energy M_e is computed over the same 256 samples time interval. Fluctuations of the SDRs curves are due to those of the original EEG signal. From Fig.6 and the next Fig.7 the advantage to apply the algorithm to remove the electrode-pop artifact becomes definitely clear.

In fact, from Fig.7 it can be noted that SDR_2 is constantly 30 dB larger than SDR_1 and is suddenly higher than 0 dB after the artefactual interval where the signal was reset and its values discarded from the following MRD analysis. Indeed, it has to be incidentally mentioned again that the part of the EEG trace between the magenta edges is not taken into account for the following analysis of the MRD and, since the signal in the same interval was canceled, the correspondent SDRs values

are unreliable. After proving the quantitative advantage of the proposed procedure, the algorithm will soon be tested in a real BCI application.

TABLE I. PARAMETERS OF SYNTHETIC ELECTRODE-POP ARTIFACT.

	A_1 [μV]	A_2 [μV]	τ_1 [s]	τ_2 [s]	f_0 [Hz]	φ_0 [rad]
Blue artifact	-1866	350	-0.3	-4	0.10352	0.55287
Green artifact	-1866	350	-0.2	-4	0.10352	0.55287

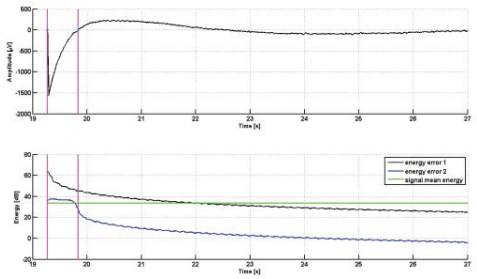

Fig. 6 Energy of the errors at the filter output along with the mean energy level of the original artifact-free signal x (green line) and the artefactual interval (magenta lines).

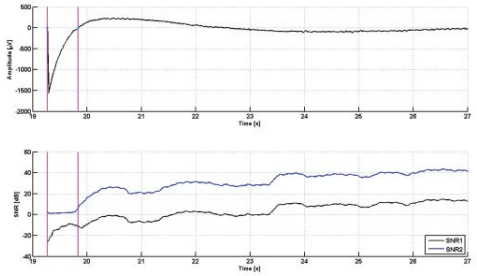

Fig. 7 SDRs at the filter output with the artefactual interval (magenta lines).

It has to be recalled that the BCI platform taken into consideration was described in [10] and its aim was to improve the reaching movement accuracy in mild-impaired post-stroke chronic patients by means of a force feedback that acts as a *mirror* of the cerebral activity related to that action: roughly speaking, while the patient is performing a reaching task on a plane, a force feedback helps him/her in completing the movement only if the expected neural pattern, i.e. spatial and frequency features, is activated. In particular, the MRD is computed in real-time by the BCI2000 software as the normalization of the spectral power around 10 Hz estimated at the current time instant on mean and standard deviation of the analogous quantity gathered during the initial relaxation period. Moreover, these computations are performed on the basis of the recordings coming from specific locations, i.e. the sensorimotor cortex, on the subject's scalp.

If an electrode-pop occurs, all these estimations become affected by abnormal values obtained by filtering the huge impulse present in the signal due to the temporary electrode displacement. Figs.8 to 10 shows the mean energy values obtained during the initial relaxation period, the movement and the correspondent MRD estimation. It has to be recalled from [10] that the more negative the values of the MRD, the more efficient the BCI training. Specifically, Fig.8 is plotted by analyzing the artifact-free dataset where x represents the signal coming from the FZ location.

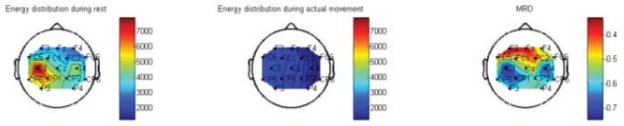

Fig. 8 MRD topography of an artifact-free EEG recording.

Then, Fig.9 shows the disastrous effect of an electrode-pop artifact occurred in the FZ sensor during the initial rest period. The MRD values of this artefactual signal were computed based on y_1.

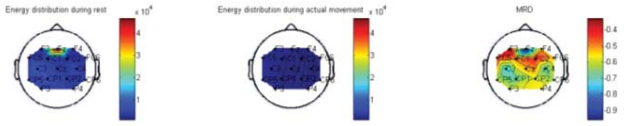

Fig. 9 MRD topography of an artifact-addicted EEG dataset with a synthetic electrode-pop artifact on the FZ site.

As clearly visible from Fig.9, an artefactually huge energy value is focused at the FZ location in the scalp frontal area. While energy distribution during the movement periods of all the following trials is almost within the range of normality, it can be easily expected that the normalization process based on the rest period will lead to unreliable estimation of the patient's cerebral activity, i.e. the MRD values, with a consequent feedback production not related to the physiological activity of the subject and thus useless for him/her motor training.

Finally, Fig.10 reports the analogous energies distributions and MRD estimations gathered after the application of the proposed algorithm that removes the artefactual peak and correctly filters the remaining slow and large overshooting oscillation. Therefore the MRD value of the FZ termination was computed based on y_2. The figure assesses, then, the benefit of such preliminary procedure to remove this kind of artifacts. Indeed, a focus of the activity in C3, Cp1 and C4 is a reasonable expectation since those sites are locations above the sensorimotor cortex: in fact, they belong to the cerebral area where the sensory and motor information is received from the external world, processed and transmitted again to the muscles, the final movement actuators. Moreover, energy values of the rest period are significantly lower than those of the previous case (Fig.9) when the electrode-pop artifact destroyed the EEG physiological waveforms.

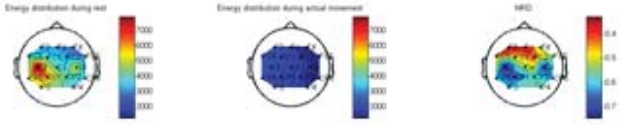

Fig. 10 MRD topography after removing the synthetic electrode-pop artifact from the same EEG dataset of Fig. 8.

DISCUSSION

The previous results assessed the necessity and the effectiveness of the algorithm proposed by the authors to detect and remove the electrode-pop artifact in real-time. From the topographical distribution of the MRD values displayed in Figs.8 to 10 it can be noted that a huge artifact like an electrode-pop occurred in one location of the scalp can compromise the MRD identification and, in particular, increase the number of false positive or false negative detections. Moreover, the effectiveness of the algorithm is also based on its real-time application: in fact, a simple difference operation between consequent amplitude samples (the first derivative step) and the check of its large decrease in few samples (less than 10, i.e. 20 milliseconds) allow the detection of the artifact due to an electrode pop. Furthermore this online identification comes at a very good performance since, as shown in Fig.7, the SDR_2 is constantly much better than the procedure that excludes this detection (SDR_1 curve). As expected, a constant increase of the SDR can be observed as far as the impact of the artifact on the informative signal decreases. As seen from Figs.6 and 7: the first part of the artefactual interval has to be excluded from the following analysis of the MRD because of its artifact abrupt negative slope. An additional interval of time where signal values have to be discarded can be roughly estimated in 1/B, where B is the filter bandwidth (B = 7 Hz in this particular case, then 1/B = 150 ms). In this prolonged period of time - lasting at most one second - the SDRs values are unacceptable (SDR_1) because of the artifact presence or unreliable (SDR_2) because of the signal cancellation in that period. But the most interesting note is that the proposed algorithm suddenly regains a good SDR into respect to the procedure without the artifact detection. As clearly visible from Fig.6, the error energy of the signal preprocessed with the electrode-pop algorithm becomes smaller than the mean energy of the signal immediately after the above defined interval, allowing a much early MRD identification. Concluding, it has to be one more time remarked that the proposed procedure removes only one second of the signal content from the analysis which is a fairly trade-off to have an artifact-free signal, while the current procedure should discard much longer time to wait for the SDR_1 to reach 20 dB (that is the minimum value to have the error energy less than 1% of the useful signal energy, a satisfactory threshold for the MRD evaluations). Finally, it can be observed that if an artifact occurs during the initial long rest period (40 seconds long), both the standard procedure and the new one can correctly estimate the MRD value from the artifact-free remaining part of the rest recording. On the contrary, if it happens during a movement trial (lasting at most one second) it disastrously impacts and the current procedure can not estimate the MRD along several trials, while the new algorithm allows this operation just one second later, that is losing at most one trial (where the BCI feedback would be not provided).

CONCLUSION

In the context of the BCI platform described in [10] an algorithm to detect and remove in real-time rare but huge electrode-pop artifacts was implemented and tested. In particular the shape of this kind of artifacts was mathematically proposed and the performance of the algorithm shown in terms of SDR computed at the band-pass filter output that estimates the signal energy content in the (7,14) Hz band, the typical cerebral rhythms associated with a movement, its planning, observation or even imagination. The energy of the error at the filter output was also computed and this outcome further proves the reliability and efficiency of the algorithm: while the current online BCI procedure provides non-physiology-related and, as a consequence, useless feed-backs to the stroke patient performing the rehabilitative exercise, the presented procedure allows to exploit the EEG data as early as one second after the electrode pop up event. This therefore confirms the convenience of the application of the new algorithm during the online BCI operations since it ensures a more reliable BCI feedback to the patient operating the system.

***Abstract*— Communication is the major problem during catastrophe. To address this problem the technology called amateur radio is used. During calamities and natural disaster times, amateur radio is recurrently used as an emergency communication system when wired line, cell phones and other contemporary means of communications goes down. This paper shows the design and implementation of wireless transceiver based on amateur radio. It also describes the concept of ham radio station. In this proposed work every block is designed for a 50 Ω impedance for input and output stage. The blocks in transceiver can be exchanged to any other frequency band, so it is like a universal block design. Here the design of transceiver is made to work within 14 to 14.35 MHz HF spectrum of amateur radio. It outlines specially the transceiver and antenna used in ham radio station.**

Keywords*— Amateur radio; Antenna; Arduino Uno; Wireless transceiver.

I. INTRODUCTION

Natural calamities like earthquake, flash flood, storms, tsunami, etc. are beyond human control. A major consequence of these calamities is to damage the existing communication infrastructure. If the infrastructure damaged, people do not get any help because their location cannot be conveyed [6]. Many people died during flash flood in Uttarakhand, India, in the year 2014, because the rescue team could not reach the stranded people in time, due to failed communication links. A potential solution to this situation is the Amateur Radio. Recently, in April 2015, in Nepal because of earthquake all communication links failed. For communication in Nepal many hams were invited, and all communication was carried on amateur frequencies.

Amateur Radio operators are called ham. HAM stands for Hertz, Armstrong, Marconi which are the inventors of the HAM. HAM also known as Help All Mankind. It is a non-commercial, non-profit radio service, friendly and a technical hobby enjoyed by nearly 6 million hams all over the world. The amateur radio service is found on an oath that includes public service, and radio amateurs [4], [6].

Ward Silver in his book [1], "Ham Radio for Dummies" explains architecture of HAM radio. Fig. 1 shows a typical ham station's components and gadgets. The radio is connected with a feedline to one or more antennas. Antenna switch allows the ham operator to select one of the antenna. An antenna tuner is used between the antenna and the transmitter to operate at peak efficiency.

One can use headphones and microphone to communicate using the various methods of transmitting speech. If Morse code (Continuous Wave) is preferred, operator use the traditional straight key, it is an old-fashioned Morse code transmission device, but recently more commonly use paddle and keyer [1].

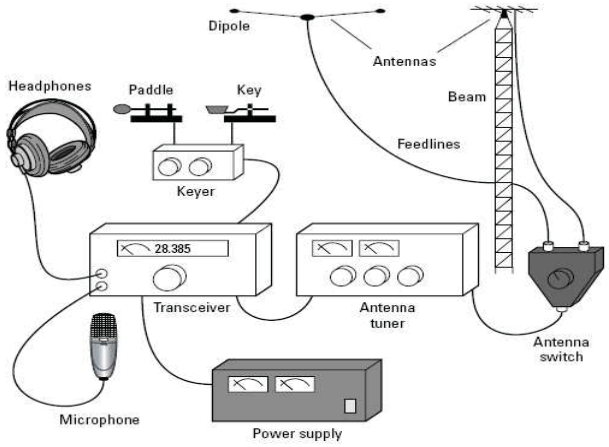

Fig. 1. Architecture of ham radio station
(Courtesy of Ward Silver [1])

There are different available frequency bands for HF, VHF and UHF. Ham voice modes are amplitude modulation (AM),

which includes the narrower-bandwidth single sideband (SSB), and frequency modulation (FM). For the most part, SSB is heard on HF, while FM is the typical voice mode used for VHF, UHF and microwave bands [6].

This paper, demonstrates the design and implementation of SSB transceiver for 14-14.35 MHz HF frequency spectrum. The paper is structured as follows: Section II describes the importance of amateur radio in wireless communication. Section III explains designing of ham radio transceiver. The result is shown in section IV followed by conclusion in Section V.

II. Importance of Amateur Radio in Wireless Communication

To provide wireless communications to an entire world, capacity of users is increased when Bell Laboratories developed the cellular concept in 1960s and 1970s [10]. During first generation the radio techniques used analog communication, which had high efficiency and easy to build. In second generation standards use digital modulation and multiple access techniques. Multi-megabit Internet access provided by third generation wireless networks [9], [10]. In 3G system users having ability to receive live music, conduct interactive network sessions, simultaneous voice and data access. with multiple access with multiple communication nodes. at the same time by using a single mobile handset at any circumstances [5]. Mobile 4G LTE (Long-Term Evolution), LTE Advanced provides faster and better Mobile Broadband, which have more data capacity [9].

During disaster only amateur radio is used, because all 2G, 3G and 4G trends depends upon BTS (Base Transceiver Station), BSC (Base Station Controller), MSC (Mobile Switching Center), PSTN (Public Switched Telephone Network) which are failed down during disaster. As a worldwide communication medium, spectrum utilization and allocation of the HF band is regulated by the International Telecommunication Union (ITU). A portion of the HF band is allocated for the use of people interested in radio technology as a hobby known as amateur radio, which follows ionospheric propagation [4], [6]. The ham radio works on the high-frequency (HF) band (2-30 MHz). The propagation is via direct wave, surface wave, near-vertical incidence sky wave (NVIS), and ionospheric propagation provides a means of communication, from line-of-sight (LOS) to beyond-line-of-sight (BLOS) and over-the-horizon (OTH) ranges [3]. For amateur communication it requires only transceiver, battery and antenna, which can be mounted very easily. Hence it can prove very effective tool when other media of communication systems are fails.

III. Designing of Amateur Radio Transceiver

Fig. 2 shows the block diagram of the proposed system. It includes both transmitter and receiver sections.

Following are the different blocks of the transceiver:

A. Antenna

Antenna is connected to the transceiver with a piece of coaxial cable. During transmission, it radiates signal in space

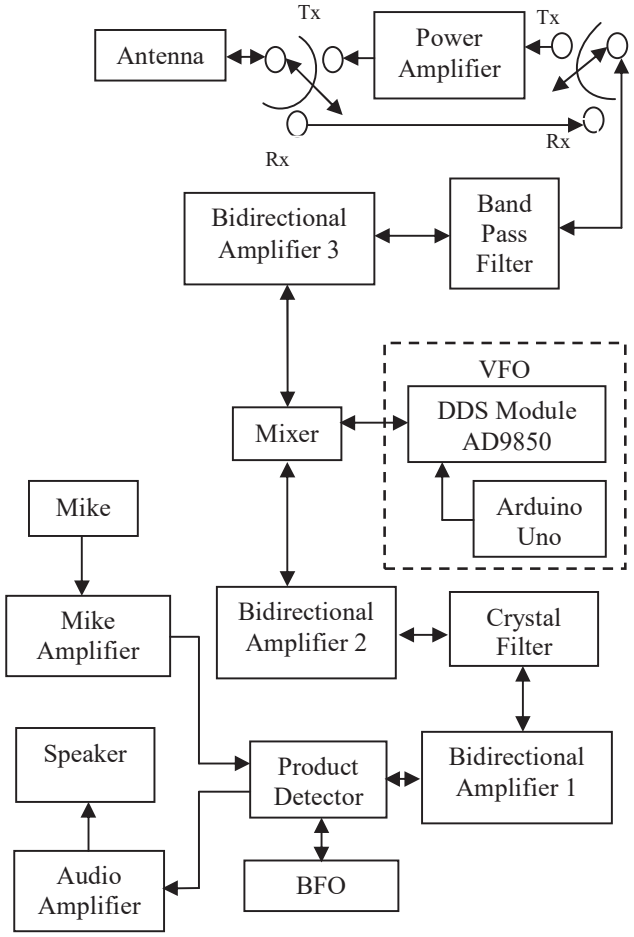

Fig. 2. Block diagram of the proposed system

and during reception it receives signal through the space. Typically, yagi, dipole and vertical antennas are used for HF, verticals for VHF and UHF, and dish antennas for the microwave frequencies [3], [4], [5]. In proposed work, we have used inverted-V dipole antenna. The halves of a dipole sloped to form an inverted-V. For dipole, antenna length is half the wavelength. It is calculated by the following equation:

$$\lambda = \frac{C}{F} \quad (1)$$

where C=Speed of the light in free space, F= Frequency

For 14 to 14.35 MHz frequency bandwidth, its center frequency is 14.175 MHz. The speed of light in free space=3×10^8 m/s, wavelength (λ), for 14.175 MHz frequency is 20.39m.

So the antenna length is given by:

$$L = \frac{\lambda}{2} \quad (2)$$

Therefore each arm of dipole is of 5.1 m length.

B. Microphone

A microphone called a mike is an acoustic-to-electric transducer or sensor which converts sound waves in air into an electrical signal [2]. In proposed work condenser microphone is used.

C. Mike Amplifier

The balanced modulator and the audio speech processor need a certain optimum level, which can be in the range of 0.3 to 0.6 V AC. For getting this level signal from microphone is passed to the mike amplifier.

D. BFO (Beat Frequency Oscillator)

To create an audio frequency signal and making transmission audible, a beat frequency oscillator or BFO is used. The signal from the BFO and modulating intermediate frequency is mixed to create a beat frequency. BFO frequency is heard as a tone in the speaker. It is used to demodulate single sideband (SSB) signals. The signal from BFO is comprehensible, by essentially replacing the missing carrier signal [10]. In proposed work BFO produced a carrier frequency of 10 MHz.

E. Product Detector

The output of product detector is the mathematical product of the BFO and the audio modulating signal. The BFO must be tuned to the same frequency as the suppressed carrier to prevent distortion of the recovered audio [2]. It produces double sideband (DSB) with carrier.

F. Bidirectional Amplifier

As the name suggests it amplifies signal in both direction, during transmission as well as reception. Direction of signal flow determined by the control voltage applied to an amplifier. Only one amplifier operates at one time [8]. In this amplifier input and output impedance is same, at both port it is matched. In proposed work, for amplifier input stage is feedback amplifier and output circuit is a Darlington emitter follower which has unity voltage gain [11].

G. Crystal Filter

A band pass frequency response is produced when group of crystals, of the same nominal frequency connected into a ladder network [11]. In proposed system ladder crystal filter is used. For selection of crystals, its parameters must be checked. To pass 10 MHz signal 4 crystals of 10 MHz are used in proposed system for making ladder network. A mesh is one loop of a ladder consisting one crystal and two shunt coupling capacitors on either side of it [12]. Capacitance of coupling capacitor is calculated as:

$$C_{jk} = \frac{C_m F}{k_{jk} B} = \frac{1}{4 k_{jk} B \pi^2 F L_m} \quad (3)$$

End terminating resistance is given by

$$R_E = \frac{2\pi B L_m}{q} \quad (4)$$

where C_m is motional capacitance, F is center frequency, k_{jk} is normalized coupling coefficient, B is bandwidth and L_m is motional inductance and q is normalized value of filter.

H. Mixer

Mixer is a nonlinear circuit or device that accepts its input as two different frequencies and produce output as a mixture of signals at several frequencies [5], [11]. In proposed work double balanced diode ring quad configuration is used that consist of four diodes. This arrangement ensures that only two diodes conduct in each cycle of AC signal. In proposed work two frequencies fed to mixer are 10 MHz from BFO and 4 - 4.35 MHz from VFO which produced desired output during transmission and reception.

I. VFO (Variable Frequency Oscillator)

For frequency control during communication it is necessary to have a frequency-tuning knob that covers the entire band and not just a few hertz. Its hard because, without the stability, an ordinary RF oscillator will drift hundreds of Hz during sending [2]. To build a VFO in proposed system, direct digital synthesizer AD9850 using Arduino microcontroller board based on ATmega328 is used. It generates frequency as an analog output sine wave. By using the frequency varying knob on front panel on metal box of transceiver, entire bandwidth of desired range is achieved. The details of Arduino Uno board and AD9850 are as follows:

1) Arduino Uno

Arduino is an open-source electronic prototyping platform. It is a microcontroller board based on the ATmega328. The functionality of Arduino contains Atmel microcontroller, USB programming/communication interface, voltage regulator and power connections, breakout I/O pins, in-circuit serial programmer (ICSP) connector [8].

2) AD9850

The AD9850 is a highly integrated device. To form a complete, digitally programmable frequency synthesizer function in AD9850, the direct digital synthesizer (DDS) technology coupled with an internal high speed, high performance D/A converter. Output tuning resolution of 0.0291 Hz for a 125 MHz reference clock input provided by a 32-bit frequency tuning word. It uses CMOS technology and performance on 155 mW power dissipation of 3.3V supply. It is available in a space-saving 28-lead SSOP, surface-mount package [8].

Algorithm for frequency generation of VFO is shown in Fig. 3:

J. Bandpass Filter

A bandpass filter is an electronic device that allows signals to pass between two special frequencies and discriminates against signals at other frequencies [11]. In proposed system triple tuned LC bandpass filter is used. By selecting center frequency F, bandwidth B in Hz. Inductance, L is calculated as L=10/F. The capacitance at both end of load is calculated as:

$$C_o = \frac{1}{\omega} \cdot \frac{1}{\sqrt{R_0 Q_E \omega L - R_o^2}} \quad (5)$$

$$Q_E = \frac{qFQ_u}{BQ_u - qF} \quad (6)$$

where ω is angular frequency as 2ΠF, Q_u is unloaded inductor and q is normalized value, R_o is load value at both ends.

18. *Sine of desired frequency obtained*
19. *Display result on LCD*
20. *End*

Fig. 3. Algorithm for frequency generation of VFO

K. Audio Amplifier

For getting the good output from speaker it is possible to use op amps as low power audio output driver [2]. In proposed work LM386 audio driver IC is used for amplification.

L. Speaker

A loudspeaker is an electro-acoustic transducer that produces sound in response to an electrical audio signal input [2]. In proposed work 80 Ω speaker is used.

M. Linear Power Amplifier

For getting more output power at load a linear amplifier is used. Linearity of linear power amplifier refers to the ability of the amplifier to increase power levels of signals that are accurate reproduction of the input signal. Load impedance, supply voltage, input bias current, and power output capabilities affected on efficiency of linear amplifier [11]. In proposed work, the low-cost medium power NPN transistor 2N2218 is used as pre-linear driver. It drives an IRF510 MOSFET as a main driver for 10 watts of power at 14 – 14.35 MHz for getting desired result.

IV. Results

A. Hardware of System

The hardware of transceiver is built. Fig. 4 shows the hardware of the system developed. Three different PCB are made. The section in the top left of the image is the main transceiver. VFO section is directly below it with Arduino board and AD9850. The entire section on the right side is linear amplifier.

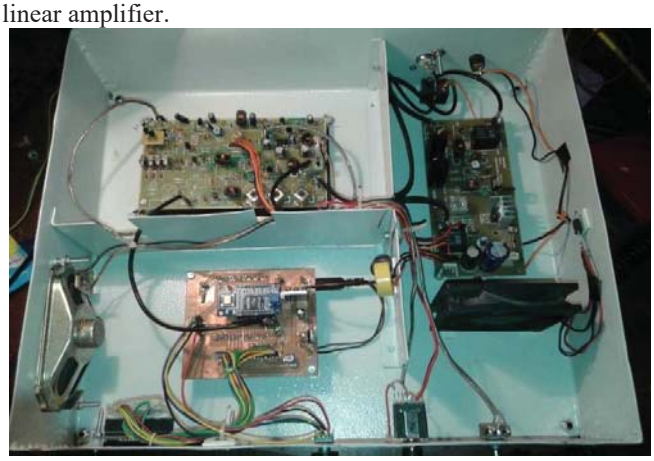

Fig. 4. Hardware of a system

Hardware is tested at the frequency range of 14 – 14.35 MHz. The system works on 13.5 V. Table 1 shows output of different parts in transceiver.

TABLE I. Output of Different Blocks

Block	Output
VFO	4 – 4.35 MHz
BFO	9.9989 MHz
Mike Amplifier	2 KHz
Audio Amplifier	2.5 KHz
Modulation Index	1
Pre-Linear Amplifier (Frequency)	14 – 14.35 MHz
Pre-Linear Amplifier (V_{PP})	4 V_{PP}
Linear Amplifier Voltage (Without load)	146 V_{PP}
Linear Amplifier Voltage (With load)	6 V_{PP}
Power of Linear Amplifier	10 Watts

Fig.5 shows the BFO frequency that is nothing but the carrier frequency as shown on DSO, getting result of 9.9989 MHz.

Fig.6 shows the VFO frequency as shown on DSO getting result from 4 to 4.35 MHz by moving the frequency varying knob on front panel of hardware box. In image it shows about 4.2025 MHz.

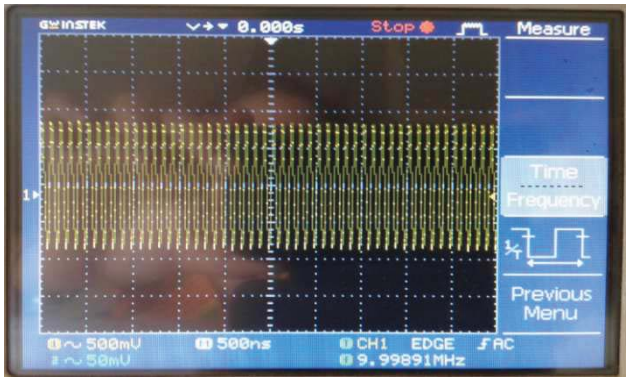

Fig. 5. BFO frequency

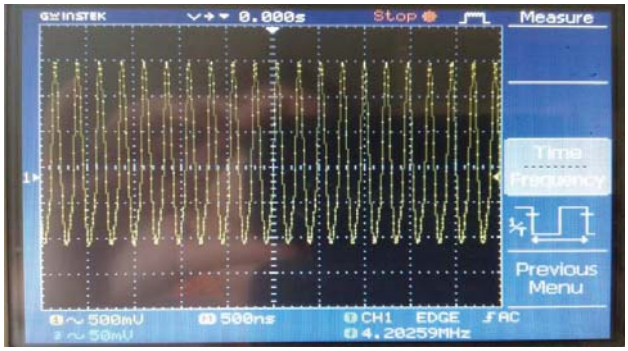

Fig. 6. VFO frequency

Fig.7 shows the frequency which is nothing but the SSB signal obtained at output of transceiver which is passed to the linear amplifier. Its frequency is from 14 to 14.35 MHz by varying the VFO frequency knob. In image by checking result on DSO we get result of 14.0408 MHz.

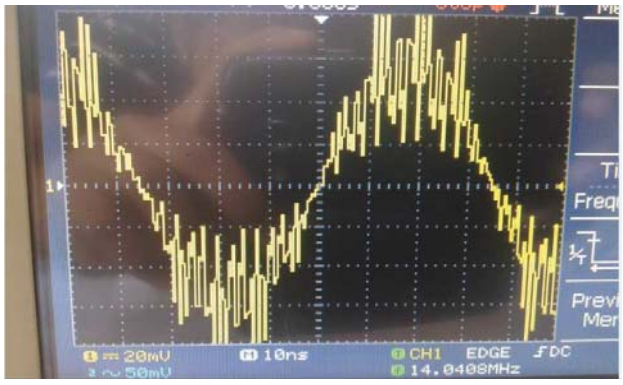

Fig. 7. Final output frequency from transceiver

B. Antenna Implementation

As the frequency of system is 14 – 14.35 MHz. In this proposed work, antenna used for this frequency bandwidth is inverted dipole antenna. Hardware implementation of antenna is done as shown in Fig.8. The halves of a dipole are sloped at apex angle greater than 90**°**, standing wave ratio(SWR) is 1.1. The centre of two arms of dipole connected to feedline cable. In proposed work coaxial cable RG58 of 50 Ω is used for connection between antenna and transceiver.

Fig. 8. Implementation of inverted-V dipole antenna mounted at SAE, Kondhwa, Pune.

V. CONCLUSION

Hardware implementation of proposed system is done to achieve desired aim. DDS VFO provides frequency between 4 to 4.35 MHz. BFO frequency obtained is 10 MHz. Output frequency from transceiver is 14 to 14.35 MHz. As VFO is implemented with DDS technology, it is effortless to tune whole band during communication with good stability. Combination of analog and digital methods gives good results. From the result it is seen that DDS VFO, SSB generation is easy, and it gives 90% efficiency of modulation. As it use only single upper side band so power required is less. Output power from linear amplifier is 10 watts. With rapid advancements in technology, it is now possible to design whole transceiver with digital concept. In future this work can be extended to design and implementation of transceiver for SDR and WSPR mode. Also by putting some extra switching functions, it can be used for multiband access of frequency during communication.

***Abstract*---In a single carrier system, a deep noise of fading can cause the entire link to fail but within a multi-carrier system, only a small percentage of the subcarriers will be affected. High Peak to Average Power Ratio (PAPR) of the transmitted signal is a major problem in the MC-CDMA system. It deteriorates the system performance due to large number of subcarriers and also reduces power amplifier efficiency, the battery life and resolution. Several methods are proposed for the PAPR reduction in the literature, such as μ-law, Exponential and Linear Non Symmetrical Transform (LNST) companding techniques. These techniques are implemented for the OFDM system over AWGN channel only. A-Law generates distortion at small signals and μ-law companding technique enlarges only small signals so that average power increases and causes spectral side-lobe generation. The PAPR reduction capacity of the exponential companding technique is very significant factor but there is an increased latency and system complexity. The LNST companding technique offers more bandwidth. In this paper, a few methods are used to reduce the PAPR, the system complexity, processing delay, distortion, noise and interference and improve the BER performance and quality of the channel. The existing and Modified Exponential Companding with Clipping Transform (MECCT) and Modified Linear Non Symmetrical Transform (MLNST) methods are implemented for the MC-CDMA system over AWGN channel.**

Keywords—MC-CDM; PAP; system; LNST; companding; MECCT; MLNST

I. INTRODUCTION

The combination of the CDMA and the OFDM based MC-CDMA system was initiated in 1993 [1]. It is a multiple access system used within the OFDM telecommunication schemes which supports many users simultaneously. The main idea of the MC-CDMA system relies on transmission of data by dividing the high rate data stream into an *N* number of low data rate parallel streams to transmit all of them on a separate subcarrier [1]. The MC-CDMA system spreads every user signal in the particular frequency domain. The MC-CDMA system transmits a single data bit at many narrowband subcarriers and every subcarrier is encoded with a phase offset from 0 to π based on a spreading code. The band of frequency offsets form code to differentiate users. Frequency domain spreading systems wherein the chips of spread data symbols are allocated across the subcarriers and are also projected independently by Yee et.al (1993), Fazel and Papke (1993) and Chouly et.al (1993) [2].

The merits of the MC-CDMA system are used in high data rates, simpler frequency domain equalization, higher spectral efficiency with better BER performance and minimum delay spread which also reduces the multipath effects.

The MC-CDMA system is employed to combat channel spreading, thereby strengthening the system capacity to accommodate a large number of users. The Long Term Evolution (LTE) gives a large range of data rates from 100 Mbps to 1 Gbps. The high PAPR result in the multi-carrier modulation is caused by the multiple subcarrier sinusoidal signals added simultaneously to form the large amplitude signal. The large amplitude signal causes IBR and increased BER and also degrades the system performance. An advanced counter is to stop the incidence of the non-linear distortion by the reduction of the PAPR of the transmitted signal. One of the challenging issues in the MC-CDMA system is high PAPR.

The signal pre-distortion method to decrease the PAPR which is based on companding was first projected by Wang [3]. A number of companding techniques are proposed by several authors. Among these the μ-Law companding expands merely small signals so that it increases the average power and causes spectral side-lobe generation and reduces the PAPR. The exponential companding is a non-linear scheme. It has less spectral side-lobe generation [4]. The linear companding transform by inflexion point, that is, the Linear Non Symmetrical Transform (LNST) can be better in performance than the μ-Law companding [5]. Clipping is easy and efficient and causes IBR and increased BER. The companding transforms are superior to clipping as they decrease distortion significantly. The main objective of this study is to reduce the PAPR and BER and improve the power efficiency of the MC-CDMA system without additional bandwidth using MECCT and MLNST companding techniques.

This paper is organized into five sections. Section I describes the introduction of the MC-CDMA system and companding function. Section II, the PAPR problem in the MC-CDMA system is described. Section III the block diagram of the MC-CDMA system is described. In section IV the existing companding techniques and also the modified companding techniques such as MECCT and MLNST are presented. In section V computer simulation results are presented. In section VI conclusions are listed.

II. THE MC-CDMA SYSTEM

Fig 1 shows the MC-CDMA transceiver system. It transmits binary data bit of a κ^{th} user concurrently on a number of narrow band subcarriers. The κ^{th} user data bits are spread, modulated and mapped within the frequency domain with the Inverse Fast Fourier Transform (IFFT) [2].

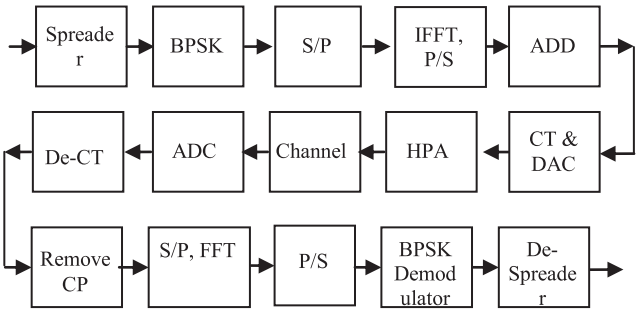

Fig 1: The MC-CDMA Transceiver

The companding techniques are proposed for the PAPR reduction and are able to increase the BER performance and minimize Outer Band Interference [OBI]. The Companding Transform (CT) output is fed to the parallel to serial converter and guard insertion block. The sequence is passed through a DAC and the High Power Amplifier (HPA). The transmitted signal is represented as

$$x^{\mathrm{K}}(t)=\sqrt{\frac{2P}{N}}\sum_{i=0}^{I-1}\sum_{l=0}^{N-1}d_i^{\mathrm{K}}c_l^{\mathrm{K}}e^{j\left(2\pi\left(f_c+\frac{1}{T_d}\right)\right)t*P_{T_d}} \quad (1)$$

Where d_i^K represents the i^{th} input data bits of the user κ and d_i^K is presumed to be an arbitrary variable which assumes values +1 or -1 by the same probability. c_l^K is the l^{th} spreading code of the κ^{th} user, P_{Td} represents the rectangular modulation, P is the power of data bit, I indicates the number of data bits, N correspond to the number of the subcarriers, f_c is the lowest subcarrier frequency, $1/T_d = f_d$ is the subcarrier separation [6]-[7].

At the receiver the de-companding transform (De-CT) is applied before CP removal and Fast Fourier Transform (FFT) block, to pick up the unique signal. This is developed through an FFT block to demodulate several subcarriers.

The demodulator demodulates the PSK signal and then de-spreads the code synchronization to accomplish fully the initial path of the desired signal. The process of the original data of the received signal at the output of the intended user can be determined by substituting base band transmitted signal with the phase shift. The received signal is obtained as

$$Y(t)=\sqrt{\frac{2P}{N}}\sum_{\kappa=0}^{\mathrm{K}-1}\sum_{i=0}^{I-1}\sum_{l=0}^{N-1}\beta_l^{\mathrm{K}}\,d_i^{\mathrm{K}}\,C_l^{\mathrm{K}}\left(e^{-j\left(2\pi\left(f_c+1/T_d\right)t+\varphi_l^{\mathrm{K}}\right)p_{T_d}(h)+W(t)}\right) \quad (2)$$

Where $h=\left(t-lT_d+\varphi_l^{\mathrm{K}}\right)$

$$\varphi_l^{\mathrm{K}}=\phi_l^{\mathrm{K}}-\theta_l^{\mathrm{K}} \quad (3)$$

φ_l^{K} Shows the phase difference between the transmitter and the receiver, $W(t)$ is the AWGN with a double sided Power Spectral Density (PSD), β_l^{K} denotes outcomes of the channel. The MC-CDMA system can handle N concurrent users by excellent BER with typical receiver methods [8]-[9] and [10].

III. PAPR PROBLEM IN THE MC-CDMA SYSTEM

The high PAPR of the transmitted signal depreciates the performance of the MC-CDMA system. The high PAPR signal is transmitted through a nonlinear amplifier which causes spectral widening and power efficiency degradation. Hence, to prevent the spectral broadening of the MC-CDMA system its power amplifier is controlled in the linear region.

In general, the PAPR of the above system signal x(t) is described as the ratio of maximum instantaneous power to its average power[11].The PAPR of the MC-CDMA system is expressed as

$$PAPR=10Log_{10}\frac{\max\left[|X(t)|^2\right]}{E\left[|X(t)|^2\right]}dB \quad (4)$$

Where $E\left[|X(t)|^2\right]$ denotes average power. It is easy to manipulate the above equation by decreasing the numerator $\max\left[|X(t)|^2\right]$ or increasing the denominator $E\left[|X(t)|^2\right]$ or both. As a large number of subcarriers (N) exist, they result in high PAPR. The relation between The Crest Factor (CF) and the PAPR is given as

$$CF=\sqrt{PAPR} \quad (5)$$

The CCDF of the PAPR of the data block with Nyquist rate sampling is given as

$$P(PAPR>X_0)=1-P(PAPR\leq X_0) \quad (6)$$

X_0 is the PAPR threshold value and N is equal to the number of subcarriers. This equation is not accurate for a small number of subcarriers [12].

IV. COMPANDING TECHNIQUES

In companding, small signals are amplified and large signals are attenuated and compression occurs. It increases the Signal to Noise Ratio (SNR), as the input signal is low and therefore reduces the effect of system noise source. Let N indicate the number of subcarriers used for parallel transmission and let x_n $(0\leq k\leq N-1)$ indicate n^{th} complex modulated data symbol in a block of N information symbols. Here, k is the discrete frequency component and n is the discrete time component. The output x_n of the N-point IFFT of X_K are the MC-CDMA signal samples over one symbol interval. This is mathematically represented as

$$X_n=\frac{1}{\sqrt{N}}\sum_{n=0}^{N-1}X_K e^{\frac{2\pi kn}{N}},k=0...N-1 \quad (7)$$

The amplitude $|x_n|$ has a Rayleigh distribution with the Cumulative Distribution Function (CDF) as follows-

$$F_{X_n}(X)==1-\exp\left(\frac{-X^z}{\sigma^z}\right),X\geq 0 \quad (8)$$

The peak power results as *N* modulated symbols are added with equal phase [4].

A. The μ-law companding

The μ-Law companding is a linear companding method which amplifies only small signals in order to increase the average power and cause spectral side-lobe generation and reduces the PAPR [11]. The μ-Law companded signal is given as

$$\begin{aligned} Y(n) &= CX(n) \\ &= \frac{V}{\ln(1+\mu)} \ln\left(1+\frac{u}{V}|X(n)|\right) \operatorname{sgn}(X(n)) \end{aligned} \tag{9}$$

Where *v* is the average amplitude of the signal and μ is the companding factor. The de-companding signal is specified as

$$\begin{aligned} \hat{X}(n) &= C^{-1} r(n) \\ &= \frac{v}{\mu}\left\{\exp\frac{\left[|y(n)|\ln(1+\mu)\right]}{V}-1\right\}\operatorname{sgn}(Y(n)) \end{aligned} \tag{10}$$

B. The exponential companding

The exponential companding is a non-linear companding scheme that regulates both high and low peak signals and can maintain the average power at the same level, with less spectral side-lobe generation and better phase error performance. The companded signal is obtained by using the exponential companding function specified by

$$C(x) = \operatorname{sgn}(x)^d \sqrt{a\left(1-\exp\left(\frac{-X^z}{\sigma^z}\right)\right)} \tag{11}$$

Where $C(x)$ is the companded signal of the exponential companding transform, sgn(x) is signum function, α is a positive constant which determines average power of output signal, $x(n)$ is the original MC-CDMA symbol [4].

To maintain input and output signals at the same average power level α is given by,

$$\alpha = \left[\frac{E\left(|X(n)|^z\right)}{E\left[\sqrt[d]{\left(1-\exp\left(\frac{-|x(n)|^2}{a^z}\right)\right)}\right]^2}\right]^{\frac{d}{2}} \tag{12}$$

At the receiver, the de-companding function of $C(x)$ is used in inverse operation, i.e.

$$c^{-1}(x) = \operatorname{sgn}(x)\sqrt{-\sigma^2 \log\left(1-\frac{x^d}{\alpha}\right)} \tag{13}$$

C. MECCT Companding

The MECCT technique combines the clipping concept and the exponential concept. It uses an algorithm known as Modified Exponential Companding with Clipping Transform (MECCT) [13]. The MECCT companding algorithm is explained below-

$$\begin{aligned} x_m &= x_n, \text{ When } 0 \le |x_n| \le T_1 \\ &= T_1 + \log\left(|X_n| - T_1 + 1\right) \text{ , when } |X_n| > T_1 \end{aligned} \tag{14}$$

The final output is expressed as

$$X_{mn} = |X_m| e^{j\theta} \tag{15}$$

Where $\theta = \tan^{-1}\left(\frac{b}{a}\right)$ and x_n is in the form of $ax_n + jbx_n$, the threshold value at the transmitter is calculated as $T_1 = \frac{median(|x_n|)}{\sigma_{x_n}}$, where, σ_{x_n} is the standard deviation, $|x_n|$ is the modulus of the MC-CDMA transmitted symbol and T_1 is the threshold value.

At the receiver, the de-companding transform operates on the received signal to obtain an estimation of the transmitted signal. The MECCT de-companding algorithm is as given below-

The original received signal after de-companding is

$$\begin{aligned} \hat{x}_n &= r_n e^{j\theta}, \text{ When } |r_n| \le T_2 \\ &= \left(T_2 - 1 + 10^{|r_n|-T_2}\right) e^{j\theta} \quad \text{When } |r_n| > T_2 \end{aligned} \tag{16}$$

The threshold value at the receiver is given by $T_2 = \frac{median(|r_n|)}{\sigma_{r_n}}$. Where, σ_{r_n} is the standard deviation, $|r_n|$ is the modulus of the MC-CDMA received symbol.

D. The MLNST companding

The Modified Linear Non Symmetrical Transform (MLNST) is an idea of the LNST with phase angle, which can outperform the LNST companding The MLNST algorithm is as follows-

$$\begin{aligned} Y(n) &= \frac{1}{\mu} X(n) e^{j\theta}, \text{When } |X(n)| \le TM \\ &= \mu X(n) e^{j\theta}, \text{When } |X(n)| \ge TM \end{aligned} \tag{17}$$

Where, $\theta = \tan^{-1}\left(\frac{b}{a}\right)$ and $x(\mathrm{n})$ is in the form of $ax(\mathrm{n}) + jbx(\mathrm{n})$, where the ranges of μ and *TM* are $0 \le \mu \le 1$ and $0 \le TM \le \max\{|X(n)|\}$. . Since $X(n)$ is complex valued, the companding function should be applied to real and imaginary parts separately [5]. At the receiver, the unique signal can be recovered as stated by

$$\begin{aligned} \hat{X}(n) &= \mu R(n) e^{j\theta}, \text{When } n \varepsilon \varphi_1(TM) \\ &= \frac{1}{\mu} R(n) e^{j\theta}, \text{When } n \varepsilon \varphi_2(TM) \end{aligned} \tag{18}$$

V. RESULTS

The MC-CDMA with *A*-Law, μ-Law, LNST and exponential and also modified MECCT and MLNST companding schemes are simulated using MATLAB with 1024 symbols. The IFFT size is 256 with 64 subcarriers and Quadrature Phase Shift Keying (QPSK) modulation and GOLD codes. The performance of the MC-CDMA system in terms of the PAPR and BER is investigated with the different companding techniques. The PAPR performance can be evaluated by using cumulative distribution function of the MC-CDMA signal.

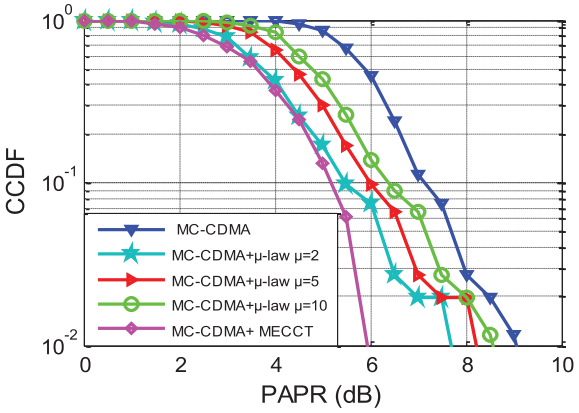

Fig 2. The MC-CDMA with μ-Law

The MECCT based system has better PAPR performance for Gold codes. The MECCT based system reduces the PAPR by 1.75 dB than the μ-law based system at μ=2 as shown in Fig 2.

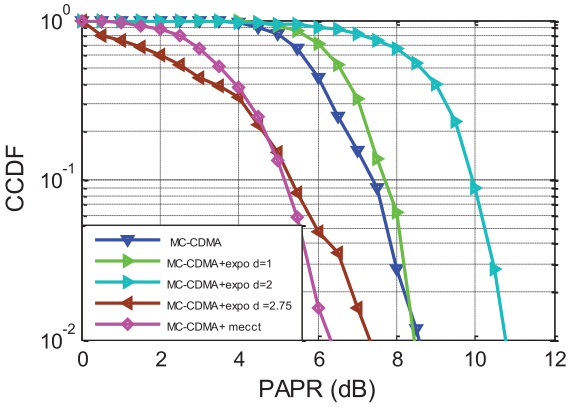

Fig 3. The MC-CDMA with exponential companding

In the MC-CDMA system with exponential companding with GOLD codes the PAPR reduces by 2.5 dB as compared to the MC-CDMA system at *d* =2.75 as shown in Fig 3. The PAPR performance of this system is better than that of the MECCT companding based system. When *d* value is above 3.0, its PAPR reduces by a maximum value.

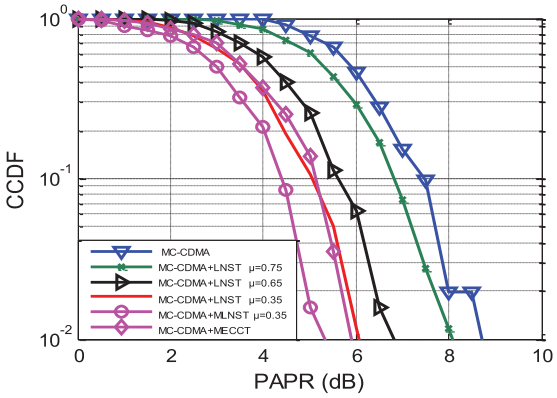

Fig 4. The MC-CDMA with LNST

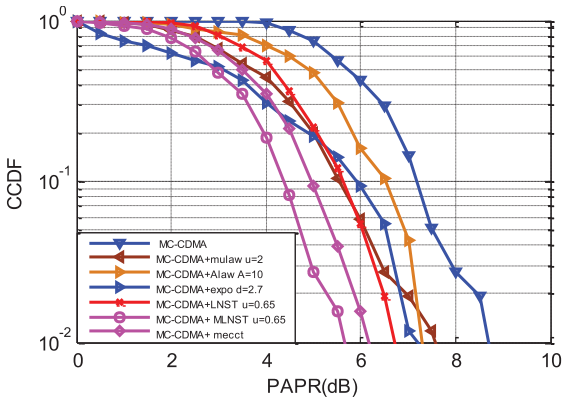

Fig 5. The MC-CDMA with different companding techniques

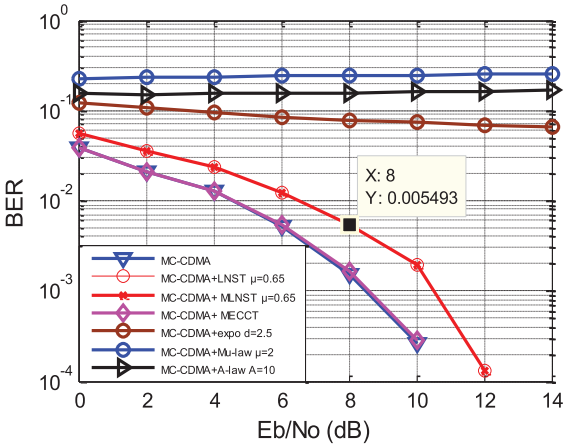

Fig 6. The BER performance of the MC-CDMA with different companding techniques over AWGN channel

The Fig 4 shows the MC-CDMA with LNST companding with Gold codes. In the MC-CDMA system with MECCT and MLNST companding, PAPR performance is better than in the LNST companding based system. MLNST companding based system, reduces the PAPR by 0.75 dB at μ=0.35 as compared to MECCT and LNST companding based system.

TABLE 1: Comparison of different companding techniques

MC-CDMA System with companding	Parameter		
	PAPR reduction in dB	*Power saving %*	*AWGN BER at 10 dB*
No companding	---	23	0.0002472
A-law	2.0	23	0.1606
μ-law	2.0	23	0.2488
Exponential	1.5	18.64	0.0729
LNST	1.0	11.76	0.001993
MLNST	3.0	35	0.001993
MECCT	2.50	29	0.0002472

In the MECCT companding based system PAPR reduces by 0.75 dB than in the MC-CDMA system with LNST companding. MC-CDMA system with MLNST companding reduces the PAPR by 0.5 dB as compared to the MECCT based system and 1.0 dB than the LNST based system as shown in Fig 5. The MECCT has lesser BER than the LNST, MLNST, Exponential, A-law and μ-law companding techniques. The MECCT based companding system has less BER than the LNST and other companding based systems as shown in Fig 6 and their parameters in Table 1.

VI. CONCLUSION

MECCT and MLNST companding techniques are employed with the MC-CDMA system to reduce the PAPR and to increase the BER performance over traditional techniques. Hence, this improves spectral efficiency. The MECCT based MC-CDMA system has less PAPR as compared to the MC-CDMA system.

This implemented method reduces the PAPR substantially by 2.5 dB as compared to MC-CDMA system. It saves bandwidth of 2.0 dB at the receiver as compared to the MC-CDMA system with LNST companding system over AWGN channel. The MECCT based MC-CDMA system has lesser spectral side-lobe generation as compared to the MC-CDMA and MC-CDMA system with LNST companding. The MECCT companding technique is of much less implementation complexity as compared to the exponential companding.

Abstract— The performance analysis of Alamouti space time block code (STBC) based orthogonal frequency division multiplexing (OFDM) assumes that the channel is constant over Alamouti code period (two consecutive OFDM symbol block). However, in fast fading channel, this assumption does not hold good and causes Co-channel Interference (CCI).To cancel the CCI effect, different detection methods are proposed earlier namely Successive Interference Cancellation (SIC), Zero Forcing (ZF), Decision Feedback (DF) and Maximum Likelihood (ML). These detection methods are performed by assuming that the complete channel knowledge is known at the receiver side. But, in practical scenario, the channel is unknown to the receiver. Hence, we have proposed a new channel estimation technique which estimate the channel and thereby cancel the CCI effect jointly.

Keywords—OFDM; STBC;CCI; Channel EStimation;

I. INTRODUCTION

Recently, the wireless communication system is more focused on reliability and spectral efficiency [1]-[2]. The link reliability is solved by STBC technique which is proposed by Alamouti [3]. Originally, the STBC technique is applied to flat fading channel and it is assumed that the complete channel knowledge is known at the receiver. But in practical scenario, the channel is frequency selective fading rather than flat fading and the channel knowledge is unknown to the receiver. This problem can be solved by applying OFDM technique to the STBC system as OFDM converts the frequency selective fading channel into many narrow parallel flat fading channels [4]. However, in time varying fast fading channel the Alamouti STBC-OFDM system undergoes two types of interfering namely inter-carrier interference (ICI) and CCI [5]. The ICI is occurred due to the loss of orthogonality among the subcarrier within the OFDM block. The CCI occurs due to the variation of channel frequency response (CFR) over Alamouti code period. Due to the CCI effect, the two consecutive transmitted OFDM symbol blocks are coupled with each other at the receiver side. Both the ICI and CCI cause significant performance degradation in time varying fast fading channel. However the power of CCI is proved to be 7 - 8 dB greater than the power of ICI regardless of the channel variation [5]. Hence, we only consider the CCI effect on the Alamouti coded OFDM system. In previous literatures, various detection methods have been addressed for cancelling the effect of CCI [5]-[8]. In [6], a diagonalized maximum likelihood detector (DMLD) is proposed to remove the CCI. But the DMLD method is more computational complexity. Hence, a similar performance with low computational complexity ZF detector is proposed in [7]. In [5] SIC method is proposed. The SIC method has a low computational cost but its performance is not accurate enough due to the error propagation problem. The decision feedback (DF) method is proposed for STBC/SFBC OFDM system in [8]. These detection methods are applied by assuming that the complete channel knowledge is known at the receiver side.

However, in such systems, CSI is required to be known at the receiver side in order to recover the transmitted signal. There are two approaches for channel estimation namely the blind channel estimation and pilot aided channel estimation. In blind channel estimation, the statistical properties of the received signal are required to recover the transmitted signal. Such system has high spectral efficiency as no pilot symbol is used for channel estimation. In case of pilot aided channel estimation, pilot symbols are known a prior to the receiver and are multiplexed with the transmitted data streams for channel estimation. As compared to pilot aided channel estimation, the blind channel estimation is limited to slow time varying channel, has higher complexity and poorer performance. Hence, in this paper, pilot aided channel estimation is carried out for channel estimation purpose. One of the main problems in pilot symbol aided channel estimation for MIMO OFDM systems is the inter-transmitter-antennas-interference (ITAI) [9]. The ITAI arises when two transmitted signal are mixed at the receiver side and hence it is difficult to separate these transmitted signals. There are two approaches to handle the ITAI problem namely zero-form and non-

zero form pilot pattern. This paper proposes a modified zero form pilot arrangement based on Alamouti principle to avoid the ITAI effect. Another important criterion of channel estimation is the interpolation techniques. Linear, spline, second order, low pass interpolation (LPI) methods have been investigated in [10] and demonstrated that pilot aided channel estimation based on low pass interpolation LPI gives the best performance among all the interpolation technique.

The proposed channel estimation is based on least square (LS) algorithm with modified zero-form of comb type orthogonal pilot structure at pilot subcarriers while the low pass interpolation method is applied at data subcarriers for STBC-OFDM system in time varying multipath fading channel.

The rest of the paper is organized as follows. In Section II, the system model for the STBC based OFDM system along with the channel model is discussed. The proposed channel estimation technique is presented in Section III. In Section IV, the performance of the developed channel estimation is analyzed. Finally, Section V concludes the paper.

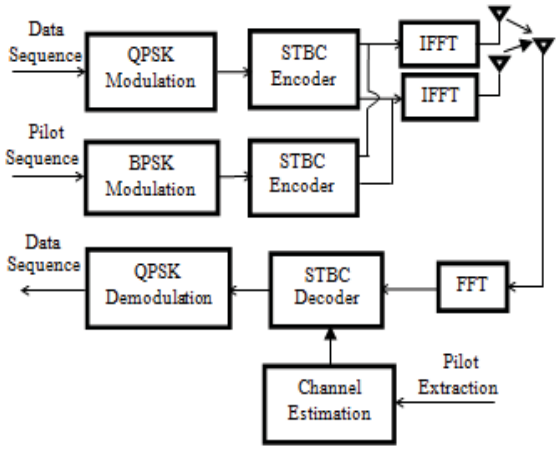

Fig. 1 Block diagram of STBC-OFDM system model

II. SYSTEM MODEL

Consider the QO-STBC proposed in [3] with 4 transmit In this section, an STBC based OFDM system with two transmit antennas and one receive antennas is described along with the exponential decaying Power Delay Profile (PDP) channel model as multipath Rayleigh fading channel.

A. System Model

The system model for STBC-OFDM with two transmit antenna and one receive antenna is shown in the Figure1. At the transmitter side, a random data sequence is generated and modulated according to any specific modulation scheme such as BPSK, QPSK or 16QAM. Then the output modulated data are passed through the STBC encoder. The STBC encoder converts the single input modulated information data into two parallel encoded output data according to Alamouti STBC scheme [3]. The Alamouti STBC scheme is described as follows. At the first time instant $X_1(k)$ and $X_2(k)$ are transmitted from the transmit antenna 1 and 2 respectively. In the second time instant $-X_2^*(k)$ and $X_1^*(k)$ are transmitted from antenna 1 and 2 respectively. Hence, the output of the STBC encoder can be written in matrix form and is given in bellow

$$X(k) = \begin{bmatrix} X_1(k) & X_2(k) \\ -X_2^*(k) & X_1^*(k) \end{bmatrix} \quad (1)$$

where $k = 0,1,2,\ldots\ldots N-1$

$X_1(k)$ is the k^{th} subcarrier for the transmitting antenna 1 before the IFFT operation and N is the number of subcarrier in a single OFDM symbol block. Then both the encoded output signal are passed through the serial to parallel converter(S/P) and finally reached at the Inverse Fast Fourier Transformation (IFFT) block. Finally, the resulting signals are transmitted from the antennas after insertion of the cyclic prefix (CP) which is assumed to be larger than delay spread of the multipath channel in order to avoid inter symbol interferences (ISI).At the receiver side, at first the CP is removed and then the received signal is processed by a Fast Fourier Transformation (FFT). The FFT output of the received signal after the removal of CP can be written in the matrix form and is given here

$$Y(k)=\begin{bmatrix} Y_t(k) \\ Y^*_{t+T}(k) \end{bmatrix} = \begin{bmatrix} H_{1,t}(k) & H_{2,t}(k) \\ H^*_{2,t+T}(k) & -H^*_{1,t+T}(k) \end{bmatrix} \begin{bmatrix} X_1(k) \\ X_2(k) \end{bmatrix} + \begin{bmatrix} Z_t(k) \\ Z^*_{t+T}(k) \end{bmatrix} = HX+Z \quad (2)$$

where $H_{1,t}(k)$ and $H_{2,t}(k)$ are the CFR for the first and second transmit antenna at the first time instant respectively. $Z_t(k)$ is the additive white Gaussian noise with zero mean and unit variance after the FFT operation.

It is to be noted that the channel is taken to be ideal where it is assumed that the perfect channel knowledge is known at the receiver side. According to Alamouti scheme, the channels are considered to be static over two consecutive OFDM symbol block, i.e., $H_{1,t} = H_{1,t+T}$ and $H_{2,t} = H_{2,t+T}$. The STBC decoding operation is performed by multiplying H^H on both the side of the equation (2), the original transmitted signal can be recovered after taking the hard decision of the decoded signal and can be written as

$$\hat{X}(k) = Q\left(\frac{\tilde{X}(k)}{\Phi(k)}\right) \quad (3)$$

where $\tilde{X} = H^H(k)Y(k)$

$$\Phi(k) = |H_{1,t}(k)|^2 + |H_{2,t+T}(k)|^2 = |H_{1,t}(k)|^2 + |H_{2,t+T}(k)|^2$$

$\tilde{X}$ is the decoded signal and Q denotes the hard

decision function. Hence, the two estimated signals $\hat{X}(k)$ are decoupled from each other at the receiver side.

However, in the fast fading channel, the channels are not same for two different time slots. Hence, $H^H H$ is no longer a orthogonal matrix and is given by

$$G = H^H H = \begin{bmatrix} \alpha_1(k) & \beta(k) \\ \beta^*(k) & \alpha_2(k) \end{bmatrix} \quad (4)$$

where $\alpha_1(k) = \left|H_{1,t}(k)\right|^2 + \left|H_{2,t+T}(k)\right|^2$

$$\alpha_2(k) = \left|H_{1,t+T}(k)\right|^2 + \left|H_{2,t}(k)\right|^2$$

$$\beta(k) = H^*_{1,t}(k)H_{2,t}(k) - H^*_{1,t+T}(k)H_{2,t+T}(k)$$

$\alpha_1(k)$, $\alpha_2(k)$ are the desired diversity gain terms and $\beta(k)$, $\beta^*(k)$ are the CCI terms. By multiplying G with FFT output of the received signal Y, the detected output signal vector can be written as

$$\tilde{X} = \begin{bmatrix} \tilde{X}_1(k) \\ \tilde{X}_2(k) \end{bmatrix} = \begin{bmatrix} \alpha_1(k)X_1(k) + \beta(k)X_2(k) + Z'_t(k) \\ \beta^*(k)X_1(k) + \alpha_2(k)X_2(k) + Z'_{t+T}(k) \end{bmatrix} \quad (5)$$

$\alpha_1(k)X_1(k)$ and $\alpha_2(k)X_2(k)$ are the desired signal. $\beta(k)X_2(k)$ and $\beta^*(k)X_1(k)$ are the CCI signal which are coupled with the desired signal at the receiver side. Hence, in order to accurately recover the original transmitted signal, these two CCI signal are to be cancelled.

B. Channel Model

In this paper, an exponential decaying PDP channel [11] is adopted for the STBC-OFDM system model. The channel is modeled as finite impulse response (FIR) with total L+1 non-zero path with zero mean and average power σ_l^2.

The channel can be expressed by

$$h_l = N(0, \frac{\sigma_l}{2}) + jN(0, \frac{\sigma_l}{2}) \quad (6)$$

where $N(0, \frac{\sigma_l}{2})$ is the zero mean with variance σ_l^2.

The power of multipath component decreases exponential. The first path of the model is chosen to be

$$\sigma_0^2 = \frac{1-\lambda}{1-\lambda^{L+1}} \quad \lambda = e^{\frac{T_s}{\tau_{rms}}} \quad (7)$$

The T_s and τ_{rms} are the sampling period and root mean squared delay of the channel. The energy of the l^{th} path can be written as

$$\sigma_l^2 = \sigma_0^2 \lambda^l. \quad (8)$$

Furthermore, each multipath is modeled as uncorrelated Rayleigh fading channel with Jakes sum-of-sinusoidal (SOS) model [12].

C. STBC-OFDM Detection Method

In the time varying fast fading channel, multiplying H^H with H does not give an orthogonal matrix. Therefore, a transform matrix (Ω) is multiplied with H matrix to make (4), an orthogonal matrix, and is given by

$$\Omega H = \mathrm{diag}(\varphi_1, \varphi_2) \quad (9)$$

where φ_1 and φ_2 are the complex number

After simplification of the equation (9), Ω can be written in the matrix form and is given here

$$\Omega = \begin{bmatrix} H^*_{1,t+T}(k) & H_{2,t}(k) \\ H^*_{2,t+T}(k) & -H_{1,t}(k) \end{bmatrix} \quad (10)$$

The φ_1 and φ_2 have the same value and is given by

$$\varphi = \varphi_1 = \varphi_2 = H^*_{1,t+T}(k)H_{1,t}(k) + H_{2,t}(k)H^*_{2,t+T}(k) \quad (11)$$

Substituting Ω in the place of H^H, the equation (2) becomes

$$\tilde{X} = \Omega Y = \mathrm{diag}(\varphi, \varphi)X + \Omega Z \quad (12)$$

The estimated original transmitted signal can be obtained by dividing the value of φ on both the side and taking the hard decision

$$\hat{X}_1(k) = Q(\frac{\tilde{X}_1(k)}{\varphi(k)}) = X_1 + Z \quad (13)$$

$$\hat{X}_2(k) = Q(\frac{\tilde{X}_2(k)}{\varphi(k)}) = X_2 + Z \quad (14)$$

The ZF method is simple and gives better result than Alamouti method as it simply forces the two CCI terms to zero.

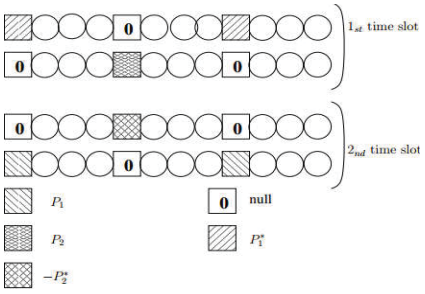

Fig. 2 Proposed pilot arrangement pattern

III. Coventional Detection Methods

The channel estimation for STBC OFDM is generally performed by assuming that the channel is constant over two consecutive OFDM symbol blocks. But in fast fading channel, the CSI are not identical for two different time slots i.e. $H_{1,t} \neq H_{1,t+T}$ and $H_{2,t} \neq H_{2,t+T}$. Hence, in order to perform perfect data detection, all the entire four channels ($H_{1,t}$, $H_{1,t+T}$, $H_{2,t}$ and $H_{2,t+T}$)

have to be estimated. To estimate the above mentioned four channels, we propose a new pilot scheme that avoids ITAI thereby facilitating perfect channel estimation. The proposed pilot scheme is shown in the Fig.2. The pilot subcarriers are designed in such a way that when one transmitting antenna transmits the pilot the other antenna is assumed to be silent and vice-versa. This assumption prejudicially avoids the ITAI effect. In this proposed method, the four channels are estimated independently thus cancelling the effect of CCI. The channel estimation is carried out by LS algorithm. After estimating the channel at pilot subcarriers LPI has been applied to estimate the channel at data subcarriers. LPI method is chosen for its better performance in fast fading scenario. The position of the pilot subcarriers during first time slot at antenna 1 is P_1 and at antenna 2 is P_2 respectively. Arrangement of P_1 and P_2 can be given as Equation (15) and (16) respectively

$$P_1 = \lfloor p_1, 0, p_3, 0, p_5, ...2N_p - 1 \rfloor \quad (15)$$

$$P_2 = \lfloor 0, p_2, 0, p_4, 0, p_6 .....2N_p - 1 \rfloor \quad (16)$$

Where, N_p stands for the total number of pilot subcarriers in a single OFDM symbol block. During 2nd time slot, antenna 1 transmits $-P_2^*$ and antenna 2 transmits P_1^*. The received signal in the frequency domain at pilot sub-carriers for 1st time slot (t = t) and 2nd time slot (t = t+T) can be written in Equation (17) and (18) respectively

$$Y_{t,p} = H^p_{1,t} P_1 + H^p_{2,t} P_2 + Z_t \quad (17)$$

$$Y_{t+T,p} = -H^p_{1,t+T} P_2^* + H^p_{2,t+T} P_1^* + Z_{t+T} \quad (18)$$

P_1, P_2 are inserted uniformly (with zero padded at alternate locations) in each OFDM symbol block. The H_{11}^p, H_{21}^p, H_{12}^p and H_{22}^p are the four CFR at the pilot subcarrier of the four different channel paths.

The four channels after LS algorithm are given by

$$H^p_{1,t} = Y_{t,p}(\text{odd postions}) / P_1(\text{odd Positions}) \quad (19)$$

$$H^p_{2,t} = Y_{t,p}(\text{even postions}) / P_2(\text{even postions}) \quad (20$$

$$H^p_{1,t+T} = -Y_{t+T,p}(\text{even postions}) / P_2^*(\text{even postions}) \quad (21)$$

$$H^p_{2,t+T} = Y_{t+T,p}(\text{odd postions}) / P_1^*(\text{odd postions}) \quad (22)$$

In order to estimate the channel at data subcarrier by using channel information at pilot subcarrier, the interpolation technique is needed. The LPI technique is applied as it performs the best in time varying channel [10]. After getting the four CFR at data subcarriers ZF detection technique has been applied to recover the original transmitted signal. We call the proposed channel estimation combined with ZF and Alamouti method as ZF and Alamouti estimated method respectively.

IV. SIMULATION RESULTS

The performance comparison of different detection methods including Alamouti, ZF methods for STBC based OFDM system is carried out on the basic of SER over various mobile speeds. The total simulation parameter used for simulation is listed on the Table1. The SER performance comparison of Alamouti and ZF detection method with perfect and proposed channel estimation scheme for normalized Doppler spread 0.03, 0.06 and 0.12 and are shown in the Fig 3, Fig 4 and Fig 5 respectively. The simulation result shows that Alamouti method suffers severe performance degradation due to CCI effect. The performance of ZF method is better than Alamouti detection method as it simply forces the CCI term to zero. The simulation results show that ZF estimated method gives better result than estimated Alamouti method. From the Fig 3 - Fig 5, it is seen that, when, the normalized Doppler frequency increases the SER increases drastically. From the simulation result, we also see that as the normalized Doppler spread increases, the estimated ZF method outperforms the perfect Alamouti method at high SNR.

Table1.Simulation Parameters

Parameter	Value
FFT Size	128
Number of Subcarrier	112
Number of CP	16
Pilot Spacing	1:8
Data Modulation	QPSK
Pilot Modulation	BPSK
Carrier Frequency	5GHz
Channel BW	1MHz
Subcarrier Spacing	7.8125KHz
Channel Model	Exponential decaying
Number of Multipath	3
Mobile speed	50/100/200 Km/h
Normalized Doppler frequency (F_dNTs)	0.03/0.06/0.12

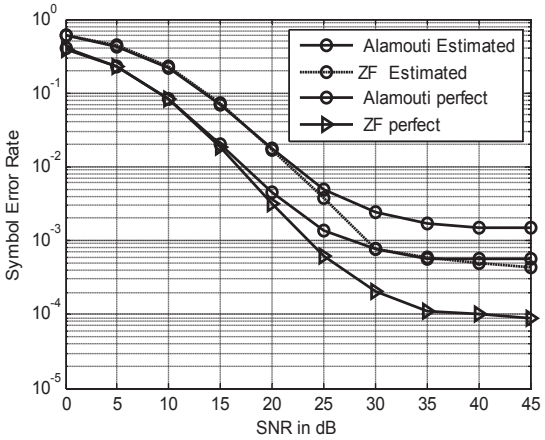

Fig. 3 SER performance comparison of Alamouti and ZF method with perfect and proposed channel estimation for normalized Doppler spread 0.03

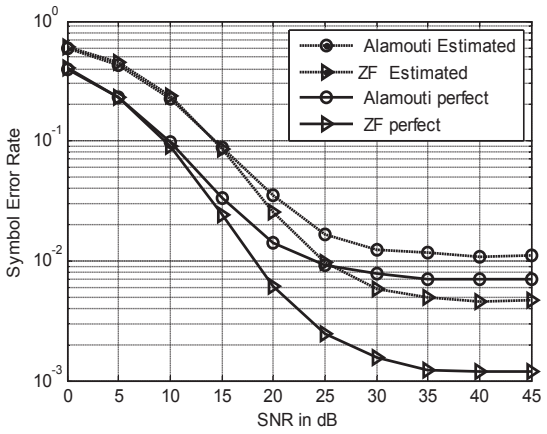

Fig. 4 SER performance comparison of Alamouti and ZF method with perfect and proposed channel estimation for normalized Doppler spread 0.06

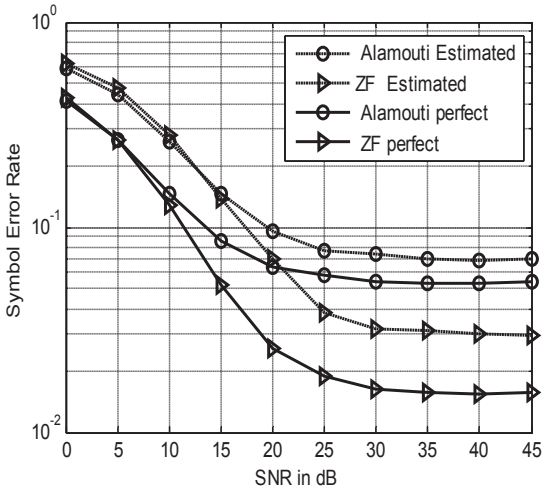

Fig. 5 SER performance comparison of Alamouti and ZF method with perfect and proposed channel estimation for normalized Doppler spread 0.12

V. CONCLUSIONS

In this paper, we have studied a combined effect of CCI cancellation and channel estimation for high mobility STBC-OFDM scheme. The proposed channel estimation method is based on LS algorithm with a modified zero form pilot arrangement based on Alamouti principle to avoid ITAI and there by facillating to estimate the entire four channels at pilot subcarrier and LPI method is applied at data subcarrier. Thus, by using the entire four channels, ZF detection technique has been implemented to recover the original transmitted signal by cancelling CCI effects. The disadvantage of the developed channel estimation method is that it suffers from spectral efficiency due to the insertion of zeros at alternative pilot location. This scheme can also be extended to other CCI cancellation schemes to improve the system performance.

***Abstract*— This paper presents visible light communication (VLC) based energy efficient lighting system in indoor parking area for illumination and at the same time the system would offer ubiquitous communication. Light emitting diodes (LEDs) based VLC is used for communication and illumination simultaneously. An attempt is made to optimize the positioning of LED emitters in the parking area on the ceiling to obtain the desired signal-to-noise ratio (SNR) and bit error rate (BER). Two lighting configurations in the parking area are discussed. We compare the power transmission from LED emitters, number of emitters, SNR distribution, BER and cost for both the configurations. Multi level pulse amplitude modulation (M-PAM) is used for modulation. Further, we compare M-PAM with on-off keying (OOK) to get the required SNR and power requirement to achieve the same BER.**

Keywords*—visible light communication, information and communication technology, light emitting diodes, multiple pulse amplitude modulation, Energy efficiency.*

I. INTRODUCTION

Providing lighting is one of the most important and expensive responsibilities of a city. Lighting can account for 10–38% of the total energy bill in typical cities worldwide [1]. The modern smart and intelligent information and communication technology (ICT) infrastructure plays very important role in developing a smart city which includes designing energy efficient public illumination systems such as road, street, parking, and offices [2]. It will save huge energy and budget for the city in developing countries because of its strategic importance for economic and social stability. This smart lighting system can be used simultaneously for illumination as well as ubiquitous communication.

Though various domains are targeted, an intelligent energy efficient parking system can be used towards the development of smart cities. This illumination system enables communication in the indoor parking area offering users to be connected with high data rate networks. The indoor parking system can be designed such that users are informed at the entrance about the availability of parking slot and assists in reaching to the slot smoothly. The networked illumination system can adjust the brightness accordingly in saving some additional energy. This is possible with LED-based illumination system which has already been said to be the future lighting system [4-5].

Recent advancements in solid state lighting (SSL) have triggered research in the domain of optical wireless communication (OWC) especially visible light communication (VLC) [3]. VLC uses visible light spectrum (380nm-780nm) normally emitted from LEDs. LED, being semiconductor device has inherent characteristic of high speed switching which makes this device suitable for data communication. LED-based VLC offers many other distinctive advantages such as low cost design, free from most popular radio frequency (RF) based system, harmless to human health and of course usage of license free spectrum. Furthermore, the LED is power efficient illuminating device. LED-based VLC can be used to offer ubiquitous communication even in the places where RF is not reachable such as underground, subway and even in indoor parking area. In these situations, remaining always connected becomes challenging.

Normally, the VLC LED emitter is designed with multiple LEDs to provide necessary illumination by the use of high brightness (HB) or white LEDs. Also, multiple LEDs can be used as multiple-input and multiple-output (MIMO) technique [7] which would support high data rate communication and would help designing a robust communication system.

In this paper, we have considered energy efficient illumination for indoor parking system. This illumination system can be used for data communication within parking area. We have optimized the positioning of LED emitters in a given parking area to achieve desired signal-to-noise ratio (SNR) for enabling communication as well as making the system energy efficient. Furthermore, we have analyzed the BER performance and power requirement. The M-PAM modulation technique is used and compared with OOK modulation performance.

The remainder of this paper is organized as follows. In section II, LED based visible light communication system discussed. The parking layout, related work and analysis are presented in the section III, while in section IV the results are discussed. Finally, conclusion is given in section V.

II. LED BASED VISIBLE LIGHT COMMUNICATION SYSTEMS

Visible Light Communication normally employs lighting sources (LEDs) as transmitters and utilizes photodiodes as receivers. In this analysis we consider only line of sight (LoS)

link. VLC transmitters modulate intensities of light at such high speed that human eyes cannot perceive any difference between before and after modulation. As a result, VLC transmitter can be used for lighting and data communication simultaneously. The emitted light travels through LoS link and intercepted by photodiode based receiver. The photodiode converts light intensity into electrical signal, which is then amplified and processed to obtain final output. The received power will normally be a function of transmitted power, distance between transmitter and receiver, receiver collecting area, field of view (FOV) of the receiver, channel gain and so on. We discuss this next.

A. Channel DC gains

The radiation pattern of LEDs approximates Lambertian pattern and Lambertian radiant intensity is given by [8-9]:

$$R_o(\emptyset) = \left[\frac{(k+1)}{2\pi}\right] cos^k(\emptyset) \quad (1)$$

where k is the order Lambertian emission, and given by semi-angle at half illuminance of an LED $\emptyset_{1/2}$ as:

$$k = -ln2/\ln(cos\emptyset_{1/2}) \quad (2)$$

The irradiance and incident angles are denoted as $\emptyset$ and φ respectively.

In an optical link, the channel direct current gain (DC) is given as:

$$H(O)_{LOS} = \begin{cases} (A_{rx}/d^2)\, R_o(\emptyset)\cos(\varphi) & 0 \le \varphi \le \varphi_c \\ 0 & \varphi > 0 \end{cases} \quad (3)$$

where A_{rx} is the detector area, d is the distance between the transmitter and receiver and φ_c is the field of view (FOV) of the photodiode.

B. Received power

At the receiver, light passes through the optical filter and concentrator, so the received power is:

$$P_{rx} = (P_{LOS} + P_{diff}) \times T_f(\varphi) \times g(\varphi) \quad (4)$$

where $T_f(\varphi)$ is the transmission coefficient of the optical filter, $g(\varphi)$is the concentrator gain. P_{LOS} is the total received power of i LEDs in directed path, given as:

$$P_{LOS} = \sum_{i=1}^{LEDs} P_{tx} H^i_{LOS}(0) \quad (5)$$

Here $H^i_{LOS}(0)$ is the i^{th} LED channel DC gain and P_{tx} is the transmitted power. P_{tx} is given as: $P_{tx} = P_{LED} \times R_o(\emptyset)$. The power emitted by the LED is P_{LED}. The received diffused power with receiving area A_{rx} is given as $P_{diff} = A_{rx} I$, where I is the total intensity.

C. Signal to Noise Ratio (SNR)

At the photodiode, the received optical power is converted into the electric current which is given as:

$$i = P_{rx} \times r \quad (6)$$

where r is the responsivity (A/W) of the photodiode. The SNR is given by:

$$SNR = \frac{(r \times P_{rx})^2}{\sigma^2_{total}} \quad (7)$$

where σ^2_{total} is the total noise variance and it is given by:

$$\sigma^2_{total} = \sigma^2_{shot} + \sigma^2_{amplifier}$$
$$= 2qR(P_{rx} + P_n)B_n + i^2_{amplifier} B_a \quad (8)$$

where $B_n = I_2 R_b$ is the noise bandwidth, P_n is the noise power of ambient light, R_b is the data rate, I_2 is the noise bandwidth factor and B_a is the amplifier bandwidth.

III. INDOOR PARKING SYSTEM MODEL

The layout of the parking system is considered as shown in Fig.1. It is consider as one way parking system i.e. car will enter at one end and will exit from the other end. The LEDs light will be fixed on the ceiling at different positions.

The system is investigated for two cases/scenarios: first, we consider that lights are placed on both sides (boundary wall) and second, over the aisle width on the ceiling towards the aisle length. The aisle length and module width are considered 100m and 16.5m respectively on x- and y- axis. The module width of parking area is selected based on both sided parking and one way aisle width. The space length and space width are considered 6.5m and 3.5m respectively. The height of the light from the surface is considered at 4.5m. The photodiode receiver is considered to be installed in front of the driver glass. The important parameters are listed in Table1. In this analysis we consider only LoS link.

A. Modulation Scheme

In this paper, M-level pulse amplitude modulation (M-PAM) is considered, where M denotes the constellation size with spectral efficiency of $R = log_2(M)$ bits/s/Hz. The M-PAM is compared with OOK modulation. The BER of unipolar M-

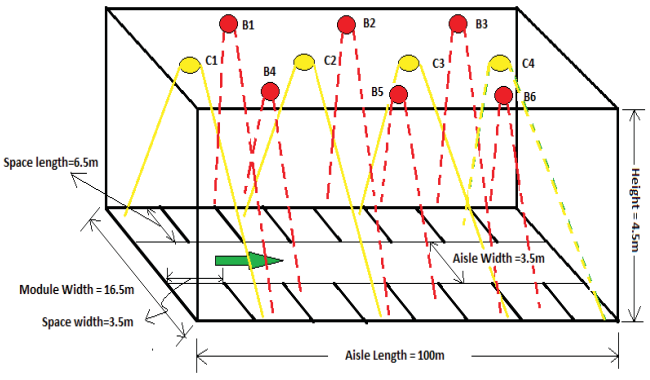

Fig.1: Parking layout/Model

PAM is given by:

$$\mathrm{BER_{M-PAM}} = \frac{2(\mathrm{M}-1)}{\mathrm{M}\log_2(\mathrm{M})}\,\mathrm{Q}\left(\frac{1}{\mathrm{M}-1}\sqrt{(\mathrm{SNR})}\right) \quad (1)$$

The BER for the case of OOK modulation is given as:

$$\mathrm{BER_{OOK}} = \mathrm{Q}\left(\sqrt{(\mathrm{SNR})}\right) \quad (2)$$

TABLE I. THE PARAMETERS OF THE SYSTEM MODEL

Parking area	$\boldsymbol{100m \times 16.50m \times 4.50m}$
Transmitters height	$4.50m$
Receiver height	$1m$
Semi-angle at half power	$22.5\ deg.$
FOV at the receiver	$15\ deg.$
Detector physical area of PD	$1\ cm^2$
Transmission co-efficient of optical filter	1
Refractive index of lens at PD	1.5
Photodiode responsivity	0.4
Amplifier bandwidth	$50\ MHz$
Wall reflectivity	0.7
Floor reflectivity	0.15
Ceiling reflectivity	0.8
Bit rate	$4\ Mbps$
Noise bandwidth factor	0.562
Amplifier noise density	$5pA/\sqrt{Hz}$
Ambient light photo current	$5840\mu A$

IV. RESULTS AND DISCUSSION

Investigation in this paper considers $\boldsymbol{100m \times 16.5m \times 4.5m}$ layout for the indoor parking system as shown in Fig.1. We tried to optimize the positioning of LED lights in a given area for the uniform SNR for the purpose to obtain acceptable data rate communication and uniform illumination. The transmitted power from each LED light is 25W. First, we consider that lights are placed on both side of the parking area. In this case, we placed 6 LED lights at the positions of $\boldsymbol{B1}$(17.5m, 3m, 4.5m), $\boldsymbol{B2}$(50.5m, 3m, 4.5m), $\boldsymbol{B3}$(83.5m, 3m, 4.5m), $\boldsymbol{B4}$(30m, 13.5m, 4.5m), $\boldsymbol{B5}$(60m, 13.5m, 4.5m), $\boldsymbol{B6}$(90m, 13.5m, 4.5m) on x-, y- and z-axis respectively.

The simulation result of SNR distribution is shown in Fig.2. It is observed that the desired SNR is obtained throughout the area. The minimum SNR is about 23dB which is at any corner and maximum SNR is about 48dB (just below the lamp), which is obvious. In fact, when we consider the data communication in the parking area and car/vehicle onboard, we have taken into account the driver seat place of the corner most vehicles which would be the furthest where the SNR is expected to be the minimum. Sometimes, it so happens that people stay back in the car and continue accessing Internet. In this situation also, we ensured that SNR value is high enough to enable BER performance. At the same time, the area is sufficiently illuminated to light up the entire space.

In the second case, we tried to place the lights on the ceiling over the aisle width area by considering 3-LED lights and 4-LED lights. 3-LED lights are placed at the positions of $\boldsymbol{C1}$(17.5m, 8.25m, 4.5m), $\boldsymbol{C2}$(50.5m, 8.25m, 4.5m), $\boldsymbol{C3}$(83.5m, 8.25m, 4.5m) on x-, y- and z-axis respectively. The layout is seen in Fig.1. The simulation result of SNR distribution for this case is shown in Fig.3. For this, we found the minimum SNR is about 20dB which is at corner end and maximum SNR is about 47.5dB. Furthermore, we placed the 4-LED lights at the positions of $\boldsymbol{C1}$(12.5m, 8.25m, 4.5m), $\boldsymbol{C2}$(37.5m, 8.25m, 4.5m), $\boldsymbol{C3}$(62.5m, 8.25m, 4.5m), $\boldsymbol{C4}$(87.5m, 8.25m, 4.5m) on x-, y- and z-axis respectively. The simulation result of SNR distribution for this case is shown in Fig.4. In this case, we observed the minimum SNR is about 24dB which is at the corner and the maximum SNR is about 47.5dB.

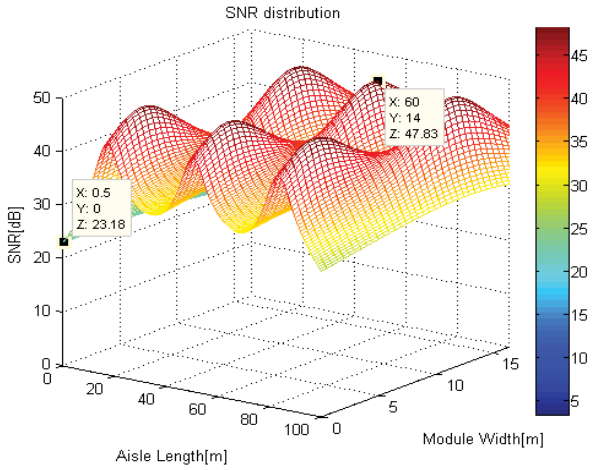

Fig.2: SNR distribution when both side LED lights are placed

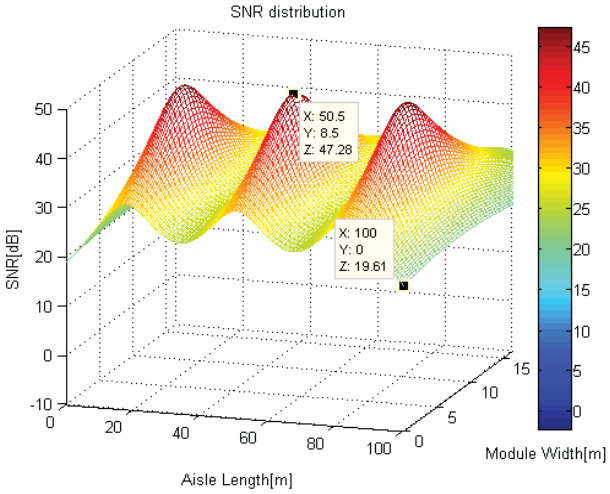

Fig.3: SNR distribution when 3-LED lights are placed over Aisle width

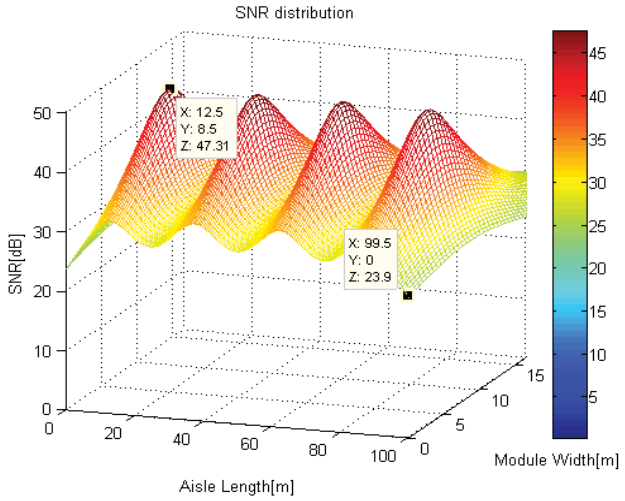

Fig.4: SNR distribution when 4-LED lights are placed over Aisle width

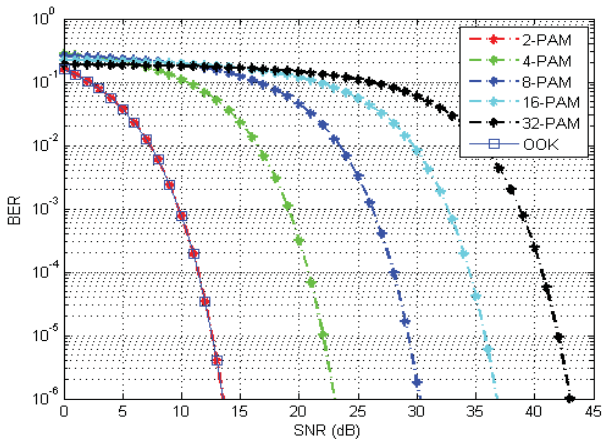

Fig.5: BER analysis of M-PAM and OOK

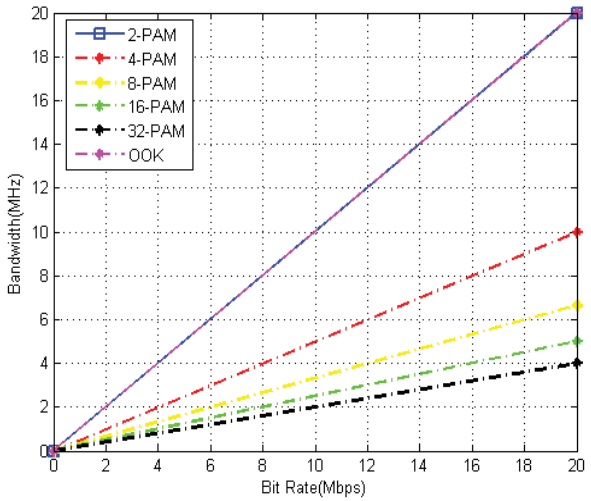

Fig.6: Analysis of bandwidth and bit rate

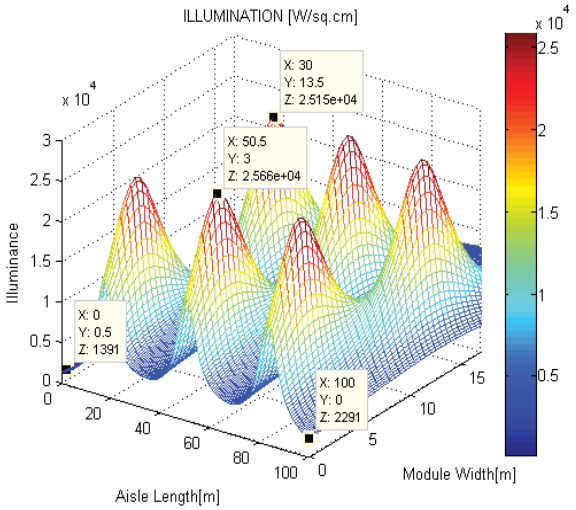

Fig.7 (a): Illumination with 6-LED lights

It is found that the desired SNR on overall surface in the parking area including corner points are obtained. And, it can be said that the second arrangement, where lamp posts are over aisle width, is found to be efficient in terms of energy.

We also investigated SNR value to support BER performance. We considered M-PAM for the modulation. The simulation result for BER for M-PAM is shown in the Fig.5. For the 2-PAM modulation, an SNR of about 14dB is needed to obtain a BER of 10^{-6} which is the same as OOK modulation technique. However, to obtain same BER, M-PAM needed SNR of about 23dB, 30dB, 36dB and 43dB when M = 4, 8, 16 and 32 respectively. However, M-PAM will offer high data rate transmission.

The bandwidth required to achieve the desired bit rate is shown in Fig.6. The OOK and 2-PAM gives the same performance in terms of bandwidth required for the bit rates. But with increase in *M*, bit rate improves and bandwidth decreases.

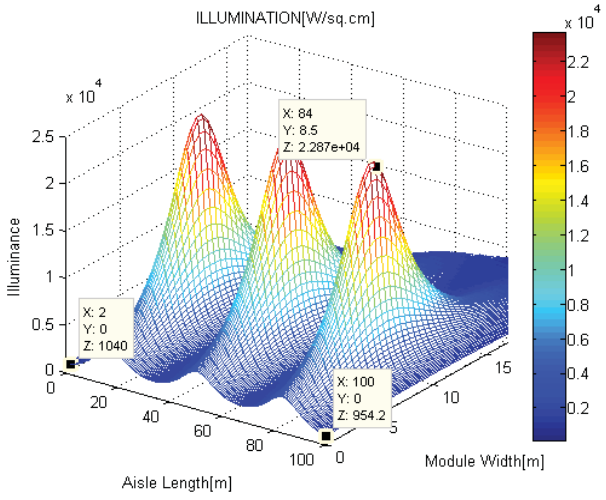

Fig.7 (b): Illumination with 3-LED lights

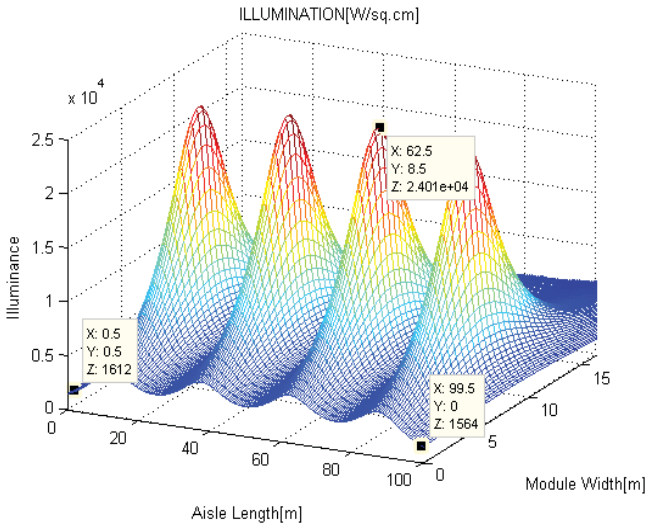

Fig.7(c): Illumination with 4-LED lights

TABLE II. CONFIGURATIONS ANALYSIS

Configurations	SNR(dB)		Illumination(W/cm^2)	
	Minimum	Maximum	Minimum	Maximum
6-LED LIGHTS	23	48	1391	2.566×10^4
4-LED LIGHTS	24	47.5	1564	2.401×10^4
3-LED LIGHTS	20	47.5	954.2	2.287×10^4

The illuminations for all the cases as discussed in section III are shown in Fig.7 (a)-(c). From the simulation, it is found acceptable illumination in all the cases over the surface. The SNR and Illumination analysis for the different cases are summarized in Table II. The minimum SNR and illuminance is observed at extreme corner area of the parking which is obvious. The minimum SNR of about 20dB is observed in all the considered configurations which is suitable for communication in the parking area. The maximum and minimum illuminations are observed about 2.566×10^4 W/cm^2 and 954.2 W/cm^2 respectively which will give proper illuminance over the surface in the parking area. Thus, LED lights can be used for illumination and at the same time for ubiquitous communication for the indoor parking systems. At the same time, the system is highly energy efficient.

V. CONCLUSION AND FUTURE WORK

The Illuminance over the surface in the parking area is analyzed for two different positionings of LED emitters. For all these positions, SNR distribution and BER performance is studied and analyzed with multi level PAM modulation technique. Further, it is compared with OOK modulation technique. The power transmission for each LED emitter is equal. So the transmitted power will be low if less number of LED emitters is placed and relatively it will be cost effective. We are in the process of finding an algorithm for automatization of placement of LED emitters for any given area depending on some inputs such as irradiation angle of emitters, receiver position and so on. We are also looking at devising suitable coding mechanism which can be efficiently and effectively used. We are also working on intelligent lighting in which all the lighting (VLC emitters) will be connected and intelligently switch adjust the intensity depending on ambient lights and motion detectors.

***Abstract*—Measured data for 5-minute, 1-minute and 30-second integration times are used to derive the power law model for 1-minute and 30-second data. These measurements are carried out in Durban (29°52'E, 30°55'S), South Africa over a period of 15 years, but segmented into three periods corresponding to the three different integration times. The measured conversion factors for conversion from 5-minute to 1-minute integration time are compared to global parameters and errors show that the global parameters may not be generalized for use globally. Furthermore, this paper proposes 30-second conversion factors for Durban. In addition, specific attenuation values on terrestrial networks are estimated for selected microwave and millimeter wave bands, namely Ku, Ka and 60 GHz.**

Keywords— Rain rate, specific attenuation, integration time, conversion factors

I. INTRODUCTION

Globally, both large and small corporate businesses are yearning for high speed and high capacity communication links for their business activities [1]. Additionally, Internet Service Providers (ISPs) and online broadcast companies rely on bandwidth scalability to provide high speed communication and high capacity data transfer to their clientele [2], [3]. This need can be fulfilled via the utilisation of high frequency communication channels available in the microwave and millimetre-wave bands. However, rainfall attenuation becomes more prominent when frequencies above 10 GHz are used - especially in tropical, sub-tropical and equatorial regions - which are often characterised by heavy rainfalls during some months of the year [3]. For successful design of satellite and terrestrial microwave systems, design engineers require sufficient information on rainfall attenuation for the region in consideration. This information can be estimated by analysis of rain rate data collected over that region for a relatively long period of time [1-4]. There is agreement that rainfall data with lower integration times provide more information for accurate prediction of rainfall attenuation. Consequently, for effective prediction of rainfall effects over radio links at microwave and millimetre bands, measured data with integration times at 1-minute and or lower, are important. They can be utilized to obtain rainfall distributions and useful conversion factors for effective radio planning.

Significant research work has been carried out associated with rainfall attenuation over South Africa, particularly in Durban, for radio propagation in microwave and millimetre wave bands [2], [4]-[7], [9]-[12]. Studies conducted on rainfall attenuation in this region were based on the microphysics of rain. In one of these studies, Odedina and Affulo [7] proposed rainfall zones for attenuation prediction based on International Telecommunication Union (ITU) recommendation P.837-4 nomenclature [8]. In their work, [7] also suggested that rain fading is severe in the north eastern provinces of South Africa compared to the western provinces. In a further experimental campaign on rainfall over South Africa, Owolawi [9] was able to develop rainfall rate contour maps for South Africa's locations for 5-minute to 1-minute integration times. This study buttressed the earlier investigations of Odedina and Afullo [7]. In addition, the rainfall drop size distribution (DSD) technique approach in [13] enhanced initial efforts on rain rate campaign over Durban. Alonge and Afullo [10] applied parameter estimation techniques to confirm that the lognormal and gamma DSDs gave the best characteristics of drop sizes over Durban. They further used this approach to establish the seasonal variability of DSDs in Durban. Their results predicted that summer and autumn seasons are periods associated with high probabilities of outages in wireless networks. A thorough examination of the overall work done in South Africa reveals that rainfall data used are mainly of one minute integration time [6], [11]. However, it has been shown that rainfall data with lower integration time of 30 seconds or less are important in outage prediction analysis for wireless networks [3]. It is with respect to this observation that this current study is undertaken.

Integration time, also referred to as resolution time, generally refers to the sampling interval of data archiving which is often dependent on the choice of the measuring instrument. In a number of research, integration times of 15 minutes, 10 minutes and 1 minute are mostly used [3], [9]. In locations where the equipment is incapable of sampling rainfall data at these high rates, one hour sampling time is often utilized – although this is not widely encouraged because resultant attenuation estimates are likely to be underestimated. Rainfall measurements with less than one hour sampling time provide better time series analysis of rainfall rate variation in the time domain. This is important for radio engineers

particularly in the determination of sufficient fade margins required to counter rain attenuation effects in microwave bands [4].

Rainfall rate measurements at any location could be obtained by collecting data over a period of time from national meteorological administrations. Alternatively, these measurements can be obtained from independent rainfall rate measurements by means of rain gauges, distrometers or radar with small integration times [12]. Among the choice of equipment, the rain gauge is prominent because it is easily installed and it is also inexpensive. Gauges at the surface measure the point accumulation of rain-water with a known time interval and provide the result as point rain rate i.e. accumulation per unit time averaged over some measurement [13]. Most common types of rain gauges include the standard (graduated cylinder) rain gauges, tipping bucket rain gauges, weighing precipitation gauges and an optical rain gauges.

In this study, rainfall data measurements were collected using the Joss-Waldv□gel (JW) RD-80 distrometer installed at the University of KwaZulu Natal, Durban, and the rain gauge data obtained from the South African Weather Service (SAWS). From these sets of data over Durban, inferences are made from rain rate cumulative distributions and their required conversion factors. The rest of this paper shall be as follows: Section II discusses the measurements and data processing; Section III examines rainfall cumulative distributions and conversion factors; Section IV discusses results associated with specific attenuation and Section V provides the conclusion of this study.

II. Measurements And Data Processing

Rainfall data collected over Durban are mainly archived data from the distrometer and the rain gauge over a period of time. These equipment have varying levels of accuracy and measurement errors and it is widely accepted that the distrometer has an improved sensitivity to rainfall measurements than the rain gauge [14]. The distrometer unit basically has two components: outdoor and indoor units. The outdoor unit is designed with droplet receiving area of 0.005 m^2 and is capable of processing rainfall data into 20 categorized channels via the indoor unit [15]. Each of these channels have rain drops with diameters ranging from 0.3 mm to 5.4 mm. The computation of rainfall rate is given by [6], [16]:

$$R = \frac{6\pi \times 10^{-4}}{A \times T} \sum_{i=1}^{20} {D_i}^3 C_i \quad [mm/h] \qquad (1)$$

where C_i and D_i are the number of rain drops and mean drop diameter (mm) in the ith class, respectively, A is the sample area (0.005 m^2), T is the sampling time given as 60 seconds and $v(D_i)$ is the terminal velocity of rain drop in m/s.

On the other hand, the tipping rain gauge measures the amount of rain when a reed sensor is triggered, signalling the tipping sequence. The rain gauge has a poor sensitivity especially at very low rainfall rates (< 2 mm/h), but, on the other hand, it is gives a more inexpensive way of collecting the rainfall data across the world.

In this study, rainfall measurements obtained from these equipment have integration times of 5-minutes, 1-minute and 30-seconds. The set of 1-minute (60-seconds) and 30-second data are both retrieved from the JW RD-80 distrometer. The 1-minute data was collected between October 2008 to December 2010, while the 30-second data was obtained between April 2013 and March 2015. The 5-minute rainfall data from SAWS over Durban was collected in the period 2001 to 2011 (11 years). Representative number of samples, as well as their periods of collection are summarized in Table I.

III. Cumulative Distributions and Conversion Factors of Rainfall Rate over Durban

This section discusses the analysis of rainfall data measurements at different integration times collected over Durban with the aim of obtaining their cumulative distributions. Furthermore, we employ regression analysis to determine relationships between data at different integration times.

The cumulative distribution represents an evaluation technique of identifying the percentage exceedence probability of rainfall rate required for optimal wireless service in a rainy medium. These probabilities enable communication engineers to determine the permissible fade margin levels required by base stations to reduce network outages during rainy periods. Generally, rainfall rate values for different locations, corresponding to 0.01% exceedence are of major interest to viability of satellite and terrestrial communication links. Hence this parameter is often referred to as $R_{0.01}$. From the data collected cumulative distributions are obtained for three categories of rainfall integration times as seen in Fig. I.

A. Rainfall Cumulative Distributions for Different Integration Times

Fig.1 shows the cumulative distributions for three integration times from 0.004% <P < 9.5% of rainfall rate exceedence. The three distributions have a similar shape profile, with the 30-second graph being a scaled version of the 5-minute graph with a factor greater than 1. It is then evident from Fig. 1 that the rainfall rate is proportional to integration time. This further proves that an instrument with a long sampling time can easily miss logging shorter peaks in the rain intensity, resulting in lower measured rainfall intensities per unit length of time.

In Table II, R_1 value for 30-second integration time is determined as 6.5 mm/h, $R_{0.1}$ = 24.7 mm/h and $R_{0.01}$ = 64.3 mm/h. For the 1-minute integration, R_1 = 5.8 mm/h, $R_{0.1}$ = 23.2 mm/h and $R_{0.01}$ = 59.5 mm/h. For 5-minute integration time, are R_1 = 3 mm/h, $R_{0.1}$ = 16.8 mm/h and $R_{0.01}$ = 55.2 mm/h. It is observed that the 30-second integration time presents more information by giving a higher value of $R_{0.01}$ of 64.3 mm/h. Thus, there is need to convert other higher rain rates to 30-seconds integration time.

TABLE I. Rainfall Measurement over Durban from Different Equipment

DATA SAMPLING TIME	SAMPLES	NUMBER OF YEARS	INSTRUMENT USED
30 seconds	45,657	2	Distrometer
1 minute	56,463	2	Distrometer
5 minute	20,459	11	Rain Gauge

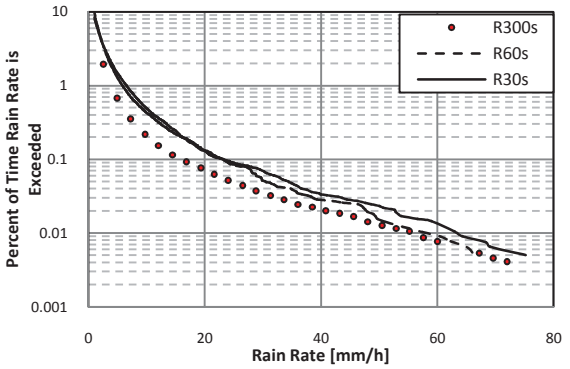

Figure 1: Cumulative distributions of rainfall rates for T-second integration time

TABLE II. PERCENTAGE OF RAIN RATE EXCEEDANCE FOR VARIOUS INTEGRATION TIMES OVER DURBAN

INTEGRATION TIME (sec)	PERCENTAGE OF RAIN EXCEEDENCE (%)					
	1	0.3	0.1	0.03	0.01	0.003
30	6.5	13.6	24.7	43.9	64.3	84.3
60	5.8	12.5	23.2	38.7	59.5	70.0
300	3.0	8.5	16.8	32.0	55.2	79.2

The $R_{0.01}$ determined was comparable to the ITU-R P.837-1 [11] predicted value of 63 mm/h for this region.

A summary of rain rate values of different integration times obtained over Durban for exceedence between 0.003% and 1% is presented in Table II.

B. Determination of Conversion Factors

In cases where data collection is done using other times, models have been developed for conversion of $R_{(\tau\ \mathrm{min})}$-values into $R_{(1\ \mathrm{min})}$-values as highlighted by [9], [17]-[19]. Conversion from a higher integration time values to 1-minute or lower rainfall rate integration time is very useful for development of rain rate models applicable in the prediction of rainfall attenuation at a given region [3], [20]. From the work of Ajayi and Ofoche [3], it was established that a power law relationship exists between the equiprobable rainfall rates of two integration times, given by:

$$R_\tau = u(R_T)^v \quad [mm/h] \tag{2}$$

where R is the rainfall rate, τ and T are integration times at the required and available rainfall rates respectively.

Segal [21] proposed a method of conversion that was expressed as the proportion of the equally probable rainfall rate,

$$\rho_\tau(P) = \frac{R_1(P)}{R_\tau(P)} \tag{3}$$

with conversion factor, $\rho_\tau(P)$, expressed as a power law

$$\rho_\tau(P) = aP^b \tag{4}$$

where $R_1(P)$ represents the rainfall rate at 1-minute integration time with the probability of occurrence P, $R_\tau(P)$ is the rainfall rate in τ-minute integration time, and the parameters a and b are coefficients regression analysis of rainfall data.

There are two main approaches used for rain rate conversion: use of equivalent rainfall rates or same probability of occurrence [22]. The method adopted in this paper is the use of same probability of occurrence. This approach is used on 5-minute data, 1-minute data and 30-second data collected over Durban. The three sets of data collected were used to generate conversion factors from higher to lower integration times using the power-law fit and are shown in Fig. 2 (a) - (c). These conversion factors are later compared in Table VI with those determined by other researchers in various regions of the world.

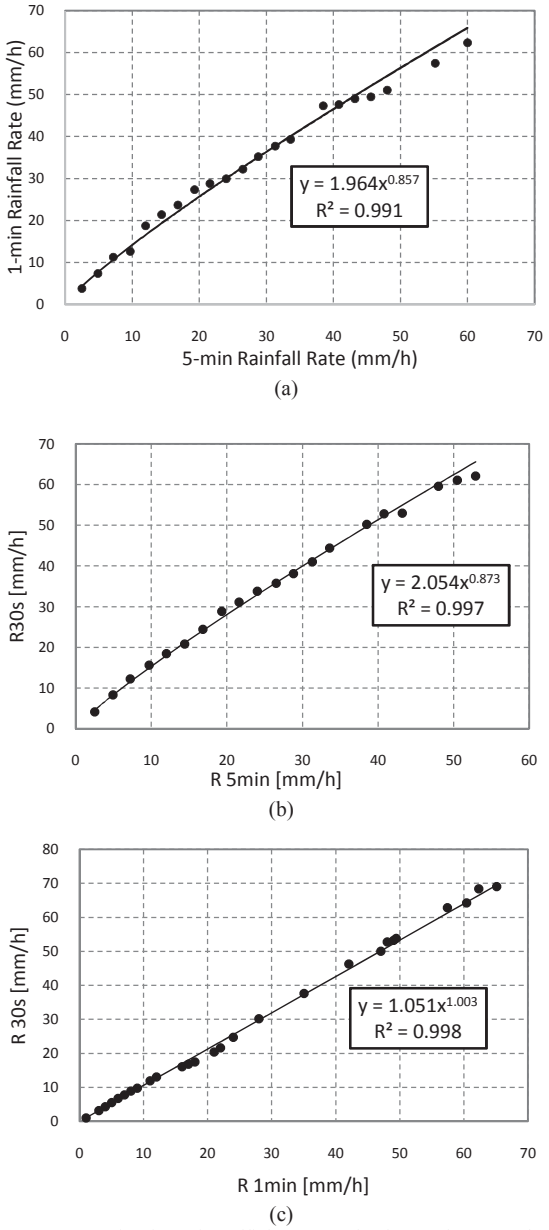

Figure 2: Determination of coefficients u and v for Durban, South Africa, in the conversion from (a) 5-minute to 1-minute, (b) 5-minutes to 30-seconds and (c) 1-minute to 30-seconds

Using (2), conversion coefficients for Durban were determined to be the following:

$$R_{30s} = 1.051{R_1}^{1.003} \quad (5)$$

$$R_{30s} = 2.078{R_5}^{0.868} \quad (6)$$

$$R_1 = 1.964{R_5}^{0.858} \quad (7)$$

where R_{30s} is the rainfall rate in 30 seconds while R_1 and R_5 are 1-minute and 5-minute times, respectively.

Estimates from our proposed rainfall rate conversion models should be representative of actual measurements. In this regard, our models in (5) - (7) were validated using the chi squared statistics (χ^2) test for goodness of fit. The function describing χ^2 is given in [23] as,

$$\chi^2 = \sum_{i=1}^{N} \frac{y_i - f(x_i)^2}{y_i} \quad (8)$$

where y_i and $f(x_i)$ are the measured and predicted values respectively, with N being the sample size.

Results from error analysis and power-law models describing the power-law conversion models are presented in Table III and Table IV. The chi-squared test was carried out at a confidence level of 0.05 and we obtained values of 2.0371, 1.0193 and 0.8452 from the three models in (5), (6) and (7) in that order. A comparison with chi-squared table showed that the three models passed the test and can be used for rainfall rate conversions in Durban.

From the power law relationship, Table V highlights comparisons of regression coefficients u and v obtained in this study with those determined previously by Ajayi and Ofoche [3] at Ile-Ife, Nigeria and Flavin [24] in Australia, USA, Europe and Canada. It is seen that the proposed model's coefficient u is higher than its counterparts from other regions of the world. Error analysis was done using $R_{0.01}$ value of 55.2 mm/h of the measured 5-minute data over Durban and the ITU-R P.837-1 [11] predicted $R_{0.01}$ value of 63 mm/h for Region M.

TABLE III. POWER-LAW CONVERSION COEFFICIENTS TO 1 MINUTE

Coefficients for $R_\tau = u(R_T)^v$, for τ = 60s					
T (Sec)	***a***	***b***	**R^2**	**RMS**	**CHI**
300	1.964	0.858	0.992	1.883	2.037[a]

[a]Significant level is given as 30.144, at DF = 19

TABLE IV. POWER-LAW CONVERSION COEFFICIENTS TO 30 SECONDS

Coefficients for $R_\tau = u(R_T)^v$, for τ = 30s					
T (Sec)	***u***	***v***	**R^2**	**RMS**	**CHI**
60	1.051	1.004	0.998	1.051	1.019[b]
300	2.079	0.868	0.997	1.324	0.845[c]

[b]Significant level is given as 38.885, DF = 26 [c]Significant level is given as 31.41, DF = 20

TABLE V. COMPARISON OF POWER LAW REGRESSION COEFFICIENTS WITH THOSE OBTAINED IN OTHER PARTS OF THE WORLD COEFFICIENTS

Coefficients for $R_\tau = u(R_T)^v$, for τ = 1 min				
Model	T (Min)	*u*	*v*	Error (%)
AJAYI [3]	5	0.991	1.098	28.6
OWOLAWI [7]	5	1.062	1.051	13.9
FLAVIN [25]	6	0.990	1.054	7.7
Proposed	5	1.964	0.858	2.6

Ajayi and Ofoche [3] model resulted in an error of 28.6%, the Owolawi [7] 13.9%, Flavin [24] model 7.7% and the proposed model in (7) produced an error of 2.6%. The highest error is thus observed from Ajayi and Ofoche [3] model. The tropical climate of Ile Ife, characterized by heavy rainfall, is largely a factor contributing to this large error. From Table V, it is observed that the Flavin [24] model is closer to the measurements in Durban with an error of 7.7%.

IV. CALCULATION OF SPECIFIC ATTENUATION VALUES OVER DURBAN, SOUTH AFRICA

Arising from the need for high capacity and high speed communication links, Ku, Ka and V bands are utilized for both terrestrial and satellite communications such as wireless broadband access (WBA), multipoint video distribution services (MVDS) and other broadband services [1]. The major challenge in operating at these higher frequencies is high signal attenuation resulting from signal absorption in high intensity rain rates. To address this setback, specific attenuation values were determined at Ku, Ka and 60 GHz bands as summarized in Table VI. The 60 GHz channel is unlicensed band that has been identified for use in short range wireless communications due to its high speed capability and frequency reuse [25].

ITU-R P.838-3 [26] provides the procedure for the calculation of specific attenuation on the link as given in (9):

$$\gamma_R = kR^{\propto} \quad [dB/km] \quad (9)$$

where R is the rain rate in mm/h at probability of exceedence while k and α are functions of polarization and frequency provided by [26].

Results of calculated specific attenuation at 1-minute integration time for Durban at Ku (12 GHz), Ka (30 GHz) and 60-GHz bands are presented in Fig. 3. From this figure, it is observed that the three curves have the same shape profile but with specific attenuation values at 60-GHz band being higher than those at 12 GHz and 30 GHz. As an example, at the same probability percentage exceedence of 0.01%, the specific attenuation is 2.99 dB/km at 12 GHz, 11.58 dB/km at 30 GHz band and 19.65 dB/km at 60 GHz band. This shows that specific attenuation due to rainfall increases as frequency of operation increases as expected. This implies that a consequent increase or decrease in rainfall rate also affects the system availability. As a result, the occurrence of high rainfall

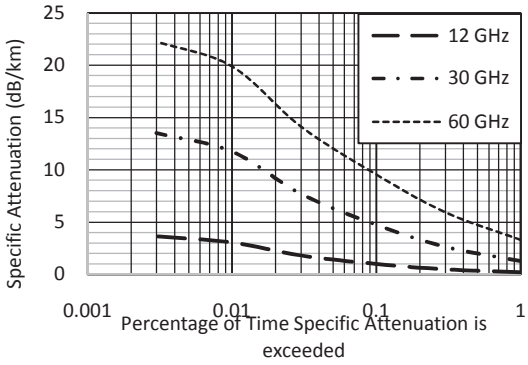

Figure 3: Computed specific attenuation exceeded for different percentages of time using 1-minute integration time data over Durban

rate in Durban will affect the performance of radio links due to measured attenuation caused by rain.

V. CONCLUSION

Using the power law relationship between equiprobable rain rates of two different integration times, we have obtained measured and predicted values of rainfall rate exceeded for 0.01% of the average year at 1-minute integration time that are comparable to ITU-R P.837-1 predicted value of 63 mm/h for Durban, South Africa. Power law models obtained at Durban, South Africa, can be used by other regions in similar climatic regions to convert rainfall rate statistics from higher integration times of 5 minutes and 1 minute to 30 seconds, respectively for more accurate prediction of rainfall attenuation especially in South Africa.

***Abstract*—Human detection is one of the important and fundamental steps in advanced applications like human activity analysis, gait recognition, human centric surveillance, intelligent video surveillance system, etc. Inaccurate detection of human in all these application leads to false alarms. The proposed method consists of four steps namely; moving object detection, blob detection, feature extraction and classification. Moving object detection is done by performing background subtraction technique which uses fuzzy logic approach. After performing background subtraction blobs are identified. Then blob feature extraction is done by using simple and efficient features like height, width, number of black and white pixels. These features are trained using Support Vector Machine (SVM). The Support Vector Machine is capable to learn all features of blob, and it is used for human or non-human classification. The system is tested on INRIA and PETS 2000 standard data-set.**

Keywords*—Object Detection; Blob Detection; Feature Extraction; SVM classification

I. Introduction

Over the recent years, detecting human beings accurately from video scene of a surveillance system is attracting field due to its wide range of applications in event detection, human gait characterization, person identification, gender classification, etc. Video surveillance system having two sub-problems, one is detection of moving objects and another one is determining whether moving object is human or not.

For moving object detection there are three basic approaches used: Background subtraction, Temporal differencing, and Optical flow. Background subtraction is one of the most popular approach for moving object detection. This method consists in finding the difference of current frames with respect to a background frame in order to detect pixels whose difference is greater than threshold value [1]. A popular mixture of gaussian technique for background subtraction approach consists in modeling each pixel with a Gaussian distribution [2]. The adaptive version of this algorithm works well when the background is dynamic. Temporal differencing approach for moving object detection simply takes difference between previous and next frame, if this difference is greater than threshold value, then moving object is detected [3]. Optical flow is another approach for moving object detection. This approach calculate motion of field, and flow distribution characteristics of image using different methods to estimate optical flow. Optical flow approach is sensitive against noise, and it is highly complex [4]. Lijun, Xiao proposed an approach for moving object segmentation using fuzzy logic algorithm [5]. Basically the fuzzy logic algorithm is used for thresholding as well as background updation part. Object segmentation is done using background subtraction which uses fuzzy approach, that is responsible for improving segmentation accuracy and reducing under-segmentation problem. In [6] Gambhir, D and Manchando presented an algorithm that automatically segment moving object in video by creating multiplicative mask, and it contains less number of noisy, false pixels. The segmented object tracked via color features, and then position of moving object predicted using kalman filter. In [7] Kalyan Kumar, and Pankaj Kumar has presented an approach for moving object detection using simple thresholding technique for background subtraction. This scheme depends on two basic algorithms; the first algorithm models background depends on first few frames, and second algorithm extract moving object based on simple thresholding. The strength of this simple thresholding technique is lies in it's simplicity, and intensity range for each pixel location define in background.

There are different methods to detect human beings from video. Template based human detection method is based on predefined template dataset defined by users. In [8] Zhujie and Yu has presented face recognition method based on eigen face technique. This face recognition method works in two part. The first part is responsible for constructing eigen faces of training images, and second part include test images that is recognized by computing the euclidean distance. In [9] Ali, Syed Sohaib and Zafar has presented method for human detection and recognition. This approach uses very effective features such as area, perimeter, centroid, principal axis of inertia for classification part. In [10] Osuna, Edgar, and Federico Girosi has presented an application for face detection using support vector machine. Support vector machine is responsible for determining appropriate class, either human or non-human. Kong, Yinghui, and Lei wang [11] proposed a method for moving object classification based on feature combination and Support Vector Machine. The method for moving object classification includes various steps such as object detection, post processing, feature extraction and SVM classification. Mahapatra, Tusar Kanti Mishra [12] proposed scale and view invariant approach for human detection based on template dataset. Scale and view invariant contour features like distance, angle, and cord to arc ratio are effective for template based human detection from video. The proposed human detection method requires following four steps; (a) Moving Object Detection, (b) Blob Detection, (c) Feature Extraction, (d)

SVM Classification. Rest of the paper is presented as follows. Section II is the discussion about system architecture and it's implementation details. Section III introduces comparative analysis and discussion. Section IV is all about experimental evaluation part. Section V is all about conclusion and future scope of the work. Fig. 1 shows flow for proposed human detection system.

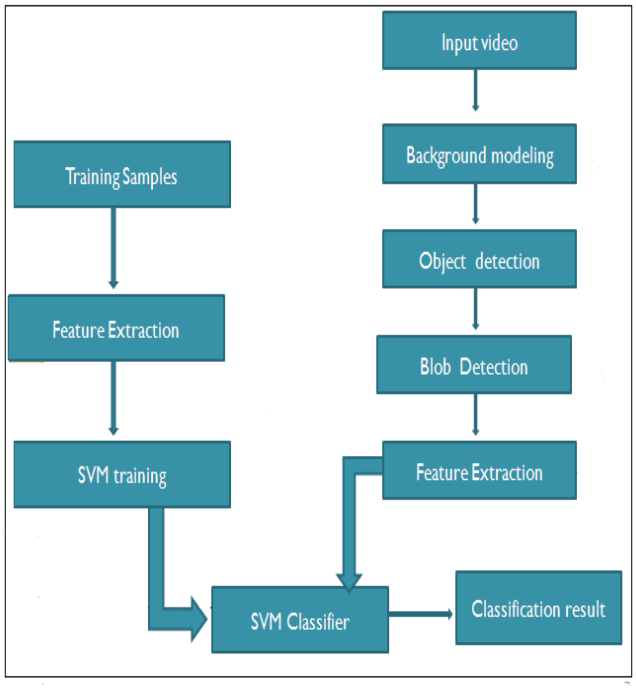

Fig. 1. Human Detection System

II. System Architecture

For human detection, the first essential step is to detect moving object from video, and then classifies it to human or non human.

A. Frame Extraction

The frame extraction module takes video as input and produces number of frames based on time delay between frames. The number of maximum frames depends on length of video and time delay between frames. Mathematically, this is shown in eq (1).

$$X_n: n>1 \ \& \ n = \text{Video length} / td, \ \& \ td > 1 \qquad (1)$$

Where,

- X_n is the n^{th} frame.
- n is the number of frames required.
- td represents time delay between frames.

Table I shows number of extracted frames that mainly depends on video length and delay factor.

TABLE I. Frame Extraction

Video Set	Size(MB)	Length (sec)	fps	Time delay(msec)	Number of frames
1	6.23	58	19.40	50	1161
2	6.23	58	25.0344	40	1452
3	6.23	58	33.3793	30	1936
4	6.23	58	1	1000	58
5	6.23	58	2	500	116

B. Background subtraction

Background subtraction is process of separating out foreground objects from maintained background model. The proposed background subtraction method uses fuzzy logic approach for calculating background frames. A foreground object is an entity that is separated based on minimum and maximum frame. For background model creation, consider first N numbers of frames are background frames, where all these background frames doesn't contain foreground objects. Apply fuzzy logic on these background frames. Let {f1, f2,..., fN} be the fuzzified background frames, which are used for background modeling part. After getting fuzzified background frames, calculate minimum and maximum background modeling frames. When new frame comes with foreground object each pixel of frame is applied to fuzzy inference system, if pixel value is in between minimum and maximum then consider background pixel, otherwise foreground pixel. Mathematically foreground or background separation is shown below in eq (2).

$$a(i, j) - \alpha < i < b(i, j) + \alpha \qquad (2)$$

where α is very useful parameter in variety of illumination conditions, and it's value is constant, a (i, j) is the minimum frame, while b (i, j) is maximum frame, and i is the fuzzified pixel value of current frame. The value of minimum frame a (i, j) and maximum frame b (i, j) is calculated from first N fuzzified background frames. The proposed fuzzy background subtraction approach directly works on color video, so that is the main reason, this background subtraction approach is efficient one. Using this proposed background subtraction method, there is no need for post processing of frames. Each pixel having three different values (i.e. for red, green, and blue) are given to fuzzy inference system for calculating fuzzified pixel value as shown in Fig. 2. A fuzzy inference system consists of four main parts: fuzzification, rule base, inference engine, and defuzzification. The basic steps required for fuzzy logic algorithm are shown in below:

1) Define the linguistic terms and variable, that comes under initialization part.
2) Then construct the membership functions, that comes under initialization part.
3) Then construct the fuzzy rules, that comes under initialization part.
4) First step is convert the crisp input data to fuzzy values using defined membership functions, that is the part of fuzzification.
5) Second step is to evaluate the rules in the rule base.
6) Third step is to combine the results of each rule, that is the part of inference engine.
7) Last step is convert the output data to non-fuzzy values, that is the part of defuzzification.

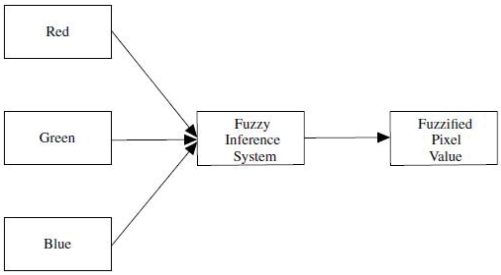

Fig. 2. Fuzzified pixel value calculation

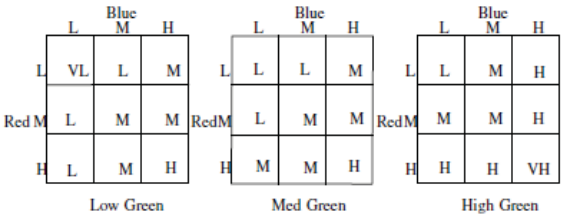

Fig. 3. Fuzzy Rules

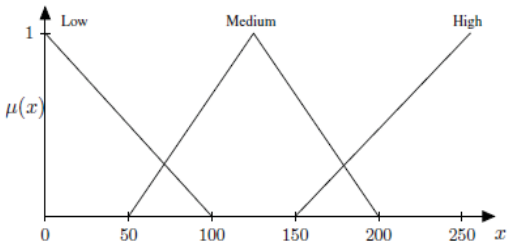

Fig. 4. Membership function for red color

Fig. 3 shows fuzzy rules, and the abbreviation for these rules are L-Low, M-Medium, H-High, VL-Very Low, VH-Very High. There are various types of membership function such as Triangular, Trapezoidal, S, Gaussian etc. [13]. Fig. 4 shows Triangular membership function for red color. This membership function having three linguistic term Low, Medium, and High. After fuzzifying inputs, fuzzy rules in the form of (if.... then) are applied for calculating final crisp value. The proposed fuzzy background subtraction method is compared with simple thresholding technique [7]. Fig. 5 shows the result of simple

Fig. 5. Result of Simple background subtraction technique using thresholding method. [7]

background subtraction technique using thresholding approach, while Fig. 6 shows proposed fuzzy logic based background

Fig. 6. Result of proposed fuzzy logic based background subtraction technique (without any post processing (a) with α = 5, (b) with α = 10 and (c) with α = 20).

subtraction approach.

C. Blob Detection

After completion of background subtraction method, object is detected. Once moving object gets detected, then capture the blob of respective moving object as shown in Fig. 7. Blob is defined as a collection of bunch of pixels within region. Whereas blob is analysed based on the identification

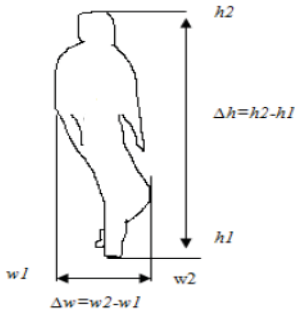

Fig. 7. Identified Blob

of connected pixel regions from the image. The blob detection algorithm distinguishes pixels by their value and mark them in two categories: white blob (foreground) or black blob (background).

D. Feature Extraction

Feature extraction holds an important stepping stone to pattern recognition and machine learning problems. To recognize and classify an object in an image, first extract useful features out of the image. Feature extraction is necessary step for extracting image attribute, to identify or interpret meaningful object from image. Four important features like height, width, number of black and white pixels are extracted from blobs of human and car. These four features are converted into two features i.e. aspect ratio of height to width, and aspect ratio of number of black to number of white pixels.

1) Width: This feature is calculated having difference of Leftmost pixel and Rightmost pixel.
$$\Delta w = w2 - w1$$
2) Height: This feature is calculated having difference of Topmost pixel and Bottommost pixel.
$$\Delta h = h2 - h1$$
3) Aspect Ratio (W/H): It is the ratio of width to height.

$\Delta w/\Delta h$

4) Aspect Ratio (B/W): It is the ratio of number of black pixel to number of white pixel.

E. SVM Classification

In recent years, SVM classifier is very effective for solving classification and regression problems [14]. The features of human and non-human blobs are given to support vector machine training part. Support vector machine is capable to learn all those features. In training part these features are divided into two classes using SVM linear kernel function i.e positive and negative class. In proposed method of human detection, SVM is based on a linear classifier in a high dimensional feature space, which has allowed the development of somewhat fast training techniques, even with a large number of input variables and training datasets. In proposed method support vector machine classifies the objects either as a human or non-human.

III. Comparative Study and Discussion

In the recent, there were several systems have been developed for human detection from videos. That are almost similar approaches, the proposed algorithm performed better in terms of detection accuracy rate. Lipton et.al. [14] used

TABLE II. Comparison of Classification Accuracy With Existing System

Sr.No	Algorithm	Detection Accuracy
1	Moving Target Classification and Tracking From Real Time Video [14]	82.80 %
2	Moving Target Classification in Video Sequences based on Feature combination and SVM [15]	80%
3	Human Motion Detection Using Fuzzy Rule base Classification of Moving Blob Regions [16]	93.75%
4	Proposed Method	95.22 %

a simple multi-feature classification approach with features like dispersedness, area and detection rate of 82.8%. Kong, Lei Wang [15] had obtained 80% detection rate of human and car. Table II shows comparative analysis with existing system. See, J., Lee [16] had obtained 93.75 % detection rate of human motion. On other hand, we introduced a novel and efficient approach for moving object detection using fuzzy logic algorithm, and support vector machine classifier gives 95.22 % classification rate of human and non human.

IV. Experimental Evaluation

The proposed system uses standard dataset INRIA and PETS 2000. The dataset comprises .avi or .mp4 videos having any size, duration 1-58 seconds, and with 2-27 frames per second. The SVM classifier was trained using 800 blobs. Among these, 500 were positive samples indicating human blobs and rest 300 were negative samples indicating car blobs for training. Table III shows classification rate of moving object. INRIA and PETS 2000 dataset used in this experiment is tested over 8 different videos that contain 2 objects (i.e human and car). Among these 6 videos contain only human and other 2 videos contain only car. Results analysis for all these scenarios are given in Table III.

TABLE III. Classification Rate of Different Moving Objects

Sr.No	Moving Object Class	Total number of blobs	Detected human blobs	Detected car blobs	Classification accuracy
1	Human	48	44	4	91.66 %
2	Human	77	72	5	93.50 %
3	Human	58	55	3	94.82 %
4	Human	62	59	3	95.16 %
5	Human	64	60	4	93.75 %
6	Human	80	74	6	92.50 %
7	Car	38	0	38	100 %
8	Car	80	3	77	96.25 %

A. Sample output

In output part video contains human. The red line depicts detected blob, that gives result human. Figure 8 gives classification result.

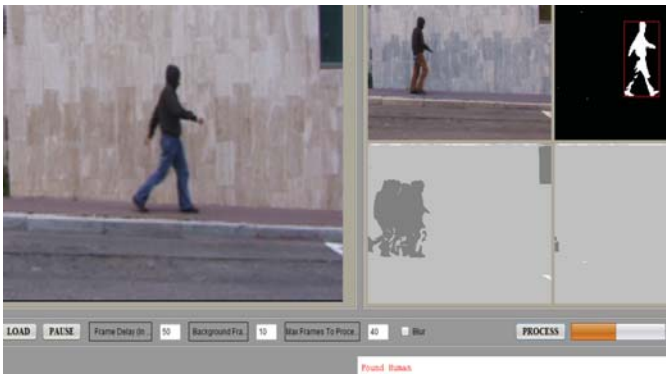

Fig. 8. Classification result of sample video

V. Conclusion and Future Work

A method for human detection in video sequences is based on mainly two aspects: Fuzzy approach for moving object detection, and Support Vector Machine is used for moving object classification. In this paper, a novel and efficient approach for background subtraction using fuzzy logic is presented. Features are extracted after detecting the blobs. These features are given as input to Support Vector Machine (SVM) to classify the object, whether it is human or non-human. SVM is used as a binary classifier, means it is used for human and non-human classification. The proposed human detection system have many aspects that can be improved in future. This system will further used for object tracking and recognition purposes. The background subtraction approach for moving object detection can be extend to various image conditions (lighting or long-term scene changes), and moving camera dataset. The objects detected are classified for only two classes, in future this could be extended to multiple classes.

***Abstract*—In this paper, a visible light communication (VLC) is analyzed for highly accurate indoor localization, high data rate information transmission while performing the function of illumination. All the functions are simultaneously achieved. The light emitting diodes (LEDs) working as VLC emitters are installed on ceiling which are placed at optimal position in order to provide uniform signal-to-noise ratio (SNR) in the entire considered area. Through analysis and simulation work, it is shown that with simplified overall system, the performance for all the functions can be optimized. The positioning error is small maximum to a few centimeters and at the same time bit error rate (BER) performance is very high.**

Keywords-visible light communications; indoor localization; received signal strength

I. INTRODUCTION

Visible light communication (VLC) is an emerging noble kind of optical wireless (OW) broad band communication technology [1]. VLC uses unregulated and unlicensed visible spectrum (380nm-760nm) of light normally emitted from light emitting diodes (LEDs) for information transmission wirelessly. VLC is particularly becoming popular for its simultaneous dual function i.e. illumination as well as high data rate transmission. In addition, it offers many other advantages leveraging from the advancement and usage of LEDs. For example, promotion of green technology, power efficient, cost effective design, no electromagnetic interference, highly secured and many more.

LED-based VLC has a number of interesting and novel applications both indoor and outdoor. While in outdoor, it can be an integral part of intelligent transportation systems (ITS) [2], road illumination and communications; in the indoor VLC can be designed for high data communication system, such as offloading data along with WiFi for upstream data in simple system, parallel communication and so on. In addition, VLC is also being considered for indoor localization. Some of the recently reported studies [3-5] reveal high accurate localization using same LED-based illumination system. This particular application of VLC is drawing reasonable attention from researchers worldwide since the most popular and widely used global positioning system (GPS) does not guarantee the accuracy in the indoor or even unable to find position of the object. Though, there are different methods based on WiFi, Bluetooth in association with cellular like GSM being examined and investigated [4]. Even radio frequency identification (RFID), Infrared (IR) and ultrasound based system is also reported [6]. These methods include variation in regard to accuracy, complexity and cost. In other hand, the optical wireless especially VLC can offer very high accuracy positioning in terms of centimeter (cm) and millimeter (mm) without significant change in existing infrastructure. Indoor navigation using LED-based VLC offers eco-friendly illumination based communications.

Indoor localization is an interesting and potential application of VLC. It would help a person to track an object within a museum or shopping mall by making use of handheld devices incorporated with VLC receiver. On considering the future scope many organizations focus on research based activities into indoor localization. LED light bulbs acting as VLC transmitters utilize its excellent characteristics for indoor localization with photo-detector as optical receiver.

There are different positioning algorithms such as triangulation and proximity [5-8] and they have different accuracy and complexity. We have used the triangulation, a more generic and relatively accurate method for location estimation. It consists of lateration and angulations. The former estimates the target location by measuring received signal strength (RSS) to find distances between the target (object integrated with VLC receiver) and several reference points (light source working as VLC emitter in this case). The later, angulations measure angles relative to several reference points and finds out estimated distance to find the location.

Authors Zhang et al [5] used RSS based triangulation techniques to find the estimated location. However, they did not consider communication aspect and the main focus was precise location detection. Authors have neither considered the energy optimization of the system. Though they used 4-set of LED illuminated lights but they are not optimized for energy. In the paper [3], authors used different set of emitter-receiver pair for data communication in addition to emitter-receiver for localization. In this also, the signal-to-noise ratio (SNR) distribution is not uniform and energy is not optimized for data communication. This results in different data rate across the considered area and relatively higher estimated error in the corner of the room.

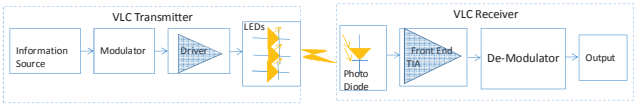

Fig.1: VCL System Architecture

In this paper, we use the same set of emitter-receiver and they are used for simultaneous function of localization and data communication. In addition, the illuminating LED lights placed in the desired area for the uniform SNR distribution and optimized transmitted power from each reference point so that energy is not wasted. The uniform SNR not only results in the greater accuracy in the entire area for location detection but also enhances the bit error rate (BER) performance when used for high data rate communication.

The contents of the rest of the paper are as follows. Section II describes overall VLC system architecture in brief. The algorithm and analysis is presented in section III while section IV discusses the results. Finally, section V concludes the paper with the intention of continued future work.

II. Overall System Architecture and Configuration

In this section, we briefly describe the overall system and then discuss the channel characteristics.

A. Overall VLC System

A generic VLC system is shown in Fig.1. The system comprises a set of LED lights which form VLC emitter. The array of LED is required for high intensity lights for relatively longer data communication range as well as sufficient light intensity in the working area. The emitter (set of LEDs) requires driver to provide sufficient current to drive the LEDs or the array of LEDs. The LED emitter must be modulated for data communication. Most widely used modulation technique is intensity modulation and direct detection (IM/DD) or on off keying (OOK). Thus in the transmitter, the data information source is modulated which is applied to the driver amplifier to deliver necessary drive current to the LEDs emitter.

The receiver is based on photo detector (PD). The amount of light falls on the collecting area of PD will get converted to electrical signal which must be amplified. Normally, transimpedance amplifier (TIA) [9] is used as front end in optical domain. A blocking capacitor is used to block the direct current (DC) resulting from natural lights. The amplified signal is low pass filtered, demodulated to get back the original signal at the receiver.

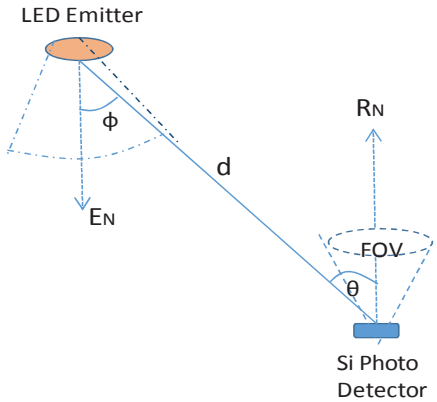

Fig.2: Channel Model

The light emitted from the array of LEDs carries the data information wirelessly and forms the channel (optical wireless channel). Normally, line-of-sight (LoS) link is considered in VLC system design.

B. The Channel Characterization

Fig.2 shows the illustration for LoS channel. The direct distance between LED emitter and receiver is considered to be *d*. The optical wireless link is characterized by direct current gain and given by:

$$H(0) = \begin{cases} \frac{m+1}{2\pi d^2} A_r . \cos^m(\Phi) . Ts(\theta) . g(\theta) . \cos(\theta), & 0 \le \theta \le \theta_c \\ 0, & \theta > \theta_c \end{cases} \quad (1)$$

where A_r area of the detector, θ is the angle between the normal of receiver to the direct distance from the emitter, $T_s(\theta)$ is the gain of optical filter, $g(\theta)$ is the concentrator gain. θ_c is semi-angle of FOV. The Lambertian order m is given by $m = -\ln 2 / \ln(\cos \Phi)$, where Φ is the half power angle of the LED. The received optical power at the detector is given by:

$$P_r = H(0) . P_t \quad (2)$$

where P_t denotes optical power of the LED.

III. Design and Analysis

In this section, we discuss the system model, frame structure and details of the algorithm.

A. System Model

The overall system model is illustrated in Fig. 3.There are five LED light points installed on the ceiling of the room. Each one of the light point with specific co-ordinates transmits its own unique identity (UI) followed by the information data

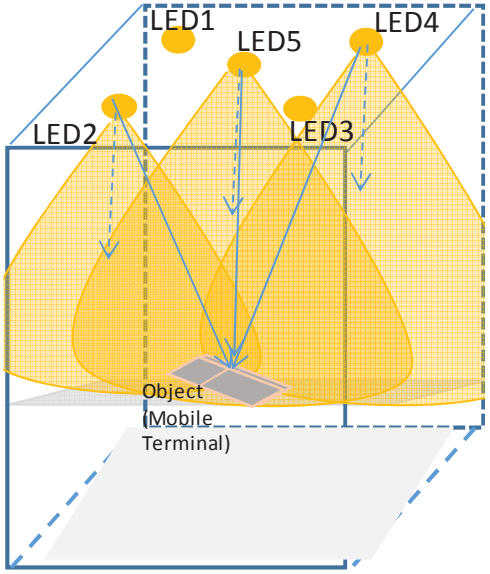

Fig.3: System Configuration for Location determination

when modulated. The position (coordinates) of the LED lights are automatically calculated by designed algorithm based on other parameters such as irradiation angle of the LEDs, field of view (FoV) of the PD, maximum dimension of the area and the desired SNR at the extreme point (corner) in the room. This not only enables the high data rate transmission in the entire area but also the least estimated positioning error. For the uniform SNR distribution, we use 5 set of LED lights of the same emitted power as shown in the system layout in Fig.3. The object which is to be detected incorporates the VLC PD receiver and at the same time has the capability to receive the information in the entire room area. We consider the PD receiver to be placed at a height of 1-m (table) from the surface (ground) within the room. However, system is designed to perform almost the same performance even the receiver is placed on the surface. The parameters for system model are shown in Table-1.

B. Channel Access and Frame Structure

To access the channel, we rely on asynchronous mechanism [5] to reduce the complexity. We use a frame slotted additive on-line Hawaii (FS-ALOHA) protocol which is approximately similar to the ALOHA (shown in Fig.4). In this, the frame is divided into a fixed number of time slots (relatively higher, over 200). Each transmitter then selects the slot randomly and transmits its data frame. It is likely that sometimes two or more transmitters select the same slot and therefore resulting in collision. This is shown in Fig.5. It is also possible that two or more emitter's transmission overlap. In this case also, there will be collision resulting in failure in location determination. As described in [5], if the number of slots (N) is relatively large (N>200), the performance of synchronous [4] and asynchronous is approximately the same. Therefore, we choose N = 250. It is also important to discuss that that N should not very large and neither be small in number. If N is small, more collision will occur degrading the performance but if N is large, it is possible to see more emptied slot. Thus,

TABLE 1: System Model Parameters

Parameters	Values
Considered room dimension (L x W x H)	3 x 3 x 3 m^2
Position of LED light	A (0.5, 0.5, 3); B(2.5,0.5,3); C(0.5,2.5,3); D(2.5,2.5,3); E(1.5,1.5,3)
Receiver Height	1m
Receiver detector area (A_r)	1cm^2
Field of View	55 degree
Responsivity of receiver	0.54 (A/W)
LED transmitted power from each emitter	6W

Fig.4: Frame Structure

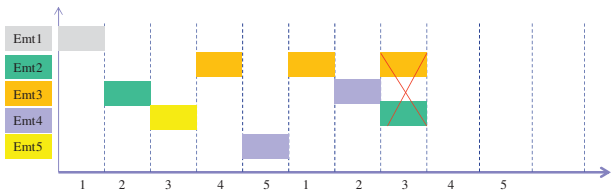

Fig.5: Illustration of frame transmission and collision of FS-ALOHA

with this number of slot, the performance of location positioning is the same as the synchronous based.

Each LED emitter is assigned a coordinate (x,y,z) based on optimized placement for uniform illumination in the given area. The coordinates are encoded into three 16-bit return to zero (RZ) codes. We use on-off-keying modulation to send the information. Normally, the transistor driver is biased so that the average power (P_0) is always transmitted and during modulation, the respective LED emitter will transmit higher intensity that is peak power (P). The receiver placed anywhere in the area will detect the signal, segregate the UI from data from any of the three LED emitter to calculate the triangulation. Thus information data and location information is separated.

C. Location Determination

Each of the LED transmits its UI modulated in OOK format to the receiver. The power difference at the receiver end is measured to find out the estimated distance. We find out the estimated distances from all the reference points and calculate the estimated location and positioning error (if any). Considering any three co-ordinates for positioning, we would have ten random ways to find the position for our system. On finding out the estimated average error for our system we would be able to define the position. This defines the object with very less positioning error. If the modulation depth of OOK at the transmitter end is η_{ook}, the power difference (P_{df}) between the transmitted ON and OFF pulse could be:

$$P_{df} = \eta_{ook} . P_{cnst} \tag{3}$$

where P_{cnst} is the optical power emitted from LED without modulation. The power difference at the receiver side (P_{dfr}) is given by:

$$P_{dfr} = H(0) . P_{df} \tag{4}$$

The direct distance d between LED emitter and the receiver from Eq. (1) is given as:

$$d = \sqrt{\frac{(m+1)A_r . \cos^{m}(\Phi) . \cos(\theta) . P_{df}}{2\pi P_{dfr}}} \tag{5}$$

The optical concentrator gain and filter gain is normalized. We also consider that the transmitter and the receiver axes are perpendicular to each other the estimated distance is given as:

$$d_{est} = \sqrt{d_{est-xy}^2 + H^2} \tag{6}$$

$d_{\text{est-xy}}$ is the horizontal distance between transmitter and the receiver, H is the vertical distance (height) between transmitter and receiver:

$$d_{est-xy} = \sqrt{\sqrt{\frac{A_r.\mathrm{P}_{df}.H^2}{\pi \mathrm{P}_{dfr}}} - H^2} \quad (7)$$

So, with the help of estimated horizontal distance we would be able to find the estimated co-ordinate by triangulation.

To estimate the unknown position, a set of two equations would be enough with the assumption that after the estimated distance between the LED's and the receiver is known. These set of equations would be helpful to solve for (*x, y*). The (x, y) would be the estimated position of receiver.

In the system described above, we have five transmitters A, B, C, D and E. The entire equations group formed by any three points can be solved and the estimations can be averaged.

$$(x - x_A)^2 + (y - y_A)^2 = d_A^2 \quad (8)$$

$$(x - x_B)^2 + (y - y_B)^2 = d_B^2 \quad (9)$$

$$(x - x_C)^2 + (y - y_C)^2 = d_C^2 \quad (10)$$

$$(x - x_D)^2 + (y - y_D)^2 = d_D^2 \quad (11)$$

$$(x - x_E)^2 + (y - y_E)^2 = d_E^2 \quad (12)$$

On solving for eq. (10), (11) and (12), we get an equivalent linear set of equations to solve for (x, y). The final averaged estimation could be helpful to find out the equivalent positioning (x,y) error given as:

$$e_r = \sqrt{(x_{\mathrm{real}} - x_{est})^2 + (y_{\mathrm{real}} - y_{\mathrm{est}})^2} \quad (13)$$

where x_{real}, y_{real} are the real position of the receiver in *x* and *y* direction respectively.

D. Data Transmission Rate

As shown in Fig.4, the frame comprises 8-bit start and 8-bit stop bit. The preamble 48-bit is the UI of individual LED emitter. We also use 16-bit cyclic redundancy check (CRC). With each frame a data of 256-bit is appended. Thus, the frame length is:

Frame Length (L) = (8+8+16+48+256) = 336-bits. (14)

Each LED emitter transmits a frame in one slot. If we repeat the transmission 40 times per second, the data rate will be:

$$\mathrm{R} = 40.\mathrm{L}.\mathrm{N} = 3.36\mathrm{Mbps} \quad (15)$$

The high brightness (HB) LED with tens of MHz switching is commercially available and we are using in our design for the demonstration. However, much higher data rate is possible with other high speed HB LED.

E. Bit Error Rate Analysis

One of the parameters to determine the performance of data communication system is the bit error rate which is the function of signal to noise ratio and it varies depending on the modulation technique. For simple OOK modulation, the probability of error is given as:

$$P_{eook} = Q(\sqrt{SNR}) \quad (16)$$

where *Q(.)* is the error function given as:

$$Q(x) = \frac{1}{\sqrt{2\pi}} \int_x^{\infty} exp\left(-\frac{u^2}{2}\right) du = \frac{1}{2}\left(1 - \mathrm{erf}\left(\frac{\mathrm{x}}{\sqrt{2}}\right)\right)$$

SNR Analysis

Uniform SNR is necessary in the given area for accurate detection of the position of the object as well as for the acceptable and uniform data rate. The signal component is given by:

$$S = \mathcal{R}^2 P_{dfr}^2 \quad (17)$$

where $\mathcal{R}$ specifies the detector responsivity.

The noise is described to be Gaussian with a total of shot and thermal noise. The shot noise is dependent on background current induced by light (I_{bg}).

$$N = \sigma_{th}^2 + \sigma_{st}^2 \quad (18)$$

where the shot noise is given as:

$$\sigma_{st}^2 = 2q\mathcal{R}(P_{rc})B + 2qI_{bg}I_2B. \quad (19)$$

where q is the electronic charge, B is the equivalent noise bandwidth, same as that of modulation bandwidth, I_{bg} is the background current which can vary depending on Sun lights. The I_{bg} is maximum of around 5100μA under direct sunlight exposure and 740μA under indirect sunlight exposure; the noise bandwidth factor I_2=0.562. Following [1], the thermal noise is calculated to be very small. We considered this value to be -225dBm.

The received power P_{rc} is given as:

$$P_{rc} = \sum_{i=0}^{5} H_{\mathrm{i}}(0)\mathrm{P}_{\mathrm{i}} \quad (20)$$

where $H_{\mathrm{i}}(0)$ is the instantaneous DC channel gain and P_i is the instantaneous emitted power from the i'th LED emitter respectively.

As can be observed from the figures (Fig.7 and 8), the SNR is uniformly distributed within the room due to the presence of five LED's positioned precisely. This kind of positioning would lead to evaluation of significant SNR even at the corners of the room. The positioning error would also be relatively less even at the corners of the room. From Fig.7, we can observe SNR is relatively higher due to indirect sunlight exposure where noise contribution would be relatively less.

IV. PERFORMANCE RESULTS AND DISCUSSIONS

Different performance results are presented in this section. We plotted for location as estimated error. Similarly, we plotted for SNR and BER.

The positioning error is shown in Fig.6. It can be seen that the error is much smaller in most of the area. However, at extreme corner the error is relatively larger but still much small.

SNR distribution is given in Fig.7. It can be seen that in the entire given area the SNR value is much larger than the acceptable value of BER for data communication. We also see that the minimum and maximum variation of SNR is around 2dB which suggests emitters are also uniformly distributed.

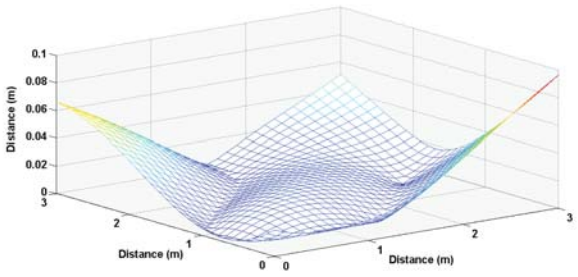

Fig.6: The positioning error in the given area

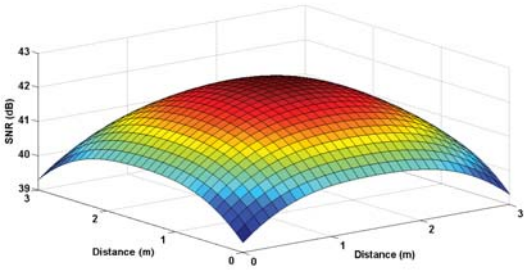

Fig.7: SNR distribution without background noise

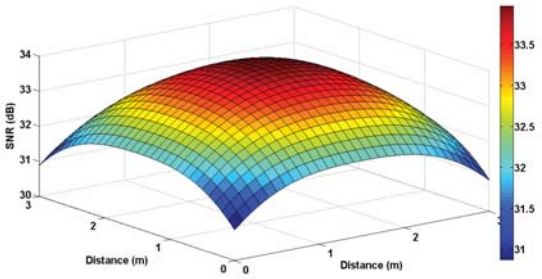

Fig.8: SNR distribution with background noise.

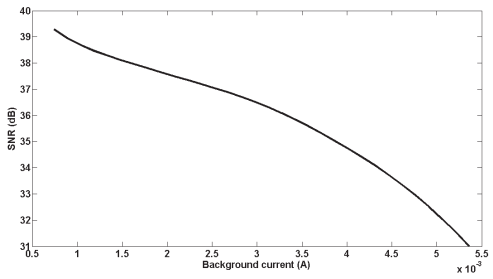

Fig.9: SNR variation with background noise.

The distribution of SNR remains the same, however, the value decreases with maximum of background noise as shown in Fig.8.

Overall variation in SNR with varying background current is also given in Fig.9. With the increase in background current, the SNR decreases which is obvious, however, with a range of background current the SNR is still enough to give the necessary data rate and BER performance.

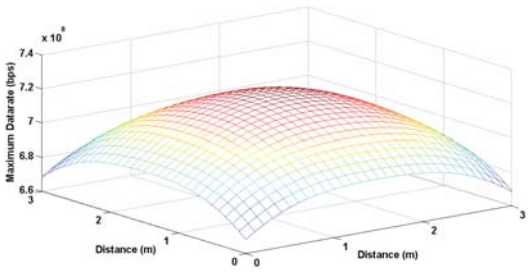

Fig.10: Data rate in the given area

The data rate for which can be achieved is shown in Fig.10. It can be seen that much higher data rate is possible in terms of few tens of MHz. However, as stated above in VLC the data rate is limited to the switching characteristics of opto-electronics circuit.

V. CONCLUSION

Studies are performed on indoor localization based on visible light communication. A simplified system is analyzed which can perform simultaneous all three functions of data transmission, localization and illumination. It is shown that high accuracy localization can be achieved and at the same time uniform SNR ratio offers better BER performance.

In fact, the paper should be supported by hardware demonstration but it is not complete. The receiver is being designed for its performance. We are also trying to further improve optimization of location of LED emitter for better SNR distribution based on few parameters only. There are possibilities for further improvement in respect of both emitter as well as data transmission. We are addressing these issues.

Abstract— ***A greedy Pursuit algorithm is developed for solving distributed compressive sensing problem in a connected network. This algorithm is based on Forward-Backward Pursuit algorithm that does not require any prior knowledge of sparsity and also gives better performance than Subspace Pursuit algorithm. So theoretically when Forward-Backward Pursuit algorithm comes in distributed scenario, it will give better performance than Distributed Subspace Pursuit algorithm. Through an experimental evaluation, we show that the proposed Distributed Forward-Backward Pursuit algorithm gives 6 dB higher Signal to Reconstruction Error Ratio (SRER) than Distributed Subspace Pursuit algorithm.***

Keywords—Distributed Compressive Sensing; Greedy Pursuit algorithm; Sparsity; Forward-Backward Pursuit algorithm; Subspace Pursuit algorithm

I. INTRODUCTION

Of late, Compressive Sensing (CS) is became a hot research topic among researchers since it is a new method which capture and compress signals at a rate below Nyquist rate. Compressive Sensing (CS) is a sampling paradigm which samples the signals at a rate below the Nyquist rate [1] [2] [3] [4]. One of the main application of CS is in the field of Wireless Sensor Networks (WSNs). There are limiting parameters on WSNs such as power consumption, life time, cost, bandwidth and traffic. The WSNs need independent energy resources and so energy consumption is one of the most important factor to determine the life time of wireless sensors. As WSNs continue to grow, there is a need for new mechanisms to reduce these limiting parameters. The compressive sensing techniques optimizes energy consumption and holds promising improvements to these parameters [5].

For a multiple-sensor scenario, most effective case is a distributed setup where several CS-based sensors are connected through a distributed (decentralized) network [5]. Several CS reconstruction algorithms have been developed, which includes convex optimization and Bayesian algorithms [6]. An important class of reconstruction algorithms is the Greedy Pursuit (GP) algorithm which gives good performance with low complexity. The GP algorithms use linear algebraic tools to estimate the underlying support-set of the sparse signal vector followed by estimating associated signal values from a measurement vector [6]. Various Greedy Pursuit Algorithms developed for distributed Compressive Sensing are Distributed Parallel Pursuit Algorithm (DIPP) [7], Distributed Orthogonal Matching Pursuit algorithm (Di OMP) [6] [9] [10], Distributed Subspace Pursuit algorithm (Di SP) [6] [8] [9] [10], Distributed Predictive Subspace Pursuit (DPrSP) [9], Distributed Forward-Reverse Orthogonal Greedy Search (Di FROGS) [6] [9] [10].

Greedy Pursuit algorithms like Subspace Pursuit algorithm and CoSaMP algorithm require a prior knowledge of sparsity level [3]. Backward Pursuit algorithm, Subspace Pursuit algorithm and Orthogonal Matching Pursuit algorithm start to fail at around Sparsity level, K = 25 [11]. This disadvantage is overcome by a new algorithm called Forward-Backward Pursuit algorithm (FBP). FBP does require any prior knowledge of sparsity level (K) and it starts to fail only when sparsity K is greater than 30 [11]. So theoretically when Forward-Backward Pursuit algorithm comes in distributed scenario, it will give better performance than Subspace Pursuit algorithm. The proposed Distributed Forward-Backward Pursuit algorithm gives 6 dB higher Signal to Reconstruction Error Ratio (SRER) than Distributed Subspace Pursuit algorithm and this has been verified through simulations.

II. DISTRIBUTED COMPRESSIVE SENSING

For observing the Distributed Compressive Sensing problem (DCS) consider the i^{th} sensor node. Then the sparse signal $x_i \in R^N$ is measured as

$$y_i = A_i x_i + w_i \quad (1)$$

where $y_i \in R^M$ is the observation vector, $A_i \in R^{MxN}$ is the measurement matrix and $w_i \in R^M$ is the measurement noise, M < N. There has been K_i non zero components with indices $T_i = \{l: x_i(l) \neq 0\}$ in signal vector x_i. This T_i is known as support set of x_i. The DCS reconstruction problem endeavors to reconstruct or x_i for all i by exploiting some common structure among i sensors well-defined by the signal model

and exchanging some information among sensor nodes over the network topology [6] [8] [9] [10].

A. *Mixed Support Set Signal Model*

The mixed support set signal model has a shared structure where the signal vector x_i consist of two parts

$$x_i = a_i^c + a_i^p \ , \ \forall \ i \in \{1, 2 \ldots I\} \qquad (2)$$

a_i^c is the common sparse component and a_i^p is the innovative component. Both a_i^c and a_i^p in (2) have independent non-zero components. There are K_i^p non-zero values in a_i^p. The non-zero values are located uniformly at random over the support set $T_i^p \in \forall \ i \in \{1, 2 \ldots I\}$. With the constraint that the support set $T_i^c = T^c$ is shared, there are similarly K^c non-zero components for a_i^c. The elements of T^c are common to all signals, but it is unknown to the reconstruction part. For the i^{th} sensor node, this contributes a support set T_i for each x_i as

$$T_i = T^c \ \cup \ T_i^p \ , \ \forall \ i \in \{1, 2 \ldots I\} \qquad (3)$$

B. *Network Topology*

The DiFBP algorithm described in this paper can work in any network topology. If the network is well connected, then this algorithm will give better performance. The effects of the network topology on the performance of DiFBP is not considered in this paper. Here, we emphasis on the development of DiFBP suitable for any network.

C. *Algorithmic Notations*

We define four algorithm functions in the algorithm. The functions are given as follows

max_indices(x, k) ≜ {the set of indices corresponding to the k largest amplitude components of x} (4)

min_indices(x, k) ≜ {the set of indices corresponding to the k smallest amplitude components of x} (5)

resid(y, C) ≜ y-$CC^{\dagger}$y, for some matrix C (6)

and

add_1(s, T) ≜ {∀ j ∈ T, performs $s_j = s_j + 1$}, (7)

where s= [s_1, s_2….,s_N] and $s_j \geq 0$

For the i^{th} sensor node, I_i^{out} denotes the set of indices corresponding to the connected outgoing nodes and I_i^{in} denotes the set of indices corresponding to the connected incoming nodes.

III. DISTRIBUTED GREEDY PURSUITS ALGORITHMS

Some of the existing distributed greedy pursuit (Di GP) algorithms are Distributed Parallel Pursuit algorithm (DIPP) [7], Distributed Orthogonal Matching Pursuit algorithm (Di OMP) [6] [9] [10], Distributed Subspace Pursuit algorithm (Di SP) [6] [8] [9] [10], Distributed Predictive Subspace Pursuit (DPrSP)[12], Distributed Forward-Reverse Orthogonal Greedy Search (Di FROGS) [6] [9] [10]. There are two principles [6] for working of Di GP algorithms. First, each CS node transmits its own full support set estimate to the neighbouring connected nodes. It also receives a set of full support-set estimates from the neighbouring connected nodes. Second, using the set of all received support-set estimates and by invoking a voting mechanism [7] [12] [6], each CS node finds an estimate of the common support-set, either serially or parallelly. Then, using the common support-set estimate as the initial knowledge, each CS node finds a new estimate of the full support-set and then again exchange the full support-set information.

DiSP [6] [8] [9] [10] is based on the existing subspace pursuit [12] algorithm and it use parallel support set construction mechanism. First modify the SP algorithm and then use it for developing DiSP. The principle strategy of DiSP [8] is to improve the common support set estimation by exchanging full support set estimates over iterations. Like DiSP [8], we can develop all other distributed algorithms.

IV. DISTRIBUTED FORWARD-BACKWARD PURSUIT

Distributed Forward-Backward Pursuit algorithm is designed based on Forward-Backward algorithm. Forward-Backward Pursuit algorithm (FBP) is an r-support algorithm, so we can develop DiFBP by using the same approach in DiSP [13]. To implement Distributed Forward-Backward Pursuit (DiFBP) algorithm, we have to first modify the FBP algorithm. Using the modified FBP algorithm presented in Algorithm 2, DiFBP algorithm is carried out in each node. By calling FBP(.), DiFBP algorithm executed in each node is presented in Algorithm 1.

Algorithm 1 (Distributed FBP (DiFBP)): Executed in the i^{th} node, where I_i^{out} and I_i^{in} are set of outgoing and incoming nodes respectively.

Input: $\mathbf{C_i}$, $\mathbf{y_i}$, $K_i^{(p)}$, $K^{(c)}$

Initialization:

1. $K_{i,max} = K_i^{(p)} + K^{(c)}$
2. $(\widehat{T}_i, \hat{\mathbf{x}}_\mathbf{i}, n_i) \leftarrow$ MODFBP ($\mathbf{C_i}$, $K_{i,max}$, $\mathbf{y_i}$, ∅)
3. $n_i^{old} \leftarrow n_i$
4. $\widehat{T}_i \leftarrow \emptyset$, $\forall \ i^* \in I_i^{in} \backslash$ i (i.e. except i)

Iteration:

1. **repeat**
2. **if** $n_i > n_i^{old}$ **then**

3. $(\widehat{\mathrm{T}}_\mathrm{i}, \hat{\mathbf{x}}_\mathbf{i}, \mathrm{n_i}) \leftarrow (\widehat{\mathrm{T}}_\mathrm{i}^{\mathrm{old}}, \hat{\mathrm{x}}_\mathrm{i}^{\mathrm{old}}, \mathrm{n_i^{old}})$
4. **end if**
5. $(\widehat{\mathrm{T}}_\mathrm{i}^{\mathrm{old}}, \hat{\mathrm{x}}_\mathrm{i}^{\mathrm{old}}, \mathrm{n_i^{old}}) \leftarrow (\widehat{\mathrm{T}}_\mathrm{i}, \hat{\mathbf{x}}_\mathbf{i}, \mathrm{n_i})$
6. $\hat{T}_{i^*}^{old} \leftarrow \hat{T}_{i^*}, \ \forall \in I_i^{in}\backslash \mathrm{i}$
7. {**Transmit:** $\widehat{\mathrm{T}}_\mathrm{i}$ to all nodes i $\in I_i^{out}$}
8. {**Receive:** $\hat{T}_{i^*}$ from all nodes i $\in I_i^{in}$ }
9. $s_i \leftarrow 0_{Nx1}$
10. for each $i^* \in I_i$ do
11. $s_i \leftarrow add_1(s_i, \hat{T}_{i^*})$
12. **end for**
13. $\widehat{\mathrm{T}}_\mathrm{i}^{(\mathrm{c})} \leftarrow$ max_indices(s_i, $K^{(c)}$)
14. $(\widehat{\mathrm{T}}_\mathrm{i}, \hat{\mathbf{x}}_\mathbf{i}, \mathrm{n_i}) \leftarrow$ MODFBP ($\mathbf{C_i}$, $\mathrm{K_{i,max}}$, $\mathbf{y_i}$, $\widehat{\mathrm{T}}_\mathrm{i}^{(\mathrm{c})}$)
15. **until** $(n_i \geq n_i^{old})$ **and** $(\hat{T}_{i^*}^{old} \ \forall \ i^* \in I_i)$

Output: $\hat{\mathbf{x}}_\mathbf{i}$, $\widehat{\mathrm{T}}_\mathrm{i}$

Inputs to Algorithm 1 is i^{th} node's sensing matrix $\mathbf{C_i}$, the measurement vector $\mathbf{y_i}$ and the number of elements in the private and common support sets ($\mathrm{K_i^{(p)}}$and $\mathrm{K^c}$). In the initial phase of the algorithm, first estimate of the i^{th} sensor node's support set is achieved by executing the function MODFBP(.). The residual norm $\mathrm{n_i}$ is stored to use as the performance measure and an empty set $\emptyset$ is initialized as the support set of neighboring nodes. There are four functionalities in the iteration phase of the algorithm. They are: (1) Steps 2-4 will prevent the result deviating from better solution if intermediate estimated support set in step 10 is worse than the estimated support set in the previous iteration (denoted by 'old'). (2) Step 7 and 8 establish the communication phase where the estimated support sets are exchanged among the nodes. (3) An estimate of the common support set with cardinality $K^{(c)}$ is achieved. (4) Using the common support set obtained, MODFBP is executed to estimate a new full support set. These four functionalities are iteratively performed until a stopping criterion based on two conditions is fulfilled together: (a) the residual norm in the i^{th} node does not decrease and (b) no new support set estimates from connected node arrive.

A. Modified Forward-Backward Pursuit(MODFBP)

Here, we describe the modified FBP in Algorithm 2. An initial support set T_{ini} is provided to the MODFBP.MODFBP will continue to improve this initial support set building the final support set. When T_{ini} =∅, MODFBP will reduce to standard FBP [3]. At k-th iteration stage, modified FBP forms the matched filter $C^T r_{k-1}$, identifies indices of alpha (forward step size) largest amplitudes and merge with old support set (step 3 and 4). This step is known as forward step. Then projection coefficients of y onto $C_{\tilde{T}^k}$ are computed and identifies the indices corresponding to the beta (backward step size) smallest amplitudes (steps 5 to 7). This step is known as backward step. This produces the final estimate of k-th iteration. Then the projection coefficients and the residue are updated until some halting condition (steps 8 to 10) is satisfied.

Algorithm 2: Modified FBP (MODFBP):

Input: C , alpha, y, T_{ini}

Define: beta, ε

Initialization:

1. $T^0 = T_{ini}$
2. r^0 = resid(y,C_{T_0})
3. k← 0

Iteration:

1. repeat
2. k← k+1;

Forward step:

3. T_f= max_indices ($C^T r_{k-1}$, alpha)
4. $\tilde{T}^k = T^{k-1} \cup T_f$
5. w= $C_{\tilde{T}}^{\dagger}$ y, projection

Backward step:

6. T_b= min_indices (w, beta)
7. $T^k = \tilde{T}^k - T_b$
8. w=$C_T^{\dagger}$ y
9. r^k= resid(y,C_{T_k}), [r^k = y- C_{T_k}w = y-C_{T_k} $C_{T_k}^{\dagger}$ y]
10. until ($\|r_k\| \leq \varepsilon \| r_{k-1}\|$)
11. k← k-1

Output:$\hat{T}$, $\hat{x}$, n

Functional form: ($\hat{T}$, $\hat{x}$, n) ← MODFBP(C, alpha, y, T_{ini})

V. SIMULATIONS AND RESULTS

In the simulation we are comparing four algorithms (SP, FBP, DiSP, and DiFBP). The results are taken for clean and noisy measurement cases. For noisy measurement, we have chosen Signal to Measurement Noise Ratio (SMNR) as 20 dB ($10log_{10}\frac{E\{||x||_2^2\}}{E\{||w||_2^2\}}$). To compare the performance of algorithms, performance measure taken is Signal to Reconstruction Error Ratio (SRER).

$$\mathrm{SRER} = 10\ log_{10}\frac{E\{||x||_2^2\}}{E\{||x-\hat{x}||_2^2\}} \quad (8)$$

We define fraction of measurement as

$$\alpha = \frac{M}{N} \quad (9)$$

For the plots given in the paper, we have chosen that each node is connected to exactly two nodes i.e. one fixed

connection matrix. The signal parameter is taken as N=500; the cardinality of private support set is taken as $K^{(p)} = 10$ and cardinality of common support set is taken as $K^{(c)} = 10$. We have chosen I=10 nodes and for each node there are Q=100 number of sensing matrices (c_i) and number of data sets x taken for each node is P=100. The total number of data for statistics is P.Q.I = 100000. The forward step size (alpha) is taken as 20 [11], termination parameter ϵ is taken as 1e-7 [11] and backward step size (beta) which is alpha-1 is taken as 19 [11].

In the figures given in this paper, there are four algorithms compared SP, FBP, DiSP and DiFBP. SP and FBP are standard Subspace Pursuit and standard Forward-Backward Pursuit algorithms respectively. For clean measurements in Fig.1, we have observed that DiFBP gives better performance than DiSP. At $\alpha = 0.16$, DiFBP gives 3 dB better performance than DiSP. For noisy measurements in Fig.2, we have observed that DiFBP gives better performance than DiSP. At $\alpha = 0.16$, DiFBP gives 6 dB higher performance than DiSP and also DiFBP gives 10 dB higher SRER compared to FBP.

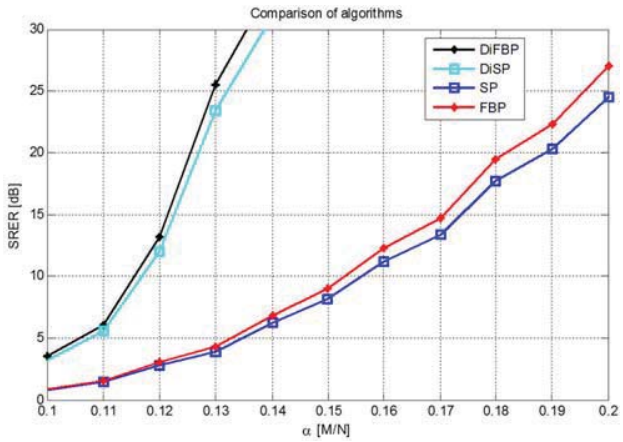

Fig.1: SRER versus fraction of measurements for clean measurements.

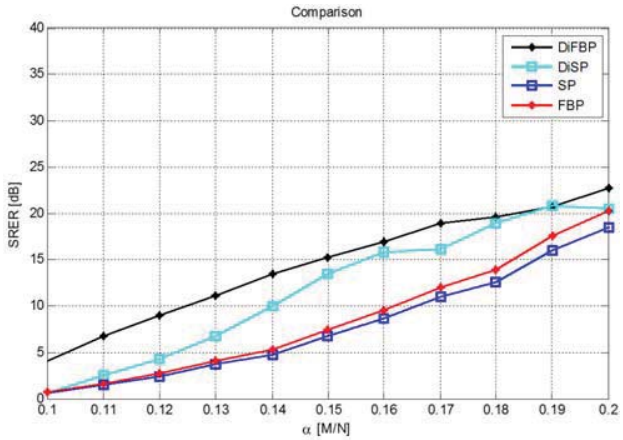

Fig.2: SRER versus fraction of measurements for noisy measurements (SMNR = 20dB)

VI. CONCLUSION

In this paper, a distributed greedy pursuit algorithm called DiFBP (Distributed Forward-Backward pursuit) is developed. Using the mixed support set model, it is shown how this algorithm can be developed based on the standard Forward-Backward Pursuit algorithm. By experimental evaluation in a well-connected network, we conclude that the DiFBP significantly improves the performance compared to the DiSP and standard FBP algorithms.

Abstract—**Frequency spectrum is an essential resource in wireless communication. Due to the rapid growth in wireless technology and increasing number of wireless users, the demand for spectrum has increased. This increased demand for spectrum leads to a problem of spectrum underutilization. The solution to this problem is accomplished through the use of cognitive radio technology, which has provided a different way to increase the efficiency of the spectrum utilization. Spectrum sensing is an indispensible function of cognitive radio to identify the available spectral holes. Energy detection is considered as a preferred technique for spectrum sensing in cognitive radio networks. Upon identifying the free spectrum, the technique to access the primary user spectrum for data transmission is dynamic spectrum access. This paper proposes an adaptive cooperative spectrum sensing and access scheme for cognitive radio networks. The main objective of this work is to improve the spectrum sensing and access and also to increase the access probability of each user. Detection accuracy decreases due to low signal to noise ratio (SNR) at the secondary user in cooperative spectrum sensing and also due to fixed collection period scheme. Low SNR secondary users are excluded in order to improve the detection probability and efficiency of spectrum sensing and access. It also uses adaptive collection period. The simulation results shows that the adaptive sensing and access with high SNR secondary user performs better when compared to all other schemes and also increase the access probability of each user.**

Index Terms **-** Adaptive collection, Cognitive radio, Cooperative sensing, Spectrum access.

I. INTRODUCTION

Radio spectrum is a limited and scarce resource in wireless technology and it is completely regulated by authorized bodies such as the Federal Communication Commission (FCC). As the usage of wireless technology increases, the demand for the spectrum is also increasing. The portion of the radio spectrum that is being allocated by the FCC to the licensed users has not been utilized fully. Cognitive radio has been proposed as a solution to improve the spectrum utilization. Cognitive radio is a radio that intelligently recognizes the status of the radio spectrum and adaptively changes the transmission parameter such as frequency, bandwidth, transmission power and modulation [1]. In cognitive radio terminology, licensed users are called the primary users and unlicensed users are called the secondary users. When the primary user is idle or not making use of the radio spectrum the secondary user equipped with cognitive radio may in future able to sense and opportunistically utilize the radio spectrum. Thus the main challenge in cognitive radio is to identify the presence or absence of primary user in radio spectrum this method is known as spectrum sensing. Spectrum sensing is the estimation of the instantaneous occupancy of the frequency spectrum and it act as an important key factor for cognitive radios. Various techniques exist for performing spectrum sensing.

The most common three spectrum sensing techniques are as Cyclostationary feature detection, Matched filtering and Energy detection (ED) based spectrum sensing technique is the mostly widely used technique for analyzing the sensing performance. This technique is commonly utilized for detecting the presence of unknown signals. The main advantage of this technique is that it does not require a prior knowledge about the signal to be detected [1]. The most widely used ED can be implemented in the time domain or frequency domain, the basic principle is to compare the energy of the signal to a threshold over a given bandwidth within

a specific sensing period. The ED in frequency domain such as Welch periodogram based estimation provides flexibility to access a multiple channels of different frequency [2]. Spectrum access is the technique mainly used to access the unutilized portion of primary user spectrum for data transmission. In [6] secondary user checks the Primary user signal based on Request to send (RTS) /Clear to send (CTS) before transmitting data, which reduces the interference to primary user. In [5], 3-phase RTS/CTS exchange is proposed. In the first phase, two secondary users exchange contention RTS(C-RTS)/contention CTS(C-CTS) messages for contention and spectrum reservation another secondary users hearing these messages are kept from accessing the medium. In the second phase, the secondary users exchange channel availability information using sensed RTS/CTS (S-RTS/S-CTS) messages. Finally, Transmission RTS/CTS (T-RTS/T-CTS) messages notify the completion of data transmission. Relationship between spectrum sensing time and access delay is analyzed using RTS/CTS exchange of each secondary user. In order to minimize the access delay, optimal sensing time and channel access are derived. Here the collection period are fixed [7]. In another study, the fixed collection period method is improved by introducing the adaptation of the collection period [4]. In the adaptive collection period scheme, the optimal stopping time of the collection period is adaptively determined based on the SRTS packets collected so far. This adaptive collection scheme is studied in a situation in which all the SNR values of primary user signal at the secondary users are equal. This paper proposes an improved spectrum access scheme which increases the access opportunity of each user.

In cooperative spectrum sensing, the decision is based on the entire secondary user participating in the network. The network consists of both the high SNR and low SNR secondary users. The low SNR secondary user doesn't contribute much to the sensing performance and hence the performance gets reduced. In proposed scheme, the low SNR value of secondary user are excluded and considering only the decision based on high SNR value of secondary user. This scheme improves the detection probability. In this method, the number of secondary user reduces, thereby increasing the access probability of each user.

Further, this paper is organized as follows. System model for adaptive cooperative spectrum and access is presented in section II. Section III presents the concept of adaptive collection period scheme. Simulation results and performance analysis are discussed in section IV and section V is the conclusion of the paper.

II. SYSTEM MODEL FOR ADAPTIVE COOPERATIVE SENSING AND ACCESS

In this system model, SU0, SU1, SU2 and SU3 are the secondary users participating in this network. Each secondary user performs spectrum sensing using Welch periodogram ED technique [2]. SU0 acts as a collecting user or fusion center. Its main function is to collect the sensed information from each secondary user and make the decision accordingly. It is assumed that the location of the primary user is known to all the secondary users. Based on this, each secondary user calculates its SNR and transmits both the sensed information and the SNR to the fusion center. In Fig.1 TX and RX represents transmission and reception.

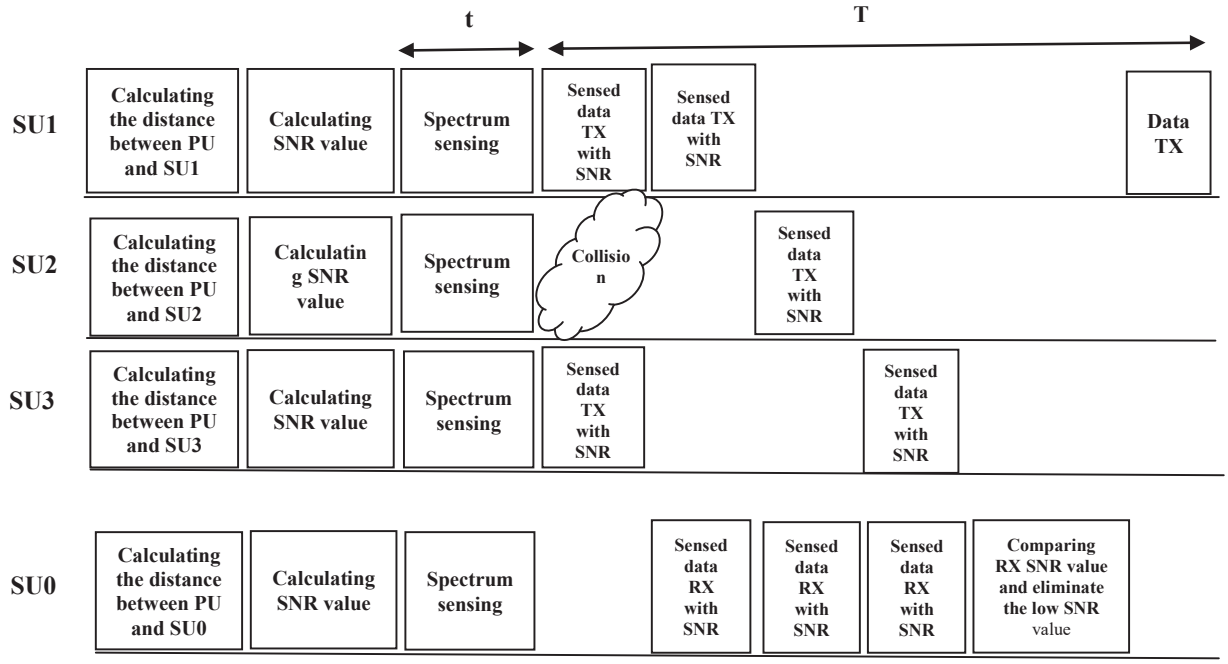

Fig.1. System model for Adaptive cooperative spectrum sensing and access in Cognitive radio

The collection period starts at the end of the spectrum sensing. The secondary user which has least spectrum sensing time will start sending the data to the collecting user. If other user sends the sensed information at the same slot then the collision occurs and information is lost. Then another secondary user having the next least sensing time will transmit its sensed information along with its corresponding SNR value. It is assumed that the each secondary user transmits its sensed information with a probability *p,* where *p* is (1/M), M is the number of secondary users. Spectrum sensing time is denoted as t. Thus the duration of the combined sensing data collection and data transmission period is fixed to *T* whose corresponding number of slots is *K*.

Proposed scheme does not make the decision based on all the secondary users and here the collection period is not fixed. The collection period stops only when the collecting user decides that sufficient number of sensed information are collected. After collecting the sensed information and their corresponding SNR, it compares the received SNR value and excludes the sensed information of low SNR secondary user. The collecting user decides the decision only based on high SNR secondary user and provides the access to that user for transmitting its data.

III. ADAPTIVE COLLECTION PERIOD SCHEME

When the collection period is used it is necessary to determine the length of the collection period. The length of the collection period is not known at the start of the collection period. Instead each slot of the collecting user decides whether to extend the collection period by one more slot or stop the collection period. This decision is based on the revenue of the collected information.

Here it is assumed that there are *q* slots remaining till the next spectrum sensing and the number of sensed information packet received at the collecting user is denoted as *r*. Consider a secondary user has sent its sensed information and SNR value to the collecting user. After receiving the fusion centre, checks whether to extend or stop the collection period based on the following [3]:

$$a(r,q)=\begin{cases} stop\,(=0) & if\ ER(r,q,end)\geq ER(r,q,extend) \\ extend\,(=1) & otherwise \end{cases} \quad (1)$$

$$ER(r,q,end)=q(1-Pf_r)$$

$$ER(r,q,extend)=(P_{s,r})ER(r+1,q-1)+(1-P_{s,r})ER(r,q-1)$$

where $a(r, q)$ represents the action of the state (r, q). The collecting user will stop collecting the sensed information when the value of expected revenue to stop is greater than the value of expected revenue to extend. Else, it will extend the collection period until revenue to stop value becomes greater. $ER(r, q, end)$ is the expected revenue to stop collection period. When it stops the collection period the remaining q slots are used for data transmission when the sensing decision results the primary user signal is absent. Pf_r represents false alarm probability of the received secondary user. $ER(r, q, extend)$ is the expected revenue to extend the collection period by one more slots or it waits for sensed information from another secondary user. $P_{s,r}$ is the probability that another sensed information are received in the next slot. $ER(r+1,\ q-1)$ represents the expected revenue when one more sensed information packet is received. $ER(r,\ q-1)$ represents expected revenue when no sensed information packet is received in next slot. The state probability is given by

$$P_{s,r}=1-(M-r)*p*(1-p)^{M-r-1}$$

The average collection period length (TC) and number of information packet collected (N_a) are given in equation (2) and (3) [5],

$$TC=\sum_{r=0}^{M}\sum_{i=1}^{\binom{M}{r}}\sum_{q=1}^{T-1}(T-q)\ P(s_r,q)\ (1-a(r,q)) \quad (2)$$

$$Na=\sum_{r=0}^{M}\sum_{i=1}^{\binom{M}{r}}\sum_{q=1}^{T-1}(r)\ P(s_r,q)\ (1-a(r,q)) \quad (3)$$

$$P(s_r,q)=\left(1-(M-r)*p*(1-p)^{M-r-1}\right)^{K-q}$$

The net normalized throughput is given by,

$$R=\frac{T_d*l}{t+(T*l)} \quad (4)$$

where T_d is the average number of slots used for data transmission incorporating the effect of sensing error probability for derivation of net normalized throughput are given in equation (5) .Where in equation (5) P_0 denotes the probability that the primary user signal does not present and P_1 represents the probability that the primary user signal is present, where l time duration of each slots which is assumed as 0.25 ms [4].

$$T_d=\sum_{r=0}^{M}\sum_{i=1}^{\binom{M}{r}}\sum_{q=1}^{T-1}q\,P(s_r,q)\left(1-a(r,q)\right)*((1-Pf_r)P_0+P_{mdr}*P_1) \quad (5)$$

IV. SIMULATION RESULTS

The simulation results describe the performance of adaptive cooperative spectrum sensing and access in

cognitive radio networks. The primary user signal is a QPSK with frequency of 6 MHZ. Here location of primary user is fixed. The secondary users are randomly located within an area of 1000 x 1000 m. Here the total number of secondary user participating in spectrum sensing is considered as 5. The location of secondary user is not fixed it keeps on changing each and every time. Fig.2. shows the random number of secondary user and its corresponding location

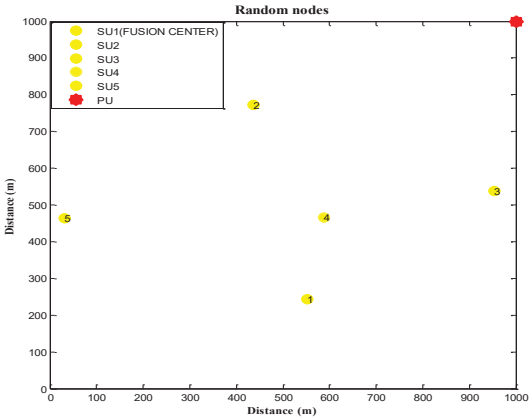

Fig. 2. Random number of secondary user, M= 5

After each secondary user calculates the SNR based on distance, each user starts sensing the spectrum and then transmits the sensed information based on adaptive collection period. Here the transmit SNR of primary user is assumed as 100dB and path loss is assumed as 2. Fig.3. shows the adaptive collection period for different number of secondary user received at the collecting user or fusion canter.

Fig.4. shows the data transmission slots against sensing time for different number of secondary user received. It clearly shows that the when the sensing time increases the number of slots used for data transmission decreases based on received number of secondary user. Here the sensing time ranges from 1 to 9 ms. when r is less, the number of slots used for data transmission will be more. There are totally 20 slots out of which one slot is used for calculating SNR value and then when the r is 2 the maximum number of slots it can obtain is 17 and the minimum of 9 slots for data transmission.

Fig.5. shows the normalized throughput against the varying sensing time for different number of received secondary users. P_0 is set to 1.The simulation results show that when only one high SNR secondary user is received in the collection period, the throughput performance is better than others. When the information from all the secondary users is collected, it becomes the adaptive scheme without excluding the low SNR secondary user. Fig.6. shows the normalized throughput when the probability that primary user signal is absent, P_0 is varied from 0 to 1. The proposed adaptive high SNR secondary user schemes show best performance for all the P_0 values because the detection probability will be more in high SNR secondary user.

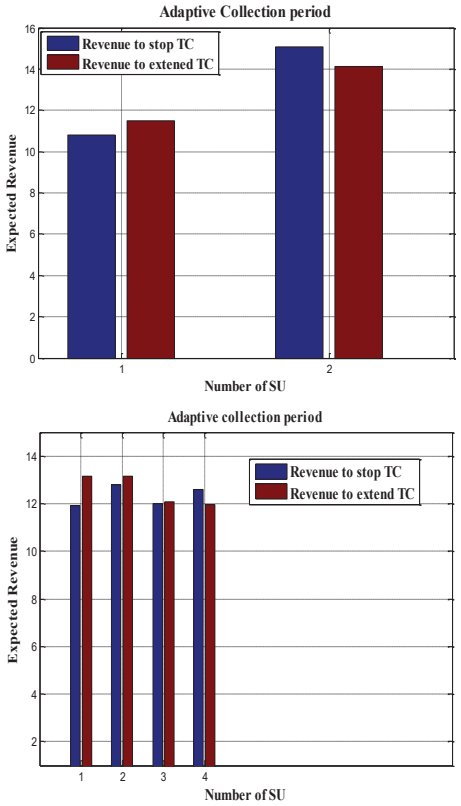

Fig.3 Adaptive collection period for different number of secondary users

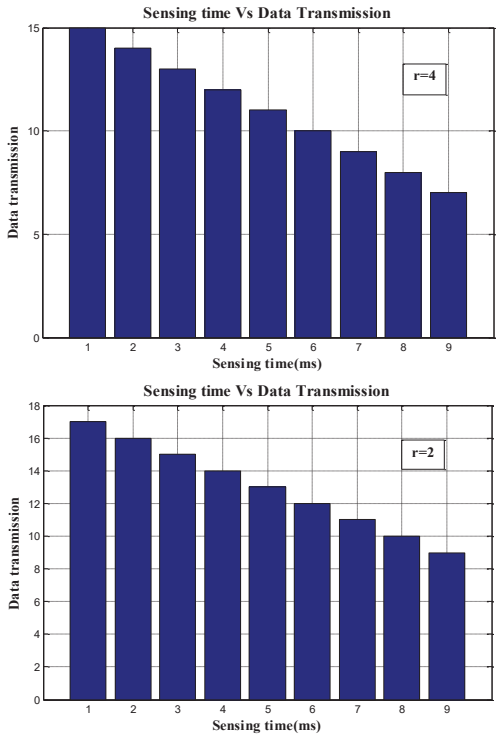

Fig.4. Sensing time Vs Data transmission for different number of secondary users

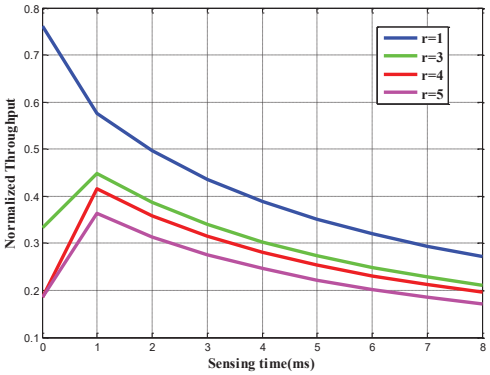

Fig .5.Sensing time Vs Normalized throughput for different value of r.

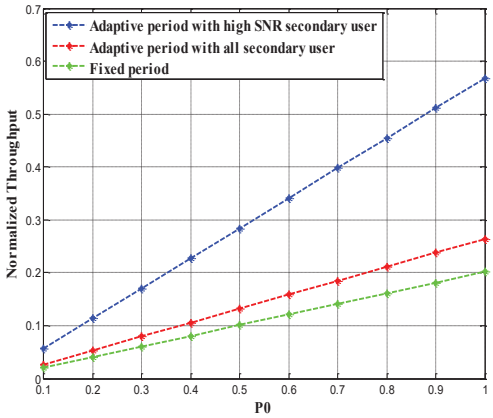

Fig.6. P0 Vs Normalized throughput, M=5, t = 1.5 ms

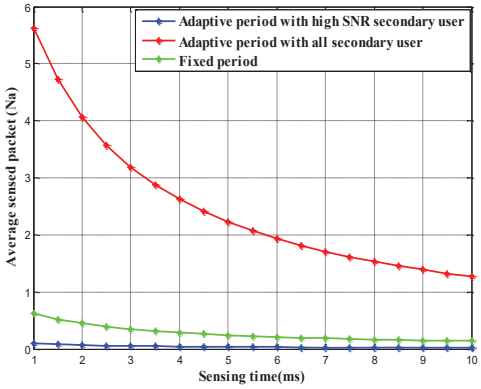

Fig.7. Sensing time Vs Average sensed packet (Na), M=5, t = 1.5 ms

Fig.7. shows the sensing time Vs average sensed packet. The proposed scheme shows the best performance when compared to all other schemes. In adaptive high SNR secondary user scheme, the number of collected and information packet are not larger compared to other schemes. The performance of normalized throughput when the combined collection and data transmission period, T, is changed is shown in Fig.8. T Vs Normalized throughput, M=5, t = 1.5 ms. The high SNR secondary user scheme shows the best performance for all the values of T. As T increases, the portion of the sensing time and collection period decreases compared with the data transmission time and hence the throughput increases.

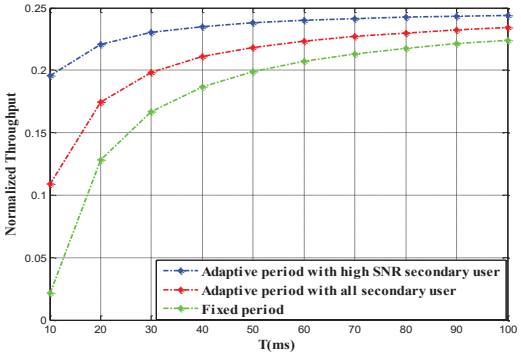

Fig.8. T Vs Normalized throughput, M=5, t = 1.5 ms

V. CONCLUSION

The proposed method uses an adaptive collection period in cooperative spectrum sensing which includes only the high SNR secondary users. In order to enhance the detection probability and spectrum efficiency the adaptive collection period scheme is used and here the low SNR secondary users are eliminated. The fusion center decides whether to stop or extend the collection period based on the expected revenue calculated at that time. The user which has the high SNR value can access the spectrum for data transmission hence the problem of interference is reduced is also reduced. Simulation results confirm that the adaptive high SNR secondary user performs better when compared to other schemes. In future, an adaptive cooperative spectrum scheme with fair policies for spectrum allocation for all secondary users can be designed.

***Abstract*—Unauthorized and unregistered sea going fishing vessels are being used for criminal activities in the coastal areas. The issue of piracy against merchant ships using illegal fishing vessels poses a significant threat to world shipping. Unfortunately counter piracy efforts and maritime security by the own and other nation enforcement often affects the innocent fishermen who go for trans-border fishing. Hence a proper vessel monitoring system is required to protect the maritime security without tampering the routine fishing activity of the sea going fishermen. This paper reports a system for the detection of genuine marine fishing vessels comparing the satellite images and GPRS signal information.**

***Index Terms*—Vessel Monitoring Systems, Satellite images, GPRS, Trans-border fishing.**

I. Introduction

Monitoring the marine vessels is crucial for increasing the safety and security of the maritime traffic and preventing illegal activities on the waters. For example, immigration, illegal fishery, pollution, smuggling and piracy. Poaching is also getting a serious problem since it will cause environmental crisis in coastal zones. As we are aware ninety per cent of the worlds commerce travels by sea. Now the issue of piracy against these merchant ships is a significant threat to the international economy. Day by day pirate attacks and merchant vessels hijack is increasing. Once a vessel has been hijacked, the pirates demands a large ransom amount for the safe return of the crew, vessel and cargo. Unfortunately counter piracy efforts and maritime security by the own and other nation enforcement often affects the innocent fishermen who go for trans-border fishing. So going beyond that limit for fishing is hazardous to the fishermen. Many fishermen got injured and even died as part of the counter piracy efforts and maritime security [1]. Though the measures to combat piracy and illegal activities cannot be unlawful, it has to be analyzed whether there is at least reasonable apprehension of a pirate attack or encroachment. Hence a proper vessel monitoring system is required to protect the maritime security without tampering the routine fishing activity of the sea going fishermen.

There are many vessel monitoring systems, that are used in commercial fishing to allow environmental and fisheries regulatory organizations to monitor, the position, time, speed and course of fishing vessels [2], [3]. For example, the Automatic Identification System (AIS), which transmits the location of the ship to the center via radio communication. The limitation of this equipment is that all fishing vessels may not be equipped with AIS transponders. The AIS might be purposely switched off, defected or simply a smaller vessel (e.g. sailboat, fishing boat) is not equipped with this system since they are very expensive [4], [5].Hence to monitor the fishing vessels and detect illegal activities it is important to locate all the vessels with or without functioning AIS. This required a proper cost effective vessel monitoring system to protect the maritime security without tampering the routine fishing activity of the sea going fishermen. This paper explains a study on cost effective GPS-GPRS based vessel tracking system [6] and also detection of marine vessels from satellite images for a comparison with GPRS signal information.

In India, there are nine marine states and four Union Territories [7]. The length of national coastline is about 7516.6 km. Name of the state and length of each coastline in kilometer is as follows. Gujarat (1214.70), Maharashtra (652.60), Goa (101.00), Karnataka (208.00), Kerala (569.70), Tamil Nadu (906.90), Andhra Pradesh (973.70), Odisha (476.70) and West Bengal. (157.50).The union territories are Daman & Diu (42.50), Lakshadweep (132.00), Puducherry (47.60) and Andaman & Nicobar Islands (1962.00). According to UN convention on the law of sea, the limits for the various maritime zones are divided into three such as

- 12 nautical miles (NM)- Territorial Sea,
- 24 nautical miles (NM) -Contiguous Zone and
- 200 nautical miles (NM) - Exclusive Economic Zone.

Beyond 200 NM are the international waters [8].

II. GPS, GPRS and Imaging Satellite - an Overview

A. Global Positioning System (GPS)

The Global Positioning System (GPS) is a satellite-based system that can be used to locate positions anywhere on the earth. It was first developed by the United States Department of Defense. The official name of GPS is NAVSTAR (Navigation Satellite Timing and Ranging).It provides a 3-dimensional

positioning, continuous, real-time, navigation and timing all over world. The GPS system consists of three segments, they are: a)The space segment: i.e. the GPS satellites b) The control segment, which is operated by the U.S. military, and c) The user segment, which includes both civilian military and users and their GPS equipment [9], [10].

B. General Packet Radio Service (GPRS)

GPRS is a Mobile Data Service accessible to Global System for Mobile Communication (GSM) and IS-136 mobile phones users. It provides packet-switched service and several number of users can divide the same transmission channel for transmitting the data. It is a third-generation step towards internet access. It replaces the wired connections which makes the system more intelligible access to the packet data networks like the internet. The principle employed by GPRS is the packet radio to transport the user data packets in a structured way between external packet data networks and GSM mobile stations. These packets can be routed directly to the packet switched networks from the GPRS mobile stations. It provides an end-to-end wireless architecture.

C. Imaging satellites

Imaging satellites which have been used for maritime security, have mostly involved Synthetic Aperture Radar (SAR) sensors as sources of the images, Indian satellites using these sensors include RISAT-I and RISAT-II. SAR sensors like other radars send successive pulses of microwaves or radar waves, from a moving platform like a satellite or an aircraft. The distance the SAR device travels over a target creates a large synthetic antenna aperture. The larger the aperture is, the higher the image resolution becomes, regardless of whether physical aperture or synthetic aperture.

This allows SAR to create high resolution images with comparatively small physical antennas. The synthetic aperture is caused by the movement of the source of the radar. As the SAR device on board the aircraft or spacecraft moves, the antenna location relative to the target changes over time. Signal processing of the recorded radar echoes allows it then to combine the recordings from the multiple antenna locations. This forms the synthetic antenna aperture, and allows it to create finer resolution image than what would be possible with the given physical antenna aperture. Usually SAR imagers find use in a lot of remote sensing applications. Fig.1 below shows the sample images.

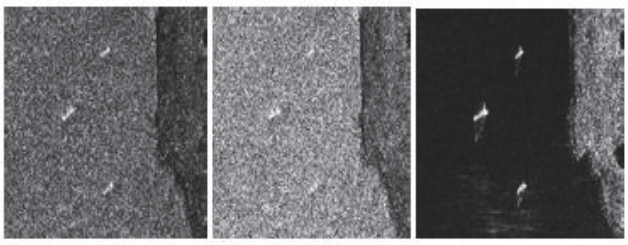

Fig. 1. Image patches from vancouver POLSAR data [11]

As these are RADAR images, there are some inherent problems in these kinds of images, these are listed below:

- Spatial resolution is limited.
- They cannot be used to detect images of length greater than 15m.
- Revisit time of the satellite to the target area is too long, hence making it difficult to use for surveillance unless many are present.
- Human interpretation of these images is very tough and involves polarimetric techniques to color the image first.

SAR imagery also has some advantages, because which it is preferred for identifying water vessels: [12], [13]

- Since the vessels are typically made of metal and their structure contains sharp edges they reflect the radar rays intensively, thus on the SAR images the vessels on open waters are bright dots and edges.
- The characteristics of SAR images enable reliable operations also by rainy and cloudy weather independent from the sun light conditions.

Optical satellite images can be used for the detection of marine vessels from satellite images. Optical imagers use mostly the visible light spectrum for the imaging purpose. Optical imaging satellites which are used for image analysis, includes SPOT which is a constellation of 7 satellites with optical imaging sensors, which together enable larger swaths while taking an image. It has an imaging swath of 60 km and high resolution enabling the detection of smaller vessels. The examples of optical images are shown in fig. 2.

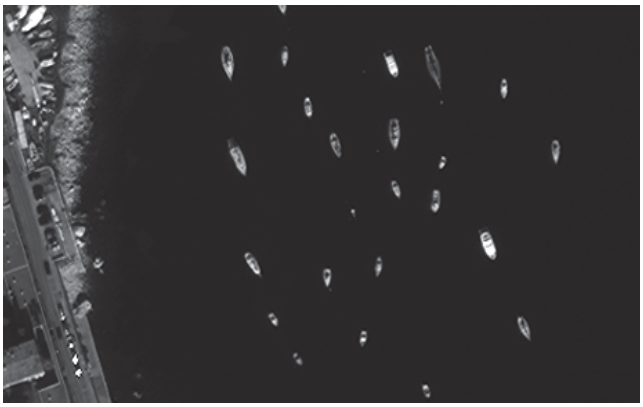

Fig. 2. Image patches from vancouver POLSAR data [13]

The advantages Optical satellite images (OSI) are as follows:

- OSI can have a higher spatial resolution, thus enabling the detection of smaller vessels and enhancing the vessel type classification.
- The human interpretation is easier than a SAR image, without the use of polarimetry.
- The tasking of an optical satellite is more simpler.

The main disadvantages of optical satellites is that they heavily depend on the weather and they can work only during daytime [14].

III. Proposed system

In the proposed system, a unit consists of GPS based location identification hardware and GPRS data communication facility along with a micro-chip that contain the whole information regarding the vessel and sailors/fisherman will attached to the sea going vessels [6]. Using this location and identity of the sea-going vessels can be easily traced and tracked out in the connectivity area in online mode with any of the enforcement authorities. The signals from the system will automatically activate immediately as the vessel start to sail and the position of the vessels will be regularly updates in the Central Monitoring System (CMS). The precompiled database of the CMS will contain all the details regarding the registered boats such as engine and hull numbers, its owners name, operating state, details regarding the dimensions, capacities and power along with fishing technique undertaken. The entire registered vessel will have specific area, scope and duration to fish. This will be regularly updated in the CMS along with current status and condition of the vessel. While the fishing vessel travelling beyond the connectivity area the communication network between the CMS and the vessel will be lost. Though the built in GPS and memory device in the system records the positions wherever the vessel roaming in the sea area, it will be communicated to the CMS while it come back to the connectivity area.

Usually the sea going fishing vessels stay in the deep sea (non-connectivity area) for fishing around 10-15 days. During this period CMS is unaware regarding their activities in the deep sea as there is no communication network. In this circumstance only enforcement teams like Coast Guard, Coastal police and Navy can monitor the fishing boats using Government approved registration number. Daily thousands of vessels will stay in the deep sea and take part in the fishing activity as fishing is one of the major incomes for the people living in the coastal areas of India. If any Unregistered fishing boats and those displaying fake registration numbers is being used for any illegal activities in the national sea boundary (deep sea) it is very difficult to identify and cross check the same by the enforcement authorities. Usually larger sea going marine vessels is always equipped with the Automatic Identification System, which might be purposely switched off, or simply a smaller vessel is not equipped with this system. In order to detect the illegal fishing vessels, it is important to locate the vessels also without functioning AIS.

Hence to detect the illegal fishing vessels, it is designed to uses the satellite images for the detection of marine vessels in comparison with GPRS signal information. Knowing the advantages and disadvantages, it has been chosen in this system to use optical images rather than SAR images because of easier access and implementation, as polarimetry is an additional step which is removed. The schematic representation diagram is shown in fig. 3.

Fig. 4 shows the flow chart of vessel detection by comparing the GPRS signal information and Satellite image.The GPS-GPRS system will automatically activate immediately as the vessel starts to sail. The GPS receiver in the system identifies the location and position of the vessels and it is send to the CMS via GPRS network. The network coverage area of GPRS in the maritime area of India is about 25-30 km. Beyond this area, i.e. GPRS non connectivity area, satellite images of the coastal territory are used to detect the vessels. From the satellite image, it is able to detect the number,time and position of the vessels using image extraction algorithms and update it to the CMS.Then compare the information obtained from GPRS signal and Satellite image. If the information same, no alert to CMS. Unless check whether the vessel is within the GPRS connectivity area or in the non connetcivity area. If it is in the connectivity area,an alert is given to CMS as well as to the enforcement auothorities. if it is in the GPRS non connectivity area, check whether the vessel is permitted in that area using the satellite image of the coastal territory.If the information of the vessels are same then send the updates of position to the CMS otherwise give an alert to the enforcement auothorities and CMS.

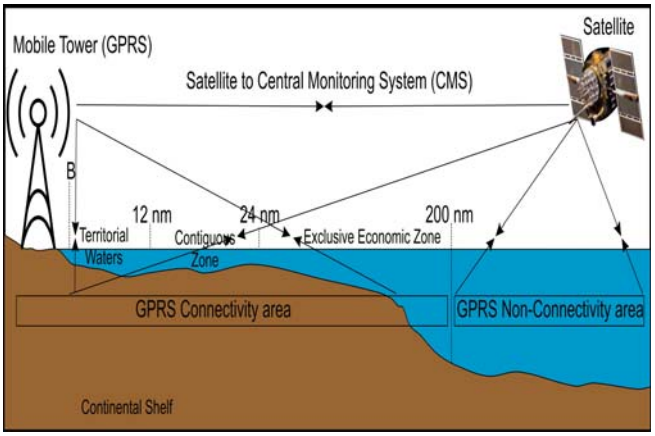

Fig. 3. Schematic representation diagram for proposed system.

The various steps involved in the digital processing of Satellite Images to isolate and identify the images of the fishing vessels are: Image rectification and restoration, Image enhancement, Information extraction [15].

Image rectification and restoration: Geometric distortions apparent themselves as errors in the position of a pixel relative to other pixels in the image. If it is left uncorrected, these distortions give any data extracted from the image is useless. Distortions occur for many reasons. For example, due to changes in platform attitude, altitude, earth curvature, earth rotation, detector delay and panoramic distortion. Most of them can be solved mathematically and are removed before you buy an image. Altitude changes are however difficult solved mathematically and thus a procedure called image rectification is performed. Satellite systems are however geometrically quite stable.

Image Enhancement:These techniques are used to improve the quality of an image as distinguished by a human. It is a most useful technique because many satellite images when

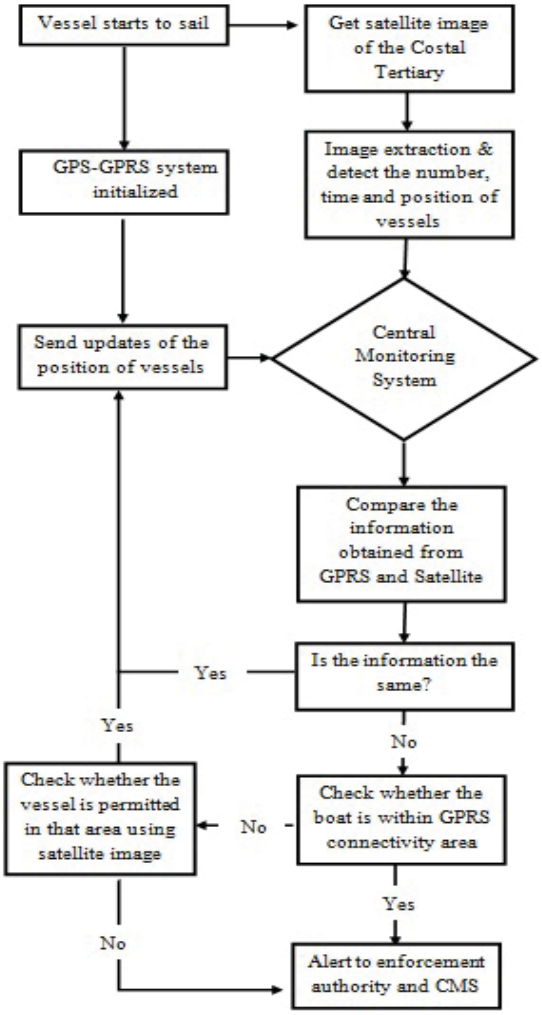

Fig. 4. Flow chart of comparion of GPRS signal & satellite image

considered on a color display give inadequate information for image interpretation. There are various kinds of techniques used for improving image quality such as contrast stretch, edge enhancement, density slicing, and spatial filtering. Image enhancement is attempted after the image is corrected for geometric and radiometric distortions.

Information extraction:It includes image classification in which it classifies the images automatically and categorizes all pixels in an image into land cover classes and themes. The term classifier refers to a computer program uses statistics and training data to divide the data into groups. There are wide varieties of techniques for classifiers, which are used for different purposes. Information extraction algorithms are specific to application. These will mostly be shape and feature detection algorithms [16].

The vessel detection problem mainly reduces to two distinct problems. One regarding the isolation of components in an image and the other regarding the classification of the isolated components as being vessel or other. Many component isolation methods are available and the most used is thresholding method. But it perform poorly on maritime vessel detection problems. So, the component isolation method can be used which is based on the image component tree algorithm. In this method two processes are used for identifying and isolating boats from satellite images. The first method is Isolation of likely candidates which can be done using Component tree formation and then deciding a height (related to the value of a component), using which we decide the components which are to be processed further. The second method is Random Forest Classifiers which are used to detect the vessel. Artificial Neural Network (ANN) method can also be used. The classifier needs to be constructed based on some training data in order to predict the data. This means that a human must identify a number of vessel targets to be used as training data.

IV. Analysis and Discussion

The major drawbacks of the existing security systems like Automatic Identification System (AIS) are: they are not cost effective, systems are very bulky, it is applicable only for the ships and not for the fishing boats and it is based on radar communication. Hence it requires large power and high gain antennas. To overcome these problems a new technology, GPS-GPRS system is proposed which is feasible and cost effective for the sea going fishing vessels. The system consists of a GPRS, GPS, and a micro-chip containing all the information about the vessels and fishermen. The position, location and identity of the seagoing vessels can be easily traced and tracked out by the enforcement authority. It can be provided with a two battery system which helps to provide long life to the equipment. Also, if one of them is tampered it automatically sends message to the CMS and the other one automatically switched on. The advantages of the proposed system are: Cost effective, Portable, Long battery life, Handy, Requires less power. But the coverage area of the GPRS network is limited. The GPRS network coverage in the maritime area is about 25-30 km and beyond this area, satellite images are used to detect illegal fishing vessels.

There are lot of algorithms for identifying boats and other water vessels. The paper [13] describes two steps for detecting water vessels. The first step involves detection of features using haar wavelet. The main purpose of using this is to reduce the in-class while increasing the out-of-class variability compared to the raw data and thus making classification easier. In the second step again a classifier is used, a more complex classifier called Adaptive Boosting. The described detection method can detect the vessels with a good quality if the water mask is accurate and the water doesnt contain large waves. The classifier is complicated to implement. Another paper [14] mainly explain with two process for identifying and isolating boats from satellite images:(1) Isolation of likely candidates is done using Component tree formation and then deciding a height (related to the value of a component), using which we decide the components which are to be processed further. (2) Machine Learning algorithm and Random Forest Classi-

fiers are used to detect the vessel. At most optimal penalty parameters, false positives were 10%. It is easy to implement but maybe not the most efficient as high resolution images were taken and image enhancement technique is also required to improve the result. Also in paper [16], it deals first with the Pre- processing using three steps: tiling, removing cloud masking using thresholding, contrast enhancement. In the next process Segmentation is done using mathematical morphology and connected components. And again a component tree and height based technique is used to filter and divide the image. In the third step Discrete Wavelet Transform and Radom Transform are performed to make certain parts more visible, further a regressive predictor is used to classify candidates. It all depends on the probability threshold. As the threshold is increased the number of false positives decreases otherwise increases. This method is also complicated to implement and the results are seemingly inefficient as the classifier used is little rudimentary. In this paper the method described in Patrik Johansson, [14] is used to detect the marine vessels which are less complicated when compared to other detection methods.

V. Conclusion

In this paper an efficient and cost effective method for marine vessel detection comparing GPRS and Satellite Images is proposed. This will definitely benefit the poor fisherman to secure their life while fishing and also enforcement to protect the coastal area, which in turn provides the national and international security. In this paper a detailed review on various algorithms for identifying marine boats from satellite images has been done. Further work is needed to fully explore the capability of the approach under a wider range and weather conditions. This study is a good basis for further development of methods that might be useful in real world applications of maritime surveillance.

Secure E- Voting System with integration of NFC, Biometrics and Cloud Computing

Tejas Upasani[1] Mrunal Satbhai[2] Ankit Panchal[3] Madhuri Taunk[4]
Department of Computer Engineering
SITRC, Nashik

***Abstract*— Smart Phones have become essential in today's digital era. Many technologies like RFID, QR Codes, Barcodes, Bluetooth and other proximity devices have been used. Out of these, NFC is an emerging technology. NFC is short range technology that enables communication between two NFC enabled devices. These devices operate at very close distance from each other, at around 3.9 and below. Moreover, cloud computing being an efficient storage technology, servers can be implemented using cloud. Biometrics has also proved to be a measure for verification and validation. Biometric results are unique and an accurate identification factor.**

Efficiency and accuracy are two important aspects of any E-voting system. Use of NFC leads to easy and secure e-voting. It makes the system easy to understand for the general public that have no technical knowledge, along with increasing its usability for all users. So NFC based E-voting can not only offer accuracy and increased usability but also reduce the scalability issues. It can bring out transparency, accuracy and efficiency.

But, in today's digital world scenario, it is very important to efficiently handle the network traffic while working with servers. Overhead may cause the failure of server, which leads to loss of critical data of the voter. The Cloud Computing Approach provides a splendid solution to this issue to efficiently maintain and access data. The proposed system uses NFC for secure voting, provides cloud computing for the database servers and biometrics for authentication.

***Keywords*— NFC Tag, NFC Reader, Biometric, Cloud computing, Secure Element.**

I. INTRODUCTION

The foundation for democracy is election. Election is the process of choosing right person for the right job. According to tradition procedure of voting huge equipments and paper work is required. The voting process is too tedious and time consuming as well is the tallying process. In the existing system, voter has to go to the voting booth, which becomes a geographical limitation. The proposed system overcomes this limitation. The resources being reusable, the system becomes inexpensive. The system also satisfies efficiency measures like scalability, authentication, voter privacy, confidentiality, integrity, accuracy, verifiability and mobility. The proposed system fits into the quality measures of an Efficient E-voting system. An effective system must give accurate results. It must provide provisions to vote beyond geographical limits. It needs to be secured and should include technology that maintains accuracy and increase user interaction and usability. The system proposed here includes NFC as the core technology for voting is proposed. In this system, an Android based NFC enabled Smart phone and posters of candidate contesting the elections containing NFC tags are used for voting. The voter will first enter their biometric information. Then the mobile device containing NFC has to be tapped on the poster of respective candidate to cast a vote to the desired candidate. Now, the voter information obtained by the biometric recognition kit and the vote from the Smartphone is sent to the authentication server on cloud. If the casted vote is valid, then the recorded vote is counted in the database on cloud. If this vote is invalid that is casted due to any illegal activity, then this recorded vote is discarded during the authentication phase.

II. REVIEW OF LITERATURE

It is important that any e-voting system has to be efficient and should fulfill the basic measures of ideal e-voting. These required measures are described as follows:

Accuracy: The vote so entered should not be altered before or after it is been counted.

Privacy: The link between the voter and the casted vote must be completely finished, so as to hide the identity of the voter after the casted vote is counted.

Verifiability: Every voter can verify whether their casted vote is been counted.

Mobility: A voting system may provide provisions to the voter to vote anywhere, breaking the geographical barriers.

Democracy: Only eligible voters can cast a vote, and authentication of every voter is necessary before voting. Verification has to be done in case of double voting by the same candidate [1].

These measures are of great importance and have to be completely satisfied. Earlier, E-voting was implemented using electronic ballot system. Some systems used touch panels and printers. Such systems were vulnerable to tampering of vote information which led to the use of Barcodes or QR codes for voting. Later RFID emerged to be used for e-voting. Yet the issue of security, remained unsolved. NFC being more secure for data transmission, it is proposed to use NFC for e-voting [2] [4]. Near Field Communication is wireless communication technology which works for radio frequency of short range. Near Field communication creates a point-to-point network for data communication. Near Field Communication works on unlicensed radio frequency band of 13.56 MHz available. When NFC enabled devices brought within close proximity i.e. a small distance around 4 cm to 20 cm, data transfer at rate of up to 424 Kbps can be achieved. It permits data transfer in the chunks of 106 Kbps and 212 Kbps as well. It can provide a bandwidth of approximately 2 MHz [8] [9].

Near Field Communication provides contactless communication. NFC technology is based on Radio Frequency Identification (RFID). It uses the magnetic field induction that is emitted by NFC enabled devices to actuate communication between them. NFC technology is emerging faster as its applications are increasing day by day in every sphere of life. And importantly, if NFC technology is being used in combination with mobile phone, then it can offer great opportunities. NFC technology provides users to just wave his mobile phone near NFC enabled tag and the task is done [13].

NFC work on frequency for data across is 13.56 megahertz and data which can be sent at 423, 212, 106 kilobits per second. NFC technology is based on two side interaction - initiator and target where initiator starts communication by producing magnetic induction field wave. While target plays the role of receiver by using

this magnetic field wave to activate it and performs necessary communication. Communication node Initiator and Target can be tags, stickers, or cards that do not require any batteries [17] NFC readers include a secure element or secure access module in their hardware. This is just a simple processor that's attached to the NFC controller. The secure element can be programmed to verify a code sent by the reader using public key encryption and decryption. Because the secure element of a reader/writer (or of a smart card) is capable of running small programs on its own (called applets or taglets), it can even generate new hashes on the fly. Along with NFC, Biometrics is also integrated into the system for accurate user identification and authentication. Face recognition, hand geometry biometrics, iris scanning, signature matching, voice analysis, vein printing and fingerprint recognition are the variants of Biometrics. Face and vein printing techniques are attain universality but are poor at uniqueness. Iris scanning provides uniqueness, but cannot be acceptable widely for every individual. Hand geometry matching matches the structure of an individual's hand, but gives average resulting performance. However, Fingerprint recognition is one such technique that offers uniqueness, high matching performance and permanence [7].

Using cloud computing users and enterprises get capability to store and process their data in third party centers. It share the resources. Cloud computing focuses on maximizing the effectiveness of the shared assets. Cloud assets are normally shared by a number of customers and in addition dynamically reallocated per demand. With cloud computing, a number of customers can entry a single server to retrieve and replace their knowledge with out buying licenses for various purposes.

Cloud companies give distant supply of computing sources using internet. Particularly Cloud environments are the place prospects get hold of companies from a third-party Cloud supplier. Cloud providers encompass computing capabilities supplied by Cloud infrastructure and communications capabilities supplied by the Web.

Networking can be a key component for offering knowledge communications in Cloud knowledge facilities in addition to amongst information facilities distributed at totally different places [14].

Measures of cloud computing:

1. Availability -Information needs to be accessible whenever required.
2. Confidentiality -Knowledge ought to be stored confidential.
3. Reliability - Information must be dependable four. Safety - Safety of information and software program interfaces ought to be maintained [15].

Cloud computing fashions [16]

A) Public cloud: Public cloud is one primarily based on the usual cloud computing mannequin, wherein a service supplier makes assets out there over the web. Public cloud providers could also be free or provided on a pay-per mannequin.

Benefits of public cloud companies:

1. Straightforward and cheap set-up
2. No wasted assets since you pay for what you employ.

B) Neighborhood cloud (inner or company cloud):- additionally referred to as inner cloud or company cloud.

Any such cloud supplies hosted companies to a restricted variety of individuals.

C) Hybrid cloud: Hybrid cloud is a Cloud Computing surroundings through which a corporation gives and manages some assets in-house and has others supplied externally. The hybrid strategy permits an enterprise to reap the benefits of the scalability and cost-effectiveness.

D) Personal cloud: A neighborhood cloud could also be established the place a number of organizations have related necessities and search to share infrastructure in order to appreciate a number of the advantages of cloud computing. However these choices are dearer for offering increased degree of privacy so as an alternative of neighborhood cloud non-public cloud is used [16].

The secure element resists the attacks that can be found in any smart card. The secure element provides storing area in smart phones and it built with different hardware and software. The SE has many different key fields for security mechanism and also provide process for authentication in system.

III. PROPOSED SYSTEM

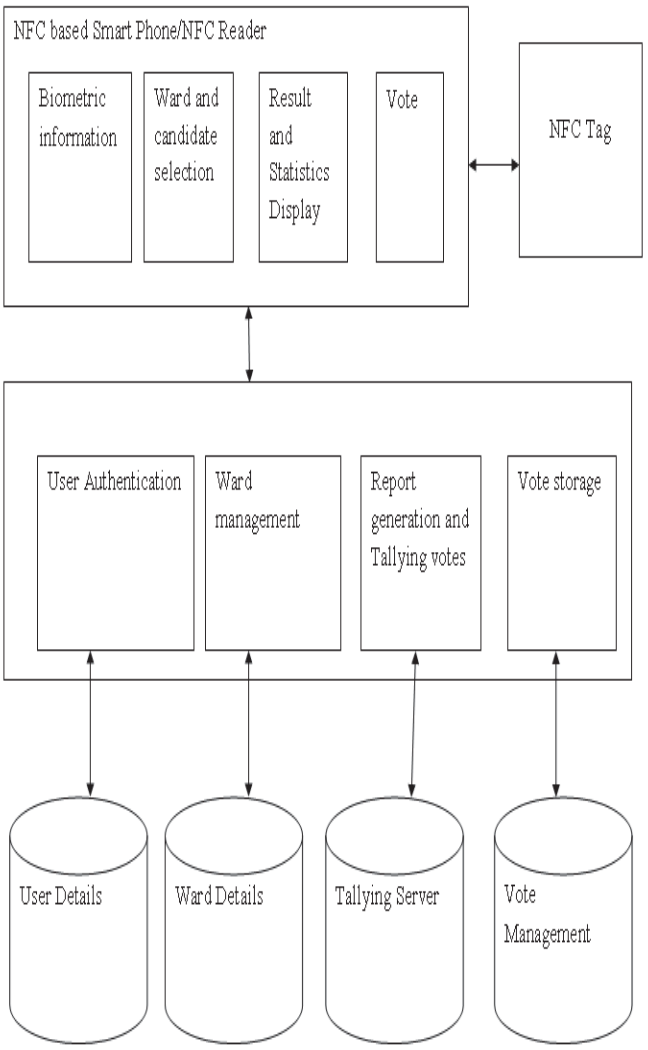

Fig 1. Overview Architecture of Secure E- Voting System with integration of NFC, Biometrics and Cloud Computing

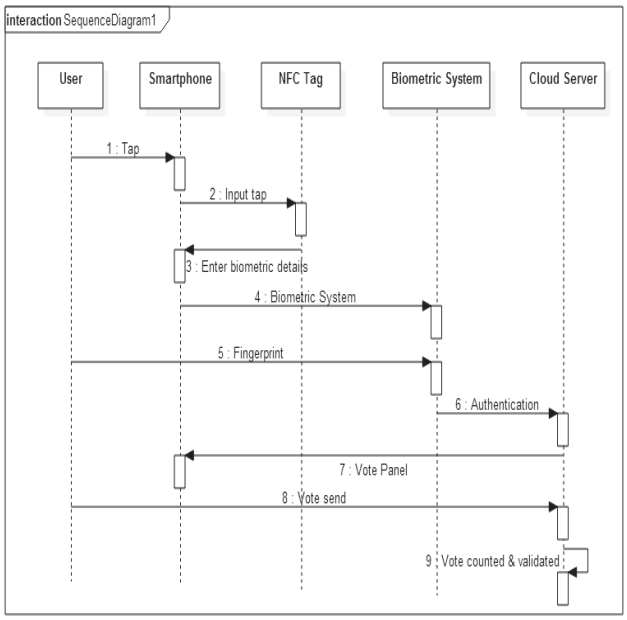
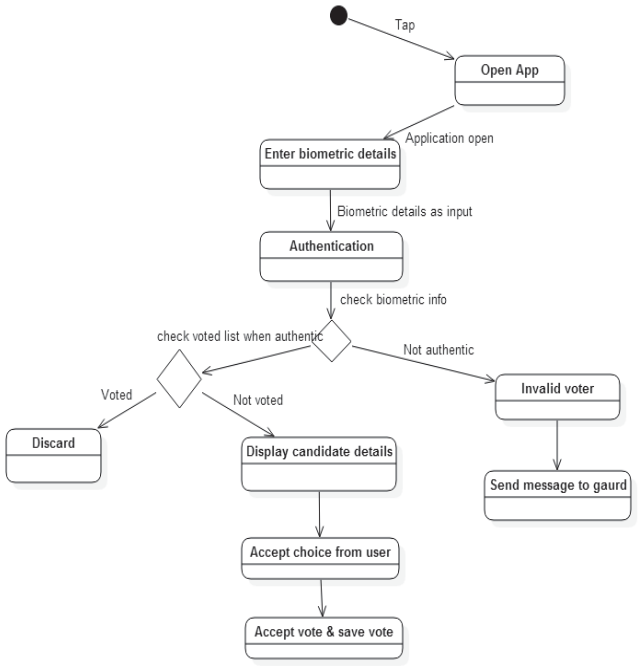
The proposed system utilizes NFC enabled mobile device/NFC reader for casting the vote. Along with this an NFC card will be used for storing the candidate information. The user's biometrics is given an ID corresponding to that of his voter ID. This information will be stored on cloud prior to the voting process. To vote, the voter must provide their NFC enabled devices in the proximity of the NFC tag for data exchange and once the NFC device is identified, the voter is asked to present their biometric details. The biometric system sends the received information received to be checked to the corresponding ID card. If the two match, the voter is allowed to select their choice of candidate from the buttons in the selection panel from a particular ward. After a vote has been casted the ID card is marked for future referencing, this prevents the voter from casting multiple votes. The

voter's information is also marked in the database of the system. The tally for each candidate's vote is stored in the database, and once the voting process has ended, the results may be obtained.

IV. SEQUENCE DIAGRAM



V. STATE CHART DIAGRAM



VI. MATHEMATICAL FOUNDATION

Let B represent the set of Biometric Recognition System:

B = {Fingerprint Scanning System}

Let M represent the set of Mobile Application to be used:

M = {{Java}, {Android}…}

Let NFC tags in the Smart Posters be denoted as,

T = {Details of Candidate}

Therefore, Let 'E' represent all the equipment used in the concerned system,

E = {{B}, {M}, {T}}

Let all the users associated with the system be represented by U:

U = {{Voter}, {Candidate}}

Hence,

Interactive Relation between the user and the equipment used in the system can be defined by Relation set 'R',

R = {(Voter, B), (Voter, M), (Candidate, T), (M, T)}

Now, the vote information and the candidate data as well as the voter Identity is sent to the Verification server.

Therefore, the entire verification process can be denoted as follows:

Let,

Event p: Vote Information

Event q: Candidate Data

Event r: Voter Identity

Therefore,

Event S should denote the validation and correct verification of the above provided details.

The Event S is true only for the TRUE Values of 'p', 'q' and 'r'. This also means that the Verification is TRUE only if the vote information and the candidate data as well as the voter Identity is VALID and TRUE.

$$S \rightarrow \{(p \wedge q) \wedge r = : \text{TRUE}$$

By integration of the above two systems, the entire logic behind the proposed system can be explained.

Therefore,

The integrated system can be denoted as:

$$\int R.S = \lim_{n \to \omega} \sum r.s$$

Where, (r, s) are the input values to the entire system and

ω is the number of votes being entered into the system.

CONCLUSION

As voting is a crucial process in democracy; it has to be conducted in a secure and fair manner, avoiding security breaches. The proposed system, in this paper, uses NFC technology for efficient E-voting system with minimum use of resources. NFC provides greater security for transmission of the sensitive data regarding the elections. Biometrics is integrated for correct identification and authentication of voter. Moreover, to avoid the server overhead and failure, Cloud computing is included. It is necessary to achieve ideal election goals like scalability, authentication, voter privacy, confidentiality, integrity, accuracy, verifiability and mobility; which will be achieved in the proposed system.

***Abstract*—After advent of Cognitive Radio networks, spectrum sensing and signal detection has received wide attention. It has been observed that simple energy detectors do not perform as desired under very low SNR regime. The radiometer performance further degrades due to noise uncertainty. Eigenvalue based detectors performs better due to their larger independence on received signal SNR. Authors have used an algorithm from their earlier work for detection of Chi-Sq distributed independent random signals using Wishart matrix which model the sample covariance matrix. The Wishart matrix has been computed by using algorithm given by Odell and Feiveson (1966). The performance of Wishart modelled MME detector is evaluated when received signal undergoes fading. Different signal fading models like Rayleigh, Rician are considered and performance is evaluated in form probability of detection.**

I. Introduction

Opportunistic Spectrum Sharing (OSA) has gained importance due to higher bandwidth requirements due to large number of digital devices. The cognitive radio technology is visualized as enabling technology for flexible usage spectrum [1], [2], [3]. In this regard, spectrum sensing is the fundamental function of Cognitive Radio (CR) wherein radio detects the current electromagnetic spectrum environment to identify unutilized idle spectrum of licensed users or Primary Users (PU) [2]. In case of IEEE 802.22 standard, due to passive DTV network and primary protection requirement, there are stringent requirements on detection at very low SNR ($-20dB \equiv -114dBm$) and entire spectrum sensing duration to be 2 seconds [4]. These constraints mandate continuous scanning of the TV spectrum [5], [4]. Furthermore, spectrum sensing by single cognitive radio has limitations due to hidden node problem [1]. Quadratic form for energy detector is realized by Urkowitz [6] wherein linear filter followed by squaring and integration system has been used. Such an operation can be described as a filtered energy detector. Test statistics for detection has generally unknown distributions. It can be observed that, signal-to-noise ratio (SNR) is an important parameter which affects the performance energy detector [6]. As distribution is unknown, characteristics of hypothesis is also unknown so generally estimation of mean and variance is carried out for designing of detection algorithm.When signal and noise power is not known apriori, generalized likelihood ratio test (GLRT) is designed for this case, which uses empirical second-order statistics of the received data. GLRT gives suboptimal detection performance. However, in spite of its simplicity, energy detector employed for spectrum sensing in very low SNR regime do not give desired performance and its performance further deteriorates under noise and interference uncertainty. Hence, Eigenvalue based detector for which detection performance is largely independent of received signal SNR, can be a better choice. Other algorithms like Cyclostationary detection algorithm, are either difficult to implement or require signal information which is not possible due to legacy considerations in case of Cognitive Radio Networks (CRN).

Pioneering work in this context has been done by Nadakuditi and Silverstein [7] and Zeng et al. [8] who made use of multivariate statistics in terms of sample covariance matrix for detection of independent random signals. Covariant matrix was used for the detection and Wishart distribution [9] and [8] is considered only for calculating the detection threshold. In this paper, the algorithm using maximum-minimum eigenvalue based detection approach with Wishart random matrices is adapted from the work of Deshmukh et al. [10]. Wishart matrix is simulated in MATLAB by using algorithm given by Odell and Feiveson (1966) [11]. This algorithm uses a centering matrix to scale sample covariance matrix which has

always a Wishart distribution [12]. Hence, a sample covariance matrix can be modeled as Wishart matrix. In the present work, different signal fading models have been considered while evaluating the performance of Wishart based MME detection algorithm.

A. Detection Model

A generalized detection model assuming multiple input signals from J sources is proposed. Detection is assumed to be carried out at K receivers. It also assumed that N number of samples collected by each k receiver during the sensing time [5]. Received discrete signal at k receivers is denoted by

$$y_k(n) = \sum_{j=1}^{P} h_{kj}(n)s_{kj}(n) + \eta_k(n) \tag{1}$$

be a kx1 vector containing k received samples at time 'n' where $n = (1, 2, ...N)$. This detection problem is posed as binary hypotheses testing problem such that [8], [13]

$$\begin{array}{c} H_1 := Y = y_k(n) = \sum_{j=1}^{P} h_{kj}(n)s_{kj}(n) + \eta_k(n) \\ H_0 := Y = y_k(n) = \eta_k(n) \end{array} \tag{2}$$

where; $S_{kj}(n) = (j = 1, 2, 3, ..., P)$, $P \geq 1$ source signals, $h_{kj}(n)$ is the channel response from signal source j to receiver k and $\eta_k(n)$ represents noise sample and the noise is assumed to be Additive Gaussian White Noise(AWGN)s.t. $\eta(n) \sim \mathcal{N}(0, \sigma_n^2)$. Furthermore, channel is assumed to be flat fading for the sensing duration [9], [8].The probability density function Y corresponding to each hypotheses are $f_{Y|H_0}(y|H_0)$ and $f_{Y|H_1}(y|H_1)$ where y is particular value of the random variable Y.If $D = D_0, D_1$ is decision space and $H = H_0, H_1$ is Hypotheses, then conditional density functions representing the different decisions are

$\mathbb{P}(D_i|H_j); i, j = 0, 1$ in terms of decision regions is given by $\mathbb{P}(D_1|H_1) = [\int_{Z_1} f_{Y|H_1}(y|H_1)dy]$ equivalently.

$$\int_Z f_{Y|H_1}(y|H_1)dy = \int_Z f_{Y|H_0}(y|H_0)dy = 1 \tag{3}$$

this allows to change the decision regions such that;

$$\int_{Z_1} f_{Y|H_j}(y|H_j)dy = 1 - \int_{Z_0} f_{Y|H_j}(y|H_j)dy; j = 0, 1 \tag{4}$$

Generalized Probability of detection P_d is given by [13], [14]

$$P_d = \mathbb{P}(T_{GD} > T|H_1) = Q(\frac{T - \mu_1}{\sigma_1\sqrt{N}}) \tag{5}$$

where; T_{GD} is a of test statistic for generalized detector, T is predetermined threshold, σ_1^2 is variance under hypothesis H_1, μ_1 is mean of T_{GD} under H_1, where

$$\mu_1 = \frac{(2(1 + \gamma_r))^{P/2}}{\sqrt{\pi}}\Gamma(\frac{P + 1}{2})\sigma^P \tag{6}$$

$$\sigma_1^2 = \frac{(2(1 + \gamma_r))^P}{\sqrt{\pi}}[\Gamma(\frac{2P + 1}{2}) - \frac{1}{\sqrt{\pi}}\Gamma^2(\frac{P + 1}{2})]\sigma^2 P \tag{7}$$

where, γ_r is average received SNR, $P > 0$ and $\Gamma(.)$ is a Complete Gamma function [14] Requirement on P_d and P_{fa} depends upon applications. Generally P_{fa} is considered to be $P_{fa} \leq 0.1$ for spectrum sensing in TV white space (TVWS) based Cognitive Radio Network(CRN).

1) Calculation of Detection Threshold: At very low SNR values, derivation of threshold become very difficult if it is based on value of P_d [15], [8] because of unknown signal. As P_{fa} is related with hypothesis H_0 [13], hence sample covariance matrix of noise is,

$$C(N) = \frac{1}{N}\sum_{n=L}^{L-1+N} \hat{\eta}(n)\hat{\eta}'(n) \tag{8}$$

where; C is special Wishart matrix. The expression of the joint PDF of the ordered eigenvalues is complicated. The derivation for the threshold can be found in Tracy and Widom [15], [8]. The distribution of largest eigenvalues of the real random matrix are given by the following Theorem-1.1. Extreme eigenvalues are calculated according to Theorem-1.2.

Theorem 1.1: If noise is assumed to be real and let $A(N) = \frac{N}{\sigma_n^2 C(N)}$, $\mu = (\sqrt{N-1}+\sqrt{d})^2$, $\nu = (\sqrt{N-1}+\sqrt{d})(\frac{1}{\sqrt{N-1}} + \frac{1}{\sqrt{d}})^{1/3}$ and assume that $\lim_{N\to\infty}\frac{d}{N} = x(0 < x < 1)$, then $\frac{\lambda_{max}(A(N)-\mu)}{\nu}$ converges with probability one(1) to Tracy-Widom distribution of order 1, dimension $d = ML$ where; M is oversampling rate and L is smoothing factor.

Let $\beta = \frac{N}{d}$, then the First order Tracy-Widom Cumulative Distribution Function (CDF) is given by [11], [15],

$$\begin{array}{l} F_1(c) = exp(-\frac{1}{2}J(c; q(c))[F_2(c)]^{1/2} \\ \text{where, } F_2(c) = exp(-I(c; q(c)) \\ I(c; q(c)) = \int_c^\infty (y - c)q(c)^2 dy \\ J(c; q(c)) = \int_c^\infty q(y)dy \end{array} \tag{9}$$

where $q(.)$ is Painlevé-II equations.

Theorem 1.2: Assuming that $\lim_{N\to\infty}\frac{d}{N} = x(0 < x < 1)$, then $\lim_{N\to\infty}\lambda_{min} = \sigma_\eta^2(1 - \sqrt{x})^2(0 < x < 1)$

Extreme eigenvalues of random matrices are calculated based upon Theorem- 1.1 and Theorem-1.2 and Sawyer [11] such that,

$$\begin{array}{l} \lambda_{max} \approx \frac{1}{N}(1 + \beta^{-1/2})^2 \\ \lambda_{min} \approx \frac{1}{N}(1 + \beta^{-1/2})^2 \end{array} \tag{10}$$

Note that $d = ML$ and $\beta = N/d$

$$\begin{array}{l} \lambda_{max} \approx \frac{1}{N}(\sqrt{N} + \sqrt{d})^2 \\ \lambda_{min} \approx \frac{1}{N}(\sqrt{N} - \sqrt{d})^2 \end{array} \tag{11}$$

Tracy-Widom distribution for the asymptotic eigenvalues of certain random matrices of order 1, denoted by $F - 1$ and it is a cumulative distribution function(CDF) of the Tracy-Widom distribution of order 1 can found in Tracy and Widom [15]. For real values of noise, probability of false alarm of MME is given as;

$$P_{fa} = \mathbb{P}(\frac{\lambda_{max}}{\lambda_{min}} > \gamma) \tag{12}$$

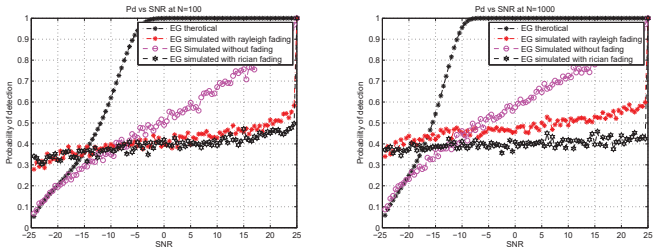

Fig. 1. Energy based detection: (a) for N=100, (b) for N=1000

Plugging in the values of λ_{max} and λ_{min} from Eq. (11), decision threshold is taken such that:

$$P_{fa} = 1 - F_1\left(\frac{\gamma(\sqrt{N}-\sqrt{d})^2 - \mu}{\nu}\right)$$

$$\text{This implies, } F_1\left(\frac{\gamma(\sqrt{N}-\sqrt{d})^2 - \mu}{\nu}\right) = 1 - P_{fa}$$

$$\frac{\gamma(\sqrt{N}-\sqrt{d})^2 - \mu}{\nu} = F_1^{-1}(1 - P_{fa}) \tag{13}$$

by putting values of μ and ν from Theorem-1.1 detection threshold is given as

$$\gamma = \frac{(\sqrt{N}+\sqrt{d})^2}{(\sqrt{N}-\sqrt{d})^2}\left(1+\frac{(\sqrt{N}+\sqrt{d})^{-2/3}}{(Nd)^{1/6}}F_1^{-1}(1-P_{fa})\right) \tag{14}$$

II. Performance of Detectors

The performance of the energy detector, covariance based MME detector and Wishart modelled MME detector is evaluated for SNR=-20dB and Pfa=0.1 are obtained for different number of samples. Signal undergoes different fading environment.

For minimum number of samples, performance of detector under Rayleigh and Rician fading conditions nearly acheives the same response 1. Detector performance enhances for signal under Rayleigh fading than that under Rician. It is observed that, energy detector shows better performance under nonfading (AWGN)channel conditions than other two fading channels. Performance is evaluated in the form of probability of detection with respect to SNR.

Covariance based MME detector performes better under Rician fading in comparision with Rayleigh case 2 and 3.

Performance under AWGN and Rician fading channels closely follows each other. For larger number of samples, detector performance improves for AWGN channel case compared to other two fading conditions. In general, Wishart modelled MME detector 4 and 5 performes better under different fading conditions than energy detector and Covariance based MME detector. Furthermore, as number of samples are increased, effect of fading is nearly nullified and detector achieves same performance under Rayleigh, Rician and AWGN fading conditions.

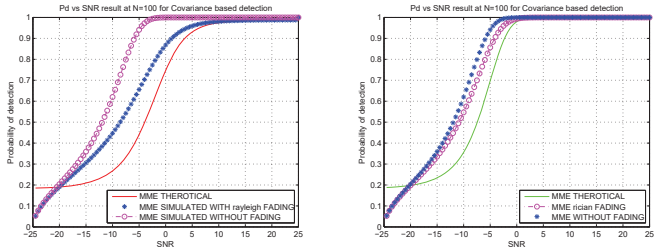

Fig. 2. Covariance based MME detection: (a) Rayleigh (N=100), (b) Rician (N=100)

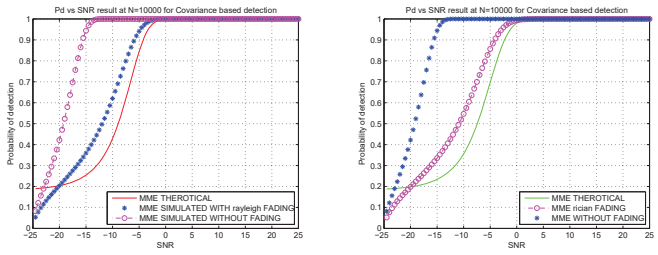

Fig. 3. Covariance based MME detection: (a) Rayleigh (N=10000), (b) Rician (N=10000)

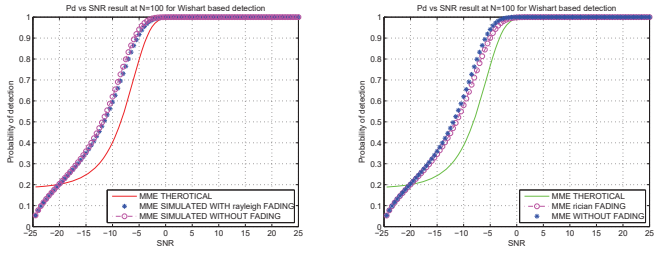

Fig. 4. Wishart base MME detection: (a) Rayleigh (N=100), (b) Rician (N=100)

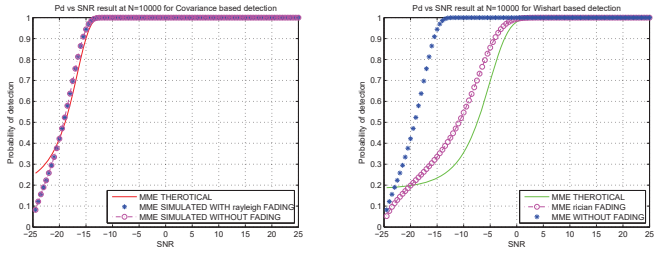

Fig. 5. Wishart base MME detection: (a) Rayleigh (N=10000), (b) Rician (N=10000)

III. Conclusion

The performance of detection algorithm for spectrum sensing in cognitive radio is presented. In this context, Maximum-Minimum Eigenvalue based detection has been reviewed. Performance of algorithm developed earlier exploiting Wishart random matrices and faster Odell and Fevison algorithm for computing the Wishart matrices is investigated under different fading conditions. The fading and non-fading environments are considered for signals to be detected. It has been observed that detector needs more number of required samples in fading environment to attain the same detection performance. It can be observed that, Wishart modelled MME detector performs better under different fading conditions than energy detector and Covariance based MME detector.

***Abstract*—In this paper a scheduling algorithm for multi-user multiple-input-multiple-output (MU-MIMO) system is considered. Users are selected at the base station(BS) based on the received signal to interference plus noise ratio(SINR). The M transmit antennas at the base-station(BS) selects M most favorable antennas from the receiver side and transmit parallel and independent data streams to them. A spatially correlated channel model is assumed. The effect of spatial correlation between channels on the average channel capacity is discussed. The distribution functions for the SINR values at the receiver side as well as the achieved sum-rate for a MIMO system with correlated channels are presented and compared with a system with independent and identically distributed (IID) channel model. The loss in achieved sum-rate in the MU-MIMO system with spatial correlation is also analyzed.**

I. Introduction

MIMO (Multiple Input Multiple Output) is one of the widely used technologies now a day. The reasons for the huge demand for MIMO are the high achieved data rate and reliable transmission of data. One of the key features that enable MIMO to achieve the large channel capacity is spatial multiplexing [1]. By using spatial multiplexing the transmitter sends data independently and in parallel so that the link capacity increases. If there are M transmit antennas at the base station(BS) and N receive antennas at the receiver side, then the capacity increases by a factor *min* $\{M, N\}$. Spatial diversity technique is implemented in MIMO systems to ensure reliable transmission. The optimal throughput in a MIMO system can be achieved by using Dirty Paper Coding (DPC) at the transmitter side[2]. But to implement DPC we need full channel state information (CSI) at the transmitter and very complex hardware circuitry is needed. To provide full CSI at the transmitter (CSIT) the reverse channels must be heavily loaded. To overcome these problems in implementation of DPC many sub-optimal user selection algorithms are proposed which are very simple to implement and which try to reduce the load on the reverse channels. Another feature that enables MIMO to increase the link signal-to-noise-ratio (SNR) and range is beamforming. Various authors discuss many suboptimal user selection algorithms using beamforming technique.

Zeroforcing beamforming(ZF-BF) technique along with a sub-optimal scheduling algorithm is presented in [3]. The proposed scheduling algorithm is called as semi orthogonal user selection(SUS) in which users orthogonal to each other are selected. In [4] a scheduling scheme is proposed for MU-MIMO system where the authors have implemented beamforming independently at the trasnmit side as well as receive side. A comparison is done to find out which of the beamforming,i.e transmit or receive achieves better result in terms of capacity.

The system performance of a MIMO system is characterized by the number of transmit and receive antennas. It also depends on the existence of channel correlation. Because in many practical scenario, correlations exist between signals from antenna elements due to the scattering environment. Correlation between channels exist between each antenna element at the transmitter and/or each element at the receiver. The degree of correlation among the channels is a function of scatters in the environment and the antenna spacing at the transmitter and receiver[5]. In [6] it is shown that with spatial correlation between channel elements there is loss in the channel capacity. Many works are also carried out where authors have carried out scheduling algorithm on spatially correlated channels. A MU-MIMO scheduling scheme for a spatially correlated channel is introduced in [7]. Here the user selection criteria is based on the Eigen values of the users. A limited feedback scheduling scheme for a MU-MIMO spatially correlated broadcast channel system is proposed in [8]. Here the scheduling algorithm is designed with an aim to maximize the sum-rate achieved by ZFBF.

In this paper we present a sub-optimal user scheduling algorithm in which we assume that each user is able to estimate its channel perfectly. Each user finds out the maximum achieved *SINR* values at its receive antennas. The maximum *SINR* values are feedback by each user to the transmitter side. At the transmitter side each of the transmit antenna selects the most favorable user and then transmit the symbol/frame to the selected antenna of that user. So only scalar feedback is used. The presentation in [8] is for users with single antenna whereas our proposed scheme is for users with multiple antennas. Another difference lies in the way in which CSI is calculated. The broadcast channels are assumed to be spatially correlated with each other. We compare the achieved throughput of the proposed scheduling algorithm in a spatially correlated channel environment with that of a system where the channel

is assumed to be IID.

The paper is organized as follows: Section II presents the system model for the MU-MIMO system. A brief introduction to spatial correlation is also made in this section. The scheduling algorithm is described in Section III. The simulation results and the corresponding analysis are done in Section IV. Finally the conclusion is presented in Section V.

II. System Model

We consider a multi-user MIMO broadcast system having M number of transmit antennas at the base-station and R_n is the number of receive antennas of n^{th} user at the receiver side where $n = 1, 2, \cdots, N$ as shown in the Fig. 1. As the usual case for any general cellular system, we assume that $N \times R_n >> M$. The objective of the scheduling scheme is to choose a set of favorable antennas/users S from the user side such that $|S| \leq M$ and then the transmit antennas transmit M parallel data streams to the selected set of antennas. The received signal at user n is represented as

$$\mathbf{y}_n = \overline{\mathbf{H}}_n \mathbf{x} + \mathbf{w}_k \tag{1}$$

where $\mathbf{x}$ is the transmitted vector of size $M \times 1$ in a given time slot t and $\mathbf{w}_k$ is an additive white Gaussian noise(AWGN) vector of size $R_n \times 1$ with zero mean and unit variance. $\overline{\mathbf{H}}_n$ is the channel matrix of user n of size $R_k \times M$. The channel matrix of n^{th} user can equivalently represented as [8]

$$\overline{\mathbf{H}}_n = \mathbf{H}_n^{iid} \times \mathbf{R}_n^{1/2} \tag{2}$$

where $\mathbf{R}_n$ is an $M \times M$ *spatially correlation* matrix of user n and $\mathbf{H}_n^{iid}$ is the usual independent and identically distributed(IID) channel matrix of n^{th} user with size $R_n \times M$. The individual elements of channel matrix $\mathbf{H}_n^{iid}$ are assumed to be Rayleigh fading coefficients which implies that the components between j^{th} receive antenna of user n and i^{th} transmit antenna $h_{j,i}^{(n)}$ is complex Gaussian distributed having zero mean and unit variance i.e. $h_{j,i}^{(n)} \sim CN(0,1)$. The channel is assumed to be flat i.e. for a symbol interval t, the signal components experience constant response from the channel. We consider a equal power allocation scheme. The total transmit power P follows the constraint $E\|\mathbf{x}_n\|^2 = P$. Here we assume a transmission scheme where the total transmit power is equally divided between the transmit antennas. Hence the allocated power to each of M transmit antenna is P/M.

User n calculates its signal-to-interference-plus-noise-ratio(*SINR*) values according to

$$SINR_{i,j}^{(n)} = \frac{|\overline{h}_{j,i}^{(n)}|^2}{\frac{M}{\alpha_n} + \sum_{i' \neq i} |\overline{h}_{j,i'}^{(n)}|^2} \tag{3}$$

where $i = 1, 2, \ldots, M$ and $j = 1, 2, \ldots, R_n$. α_n is the average *SNR* of user n. i' terms are the interference terms. $\overline{h}_{i,j}^{(n)}$ are the components of the channel matrix $\overline{\mathbf{H}}_n$. The individual components of the spatial correlation matrix are found out as[6]

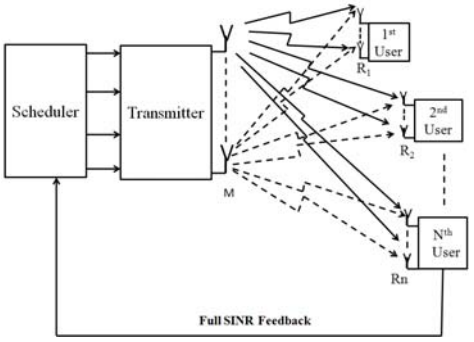

Fig. 1. System model for MU-MIMO system with M transmit antennas at BS, N users with user n having R_n antennas

$$R_{mn} = \frac{1}{2\Delta} \int_{\phi-\Delta}^{\phi+\Delta} \exp\left[j\tau(i-k)\sin\beta\right] d\beta \tag{4}$$

where $\tau = \frac{2\pi d}{\lambda}$ and d and λ are the distance between elements and wavelength of the signal respectively. The angel spread by the incoming multipath is described as 2Δ and the average arrival angle is represented as ϕ.

III. Scheduling Algorithm

A sub-optimal scheduling algorithm is discussed which is based on selecting users with highest *SINR* values. The algorithm is presented in two parts. In the first part each user calculates the achieved *SINR* values at each of its receiving antennas according to (3), i.e. each user calculates $R_n \times M$ *SINR* values. As the main objective of the algorithm is to reduce the load on the feedback channel each user, instead of making available all *SINR* values, finds out the maximum *SINR* value and feed it back to the transmitter side. Each user also finds out the indices of transmit and receive antenna corresponding to the maximum *SINR*. Along with the *SINR* value the transmit antenna index is also feedback by each user. The scheduling is performed at the base-station side in the second part. After getting all the feedback from the user side each transmit antenna selects one of the favorable user based on the *SINR* value.

We also present the achieved sum-rate capacity by the scheduling algorithm. The probability distribution function (*PDF*) of the *SINR* values at the receiver side is also presented subsequently.

A. Throughput Analysis

Once each of the transmit antenna m selects the favorable user n^* and the corresponding receive antenna B_n, the total sum-rate capacity can be found out by

$$R = \sum_{m=1}^{M} \log_2\left(1 + SINR_{m,B_n}^{(n^*)}\right) \tag{5}$$

where $SINR_{m,B_n}^{(n^*)}$ is the *SINR* of the selected user n^* at the receive antenna B_n from transmit antenna m.

Algorithm 1 Scheduling Algorithm

FEEDBACK PART

Set $\kappa_t = 1, 2, \cdots M$, and $\kappa_r = 1, 2, \cdots N$

For $n = 1, 2, \cdots N$

1: User n calculates its SINR values using equation (3). Maximum SINR values are calculated:

$$V_n = \max_{i \in \kappa_t, j \in \kappa_r} SINR_{i,j}^{(n)}$$

2: The corresponding transmit and receive antenna indices are obtained as:

$$T_n = \arg_i \max_{i \in \kappa_t, j \in \kappa_r} SINR_{i,j}^{(n)}$$

$$B_n = \arg_j \max_{i \in \kappa_t, j \in \kappa_r} SINR_{i,j}^{(n)}$$

3: Each user n feedback the corresponding V_n and T_n to the base-station.

SCHEDULING PART

After getting all the feedback from the user side, the BS performs the following:

4: For $m = 1, 2, \cdots M$

Set J_m is formed which contains the user whose $V_n = m$.

5: Antenna m at the BS selects one user from J_m randomly.

B. PDF Analysis

In this section we present the distribution function for the maximum *SINR*(V_n)values of each user. Assuming $R_1 = R_2 = \cdots = R_n = R_N$, $SINR_{m,B_n}^{n^*}$ can be written as [10]

$$SINR_{m,B_n}^{n^*} \approx \max Z_p \tag{6}$$

where

$$Z_p = \frac{|q_p|^2}{\frac{M}{\alpha_p} + \sum_{j=1}^{M-1} |q'_{p,j}|^2} \tag{7}$$

the elements of Z_p in the numerator and denominator i.e. $q_p, q'_{p,j} \sim CN(0,1)$ $p = 1, \cdots, NR_n$, and $j = 1, \cdots, M-1$.

We can write

$$Z = \frac{A}{\frac{M}{\gamma_p} + B} \tag{8}$$

as the Z_p^is are IID. A and B are chi-squared distributed as $A \sim \chi^2(2)$ and $B \sim \chi^2(2M-2)$.

We take

$$P_d = \max_{n \in J_m} \max_{i \in \kappa_t, j \in \kappa_r} SINR_{i,j}^{(n)} \tag{9}$$

Then the *PDF* of the Z_p is given by

$$f_Z(t) = \frac{e^{-Mt/\alpha_p}}{(1+t)^M} \left(\frac{M}{\alpha_p}(1+t) + M - 1 \right), t \geq 0 \tag{10}$$

IV. Results and Analysis

We consider a MU-MIMO BC system with M=2 and $R_1 = R_2 = \cdots, R_N = R = 2$. All the simulations are performed by taking 10000 realizations. First the simulation is done considering the channel to be simple Rayleigh fading

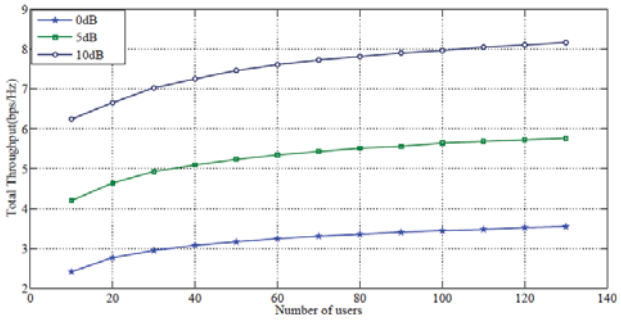

Fig. 2. Sum-rate capacity Vs. number of users for SNR=0 dB, 5dB and 10dB for a system with $M = 2, R_n = 2$ with spatially correlated channels

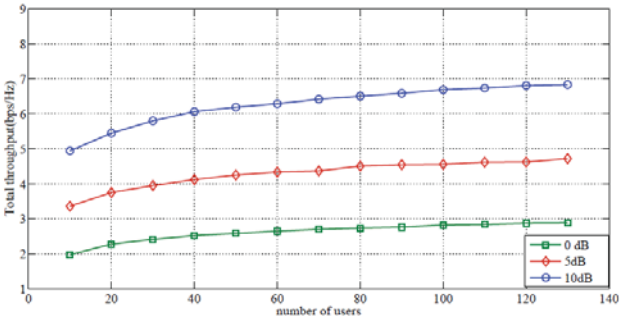

Fig. 3. Sum-rate capacity Vs. number of users for SNR=0 dB, 5dB and 10dB for a system with $M = 2, R_n = 2$ with IID Rayleigh fading channels

Gaussian channel. We find the achieved throughput using the scheduling algorithm as discussed above and Fig.2 represents the the throughput Vs number users is for *SNR* values of 0dB, 5dB and 10dB. The same scheduling algorithm is simulated for a spatially correlated channels and the achieve throughput for the system is obtained for various set of users. The spatial correlation matrix is found out as mentioned in (4). Fig. 3 present the corresponding curve for a spatially correlated channel. We compare the achieved throughput using the scheduling algorithm considering spatial correlation between channel elements (i.e. spatially correlated channel)and IID channel for *SNR*=10 dB and presented the curves in Fig. 4. It is observed from both Fig. 2 and Fig. 3 that as the

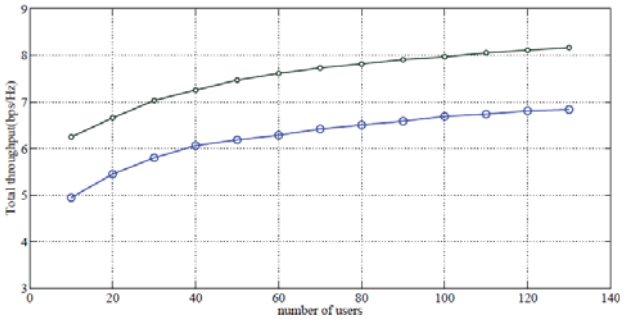

Fig. 4. Sum-rate capacity comparison between spatially correlated channels and IID Rayleigh fading channels with $M = 2, R_n = 2$ and SNR=10dB

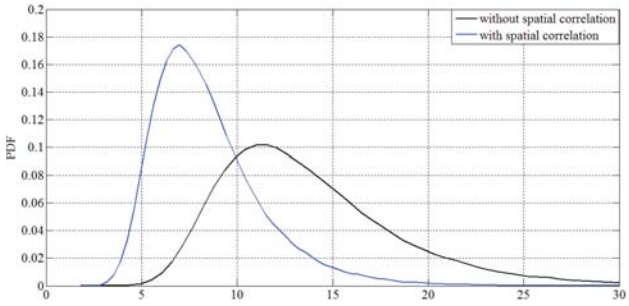

Fig. 5. Comparison between PDF of the highest SINR values of users between a system with IID channels and a system with spatially correlated channels for $N = 130$,$M = R_N = 2$, and SNR=10dB

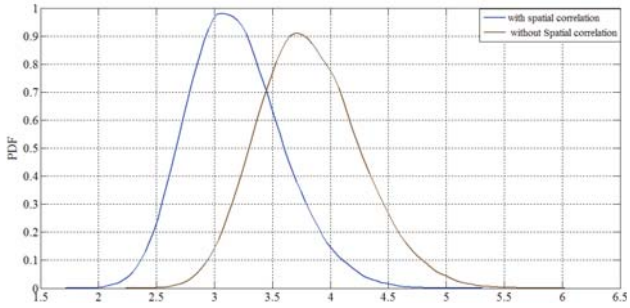

Fig. 6. Comparison between PDF of the achived sum-rate between a system with IID channels and a system with spatially correlated channels for $N = 130$,$M = R_N = 2$, and SNR=10dB

number of users are increasing the sum-rate capacity is also increases. But in Fig. 4 it is observed that if we consider the spatial correlation between channel elements, there is loss in the sum-rate capacity. For *SN*R=10dB and $N = 130$, we get a throughput of 8.1 bps/Hz without taking correlation,i.e if the channel is assumed to be IID. But if correlation is taken into consideration then throughput is scaled down to 6.8 bps/Hz.The loss in the sum-rate capacity remains nearly uniform for different set of users.

The probability distribution analysis for the $SINR^n_{m,B_n}$ is done in section (III-B). The P_d is simulated for 100000 random times and the PDF $f_P(f)$ is plotted in Fig. 5. In the same figure we also present the PDF of same P_d considering a spatially correlated channel matrix. The PDF of the total throughput for both type of channel models, i.e. spatial correlated channel and IID channel is also generated and presented in Fig. 6. It is observed Fig. 6 the probability distribution of sum-rate for both the cases are nearly equal.

V. Conclusion

We consider a MU-MIMO broadcast system in which a simple limited feedback scheduling algorithm is implemented. The scheduling algorithm is based on selecting users with highest *SINR* values. When the algorithm is considered for a system where the channel is IID, it is observed that as the number of users is increased, the sum-rate achieved also increases. We get the same observation when we run the simulation for spatially correlated channels. But the achieved sum-rate capacity for a system with spatially correlated channel element is less than the case for an IID channel element. As the number of users increases the loss in the sum-rate capacity maintains nearly a constant level. We also compare the PDF of *SINR* at the user side and the achieved sum-rate for both the cases. From the plots depicting the PDF of the achieved sum-rate in both the cases, it is clear that the probability distribution if of same type with difference statistical parameters. So work can be carried out to find out some weighing factor so that the sum-rate capacity achieved in the case of a spatially correlated channel approaches to the achieved sum-rate capacity in case of IID channels.

Real Time Evaluation of Energy Detection and Covariance based Spectrum Sensing Algorithms

D.K.Sunil, Samrat.L.Sabat

***Abstract*—Spectrum sensing is one of the major components in cognitive radio architecture. Many algorithms are being reported for spectrum sensing by restricting the study to only theoretical simulation. In this paper we propose a detailed methodology for real time implementation and evaluation of spectrum sensing algorithm. We compare the real time performance of two algorithms namely Energy Detection(ED) and CAV (Covariance Absolute Value) on a Virtex 6 FPGA platform. BFSK signal corrupted with Additive White Gaussian Noise (AWGN) is used for real time performance evaluation. The probability of detection, sensing time and resource utilisation are used as the metrics for measuring the efficiency of algorithm. It is observed that the real time results are lower than simulation results by 5 dB and 1 dB for ED and CAV respectively. The sensing time varies between 2 to 4 milliseconds within their SNR range of detection. Simulation on a DVBT signal demonstrates that ED algorithm can achieve SNR_{wall} of -8dB SNR, whereas CAV fails to detect, due to lack of correlation in the signal. However when the signal is correlated, CAV outperforms the ED algorithm.The FPGA resource utilization is lower for ED compared to CAV.**

I. Introduction

Cognitive radio (CR) is the technology proposed to overcome the spectrum scarcity problem in wireless communication by using its unique feature of dynamic spectrum acess. Spectrum sensing is first and critical component of Cognitive radio. In this stage, the channels are scanned to determine whether it is occupied or vaccant. Many signal processing algorithms such as energy detection, moment based, matched filtering, cyclostationary, covariance absolute value, wavelet based have been reported for spectrum sensing [1], [2], [3], [4], [5], [6]. Among them energy detection is computationally simple and fast. However its performance degrades for low Signal to Noise ratio signal. In practice, the sensing algorithm needs to be implemented in the hardware. Thus a spectrum sensing algorithm preferrably should be computationally simple and able to detect the signal at low SNR. In literature, there exists many algorithm limited to theretical analysis only, where as its real time implemetation analysis are limited. A few studies have been reported about the real time implemetation of sensing algorithm for cognitive radio [7], [8], [9], [10], [11], [12], [13]. A detailed hardware implementation methodolgy is also missing in the literature. Thus it is necessary to study the performance of sensing algorithm in the real time and provide a detailed methodology for its implementation. Although energy detection algorithm has low computational complexity, it is sensitive to noise variance. The performance of sensing algorithm is improved by exploiting the correlation in the samples using covariance absolute value algorithm. The reported simulation study shows that the CAV algorithm can achieve much better perfromance than ED and cyclostationary algorithm. This paper presents the performance comparison of ED and CAV algorithm on XILINX Vertex 6 FPGA development board. BFSK signal and noise are generated using signal and noise generator and detected pulses are observed in the oscilloscope. From the detected signal the sesnig time and probability of detection for different SNR are reported.

The paper is organised as follows: Section II gives the sensing model , Section III the details of the two Sensing schemes, Section IV details the hardware, calibration and signal processing and Section V gives results and Section VI concludes.

II. Sensing model

Let the received signal $y(t)$ be defined by :

$$y(t) = hx(t) + w(t) \quad (1)$$

$x(t)$ is the transmitted signal and $w(t)$ is a zero mean Gaussian random variable with unit variance , h is the channel gain (a random variable with a known or unknown probability density function). The channel is assumed to be flat fading with no Doppler shift. The sampled signal is denoted by $y(n)$. The detection is a

binary hypothesis test between the two hypotheses:

$$H_1 : y(n) = hx(n) + w(n); \quad (2)$$

$$H_0 : y(n) = w(n); \quad n = 1, 2, ...N; \quad (3)$$

where N is the number of samples related to the observed duration. The decision logic is

$U(k) > \gamma$; choose H_1 ; signal present

$U(k) < \gamma$; choose H_0 ; signal absent

where $U(k)$ is the test statistic and γ is the threshold.

III. Spectrum Sensing Methods

A. Energy Detection(ED) Algorithm

Energy detection is a simple technique for detecting the presence of a signal. The hardware requirements are low; but its sensitivity is poor [1]. In ED the frame energy is computed as follows:

$$U(k) = \frac{1}{N} \sum_{n=1}^{N} y(n)^2 \quad (4)$$

where $U(k)$ is the frame energy for the k^{th} frame, k and n are the frame and sample indices respectively and N is the number of samples per frame. $U(k)$ is the test statistic. Under H_0, the test statistic has a Central Chi-square distribution with N degrees of freedom and under H_1 it has a non-central Chi-square distribution with N degrees of freedom and the non-centrality parameter proportional to the SNR. For low SNR conditions ; $N = O(1/SNR^{-2})$. For detection under low SNR conditions N is large. If N is large, as per the Central Limit theorem, the test statistic can be approximated as a Gaussian [14]:

$U(k) : N(\sigma^2, 2\sigma^4/N)$; under H_0

$U(k) : N(P + \sigma^2, 2(P + \sigma^2)^2/N$; under$H_1$;

The threshold γ can be set as:

$$\gamma = Q^{-1}(P_f)\sigma^2(2/N)^{-2}; \quad (5)$$

where P is the average signal power, P_f is the desired probability of false alarm, $Q(.)$ is the Gaussian tail probability function.

B. Covariance Absolute Value Detection Algorithm

The CAV algorithm works on the concept that the covariance matrix of a totally un-correlated signal is diagonal [5]. In this method, the test statistic is the ratio between $T1$ and $T2$, where $T1$ is the sum of all the elements of the sample covariance matrix and $T2$ is the sum of the diagonals. Both are scaled by a smoothing factor L which is the number of lags selected for computing the sample autocorrelation. The statistical covariance matrix is approximated by the sample covariance matrix $R_x(N)$ [5]:

$$R_x(N) = \begin{pmatrix} \lambda(0) & \lambda(1) & \cdots & \lambda(L-1) \\ \vdots & \ddots & \dots & \vdots \\ \lambda(L-1) & \lambda(L-2) & \cdots & \lambda(0) \end{pmatrix} \quad (6)$$

$$\lambda(l)) = \frac{1}{N} \sum_{m=0}^{N-1} x(m)x(m-l)); l = 0, 1..L-1 \quad (7)$$

$$T1(N) = \frac{1}{L} \sum_{n=1}^{L} \sum_{m=1}^{L} |r_{nm}(N)| \quad (8)$$

$$T2(N) = \frac{1}{L} \sum_{n=1}^{L} |r_{nn}(N)| \quad (9)$$

$$\gamma = T1/T2 \quad (10)$$

where, r_{nn} and r_{nm} are the diagonal and other elements of the Covariance matrix R. $\gamma > 1$ indicates the presence of a signal, else there is no signal in the scanned band.

IV. Experimental setup

A. Hardware details

The experimental setup in shown in Fig. 1. A BFSK signal of bandwidth 200kHz centred at 70 MHz is generated using Agilent 4430B signal generator. Random noise of fixed power is generated using a noise generator (RS SMBV 100A). The signal power is combined with the noise power in a power combiner (Pasternak 2000).The signal of desired SNR is generated by keeping the noise power fixed while varying the signal power to the combiner using attenuator. The test conditions of the signal and noise are given in Table I. The resultant signal of desired SNR is input to an analog bandpass filter of centre frequency 70 MHz with a bandwidth of 10 MHz. The filtered signal is input to an Add-On FMC 150 Mezzanine card [15] on the ML605 FPGA board [16]. Here it is sampled at 61.44 MHz. This results in an aliased signal at 8.56 MHz.The signal of interest is extracted by applying this to a digital bandpass filter centred at 8.56 MHz and with a bandwidth of $\pm$ 3 MHz. Rate reduction is obtained by decimating the signal by a factor of 10. Due to rate reduction the signal is effectively resampled with a sampling frequency of 6.144 MHz thus resulting in the signal getting translated to 2.416 MHz. This input is fed to a mixer with a local oscillator frequency of 2.416 MHz. The local oscillator is generated by a high accuracy Drect Digital Synthesizer (DDS). The resulting baseband signal is low pass filtered with a corner frequency of 200 KHz. This is followed by a rate decimation by a factor of 10 for generating the baseband $I(n)$ and $Q(n)$ samples at 614.4 KHz rate. The signal flow is shown in Fig. 2.

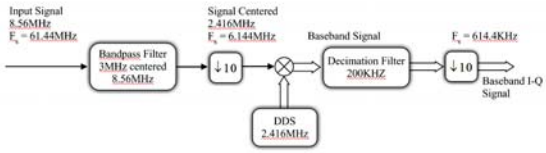

Fig. 2. Digital downconversion , filtering, decimation and spectrum sensing implemented on the Virtex-6 FPGA.

B. Digital downconversion and SNR Calibration

A calibration is carried out to ensure that the noise added to the signal is resulting in the desired SNR. To validate this a 64 k FFT is computed on the sampled data and the SNR is computed. The 64K FFT of the captured signal at SNR of -11.5dB is shown in Fig. 3. This figure clearly indicates that the 70 MHz carrier is positioned at 8.56 MHz as expected. The agreement between actual and computed SNR is less than 0.4 dB as listed in Table II.

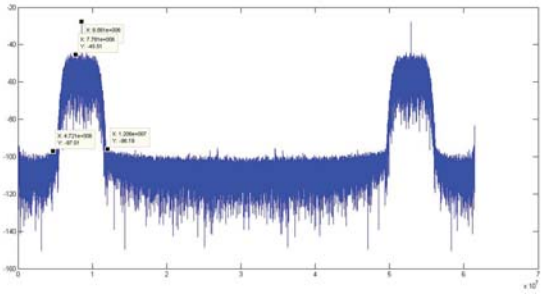

Fig. 3. 64 K FFT of the noisy signal at an SNR of -11.5 dB. The carrier can be seen at 8.56 MHz above the noise. The X axis values are from zero to 70 MHz. The spectrum has a distinct bandpass shape due to the filtering action of the 70 MHz Bandpass filter.

C. Simulation and Realtime test

For computer simulation random burst of a BFSK modulated signal of 450 frames, of 512 samples each, are created. The modulated signal power is normalised to unity. Flat Rayleigh fading is added to the signal and the necessary SNR is created by adding random noise, of unit variance, to the scaled signal power. The SNR is varied from -20 dB to +10 dB. The received $I(n)$ and $Q(n)$ are generated and the energy is computed for energy detection . The leading and trailing edges of the burst are detected. The first and second edges indicating that the channel is occupied or vacant respectively. The number of frames between the two detected edges is the sensed length. The ratio of sensed length to total burst length gives the probability of detection (Pd). For the CAV simulation the sample covariance matrix is computed and the ratios of $T1$ and $T2$ are computed. Rising and falling edges are detected when $T1/T2 > 1.1$ and < 0.8 respectively.

For the real time burst generation the signal generator is set to pulsed mode, with BFSK modulation. The gating clock is set to 1 KHz and this is fed to the

TABLE III
DETECTION SENSITIVITY VS NUMBER OF SAMPLE PER FRAME

Number of samples	ED	CAV
32	+2	–

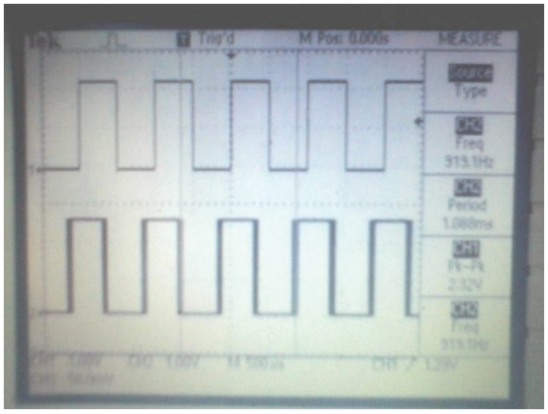

Fig. 4. Real time sensing capture on digital oscilloscope. Top trace is the Pulsed input waveform and bottom trace is the output from the FPGA after detection. The offset from the leading edge of the first pulse on the top trace to the leading edge of the second pulse on the botom trace is the sensing time. Note the jitter on the bottom trace, which will not be seen in simulation, due to variation in sensing time on hardware. The jitter is about 75 μSec.

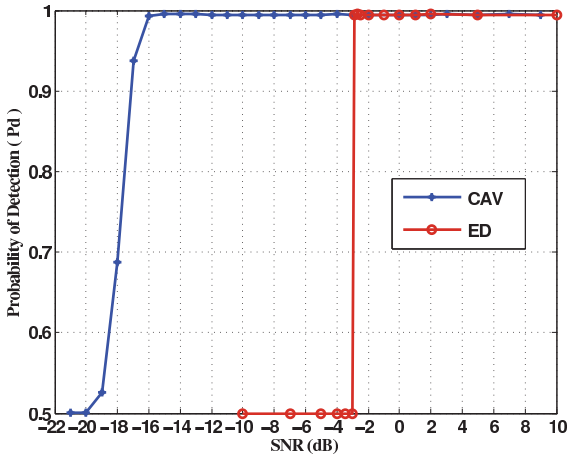

Fig. 5. Pd vs SNR Comparison of two schemes in real time on FPGA with pulsed input.

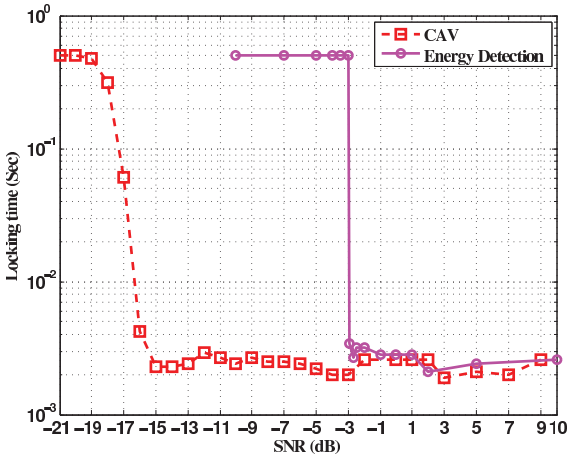

Fig. 6. Sensing time vs SNR of the pulsed signal in real time on FPGA. The sensing times are 2- 3 mSec for ED and CAV.

external trigger of the signal generator. The output is therefore pulsed with an ON time of 0.5 mS and an OFF time of 0.5 mS. This gating clock is fed to the Channel A of the oscilloscope. The FPGA executes the algorithm and outputs a discrete which goes high on the rising edge and goes low on the falling edge. This is fed to Channel B of the Oscilloscope. This is shown in Fig. 4. The ratio of the ON time of the input pulse and detected pulse is used to calculate the Pd. Table III shows the detection sensitivity of the two schemes as a function of number of samples. Beyond 512 samples there is little improvement in sensitivity. Therefore all real time implementations were carried out at a frame size of 512 samples.

V. Results and Discussion

For performance comparison (SNR vs Pd) of the two algorithms namely ED and CAV are implemented on the FPGA and the results are shown in Fig. 5. It is observed that Pd=0.9 was achieved at SNR of -3 and -17 dB for ED and CAV algorithms respectively. For energy detection the threshold is fixed and a function of only the number of samples per frame [17]. Therefore the detection performance falls suddenly below -3 dB SNR when the frame energy falls below the threshold. The $SNR\ Wall$ phenomenon [18] is valid for energy (radiometer) detection. Fig. 6 plots the sensing(locking) time for the two algorithms. The ED and CAV take about 2-3 mS for execution. The processing time changes sharply and becomes large at the SNR where the algorithm starts failing. Considering that normally a burst to be detected will last for tens of seconds this delay is not significant. This result indicates that about 1000 channels can be scanned in the 2 seconds allowed by the standard and their occupany decided for use.

Fig. 7 shows performance comparison using Matlab simulation, Simulink with SYSGEN blocks, Hardware Cosimulation and in Real time (RT). From this figure it is inferred that Pd = 0.9 occurs at SNR of -8 and -18 dB for ED and CAV algorithms respectively. The degradation from simulation to real time is 5 dB for ED and less than 1 dB for CAV indicating its robustness. It is clear that the degradation in sensitivity from Matlab simulation to real time can range from 1 to 5 dB. This margin has to be built into system design to ensure reliable performance. Table IV gives the resource utilization on the FPGA for the real time implementation of the two algorithms. As expected the ED utilizes the least-resources followed by CAV. Fig. 8 shows the performance of ED and CAV algorithms for BFSK and DVBT signals. ED performs identically for BFSK and DVBT whereas CAV detects BFSK but fails

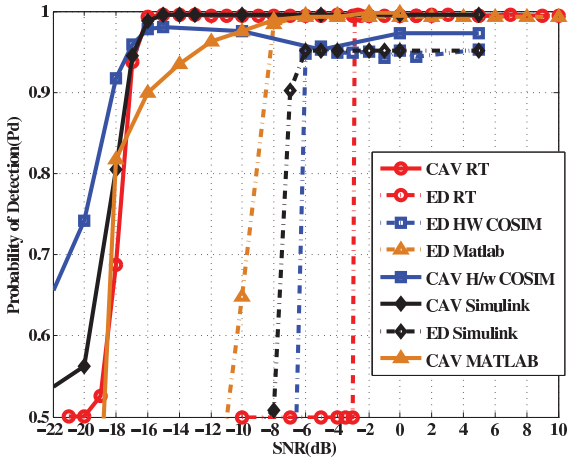

Fig. 7. Pd vs SNR Comparison of two schemes in all four stages. This plot is combination of four plots. Note the spread of the traces , going from simulation to Real time.

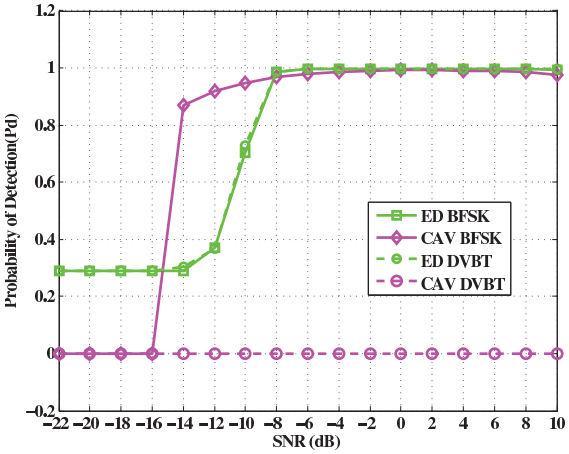

Fig. 8. Pd vs SNR for ED and CAV for BFSK and DVBT. Note that ED works for both BFSK and DVBT whereas CAV fails in the case of DVBT , due to lack of correlation.

to detect the DVBT signal. This can be attributed to the lack of correlation in the DVBT signal.

TABLE IV
RESOURCE UTILIZATION ON FPGA

sl	Resource on Virtex 6 FPGA	Available	Utilization		Percentage	
			CAV	ED	CAV	ED
1	Number of Slice Registers	301,440	8,442	1800	2	1
2	Number of Slice LUTs:	150,720	8,502	1401	5	1
3	Number of occupied Slices:	37,680	2,552	519	6	1
4	Number of bonded IOBs:	600	76	25	12	4
5	Number of RAMB36E1/FIFO36E1s	416	0	0	0	0
6	Number of RAMB18E1/FIFO18E1s:	832	1	1	1	1
7	Number of DSP48E1s:	768	129	44	16	5

VI. CONCLUSION

We have implemented two spectrum sensing algorithms on a Virtex 6 FPGA and have demonstated a calibration method for proper evaluation of spectrum sensing algorithms in real time. We have shown that real time results could be many dB off from the simulation for ED whereas CAV performance is consistent. However, CAV would fail if the signal lacks correlation whereas ED algorithm would still perform. Future work will focus on optimising the FPGA resource utilization for these algorithm.

***Abstract*—Rainfall parameters are required to understand the effects of precipitation over satellite and terrestrial links operating at microwave and millimeter wave bands. Among these parameters is the rain Drop Size Distribution (DSD) in which the contributions of rain droplets in the atmosphere are considered in estimating attenuation due to rainfall. In this paper, we present the three-parameter modified Erlang-*k* distribution as an alternative approximation of rainfall DSD. The Method of Moments (MoM) parameter estimation technique is applied to evaluate the required input parameters from rainfall measurements over subtropical Durban (29°52′S, 30°58′E) archived between 2008 and 2010. Estimates from the proposed Erlang distribution at different rain intensities are compared to other popular existing DSD models like the lognormal and gamma distributions. Our proposed distribution – is seen to conform to acceptable Self-Consistency (SC) rule and minimal error statistics – compared to other existing models. This is evident in the Root Mean Square Error (RMSE) and Chi statistics obtained from simulations. It is inferred from investigations that the proposed Erlang-*k* distribution offers a better computational advantage of rainfall DSD over subtropical locations.**

Keywords—Rainfall attenuation; Erlang-k DSD model; Method of Moments; Rainfall rate; Rainfall DSD

I. INTRODUCTION

Precipitation features prominently among the major source of attenuation for satellite and terrestrial communication systems operating at microwave and millimeter wave bands [1]. Exhaustive literature is available on the adverse role of rainfall phenomena in transmission systems operating above 10 GHz, particularly in the tropical and equatorial regions [2], [3]. An approach applied in the prediction of rainfall attenuation requires the knowledge of rainfall DSD. The DSD approach presents a unique way of estimating attenuation by accounting for the populations of varied rain drops in the atmosphere – vis-à-vis the theory of scattering and absorption. There is however, a huge preference for modified gamma and lognormal distributions in the modelling of rainfall DSDs, particularly in tropical and equatorial regions with high rainfall [4]. These models have also been shown to give good estimates in subtropical regions, to which South Africa belong [5]-[6].

The process of DSD formation over terrestrial and satellite radio links during rainfall events is of significance importance. From recent propagation studies, it has been empirically shown that rainfall processes over radio links rmanifest as a semi-Markovian queue, with individual rain spikes possessing Erlang-*k* distributed service times [7], [8]. This discovery may imply that several elements of the rainfall process, including rainfall rate and rainfall DSD also exhibit similar probability behaviour representative of the generic Erlang family of distribution. It is on this premise that a further investigation on the suitability of this distribution for DSD modeling is importantly undertaken. It is expected that Erlang distribution will provide some form of DSD approximation, since it is closely related to gamma distribution.

In this paper, an investigation is undertaken on the suitability of the modified Erlang-*k* distribution for DSD modeling using rainfall measurements in Durban, South Africa. The input parameters are obtained by applying the parameter estimation technique of Method of Moments (MoM). The proposed model is later compared with existing models applied in subtropical regions. The Self-Consistency (SC) rule, alongside error statistic tests, is applied to comparably determine its performance.

II. ERLANG-K DROP SIZE DISTRIBUTION MODEL

For this study, the Erlang-*k* distribution is proposed for the modeling of rainfall DSDs. The Erlang-*k* DSD represents a *scaled* Probability Density Function (PDF) belonging to the family of multiplicative PDFs, in which several stages are encountered, in a system [9]. The popularity of this model is attributed to its high-end application in classical telephone networks as advocated by *Agner Krarup Erlang* (1878-1929). In contemporary communication engineering, it is predominantly applied in queueing systems and complex teletraffic analysis [10].

The Erlang-*k* DSD is a statistical distribution mathematically given by (1):

$$N(D) = N_m \frac{\lambda^k D^{k-1}}{\Gamma(k)} exp(-\lambda D) \text{ for } \lambda > 0, \forall k \in \mathbb{Z}^+ \quad (1a)$$

and,

$$\lambda = k\mu \qquad [mm^{-1}] \qquad (1b)$$

where N_m is the scaling parameter in mm^{-1}, k is the number of stages or shape parameter, μ is the scale parameter and D is the average diameter of rain drops per channel ranging from 0.3 mm to 5.4 mm. The Erlang-k distribution is a special case of the gamma distribution, such that $\lambda = \frac{1}{\theta}$ and k is always a real positive integer. In relation to the popular modified gamma DSD, the parameters from (1) are such that $m = k - 1$ and $N_o = \frac{N_m \lambda^k}{\Gamma(k)}$.

The Moment Generating Function (MGF) of the Erlang-k distribution is given by:

$$M_n = N_m \left(1 - \frac{n}{\lambda}\right)^{-k} \cong N_m \sum_{i=0}^{\infty} (-1)^i \binom{-k}{i} \frac{n^i}{\lambda^i} \qquad (2a)$$

where n is a positive integer representing the moment number. (2) gives a clear definition of the Erlang-k MGF as a power series where nth raw moments are related to derivative of specified series terms when n is set to zero [11]. In literature, a much more modified form of determining the exact nth moment as proposed in [12] is given by:

$$M_n = N_m \frac{\Gamma(k+n)}{\Gamma(k)} \frac{1}{\lambda^n} = N_m \frac{(k+n-1)!}{(k-1)!} \frac{1}{\lambda^n} \qquad (2b)$$

The eventual MGF arising from several stages as obtained in (2b) gives credence to the multiplicative characteristics of Erlang-k distribution. This function contains all the known information of the layered Erlang-k PDF as embedded in the parameters of N_m, k and λ.

III. Data Measurement, Modelling and Simulation

The rainfall measurements applied in this study are obtained from RD-80 Joss-Waldvögel distrometer installed at the University of KwaZulu-Natal, Durban at geographic coordinates of 29°52′S, 30°58′E. The processed data applied represents drop size spectra (of one-minute sampling time) collected over a period of October 2008 and December 2009. The spectra signature consists of rainfall rates ranging between 0.0003 mm/h to 117.49 mm/h. For the sole purpose of this experiment, only rain rates above or equal to 1 mm/h are processed. This reduces the available dataset to 7366 minutes of processed data. This is to discourage the presence of measurement errors arising from dead time and noisy low rain rates which are predominant. An effective way of processing the filtered dataset at this location is to determine the averaged values of similar rain rates as undertaken in [5]. Using this approach, a total of 52 unique rain drop size spectra (all averaged) were obtained in Durban.

The computational procedure for estimating the input parameters of the proposed distribution is undertaken by Method of Moments (MoM) as applied in related literature [4], [13]. This technique involves equating the theoretical moments of the Erlang-k DSD as given in (2b) to the computed moments from measurements. The nth moment of measurement is obtained with the knowledge of the DSD such that:

$$M_n = \sum_{i=1}^{20} {D_i}^n N(D_i) \Delta D_i \qquad (3)$$

where $N(D_i)$ is the rainfall DSD and $\Delta D_i$is the interval between the average diameters of the different channels, D_i.

The accrued rainfall DSD from measurements is computed directly from the dataset given by [16]:

$$N(D) = \frac{c_i}{s \times T \times v_t \times \Delta D} \ [mm^{-1} m^{-3}] \qquad (4)$$

where c_i is the number of drops per channel, s is the sampling area of the conical surface of the distrometer in m^2, T is the sampling interval in seconds and v_t is the terminal velocity in *m/s*.

With regard to the theoretical moments to be generated from (2b), certain combinations of moments are expected to give appropriate results. Researchers in radar and microwave studies have identified specific combinations, with guaranteed moment numbers related to radio engineering [13]. For example, the combination of the 3rd, 4th and 6th moments (MM346) for resolving three-parameter probability distributions has long been described as the most suitable [4], [13]. This is mainly due to the stability and kernel similarity of this combination to unique rainfall indices such as rainfall rates, rain attenuation and radar reflectivity. Using this combination, it is inferred from (2b) that:

$$M_3 = N_m \frac{k(k+1)(k+2)}{\lambda^3} \qquad (5a)$$

$$M_4 = N_m \frac{k(k+1)(k+2)(k+3)}{\lambda^4} \qquad (5b)$$

$$M_6 = N_m \frac{k(k+1)(k+2)(k+3)(k+4)(k+5)}{\lambda^6} \qquad (5b)$$

By solving (5*a*), (5b) and (5c) as simultaneous equations, solutions of related Erlang-k DSD parameters are given as:

$$k = round\left\{\frac{(6\alpha - 9) - \sqrt{1 - 8\alpha}}{2(1-\alpha)}\right\} \qquad (6a)$$

where,

$$\alpha = \frac{M_6 {M_3}^2}{{M_4}^3} \qquad (6b)$$

$$\lambda = \frac{M_3(k+3)}{M_4} \qquad (7)$$

$$N_m = \frac{M_3 \lambda^3}{k(k+1)(k+2)} \quad (8)$$

IV. Results and Discussions

In this section, derivation of parameters for the proposed Erlang-*k* DSD, as well as its performance over different rain rates are discussed.

A. Derivation of Parameters for Erlang-k DSD model

By applying results from the MoM solutions as proposed in (6) – (8), scatterplots are obtained as seen in Fig. 1. For each of these scatterplot, the plotting of Erlang-*k* input parameters and their corresponding rainfall rates are undertaken. From Fig. 1, it is observed that each of these parameters form a unique relationship with rainfall rate as implied from their scatterplots. For example, the parameter, N_m, is observed to be positively correlated to rainfall rate as seen in Fig. 1a. However, the parameters, μ and *k*, are found to be negatively correlated to the rainfall rate as seen in Fig. 1b and 1c. This suggests that the drop concentration (N_m) increases as higher rainfall rates are attained. This is expected as total drop contributions present along the radio links or radar paths increases as rain builds up. In any case, it also confirms that moments considered in this work *i.e.* M_3, M_4 and M_6 similarly follows this same trend. For parameter μ, the scatterplot in Fig. 1b implies that the mean diameter of Erlang-*k* DSD will shift leftward as rainfall rate increases. This is mainly reliant on the premise that this input parameter is always the reciprocal of mean of the data. Finally, parameter *k* as seen in Fig. 1c follows the same trend as μ. This is possible because their product always result in λ (see Eqn. 1b). This parameter generally refers to the number of stages for the proposed modified Erlang-*k* DSD. Our results show that *k* should range between the values of 3 and 6, depending on the maximum recorded rain rate. Infact, *k* gives 3 at low rainfall rates (R < 5 mm/h). For medium rain rates (5 mm/h ≤ R < 17 mm/h), *k* is predominantly 4. For high rain rates under shower and thunderstorm conditions (17 mm/h ≤ R < 50 mm/h), *k* is mainly 5. For much higher rain rates (R > 50 mm/h), *k* is typically given as 6 (and above in some cases).

It follows from the scatterplot results that suitable expressions for the proposed model could simply be obtained by regression analysis. By applying this procedure, the following expressions are derived as input parameters of the Erlang-*k* DSD in (1) as follows:

$$k + 3 = round\{2.6105R^{0.19}\} \quad (9)$$

$$N_m = 808.99R^{-0.087} \quad (10)$$

$$\mu = 2.3326R^{-0.334} \quad (11)$$

where R is the rainfall rate in mm/h.

On the general approach applied, we can indeed affirm that the combination of the 3rd, 4th and 6th moments (MM346) gives a good approximation of the estimated input parameters for other models. Kozu and Nakamura [13] and Timothy *et al.* [4] independently considered these combinations in their publication on modified gamma DSDs in Japan and lognormal DSDs over Singapore respectively. Several other researchers estimated statistical DSDs from distrometers in India [4], Nigeria [14], Malaysia [15] and South Africa [5]–[6] using either the lognormal, modified gamma or Weibull distribution.

B. Performance of the Erlang-k DSD model

As obtained from the combination of regression functions as derived in (10) – (11), the performance of the proposed Erlang-*k* DSD is undertaken. This is analysis is undertaken over four averaged rainfall rates namely 5mm/h, 25 mm/h, 75 mm/h and 120 mm/h. These selected rainfall rates are representative of different regime conditions of rainfall in Durban: drizzle, widespread, shower and thunderstorm [5].

These results presented in Fig. 2 show that the proposed model gives good fits at different rainfall rates. The modification to the shape parameter in (9) *i.e.* (k + 3), is seen to improve the robustness of the model especially in conjunction with N_m. This modification is significant because it demonstrates the similarity between the modified version of gamma distribution in [13] and the currently proposed modified Erlang-*k* distribution. At high rainfall rates (Figs. 2c and 2d) for instance, our proposed model however gives a good approximation of both smaller and larger diameters of rain drops over our location in Durban.

C. Comparison of Proposed Model over Existing Models over Durban

The development of Erlang-*k* DSD model as undertaken in this work requires a valid comparison with other useful DSD models applicable in this field. For the purpose of this comparison, the modified gamma DSD and lognormal DSD models are applied based on their wide applications for DSD estimation at tropical, subtropical and equatorial regions. The modified gamma DSD model given in [13]; in this study, m is approximated to the values of 2 and 3. The statistical function for lognormal DSD model is given in [14].

A summary of the input parameters for compared Erlang-*k*, gamma and lognormal DSD models in Durban, derived from MoM, is given in Table I. To make a valid comparison, the Self-Consistency (SC) rule is applied for each of these different DSD models. The SC rule implies that any probability distribution must be able to estimate accurately the random variable that generated its input parameters. In this case, the random variable is rainfall rate, as the input parameters are dependent on rainfall rate. The estimated rainfall rate from the DSD models to be compared is obtained from given by:

$$R_{estimated} = \frac{6\pi}{10^4}\sum_{i=1}^{20} {D_i}^3 N(D_i) v_t \Delta D_i \quad [mm/h] \qquad (12)$$

where v_t and $\Delta D_i$are the terminal or fall velocity and diameter interval respectively.

In Fig. 3, we compare the linear plots obtained from actual rain rates and the estimated rain rate from self-consistency rule. It is observed that all the compared models have closer predictions at lower rain rates. However, at higher rainfall rates, the Erlang-*k* DSD model gives a more accurate prediction, with the lognormal and gamma ($\lambda = 2$) DSD models predicting less accurately. This is also confirmed in the error statistics for each of these models. The error statistics is determined by considering the error deviations between the estimated rain rate from DSD models and actual rain rate by applying both the Root Mean Square Error (RMSE) and Chi Square statistic (χ^2). The corresponding expressions for these error statistics are thus given:

$$RMSE = \left[\frac{1}{n}\sum_{i=1}^{n}\left(R_{actual,i} - R_{estimated,i}\right)^2\right]^{1/2} \qquad (13)$$

$$\chi^2 = \sum_{i=1}^{n}\frac{\left(R_{actual,i} - R_{estimated,i}\right)^2}{R_{actual,i}} \qquad (14)$$

where *n* refers the total number of samples compared for each DSD model which is taken as 52.

At 5% significant level, the critical value for this work is taken as 68.669 [16], which imply that compared DSD models' hypothesis are valid. From the computed error statistics results in Table I, it can be seen that the proposed Erlang-*k* DSD

TABLE I. INPUT PARAMETERS OF DIFFERENT DSD MODELS IN DURBAN, SOUTH AFRICA

DSD MODEL	PARAMETERS	INPUT PARAMETER FUNCTIONS	RMSE	CHI
ERLANG (Proposed)	N_m, k, μ	$N_m = 808.99R^{-0.087}$ $\mu = 2.3326R^{-0.334}$ $round(k+3) = 2.6105R^{0.19}$	1.52	2.84
GAMMA (μ = 2)	N_o, Λ, λ	$N_o = 1.1031 \times 10^5 R^{-0.732}$ $\Lambda = 6.6731R^{-0.259}$ $\lambda = 2$	2.62	3.92
GAMMA (μ = 3)	N_o, Λ, λ	$N_o = 3.609 \times 10^5 R^{-0.991}$ $\Lambda = 7.7853R^{-0.259}$ $\lambda = 3$	2.17	2.84
LOGNORMAL	N_T, μ, σ	$N_T = 1145.2\, R^{-0.136}$ $\mu = -1.1063 + 0.3654\, ln(R)$ $\sigma = 0.5408 - 0.035\, ln(R)$	2.57	4.05

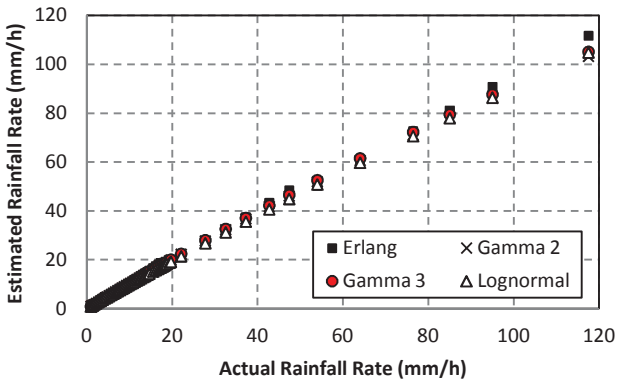

Fig. 3. Self-consistency plots for different DSD models in Durban

model gives the lowest RMSE at 1.52 at all compared rain rates in Durban. This suggests that Erlang-*k* distribution gives an improved prediction of rainfall DSD over all known existing models applied in subtropical South Africa.

V. CONCLUSION

In this paper, the Erlang-*k* distribution is proposed as a suitable model for predicting rainfall DSD over Durban. Results obtained in this work clearly imply that this model gives a better performance compared to existing models. This proposed DSD model can be applied in the design of efficient and viable microwave and millimeter wave communication links, for both terrestrial and satellite purposes.

***Abstract*—This paper presents recent developments in the area of radioclimatological modeling over equatorial and tropical Africa. The work mainly highlights current efforts targeted at understanding the effects of precipitation over microwave and millimetric wave propagation. Interpretation and analysis of rainfall measurements undertaken at two African sites of subtropical and equatorial climate are examined in the context of new investigations. The determination of critical diameters of rain drops responsible for total specific attenuation of rainfall over South Africa and Rwanda is presented. Under time series analysis of rainfall processes, the novel approach of queueing theory to determine the underlying characteristics of rainfall over radio links at these locations is discussed. Conclusions from these diverse studies show that these locations exhibit similar precipitation characteristics in terms of critical diameters and semi-Markovian rainfall queues.**

Keywords—Radioclimatological modeling; Critical diameters; Specific Attenuation; Rainfall rate; Queueing theory

I. INTRODUCTION

The increasing global demand for larger bandwidths in the microwave and millimeter bands is a contemporary issue in the communication industry [1]. In sub-Saharan Africa, this is complicated by rapidly increasing customer base for broadband connectivity and high-quality data content. The technical panacea for this recurring problem requires the adoption of tripartite transmission conditions: migrating to higher frequency bands, utilizing complex modulation schemes and compensating for power losses [2]. Migration to higher frequency bands vis-à-vis power compensation falls into large-scale propagation requirements, which can be optimised by radioclimatological modeling. Therefore, the need for accurate propagation studies is therefore an advantage in the availability of communication systems, especially in areas with exceptional climatic phenomena in Africa.

A history of propagation measurement campaigns and efforts already undertaken at different locations of the Southern Africa were presented in [3]. In this current work, recent progress on the investigation of the role of precipitation in radiopropagation is discussed based on results obtained from subtropical and equatorial Africa [4] – [9]. Precipitation belongs to the group of hydrometeors, which affects the performance of wireless systems, operating at microwave and millimeter wave bands [10]. Its effects dangerously become dominant at transmission frequencies from 10 GHz and above, especially in areas of tropical, subtropical and equatorial climatic characteristics.

In this paper, recent investigations on two principal concepts are primarily discussed to understand the effects of precipitation over radio links at Durban (29°52′S, 30°58′E), South Africa and Butare (2°36′S, 29°44′E), Rwanda.

II. CRITICAL DIAMETER ANALYSIS OVER EQUATORIAL AND SUBTROPICAL AFRICA

The subject of rainfall attenuation is particularly a topical one, especially in regions characterized with intense rainfall. Subtropical and equatorial regions of Africa fall among these locations, where signal disruptions could affect the availability of communication systems [2], [10]. In theory, attenuation due to rainfall is the result of the mechanism of scattering and absorption effects on rain drops in the atmosphere. There have been discussions on the actual contributions of rain drops of different sizes to signal attenuation. The earliest works on this subject was undertaken by Lee *et al.* in Singapore [11], Lam in Malaysia [12], Marzuki in Equatorial Indonesia [13] and Fiser in Czech Republic [14]. In these studies, certain sizes of raindrops were classified as being important contributors to the resulting rain attenuation over radio links.

A. Critical Diameters for Rain Attenuation in Durban

In subtropical and equatorial Africa, an initial study undertaken in Durban, South Africa [4] confirmed the observations in [11] - [14]. The so-called specific ranges of rain drops mainly associated with rainfall attenuation are described as the critical diameters for rainfall attenuation [11],[12]. These diameters are found to be strongly dependent on the Drop Size Distribution (DSD). Mathematically, rainfall DSDs have been found to be approximated in many tropical, subtropical and equatorial regions with minimal errors, by lognormal and modified gamma distributions [10]-[12]. By putting this into consideration, Adetan and Afullo [4] computed the critical diameters for rainfall specific attenuation in Durban by applying [15]:

$$A_s = 4.343 \times 10^{-3} \int_0^{D_{max}} Q_{ext}(D, \lambda, m).N(D)dD \; [dB/km] \quad (1)$$

where Q_{ext} is the extinction cross section dependent on diameter, D, wavelength, λ, and the complex refractive index, m. $N(D)$is the rainfall DSD.

In [4], the incremental total specific attenuation for lognormal DSD model computed numerically is given by:

$$dA_s = 4.343 \times 10^{-3} \frac{\kappa N_T}{2^{\alpha}\sigma\sqrt{2\pi}} \left[D_j{}^{\alpha-1}.e^{-t}\right] \quad (2a)$$

where,

$$t = \frac{1}{2}\frac{\left[ln(D_j) - \mu\right]^2}{\sigma} \quad (2b)$$

where κ and α are the Mie coefficients obtained at 20°C over Durban. N_T, μ and σ are the inputs of the lognormal DSD.

Similarly, for the gamma DSD for μ = 2, the incremental specific attenuation from [4] is likewise given as:

$$dA_s = 4.343 \times 10^{-3} \frac{\kappa N_o}{2^{\alpha}} \left[D_j{}^{\alpha+2}.e^{-\Lambda D_j}\right] \quad (3)$$

where N_o and Λ are the inputs of the gamma DSD.

Plots arising from the numerical solution of (2a), (2b) and (3) over different frequencies are shown in Fig. 1 at $R_{0.01} = 60\ mm/h$ over Durban. The peaks of these plots indicate the maximum critical diameter(s) responsible for the highest contributions to specific attenuation. It is evident from the conclusions of Adetan and Afullo [4] that the overall critical diameters of rain drops responsible for total specific attenuation in Durban lies between 0.5 mm ≤ D ≤ 2.5 mm.

B. *Comparison of Critical Diameters over South Africa and Rwanda*

A further comparison of critical diameters over subtropical African location of Durban and equatorial African location was undertaken in [6] over different microwave and millimeter bands. In this work, the critical diameters contributing to total specific attenuation were examined. By considering the rainfall availability at 99.99% at these two locations (Durban = 66.25 mm/h; Butare = 73.88 mm/h), the effects of bin removal was also considered. This systematic approach considers the gradual removal of unimportant bins while examining their overall effect on total specific attenuation. Results from this experiment are found in Table I. Using this approach, results from investigations on effects of critical diameters over subtropical and equatorial Africa was thus concluded in [6] as:

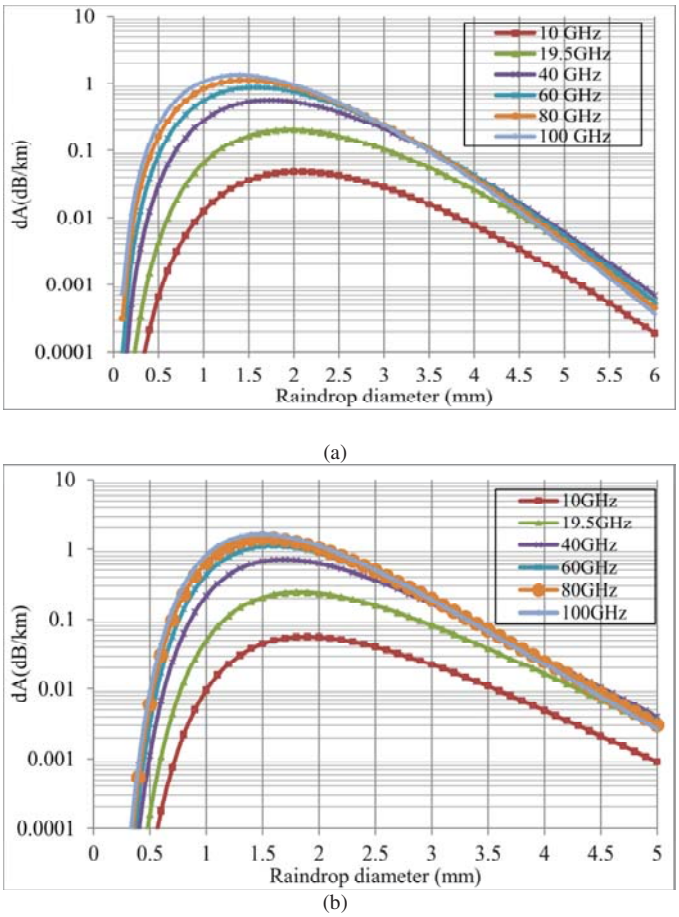

Fig. 1. Overall specific attenuation against the drop size diameters at various frequencies at $R_{0.01}$ = 60mm/h (a) Lognormal DSD model (b) Gamma DSD model.[5]

> *"The largest contribution to the total attenuation is observed at the diameter range 1.5 ≤ D ≤ 3.5 mm at Butare and for Durban, at frequencies below 40 GHz. At frequencies above 40 GHz, the maximum contribution to the rain attenuation is observed in the diameter range 1.0 ≤ D ≤ 3.0 mm in Durban. A minimal percentage contribution is observed at larger diameters as the frequency increases"*

TABLE I. PERCENTAGE FRACTION OF THE TOTAL SPECIFIC ATTENUATION FORMED BY RAIN DROPS DIAMETERS AT SELECTED FREQUENCIES [6]

CRITICAL RANGE (mm)	DURBAN (SOUTH AFRICA)				BUTARE (RWANDA)			
	10 GHz	40 GHz	80 GHz	150 GHz	10 GHz	40 GHz	80 GHz	150 GHz
0.1 ≤ D ≤ 2.0	5.66	10.47	16.32	21.50	27.84	40.33	51.59	59.46
0.5 ≤ D ≤ 2.5	18.16	28.02	37.86	45.34	52.46	65.70	75.45	81.28

III. Rainfall Queueing Theory Over Equatorial and Subtropical Africa

One of the dynamic problems facing wireless communication systems, especially in Radio Resource Management (RRM) is the issue of adaptive power management in rainy medium [16]. This problem becomes more critical, when combined with the availability of communication systems operating at microwave and millimetric bands, under the harsh conditions of precipitation. The issue of adaptive power management in rainy medium, often deployed in the form of Adaptive Power Control (APC), clearly offers improved signal reception in both terrestrial and satellite communication. However, certain time domain characteristics of the rainfall process must be considered to achieve seamless power control in real time. It is from this perspective that recent studies on rainfall at equatorial and subtropical Africa were approached in [7] - [9].

The major objective of describing the underlying characteristics of rainfall over radio links was firstly hypothesized as a queueing problem [7]. In this work, an established radio link is assumed to exist between any two fixed points, either from the terrestrial or satellite communication perspective. A rainfall process is said to occur when rain clouds, while producing rain droplets, are propelled across the radio link by advective forces. This scenario is depicted in Fig. 1 as a First In, First Out (FIFO) process. In the pioneer effort of Alonge and Afullo [7], [8], the problem of a queue in rainfall process became evident when several arrivals of rain clouds, and consequently rain rates are encountered within a rainfall event. This overall mechanism results in two possibilities: fluctuation of rainfall rate values, whose time domain probabilities are often stochastic in the time domain, and, the existence of unique rain spikes in a typical rainfall time series. These two possibilities reflect the need to ascertain the existence of queues in any rainfall process.

Initial studies on the existence of queues was first undertaken using the rain rate time series data (at one minute sampling time) obtained from the Joss-Waldvogel RD-80 distrometer installed at the University of KwaZulu-Natal, Howard College, Durban [7], [9]. The rainfall time series

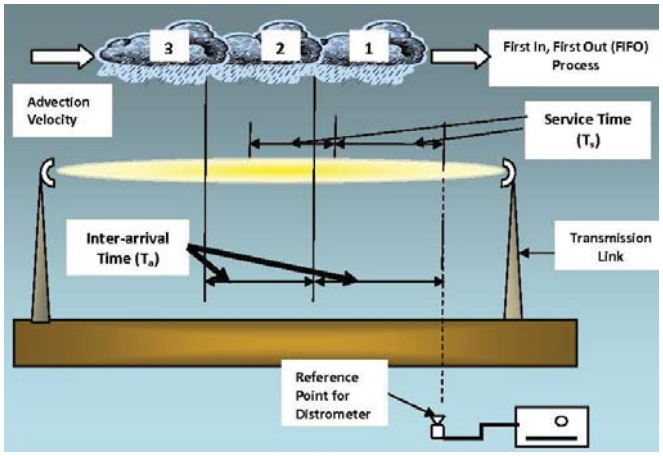

Fig. 2. The concept of rainfall process as a queue [7]

measurements were partitioned into rainfall events, and the rainfall events segmented into sub-events [7]. This procedure follows the earlier assumptions of validating the components of the queue process, which in this case manifests as rain spikes. The individual queue parameters for each of the retrieved spike were estimated accordingly. In this regard, three major queue parameters were considered: service time, inter-arrival time and overlap time [7].

A. Modeling of Queue Distributions of Rainfall Time Series in Durban

The basic assumption would be that the queue discipline is either Markovian or non-Markovian, with time as the independent variable. Based on this knowledge, two distributions considered in the modeling of queue parameters over radio links in Durban belong to the group of exponential family. The simplest distribution in a Markovian queue process is the exponential distribution given by [7]:

$$f(t) = \lambda \ exp\,(-\lambda t), \quad \text{for } t \geq 0, \qquad \forall t \in \mathbb{R} \qquad (4)$$

where λ could be the service, arrival or overlap rate as the case may require. The variable, t, could represent the service, inter-arrival or overlap time.

The most appropriate distribution for a non-Markovian queue process is the Erlang-k distribution given by [7]:

$$f(t) = \frac{k\mu\,(k\mu t)^{k-1}\ exp\,(-k\mu t)}{\Gamma(k)} \quad \text{for } t \geq 0 \qquad (5)$$

where k refers to the number of stages and μ could assume the service, arrival or overlap rate.

Fig. 3 depicts the queue modeling undertaken for service time and inter-arrival time in Durban. This modeling clearly implies that the service time distribution for shower rainfall regimes over Durban is unimodal and non-exponential as seen in Fig. 3a. This suggests that this process is non-Markovian process. On the other hand, Fig, 3b clearly implies that the inter-arrival time distribution is an exponential curve, suggesting a Markovian process. A summary of the overall results in Durban showing estimated error statistics, as well as strengths and weaknesses of the two distributions for different regimes are shown in Table II [8]. According to Table II, RMSE refers to Root Mean Square Error, χ^2 is the Chi statistic, DF is the Degree of Freedom and SL is the significant level (related to the critical value). These results clearly shows that Erlang-k distribution is the most preferred in the modeling of rainfall process over radio links when considering the service and overlap times. However, the exponential distribution is undisputably preferable in modeling the inter-arrival time distribution.

The results clearly described the underlying process of rainfall over radio links as a semi-Markovian queue, with Erlang-k distributed service time (E_k) and exponentially distributed inter-arrival time (M). Clearly, this confirms that

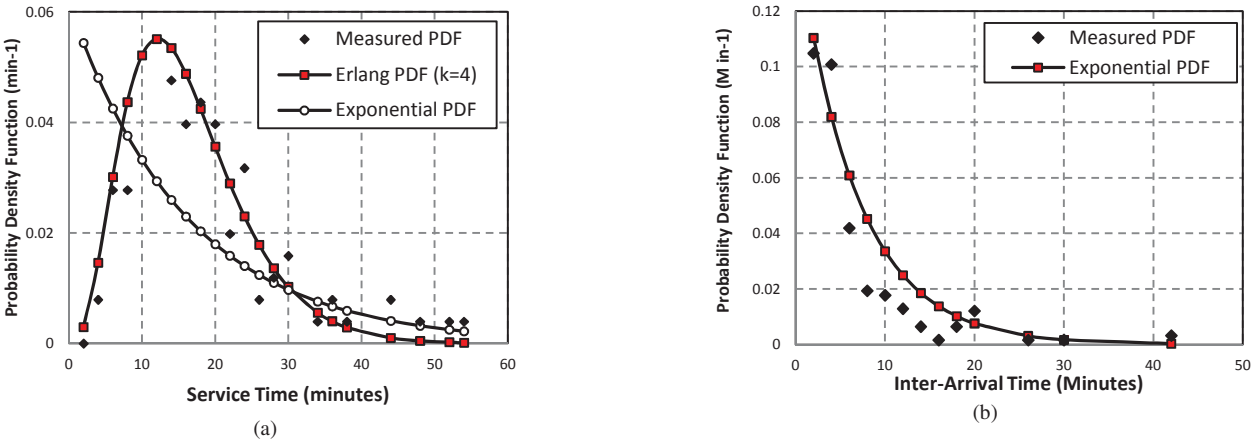

Fig. 3. Distribution modeling for queue parameters for shower regime in Durban, South Africa (a) Service time (b) Inter-arrival time [7]

TABLE II. ERROR ANALYSIS OF FITTED QUEUE DISTRIBUTIONS OVER DIFFERENT REGIMES IN DURBAN, SOUTH AFRICA [8]

queues are present in the overall process of precipitation over subtropical Durban.

B. Comparison of Queue Parameters over South Africa and Rwanda

The confirmation of queuing characteristics over Durban, South was further compared with queue characteristics at the tropical location of Butare. Alonge and Afullo [8], [9] found that the same queueing conditions generating rainfall rates over radio links in Durban was clearly present in Butare. This led to the designation of rainfall process according to the Kendall notation of $M/E_k/s/\infty/FCFS$, which is representative of a semi-Markovian process. The stability of the rainfall process as a self-generating queue is of utmost important. The queue stability is mainly determined by applying the condition [8]:

$$\rho = {}^{\lambda_a}/_{\mu_s} \leq 1 \qquad (6)$$

where λ_a and μ_s is the arrival rate and service rate.

TABLE III. GENERAL COMPARISON OF QUEUE PARAMETERS IN DURBAN AND BUTARE [8]

SERVICE TIME							
LOCATION	μ_s	t_s	k	RMSE	χ^2	DF	SL
DURBAN	0.0659	15.1801	5	0.0033	1.218	547	605.52
BUTARE	0.0653	15.3152	6	0.0053	0.3578	445	495.17
INTER-ARRIVAL TIME							
LOCATION	λ_a	t_a		RMSE	χ^2	DF	SL
DURBAN	0.1425	7.0169		0.0076	0.0095	495	547.86
BUTARE	0.1476	6.7754		0.0788	0.0521	385	431.73
OVERLAP TIME							
LOCATION	σ_o	t_o	k	RMSE	χ^2	DF	SL
DURBAN	0.2053	4.8714	3	0.0065	0.0168	494	546.81
BUTARE	0.2267	4.4097	4	0.2278	0.1209	383	429.61

From results obtained in [7]-[9], it was generally concluded that the rainfall queueing process over Durban and Butare are clearly unstable semi-Markovian queues. It would appear that the inherent meteorological mechanism of rainfall conditions simultaneously provides some form of natural servers. The numbers of these natural servers tend to be around 5 or 6 at the both locations. A summary of the queue parameters obtained from time series measurements in Durban and Butare is presented in Table III. From the set of results available, the queue parameters obtained for service, inter-arrival and overlap time are very similar in South Africa and Rwanda. This implies that there is virtually no difference in the queue conditions in subtropical and equatorial Africa. However, there is a clear difference in the number of stages required to estimate the service time and overlap time distributions. In addition, it is observed that distribution model errors (from RMSE) for service time, inter-arrival time and overlap time may not exceed values of 0.5%, 0.8% and 12% respectively.

V. CONCLUSION

In this paper, we present the current status of research in the area of radioclimatological modeling in Southern and equatorial regions of Africa. The study is based on measurements undertaken in Durban, South Africa, and in Butare, Rwanda. The critical diameters for rain attenuation at microwave and millimetric waves are presented for the two regions. In addition, we present the queuing theory approach to rain attenuation studies, in which the inter-arrival rate, the service rate are presented for the various rainfall regimes. Further studies are being undertaken to further refine the model, and thus properly interpret all parameters obtained.

***Abstract*—The phenomenal growth in mobile data traffic calls for a drastic increase in network capacity beyond current IMT (3G/4G) networks. There is a call for the next generation mobile communication system (5G). The 5G network envisages data speed of 1Tbps and beyond. Presently, mobile communications are operating between 700 MHz to 2.6 GHz. These spectrum bands do not have the capacity to carry such enormous data. Millimeter (mm) frequency band beyond 10 GHz is the obvious and the most preferred band for 5G. In this paper, we analysed frequency bands for 5G communication services.**

I. Introduction

Advancement in mobile communication has made peoples life easier, whether it is ordering a pizza, accessing internet, searching an address in a city or connecting with others via social networking site. Essential services such as e-commerce, e-banking, e-governance, e-health etc. will continue expanding their coverage and heading towards more mobility. These expansions will lead to need for enormous wireless traffic in future. Ericsson has predicted that the wireless traffic would be increased by 1000 times in 2020 than seen in 2010. This traffic is primarily driven by increased usage of mobile multi-media services [1]. Todays wireless traffic is largely contributed by human centric applications. Machine centric traffic will contribute equally (or even more than human centric) in the future as there is a forecast of approximately 50 billion connected devices by 2020 [2]. The combination of human and machine centric applications will diversify the landscape of the telecom industry in terms of size, cost, energy dissipation and services. Machine centric applications require data delivery of high reliability, and on the other side human centric applications require data delivery at high speed and always connected. Therefore, the next generation of mobile communication will be moving towards to a future state of everything everywhere and always connected with reliability [3]. The existing 4th generation mobile communications (also known as IMT-A [International Mobile Telecommunications-Advanced]) is all IP based network with packet switched delivery for efficiently meeting the needs of the future generation networks with high data rates of 100 Mbps (high mobility) /1Gbps (low mobility). Various networks such as the wired (PSTN - Public Switched Telephone Networks), LAN (Local Area Networks), IP based mobile network, cellular (2G/3G), WiMAX (Worldwide Interoperability for Microwave Access), nomadic, ad-hoc and sensor networks are able to communicate with the core network. The 4G network is fulfilling the present demands. However, the needs for high throughput will continue to increase in future wireless networks due to high bandwidth demanding applications such as entertainment, multimedia, Intelligent Transport Systems (ITS), telemedicine, emergency, safety/security applications and other futuristic applications. These applications will push the demand for real-time, symmetric, wireless ubiquitous connectivity to an individual with a data rate that far exceeds the capacity offered by the current 4G network [4]. The vision of the 5G communication system is universally deployable converging technologies, which enable wireless services and applications at a data rate more than one terabit per second (Tbit/s) with coverage extending from a city to a country to the continents and to the world that will enable user-centric mega-communications [4]. The growth of 5G network would drive substantial economic benefits by serving as a platform for innovation in many areas of public and commercial importance, and benefits will lead to more investment, faster economic growth and new jobs. Radio spectrum is a prime factor in driving the growth of mobile services. The success of 5G network is based on the unconstrained availability of spectrum. About 1200 MHz of spectrum in the frequency bands below 5GHz has been identified for IMT services during the World Administrative Radio Conference (WARC) -92, World Radiocommunication Conference (WRC) -2000 and WRC-2007. These frequency bands are 450-470 MHz, 698-960 MHz, 1710-2025 MHz, 2110-2200 MHz, 2300-2400 MHz, 2500-2690 MHz, and 3400-3600 MHz. The identified spectrum is non-contiguous and scattered in different frequency bands from 450 MHz to 3.4 GHz. However, the actual allocation is ranging between the frequency band 700 MHz to 2.6 GHz. The spectrum available for cellular mobile services does not exceed a total of 780 MHz, and an operator has approximately 200 MHz spectrum across all IMT bands for providing telecom services with different access technologies from GSM to LTE [5]. However, 1200 MHz non-contiguous spectrum would not hold the pressure of high mobile data growth, demand for convergence of different varieties of services and speed. Therefore, more spectrum bands would need to be explored. Presently, frequency bands under consideration are: 470-698 MHz, 1300-1400 MHz, 1427-1 527 MHz, 1695-1700 MHz, 2025-2110 MHz, 2200-2290 MHz, 2700-3100 MHz, 3400-4200 MHz, 4400-5 000 MHz, 5350-5 470 MHz and 5725-6425 MHz. Some of them will be finalised during WRC-15 and thereafter will be earmarked for IMT-A services.

II. CONCEPT OF 5G NETWORK

The 4G network offers a convergence of heterogeneous wireless network of different access technologies and wireless networks and has the ability to connect anywhere and anytime. The future network will be the extension of the existing 4G network. The 5G wireless network will have capabilities for supporting high capacity and massive connectivity for an increasingly diverse set of services, application and users, and flexible

and efficient use of all available contiguous/non-contiguous, licensed/unlicensed spectrum. Convergence of technologies, ultra-high capacity, universal coverage, minimum energy usage and cost-efficiency are key characteristics of the 5G wireless system concept. At the core of 5G applications are M2M communications enabled by technological breakthroughs in a plethora of scientific areas, wireless and wired communications, artificial intelligence, the Internet, robotics and space [4]. Currently, operators are providing services using multiple RATs (2G, 3G, WiMAX, LTE, WLAN, Bluetooth and other emerging access technologies, etc.). For example, operators rely on unlicensed Wi-Fi network to offload traffic demand at hot-spots. Devices are equipped with multiple RATs like cellular, Wi-Fi and Bluetooth to connect the peripheral devices and internet. The 5G network should have the capability to integrate multiple radio access technologies seamlessly and to choose a suitable one among them, and to switch over between various access technologies, combine different streams coming from different technologies during a session to meet capacity demands [6].

The constant decrease in cell size enhances the cell capacity, spectral efficiency by exploiting spatial reuse and brings the communication services closer to the user [7]. The small cell with low transmit power provides flexibility in managing high data traffic hot spots. The future 5G network will have a relatively large number of small cell sites with different cell size from macro to femto and with low transmit power to meet the high traffic demand. The low-powered small cell sites will use to enhance the capacity, whereas macro cells will use to enhance the coverage. The 5G networks offer multiple options in respect of transmit power, coverage, capacity, spectrum usage and choice of RATs, and move towards cost reduction, green energy and better resource utilisation.

The network would also create a dynamic environment to cover D2D and M2M communications so that such communication takes place directly between user equipment or between machines (in the context of Internet of Thing) without use of base stations or core network [7]. Such type of communications will coexist dynamically within the network and will help to improve the area spectral efficiency, cellular coverage and reduce end-to-end latency and power consumption.

Therefore, the 5G network would be an integrated wireline/wireless network, where the wireless part comprises a dense network of small cells with capacity enhanced through high-order spatial multiplexing (MIMO), cell data rates of the order of 10 Gbps and round-trip latency of 1 ms. With these attributes, the combined network will support everything from simple M2M devices to immersive virtual reality streaming, with monitoring and control of literally billions of sensors and multiple simultaneous streaming services, and will support the massive data collection and distribution needs of the Internet of Things (IOT) [3]. There are three main aspects to realizing 5G communication systems in figure 1 [4].

Enabling 5G intelligent core: Intelligent core will be the soul of the 5G network. M2M and IoT are keys for realizing the intelligent core which provides seamless ubiquitous networking and connectivity in the 5G network.

Enabling ubiquitous connectivity: Ubiquitous connectivity will be for coverage under high mobility and data rates,

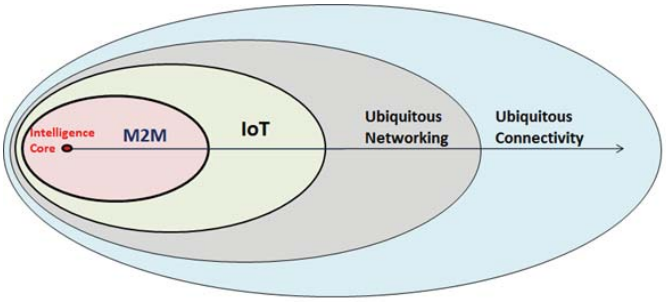

Fig. 1. Concept of 5G network

and to moving application from device to device without any content interruption. Use of millimeter wave links, high-order spatial multiplexing (MIMO) antenna, virtualization, small cell deployments and novel spectrum usage methods, are some of the keys for ubiquitous connectivity.

Enabling Ubiquitous networking: The ubiquitous networking will provide the same quality of services to end users, regardless of how many access networks, and spectrum bands are integrated for connectivity purposes.

The 5G network is conceptualized as a multi-layers heterogeneous network. Primary layer will be a macro layer which responsible for ubiquitous connectivity. Secondary layers, embedded in the primary layer, will be a combination of small cells (micro, pico and femto) to provide additional capacity to end users. This additional capacity will be in the form of extra spectrum on the same carrier, different access technology or an additional stream on a different carrier. The network will be controlled by an intelligent unit WISDOM [4], [8], [9]. The function of multilayer network is conceived as initially, a user will be connected to the primary layer. When data requirements go beyond the primary layer network capacity after providing the additional spectrum (if available) and change in radio access technology available within the primary layer, the user will also get connected to the nearest secondary layer through the WISDOM network. This has been depicted in the figure 2, where three users A, B and C have been shown. The requirements of the user A and B is beyond the capacity of primary layer, they have also been connected to secondary layers, whereas the user C requirement is within the capacity of primary layer.

With the above- mentioned features, a modification in 4G networks could make the best candidate for 5G network. Based on this assumption, the concept of 5G has been introduced as integration of 4G with WISDOM as given below [8], [9]:

$$4G\&WISDOM = 5G$$

The Wireless Innovative System for Dynamic Operating Mega Communications (WISDOM) is a communication system for ubiquitous trustworthy human-centric connectivity via an arbitrary infrastructure support. The WISDOM, as shown in Figure 3, principle brings unlimited wireless world interconnection, convergence, and cooperation (geographically including cities, countries, continents, and finally, the whole world), together with a large variety of multimedia services

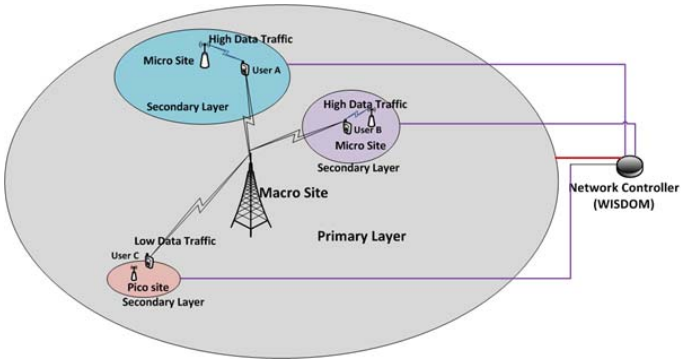

Fig. 2. 5G Network: Primary and secondary layers

at very high data rates, and becomes the main 5G definition point.

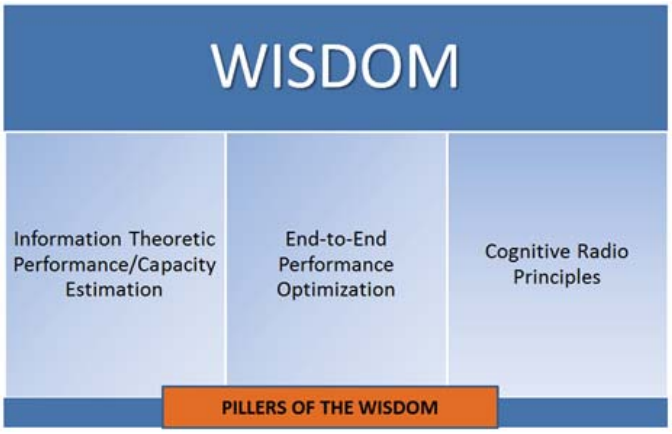

Fig. 3. WISDOM Principle [4]

The three founding pillars of WISDOM are [9]:

- An information theoretic performance/capacity estimation of different types of networking paradigms
- Design of protocols based on end-to-end, cross- layer and cross-network-domain performance optimization
- Cognitive radio (CR) network based self-organizing networks for management of possible usage scenarios and minimize the spectrum and energy requirements.

WISDOM aims to design and develop technologies, system that could globally integrate, interconnect and communicate into a flexible and dynamic system for the human-centric and machine centric communications in 2020 and beyond [8]. The operational domain of WISDOM concept requires well-defined network protocols, architecture for heterogeneous network, integration between different kinds of terrestrial and satellite network to provide applications upto 1Tbps link rate at short distance or as system aggregate operating in burst mode, and at least 250 Mbps to the end user for real time applications with coverage extending from a city, to a country, the continent and the world (4). The WISDOM concept will lead wireless communications beyond the emerging technologies and towards the realization of that new paradigm, based on the combination of five independent elements, Communication, Connectivity, Convergence, Content and Cooperation [9].

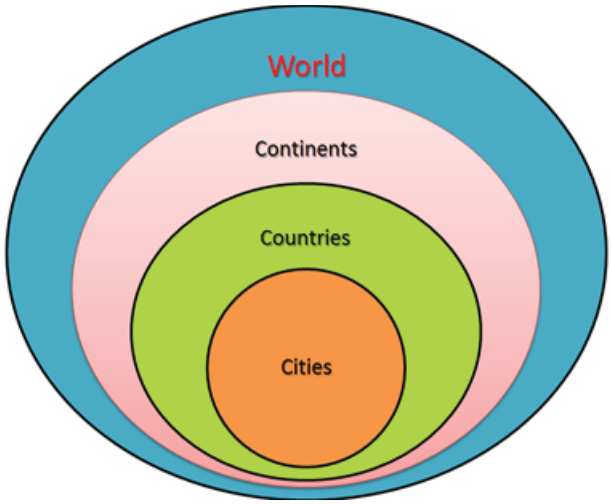

Fig. 4. Globel connectivity through WISDOM

III. IMPLEMENTATION CHALLENGES

5G network is basically delivery of services at any user platform using various wireless access technologies over any kind of network (all kinds of wireline, wireless, satellite networks) and spectrum band with a speed of more than 250 Mbps at end user. Therefore, a general framework should be developed to evaluate the performance of 5G wireless systems, taking into account as many performance metrics as possible from different perspectives. Besides, coexistence study between heterogeneous, the following implementation challenges should also need to be addressed:

In order to offer the services in a personalized form, the 5G technology must know some primary information about its users: identity, location, and privacy issues. 5G will have the hard task of operating an ever-growing number of heterogeneous networked devices that can communicate with each other or with people or robots to satisfy dynamic and high-level user expectations. 5G standardization must define uncertainties relating, for example, to new threats to cyber security, trust or privacy; trends in economic growth around the world; public acceptance of wireless and applied-field technologies; and legislative restrictions.

5G network envisages delivery over any kind of network. Therefore, a realistic channel models with proper accuracy complexity trade-off are required for 5G network. Massive MIMO channel model is an option. The technical challenge in developing massive MIMO systems is the signal processing complexity. Simplification of algorithm in massive MIMO system is a challenge. The massive MIMO should have the capability [12]: i) to support 10-100 times more devices than today ii) to allow very long battery lifetimes of the wireless device iii) to incur minimum signalling overhead iv) to enable low cost wireless devices v) to support efficient transmission of small payloads with fast setup and low latency.

At the same, it is desirable to have 99.999% coverage, while energy consumption and cost for the infrastructure should not increase.

The network should be energy efficient. Energy efficiency has two aspects; the first one is energy spend for maintaining infrastructure, which have a direct link with operational overhead and the other one is energy consumption in the end users devices. There are communication strategies, which require high energy for computation. Such applications will drain users device battery. To reduce energy consumption, two different approaches are under consideration. The first approach is creation of small cells with high capacity density. The main challenges of this approach are related to providing an economic backhaul solution and to minimise the additional deployment cost. The second one is use of massive MIMO system. The challenges of massive MIMO include the diffusion of energy due to scattering in NLOS scenarios, limiting the achievable directivity, and the complexity of spatial multiplexing of users.

The interference-tolerant CR networks is very much part of the 5G network. Reliable and practical management of the mutual interference of CR and primary systems is essential for 5G network. Therefore, regulation of the transmit power is essential for the CR system to coexist with other licensed systems.

5G network will be a step further towards low cost, plug and play, self-configuring and self-optimising networks. 5G system will be combination of macro and several micro, pico and femto cells embedded within the macro cell and will be deployed dynamically and in a heterogeneous manner, combining different radio technologies. Such configuration will improve spectral efficiency and coverage within an area. A massive deployment of small access nodes induces several challenges such as an adverse interference scenario or additional backhaul and mobility management requirements, which 5G needs to address. Different levels of coordination/ cooperation among small cells are keys to enhance the network capacity and keep interference at an adequate level, to manage mobility and spectrum, to ensure service availability and response to non uniform traffic distribution between neighbouring access points [13].

IV. SPECTRUM FOR 5G SERVICES

The network capacity depends on the number of base stations, radio access technology and frequency bandwidth. The 5G network will have several short range cell base stations for capacity boosting, which works alongside macro cells. The spectrum requirements for macro cell and short range cells are different. Macro cells will be for ubiquitous connectivity, and small cells will be for capacity booster [7]. Low frequency waves are suitable for macro cells due to its wide coverage and better penetration, and high frequency waves are suitable for booster cells due to large data carrying capacity. Therefore, spectrum requirements for the 5G networks could be divided into two different categories, low and high frequency waves.

A. LOWER SPECTRUM BANDS

As stated above, approximately 1200 MHz of spectrum has been identified for IMT-A services in the different frequency bands below 5GHz. These frequency bands are suitable for macro cell sites due to better propagation and penetration properties. If we look at the frequency allocation table, almost 50% of the total spectrum between 300 MHz to 6 GHz has been earmarked for mobile services as primary services. It means that this 50% of the total spectrum can be utilized for mobile services alone or in sharing with other primary services. The frequency bands below 6 GHz have already been allocated to legacy services long back. Therefore, no vacant spectrum is available below 6 GHz at present. The two options are available to enhance the spectrum availability for 5G communications; spectrum re-farming and spectrum sharing.

The spectrum re-farming is basically allowing existing license holders to utilise the allocated spectrum for some other purpose or migration of license holders from the existing band to some other band and reuse of the current band for other radio services. For example, re-farming of 900 MHz or 1800 MHz band, which was earlier allotted for 2G GSM services, is now being replaced by 3G or 4G network. Another example is the vacation of spectrum in the 700 MHz band by broadcasting services due to the digital switch over. Re-farming is a cumbersome process involves protracted negotiation with existing operators for migration, and also invites additional expenditure in migration.

Spectrum sharing is another option, where two or more than two operators share the same spectrum in frequency, time and geographic dimensions for providing same or different services. For example, there are several services, which use spectrum for a certain period of time or at certain locations. Such spectrum could be considered vacant, during the period or at the locations, where existing licensed operator is not using and the same could be utilised by mobile operators to provide IMT services. This type of sharing is known as static spectrum sharing. Another possibility is the dynamic spectrum access (DSA) that allows to access spectrum in opportunistic manners. CR is the basic tool for exploiting DSA. The CR enabled system sense the vacant spectrum and operates from the vacant spot, and retreat occupied spectrum on arrival of the primary user. A big chunk of already identified 1200 MHz spectrum has not yet been freed for IMT services worldwide. If we allow DSA, the spectrum crunch for the 5G network in lower bands would get resolved without doing large scale spectrum re-farming.

B. Higher Spectrum Band: MM-WAVES

The spectrum bands identified under the IMT umbrella do not have the capacity to carry such enormous data which required for 5G services. Therefore, mm-waves could be the candidate bands for 5G mobile communications, especially for second layer network due to high data carrying capacity. The mm-waves have the following advantages [11]:

1) Not much operation at mm-waves so more spectrum is available at mm-waves
2) Very large blocks of contiguous spectrum to support future applications
3) Due to high attenuation in free space, frequency reuse is possible at short distance
4) Spatial resolution is better at mm-waves hardware with CMOS technology

5) Advancement in semiconductor technology allows low cost
6) Small wave-length makes possible use of large antenna arrays for adaptive beam forming
7) The small size of the antenna at mm-waves facilitates easy integration on chip and installation at suitable locations.

Millimeter waves allow larger bandwidth and offer high data transfer and low latency rate that are suitable for high speed reliable internet services. The small wavelength facilitates small size antenna and other part of radio hardware, which reduces costs and also easy to install. The transmitters antenna would be like a lamppost, which could be installed on building, street lamppost, etc.

At such high frequency, waves are more prone to rain and other atmospheric attenuation. The wavelength is in the order of millimeters, and rain drops are also of the same size. Rains absorb high frequency waves and make it difficult for propagation. However, the experimental results show that in heavy rain condition, attenuation is 1.4 dB and 1.6 dB for 200 meters distance at 28 GHz and 38 GHz respectively [5]. A proper link design with slight high transmit power may take care of rain attenuation.

Wavelength at such high frequencies is in the range of millimetres. Any slight change in the position would affect the signal strength at the receiving end, due to which mm-waves are deeply affected by scattering, reflection and refraction. The r.m.s. delay spread for mm-wave is of the order of few nano seconds, and it is high for are non-line of sight (NLOS) links than line of sight (LOS) links[6]. Similarly, path loss exponent for NLOS links is higher than LOS links. Due to higher path loss and r.m.s delay spread, it is assumed that mm-waves are not suitable for non-line of sight (NLOS) links. However, these difficulties could be managed by using carrier aggregation, high order MIMO, steerable antenna, beamforming techniques. Propagation feasibility studies for mm waves have been carried out at research institutes, and concluded that propagation is feasible upto 200 meters of distance [5], [11] in both the conditions i.e. line of sight (LOS) and non-line of sight (NLOS) with transmit power of the order of 40-50dBm in a difficult urban environment. The cell size in dense urban areas normally varies between 100 meters to 300 meters. Therefore, mobile cellular is possible at mm-waves.

The traditional uses of the mm-waves include radio navigation, space research, radio astronomy, earth exploration satellite, radar, military weapons and other applications. The backbone/backhaul networks (point to point network) for existing telecom network to connect base station to main switching centre (MSC), Local Multipoint Distribution System (LMDS), indoor WLAN, high capacity dense networks are also present in the mm-waves. The typical microwave backhaul bands are at 6.0 GHz, 11.0 GHz, 18.0 GHz, 23.0 GHz, and 38.0 GHz frequency bands.

The Radiocommunication Sector of International Telecom Union (ITU) is responsible for management of radio spectrum at international level. As per ITU-R frequency allocation plan, the frequency band 10 40 GHz has been earmarked for satellite based services in all the three regions along with Fixed and mobile services. Local Multipoint Distribution System (LMDS), WLAN, Satellite services and High capacity dense network etc. are main services present in mm-waves. Several point to point fixed microwaves links are also working in this band. These links are basically for backbone/backhaul network for GSM and other services. A good amount of vacant spectrum is available at mm-waves which could be utilised for 5G communications services. 5G services may transmit high power approximately 40 -50 dBW. Therefore, coexistence study needs to be carried out with existing LMDS and satellite services, which working in neighbouring spectrum bands.

V. Conclusion

In this paper we discussed frequency bands for 5G mobile communications services. Lower band is suitable for the primary layer due to better propagation characteristics. Exclusive spectrum below 6 GHz is not available. The availability can be increased through spectrum sharing as primary and secondary user concept. The Millimetres waves are most suitable candidate bands for secondary layer of 5G network. Analysis of candidate bands shows that sufficient spectrum is available, which could be allocated for the 5G services. However, extensive co-existence study with existing usage is required to be carried out for making provision for the 5G communications services.

***Abstract* — the proposed paper demonstrates an improved data authentication technique based on Daubechies Discrete Wavelet Transform (DWT). The primary concern is to maintain uncompromising visual quality and prevent unauthorized manipulation of the secret data during wireless communication. The secrecy of hiding is inflated by hiding the secret data in the high frequency transformed coefficients of two distinct levels concurrently. Proper measures are taken to increase the imperceptibility of the added noise. At the receiver's end, a blind reverse process is applied to obtain the secret information from authenticated image and authenticity of the extracted data is verified by using a message digest. The algorithm has been tested against some related attacks and also may prove effective in designing a secured smart health card. Extensive experimental results show better performance over other similar techniques.**

Keywords—image authentication; daubechies 2; message digest; ssim; copy attack.

I. INTRODUCTION

In modern days there is an incremental advancement in the use of technology for facilitating day to day activities. So, the biggest challenge is information security when sending information from one place to another with the aid of wireless technology. Efficient security techniques evolved from time to time and digital data authentication [1, 2] is considered as one of the techniques for safe transmission. The technique is implemented by hiding information generally with other information that is only known to the intended receiver. Hiding involves two factors: 1) perceptual transparency and 2) the volume of payload data [3] and robustness of embedding [4].

Recently, algorithms are designed using Discrete Wavelet transforms (DWT) for its two prominent features namely Multi-resolution analysis (MRA) and rectification of the problem of time - frequency resolution as mentioned in the theoretical aspects of Human Visual System (HVS). A wavelet transform can be represented as a function using wavelets and termed as daughter wavelets. These are then scaled and translated copies of the main oscillating waveform is called the mother wavelet. Some of the recent works shows involvement of DWT coefficients at different levels. Souvik Bhattacharyya et al. [5] implemented 1-level resolution using DWT and embedded in all the four coefficients. In another algorithm, Vanitha T et al. [6] considered only the LSB positions of DWT coefficients to embed the message bits. An attempt had been made by Aayushi Verma et al. [7] to insert the secret data in the LL sub-band of the transformed coefficients. Embedding of secret messages in high frequency coefficients and utilizing the unchanged low frequency coefficients for improving the image quality was proposed by Po-Yueh Chen et al. [8]. To improve the quality of the reconstructed image, different compression thresholds for the wavelet coefficients was proposed by P. Raviraj et al. [9].

Some of the above algorithms used lossy compression technique [10], some used 1-level decomposed coefficients for embedding and in others there is a degradation in the image quality after the embedding of secret data. In the proposed algorithm, Daubechies Wavelet Transform [11] is used because the feature of orthogonality increases the bandwidth efficiency. The wavelet is more robust to narrowband interferences than the Orthogonal Frequency-Division Multiplexing (OFDM) modulation in wireless communication and also proves efficient in compression [12], image analysis [13] and classification of signals [14]. The next section deals with the mathematical representation of Daubechies DWT.

II. CONCEPT OF DAUBECHIES WAVELET TRANSFORM

The Discrete Wavelet Transform of a signal is implemented by passing a signal through a series of filters called filter bank. The Daubechies wavelets generally have the highest number i.e. A of vanishing moments, for given support width (2A – 1). These are more accurate, since change in the input data set is reflected in the high pass filter results at each transform step. In the proposed algorithm we have used D4 or db2 wavelet transform where there are 2 vanishing moments. In D4, a polynomial with two coefficients i.e. constant and linear signal components is encoded. Mathematically the coefficients are represented as

$$b_k = (-1)^k a_{(N-1-k)} \quad (1)$$

where *k* is the coefficient index, *b* is a coefficient of the wavelet sequence, a coefficient of the scaling sequence and N is the wavelet index (here N=4). In D4 the coefficients for the scaling functions are taken as {0.6830127, 1.1830127, 0.3169873 & -0.1830127}. The wavelet coefficients are derived by reversing the order of the scaling function coefficients and then reversing the sign of every second one, i.e. {-0.1830127, -0.3169873, 1.1830127, -0.6830127}.

The forward transform is implemented as: Let us consider a list S with 2 halves. The first half (S_0 to $S_{(1/2-1)}$) contains even elements and the second half ($S_{1/2}$ to $S_{(N-1)}$) contains odd elements. In the forward transform S[1/2 + n] references an odd element and S[n] references an even element. The steps are:

- U1: for n=0 to (1/2 -1), S[n] = S[n] + √3S[1/2+n].
- P1: S[1/2] = S[1/2] – (√3/4) S[0] – ((√3-2)/4)S[1/2-1].

  For n=1 to (1/2 -1)

  S[1/2+n] = S[1/2+n] - (√3/4) S[n] -((√3-2)/4)S[n-1].
- U2: for n=0 to (1/2 -2), S[n] = S[n] – S[(1/2) +n+1].

  S[(1/2)-1]= S[(1/2)-1] – S[1/2].
- N: for n=0 to (1/2 -1), S[n] = ((√3-1)/ √2) S[n].

  S[n+1/2] = ((√3+1)/ √2) S[n+1/2]. (2)

In the above steps U1 and U2 stand for Updates, P1 stands for Predicate and N stands for Normalize.

The inverse transform is the mirror reflection of the forward transform.

Section III deals with encryption of the payload, embedding of encrypted data, adjustment for maintaining proper image property, extraction of the encrypted data and decryption of the payload after receiving the authenticated cover image via wireless communication.

III. THE TECHNIQUE

Separate sub sections are defined for different aspects in data authentication in wireless domain. In sub-section A, the secret data is encrypted with the help of 4 keys to increase the robustness of imperceptibility. The sub-section B deals with the proposed embedding technique for authentication in HH block of the transformed cover image. The high frequency coefficient set HH include the edges and textures of the image and HVS is insensitive to changes in such coefficient sets. So, HH block of both the levels are used for embedding the encrypted payload. Hiding for authentication is done at pseudorandom position without distorting the image quality. In the third sub-section C, accurate measures are taken to bind all the pixels within proper image property even after embedding the payload in a transformed block. The above procedures are framed keeping in mind that the secret data is to be transmitted through a wireless communication medium and there is be a chance of unauthorized interference. Lastly, the sub-sections D and E are responsible for proper extraction and presenting authentic payload to an intended receiver.

A. Encryption of the payload image

Pre-calculated size of blocks taken from the payload image are encrypted within its boundaries one at a time. The rearrangement of blocks defines a transformation of reallocation of blocks in such a manner that the correlation of a pixel with the neighboring pixel decreases. The process is done in two steps:

- Firstly every pixel location is modified to a new location with the help of 2 keys each of size 2 bytes. The equations are:

  $X` = (K_0 \times X + K_1) \oplus N$ and

  $Y` = (K_0 \times Y + K_1) \oplus N.$ (3)

  (X, Y) is the original location of a pixel, (X`, Y`) is the modified location of a pixel and N denotes the length of the image. Two keys (K_0, K_1) are used to authentic the process.
- In the second step, the output image is divided into a set of 2 x 2 non overlapping blocks. The pixels of each of the blocks undergo ⊕ operations with 2 more keys (K_2, K_3) each of size 2 bytes to produce a new set of pixels. The equation is:

  $X` (i, j) = X (i, j) \oplus (K_2/ K_3)$ (4)

  The values of i and j are both (0, 1), X (i, j) is the original value of a pixel and X` (i, j) is the modified value. If (i == j) then K_2 is used, otherwise K_3 is used.

B. Embedding procedure

An image as cover and the encrypted image as payload are taken as input. The output is an authenticated image. A message digest (SHA-1) of size 160 bit is generated from the encrypted payload and the cover image is considered as a set of 4x4 non overlapping sub-images.

Repeat the following steps until the payload gets fully fabricated.

- Each of the sub-images is converted to transform domain by applying 2-level Daubechies DWT (D4/ db2).
- The integer part of the target frequency coefficients (i.e. HH2 and 4 coefficients of HH1) of a block are chosen for embedding.
- The current block number is represented as a combination X_i (i =0 to 16) of bits. A pseudo-random position is generated by the expression: ipos = ($X_3 \oplus X_2 \oplus B_p$) where B_p is the last embedded bit.
- The payload bits are scanned one at a time and is fabricated in pseudo-random position in each of the target frequency coefficients.
- In some cases, an adjustment is required to reduce the degree of the embedded noise. The bit of the binary representation on the right of s (1 to 0) is altered, where

s is the current modified bit in the target frequency component.

- The authenticated pixels are generated by applying Inverse Daubechies DWT (D4/ db2) on the respective sub-image block.
- To restore proper image property, necessary readjustments are applied on the adverse authenticated block.
- The correct spatial block is returned back into the output image in the same location.

C. Retention of image property

Some authenticated pixel values may contradict the image property. Rectification is done on the required authenticated pixels of a block and the embedding algorithm is repeated for that block. A threshold value T determined after experimentation on a number of images is considered to ease the process. The possible causes and the remedies are mentioned below:

- If the spatial pixel values lie either in [0, T]/ [255-T, 255] / [0, 255], and there is a generation of either (-) ve authenticated pixels/ (+) ve authenticated pixels/ both. Then as per the range a value A = [0- (highest (-) ve pixel value)] is added, a value B = [(highest (+) ve pixel value) – 255] is subtracted and [2 x max (A, B)] is either added or subtracted from the default pixel values in the respective range.
- If the spatial pixel values are in the range (0, T)/ (255-T)/ 255) and there is generation of both (-) ve and (+) ve pixel values. The spatial pixel values are adjusted as: 1) values below T by the value (2 x max (A, B)) and 2) the values above T by the value max (A, B).
- If the spatial values are in the mid-range [(T+1), ((255-T) - 1)], then no rectification is necessary.

D. Extraction procedure

The input is an authenticated image and the output is an encrypted image (payload).

- Non-overlapping blocks of size 4 x 4 are read in sliding window pattern from the authenticated image.
- Each of the sub-images is converted to transform domain by applying 2-level Daubechies DWT (D4/ db2).
- The integer part of the target frequency components is chosen and the pseudo-random positions are generated.
- The embedded bits are extracted from the designated areas.
- The bits are arranged sequentially to form payload size, message digest (SHA–1) of size 160 bit and the encrypted payload itself.
- From the extracted payload, a message digest (SHA-1) of size 160 bit is also generated.
- The extracted and the generated message digest is compared to check the authenticity of the extracted encrypted payload.

E. Decryption of the extracted payload

- In the first step, the extracted payload is divided into a set of 2 x 2 non overlapping blocks. The pixels of each of the blocks undergo $\oplus$ operations with the two keys (K_2, K_3) to re-produce the original set of pixels. The equation is:

$$X(i, j) = X`(i, j) \oplus (K_2/ K_3), \quad (5)$$

The values of i and j are both (0, 1), X` (i, j) is the modified value of a pixel and X (i, j) is the original value. If (i == j) then K_2 is used, otherwise K_3 is used.

- In the second step, the modified pixel location is reallocated to the original location by using the equations:

$$X = ((X` \oplus N) - K_1) / K_0$$

$$Y = ((Y` \oplus N) - K_1) / K_0 \quad (6)$$

(X`, Y`) is the modified pixel location, (X, Y) is the original pixel location and N denotes the length of the image. K_0 and K_1 are the two keys.

The above two steps help to frame the desired payload at the receiver's end.

A flowchart for the technique is shown in Fig. 1.

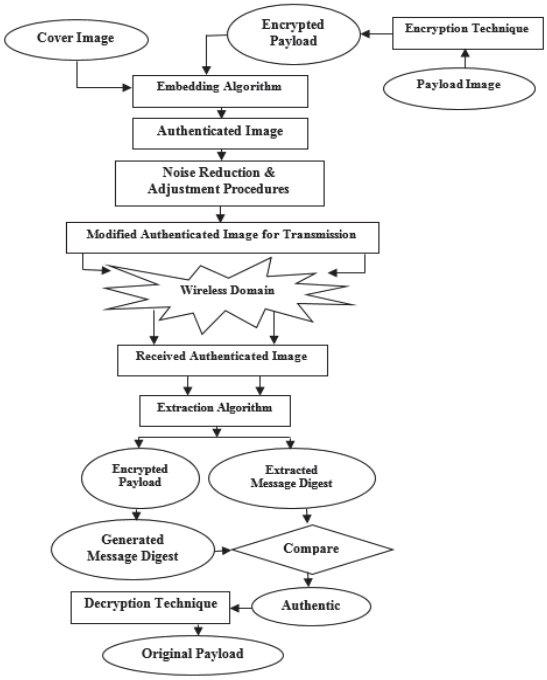

Fig. 1. *The TECHNIQUE of DWEDAWD*

IV. Result, comparison and analysis

A number of gray scale images are considered to test the effectiveness of the proposed algorithm. The experimentation has been done in a system with 4 GB of main memory, processor of at least 1 GHz clock speed, 1 GB of graphics memory and 4 GB of free disk space. The imperceptibility of data hiding is measured in terms of Peak Signal to Noise Ratio (PSNR) [15], Image Fidelity (IF) and Structural Similarity Index Metric (SSIM) [16]. The computed metric values are shown in Table I.

TABLE I. ANALYSIS OF PSNR, MSE, IF AND SSIM

Source Images	Capacity (Byte)	PSNR	IF	SSIM
Monalisa	12100	38.01	0.9934	0.9979
Lenna	12100	37.24	0.9345	0.9960
Baboon	12100	37.90	0.9919	0.9976
Oakland	12100	37.68	0.9952	0.9932

Average	**12100**	**37.34**	**0.9854**	**0.9954**

The degradation level of an authenticated image is considered to be quite acceptable if the PSNR value is greater than 35 dB. The proposed algorithm is quite successful in achieving a decent average PSNR value i.e. 37.34 dB in spite of hiding quite a volume of secret data in both the levels of resolution simultaneously. Moreover the average values of IF and SSIM i.e. 0.9854 and 0.9954 respectively proves that the authenticated image more or less resembles the cover image.

The visual interpretation of some gray cover images used for experimentation are shown in Fig. 2. The dimension of each such grayscale image is 512 x 512 and that of the payload image 'Earth' is 110 x 110. From the figure it can be observed that there is hardly any difference between the source and embedded images in terms of HVS.

Source Images	Authenticated Images	Magnified Source Images	Magnified Authenticated Images

Fig. 2q
Embedded Payload (Earth)

Fig. 2q
Extracted Payload (Earth)

Fig. 2. *Visual Interpretation of images in DWEDAWD*

In addition to this, a performance comparison is also done with some of the existing algorithms as shown in Table II.

TABLE II. COMPARATIVE ANALYSIS OF PSNR

No	Algorithm	Level of Resolution	Avg. PSNR (in dB)
A	[5]	1	34.60
B	[17]	1	38.52
C	[18]	2	26.30
D	[19]	2	33.08
E	[20]	2	36.04
F	**DWEDAWD**	**2**	**37.34**

In the above table, the proposed algorithm shows an increase in the average PSNR value (i.e. 37.34 dB) even with 2-level of resolution as compared to the algorithms A and B with 1-level of resolution and less or similar embedding capacity. The algorithm also proves an enhancement in data authentication as compared with the algorithms C to E, with 2-level of resolution and similar embedding capacity.

The proposed algorithm also proves its grittiness against some of the related attacks and is also effective in smart health card technology as discussed below.

A. Attacks

- Visual Attack: An initiative is taken to resist this attack by eliminating certain issues like 1) embedding in a sequential order and 2) length is less than the maximum size of the bit plane.
- Statistical Attack: A histogram analysis is done on both the cover and authenticated images and it may be inferred that the proposed algorithm shows resistance against this kind of attack.

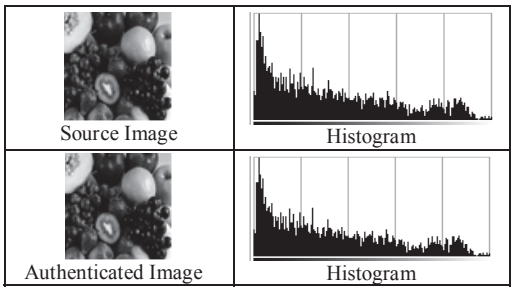

Fig. 3. *Histogram Analysis of Source and Authenticated Images*

- Copy Attack: The embedding of payload is dependent on a self-defined pseudorandom function which establishes a link between the payload and the cover

image. The link can only be verified by an authorized receiver during the extraction of the payload. This will cause a problem in terms of the marked target cover image and also helps to restrict protocol attack.

- Collusion Attack: Every copy of a cover image have different embedding policy, and the attacker cannot predict the embedding location and hidden data by colluding many copies of the authenticated image. Only the owner has the record of different embedding policies and can always extract the payload from the attacked authenticated image by applying the different policies.

B. Social Implication

Smart Health card is a useful option to define basic health information of an individual like blood group, current health problems and current medications while treating an accident or medical emergency. Citizens having certain health problems and are constantly on the move are at a high risk. Since the cards have up-to-date information, doctors can have access to all the information they need during emergencies which will reduce chances of medical errors. Every Smart card is linked via wireless communication to an online Personal Health Record that is created when the patient gets registered in a hospital and given the Smart card. To enhance the robustness of data authentication the patient's information will be encrypted before being fabricated into the smart card.

V. CONCLUSION

The proposed algorithm defined in frequency domain helps to enhance the security in wireless communication. Use of gray images helps efficient routing in terms of energy. Efficient authentication prevents attenuation of the signal strengths. Pseudo-random embedding position obstructs tracing a payload by unauthorized user and the control technique helps to optimize the noise integration. Due to the effectiveness of encryption procedure, the proposed scheme may be more robust against brute force attack applicable in wireless systems.

***Abstract*—In order to support Variable Bit Rate (VBR) data transmission in frequency selective channel, we propose a rate-independent multicarrier based scheme. The purpose of the present work is to implement rate independent transmission scheme over the frequency selective channel while maintaining the desired QoS. In this paper, the VBR Spread Orthogonal Frequency Division Multiplexing (SOFDM) transmission scheme is proposed and compared with Variable Spreading Length (VSL)-OFDM. For all the schemes, three Variable Rate classes are considered for analysis and simulation. Results show that the BER performance of SOFDM is independent of rate. It is shown that, SOFDM outperforms VSL-OFDM for all the considered VBRs. Hence, SOFDM transmission scheme could be a suitable candidate for variable rate communication system.**

***Index Terms*—SOFDM, VBR, Multicarrier, VSL-OFDM**

I. Introduction

In wireless communication, various services like voice, image, data and video etc. need to be integrated to support multimedia services in 3G and beyond systems. Hence variable rate systems aim to provide broadband services and require a great amount of integration among available schemes. The bottleneck to provide such services include higher bandwidth and hostile wireless channel, while maintaining required QoS and reliability [1].

Based on the rigorous research in the past the combination of multiplexing schemes namely Orthogonal Frequency division Multiplexing (OFDM) and Code Division Multiple Access (CDMA), termed as Multicarrier (MC-CDMA) had been proved to be suitable to combat such difficulties [2]. MC-CDMA was first proposed in [3], and analyzed in [4] over the frequency selective channel. Later, in order to support reliable multi-user communication, Group Orthogonal (GO) MC-CDMA [5], GO-OFDMA [6], Variable Spreading Length (VSL) MC-CDMA [7] etc. transmission schemes were proposed and analyzed over the frequency selective channel. In [7], both variable rate Multi-Code and Variable Spreading Length (VSL) access schemes of MC-CDMA are implemented over the slow Rayleigh fading channel. It is illustrated that Multi-Code MC-CDMA has better BER performance than VSL MC-CDMA for higher data rates. In this work, the Multi-code and VSL spread MC-CDMA schemes are implemented and compared for the single user case, terming it as spread-OFDM and VSL-OFDM respectively. Although, the concept of SOFDM has also been discussed in [8].

Till date, to the best of our knowledge no analytical/simulation work employing variable rate multicarrier transmission schemes, for such system has been discussed in the literature. In this paper, variable rate SOFDM and VSL-OFDM schemes for single user are implemented over slowly varying frequency selective fading channel. It is shown that the BER performance of SOFDM scheme is independent of transmission rate.

Section II describes about the system model and performance analysis of VBR single user spread-OFDM. In Section III, the system model of VBR VSL-OFDM is presented. In Section IV, the simulation results are shown. Finally, Section V concludes the paper.

II. Variable Rate Single User Spread-OFDM

A. Proposed System Model

In this work, spread OFDM technique has been used as VBR transmission scheme. Walsh Hadamard (WH) code has been employed as spreading code. Spreading provides the diversity in the frequency domain and thus improves the error performance of the wireless communication systems. The transmitter model of the variable rate spread-OFDM scheme is shown in Figure 1. The incoming serial modulated data bits $d_r = \left\{d_0, d_1, \cdots, d_{\frac{r}{R}-1}\right\}$ are converted into parallel form with symbol duration T, depending upon the transmission rate $r \in \{4R, 8R, 16R\}$, where R is the basic rate. For higher rate transmission, $\frac{r}{R}$ is taken to be higher value and vice versa. Each parallel stream of rate r, is spread by a row of orthogonal Walsh Hadamard (WH) code matrix $C_r = [C^0_{1\times N}; C^1_{1\times N}; \cdots C^{\frac{r}{R}-1}_{1\times N}]$ of dimension $\frac{r}{R} \times N$, and then modulated over N different subcarriers. Cyclic prefix (CP) of length $\frac{N}{4}$ is added to form the OFDM symbol to avoid the Inter Block Interference (IBI) caused due to multipath propagation of the signal [9]. This length of cyclic prefix is considered so as to insure that the cyclic prefix duration is4 greater than the delay spread due to the channel.

The transmitted signal employing spread-OFDM scheme for particular r is expressed as:

$$s_r(t) = \sqrt{2P}\sum_{k=0}^{N-1}\sum_{p=0}^{\frac{r}{R}-1} d_p(t)C^k_p(t)exp(2\pi j f_k t) \quad (1)$$

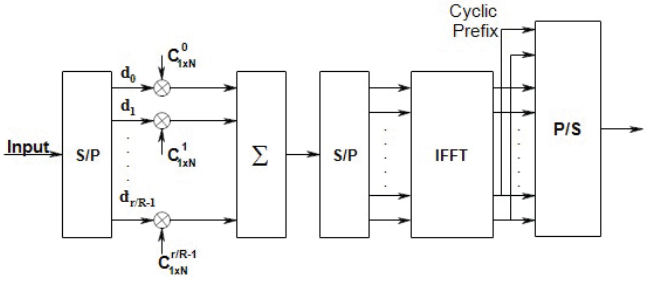

Figure 1: Transmitter model for the variable rate Spread-OFDM

where, $f_k = f_0 + \frac{k}{T}$.

B. Analysis over AWGN Channel

Spread-OFDM system is considered with N subcarrier and rate r. The sum of the parallel spread data is represented as

$$X_r(i) = \sum_{p=0}^{\frac{r}{R}-1} d_p C_p(i), \qquad 0 \le i \le N-1 \tag{2}$$

Equation (2) can be written in the vector form of order $1 \times N$ as,

$$\mathbf{X}_r = \mathbf{d}_r \mathbf{C}_r \tag{3}$$

In the above equation, $\mathbf{d}$ is of order $1 \times \frac{r}{R}$ and $\mathbf{C}$ is of order $\frac{r}{R} \times N$. For instance, if r =8R then the dimensions of $\mathbf{d}$ and $\mathbf{C}$, and hence $\mathbf{X}_r$ are 1×8, $8 \times N$ and $1 \times N$ respectively. Thus for any rate r, the sum $\mathbf{X}_r$ would be modulated onto all N orthogonal subcarriers. For any considered data rate, the spreading length of the code remains same. The difference lies only with the number of the codes employed based on the number of parallel substreams as shown in Fig. 1.

After IDFT operation, users data can be represented as,

$$s_r(n) = \frac{1}{N} \sum_{k=0}^{N-1} X_r[k] e^{\frac{j2\pi kn}{N}}, \qquad n = 0, 1, ..., N-1 \tag{4}$$

Considering only the effect due to AWGN noise with zero mean and variance of $N_o/2$, the received signal will be

$$v_r(n) = s_r(n) + w_r(n) \tag{5}$$

where, $w(n)$ is the AWGN noise vector. Received signal after DFT operation at the receiver gives

$$v_r[k] = \sum_{n=0}^{N-1} v_r(n) e^{\frac{-j2\pi kn}{N}}, \quad 0 \le k \le N-1 \tag{6}$$

From equation (5) and (6),

$$v_r[k] = \sum_{n=0}^{N-1} \left[\frac{1}{N} \sum_{l=0}^{N-1} X_r[l] e^{\frac{j2\pi ln}{N}} \right] e^{\frac{-j2\pi kn}{N}} + W_r(k) \tag{7}$$

$$v_r[k] = \underbrace{\frac{1}{N} \sum_{n=0}^{N-1} \sum_{l=0}^{N-1} X_r[l] e^{\frac{j2\pi(l-k)n}{N}}}_{F} + W_r(k) \tag{8}$$

where,

$$F_r = \begin{cases} X_r(k), & for\ \ l = k \\ 0, & otherwise \end{cases} \tag{9}$$

Final recevied vector at all the subcarriers are as,

$$v_r = [X(0)+W(0),\ X(1)+W(1),\ ....X(N-1)+W(N-1)]_{1\times N} \tag{10}$$

$$\mathbf{V}_r = \mathbf{X}_r + \mathbf{W}_r \tag{11}$$

At the receiver, particular data rate is obtained as

$$\begin{aligned} \tilde{\mathbf{V}}_\mathbf{r} &= \mathbf{V}_r [\mathbf{C}_r^T]_{N \times \frac{r}{R}} \\ &= \mathbf{X}_r . \mathbf{C}_r^T + \mathbf{W}_r \mathbf{C}_r^T \\ &= \mathbf{d}_r \mathbf{C}_r \mathbf{C}_r^T + \mathbf{W}_r \mathbf{C}_r^T \\ &= \mathbf{d}_r + \mathbf{W}_r \mathbf{C}_r^T \end{aligned}$$

Now finding the mean of the decoded signal over a particular subcarrier g assuming zero mean noise,

$$\begin{aligned} E[\tilde{V}_r^g] &= E[d_r^g] + C^T E[W_r^g] \\ &= E[d_r^g] = \pm\sqrt{E_b} \end{aligned}$$

The variance of the decoded signal,

$$\begin{aligned} Var[\tilde{V}_r^g] &= Var[W_r^g C^T] \\ &= C_r C_r^T Var[W_r^g] = \tfrac{N_o}{2} \end{aligned}$$

Therefore, the average error probability for BPSK modulated signal is given as [10],

$$P_e = Q\left(\sqrt{\frac{2E_b}{N_o}}\right) \tag{12}$$

Equation (12) is independent of data rate and hence the performance is same for the three rates considered. Analytical and simulation results over AWGN for three rates (i.e. 4R, 8R and 16R) are shown in Figure 2.

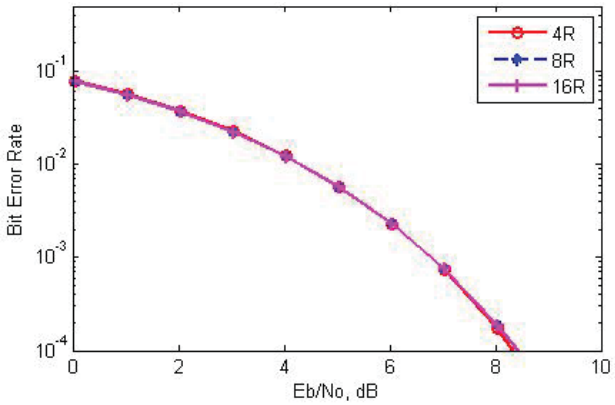

Figure 2: BER Performance of spread-OFDM over AWGN Channel

C. Analysis over Frequency Selective Channel

User's rate dependent data after multiplying with the code matrix of dimension $\frac{r}{R} \times N$ yields a summation of dimension $1 \times N$, and is expressed as,

$$\mathbf{X}_r = \sum_{p=1}^{\frac{r}{R}-1} \mathbf{d}_p \mathbf{C}_p(i) = [\mathbf{d}_r \mathbf{C}_r]_{1\times N}^T \tag{13}$$

The output of N point IDFT unit for particular rate can be expressed as

$$\mathbf{S}_r = \mathbf{D}^N \mathbf{X}_r \tag{14}$$

where $\mathbf{D}^N$ is the IFFT matrix of dimension $N \times N$. The transmitted signal gets linearly convolved with the channel implse response and is additionaly affected by the AWGN noise at the receiver.

$$\mathbf{V}_r = \mathbf{S}_r \otimes \mathbf{h} + \mathbf{n} \tag{15}$$

The output of N point DFT unit at the receiver can be expressed as

$$\mathbf{V}_{r_F} = \mathbf{H}\mathbf{X}_r + \mathbf{n}_F \tag{16}$$

where, $\mathbf{H}$ denotes the diagonal $N \times N$ channel impulse response (CIR) matrix in frequency domain as

$$\mathbf{H}_{k,k} = \sum_{n=0}^{L-1} h_n e^{-j2\pi(k-1)n/N} \tag{17}$$

Let us consider σ_s^2 and σ_z^2 denotes the variance of signal and noise respectively. The output of the N point DFT at the receiver is given to an $N \times N$ MMSE equalizer denoted by $\tilde{\mathbf{H}}$ as [11]

$$\tilde{\mathbf{H}}_{k,k} = \frac{(\mathbf{H}_{k,k})^*}{\left|\mathbf{H}_{k,k}\right|^2 + \frac{\sigma_n^2}{\sigma_s^2}} \tag{18}$$

$$\tilde{\mathbf{X}}_r = \underbrace{\tilde{\mathbf{H}}\mathbf{H}}_{\mathbf{F}}\mathbf{X}_r + \tilde{\mathbf{H}}\mathbf{n}_F \tag{19}$$

where, $\mathbf{F}$ is a $N \times N$ matrix,

$$\mathbf{F}_{n,r} = \frac{1}{N}\sum_{k=0}^{N-1} \frac{|\mathbf{H}_k|^2}{|\mathbf{H}_k|^2 + \frac{\sigma_n^2}{\sigma_s^2}} \tag{20}$$

$$\Lambda = diag[\mathbf{F}] \tag{21}$$

from equation (19), we get

$$\tilde{\mathbf{X}_r} = \Lambda\mathbf{X}_r + \tilde{\mathbf{H}}\mathbf{n}_F \tag{22}$$

Multiplying the above equation (22) with the code matrix $\mathbf{C}_r^T$ of order $N \times \frac{r}{R}$ to get back the actual information bits

$$\begin{aligned} \tilde{\mathbf{d}}_r &= \tilde{\mathbf{X}}\mathbf{C}_r^T \\ \tilde{\mathbf{d}}_r &= \Lambda\mathbf{X}_R\mathbf{C}_r^T + \tilde{\mathbf{H}}\mathbf{n}_F\mathbf{C}_r^T \\ \tilde{\mathbf{d}}_r &= \Lambda\mathbf{d}_r + \tilde{\mathbf{H}}\mathbf{n}_F\mathbf{C}_r^T \end{aligned} \tag{23}$$

In equation (23), first term denotes the desired signal and the last term denotes the noise component.

From equation (23), for a particular subcarrier g assuming β_0

$$P_e(\tilde{\mathbf{d}}_r^g < 0) = erfc\left(E\left[\tilde{\mathbf{d}}_r^g\right] / \sqrt{\left(2 * Var\left[\tilde{\mathbf{d}}_r^g\right]\right)}\right) \tag{24}$$

$$\gamma = \frac{\left(E\left[\tilde{\mathbf{d}}_r^g\right]\right.}{\sqrt{\left(2 * Var\left[\tilde{\mathbf{d}}_r^g\right]\right)}} = \beta_0\sqrt{\frac{E_b}{No}} \tag{25}$$

Instantaneous received SNR of equation (25) is determined using equation (23) through MATLAB simulation. Then, the probability of error for BPSK transmission in general can be calculated as,

$$P_e = \frac{1}{2}\int_0^\infty erfc(\gamma)p(\gamma)d\gamma \tag{26}$$

where, $p(\gamma) = \frac{1}{E_b/N_o}e^{\frac{-\gamma}{E_b/N_o}}$

The results obtained using equations (23), (24), (25) and (26) for different rates are shown in Fig. 4.

III. Variable Rate VSL-OFDM

In this paper, single user VSL-OFDM is considered for the purpose of comparison with the proposed scheme. The transmitter model of VBR single user VSL-OFDM transmission scheme is shown in Figure 3. Unlinke SOFDM, the modulated data bits are converted from serial to P parallel streams depending upon the specific transmission rate r, where $r \in 2^n R, n \in I^+$ and $P \in \frac{r}{R}$. Each parallel output symbol is copied onto $F = \frac{N}{P}$ branches and then respectively multiplied bit-by-bit by the row of orthogonal WH code matrix of order $F \times F$, where $F \in 2^n, n \in I^+$.

Irrespective of any data rate, there are a total of PF parallel symbol outputs after such frequency domain spreading, which are then transmitted simultaneously by modulating over PF orthogonal sub-carriers. In this scheme, the value of P and F are selected such that PF equals to the N-point IFFT size or the number of subcarriers onto which the data is modulated. The length of CP is same as that considered for SOFDM.

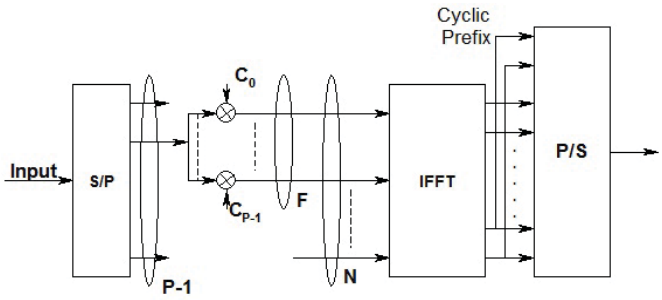

Figure 3: Transmitter model for the variable rate VSL-OFDM

The transmitted signal employing VSL-OFDM scheme, for particular r, as shown in Fig. 3 is of the form

$$s_r(t) = \sqrt{2P}\sum_{p=0}^{P-1} d_p(t)\sum_{k=0}^{\frac{N}{P}-1} C_p^k(t) exp\left[2\pi j\left(\frac{N.p}{P} + k\right)\frac{t}{T}\right] \tag{27}$$

IV. Simulation and Results

The Simulation Results for the variable rate Spread-OFDM and VSL-OFDM are shown in this section. All the simulations are done over frequency selective pedestrian channel-A [12] in MATLAB using Monte-Carlo simulations. In this paper, three different data rate (4R, 8R and 16R) are considered for simulation and analysis. In this work, BPSK modulation scheme is considered for both the VBR schemes. For each data rate, the energy per bit varies i.e. the highest rate users will transmit at reduced energy compared to lower bit rate users. Fig. 4. shows the simulation results for the three different rates (4R, 8R and 16R) of spread-OFDM scheme over the considered channel. From Fig. 5., it could be observed that the

BER performance for all the rates, are identical and match well with the analytical results. Such identical performance is due to the proportionate increase in the number of codes employed as the data rate (parallel substreams), which leads to the higher coding gain. For higher data rates such as 16R, higher number of orthogonal rows of WH code matrix are employed which leads to higher coding gain, and hence compensates for the performance degradation caused due to the lower received SNR. Thus, the trade off exists between the system complexity due to the usage of increased number of codes, and the data rate.

In Fig. 6, the bit error rate performance of the spread-OFDM scheme is compared with the VBR VSL-OFDM. Results obtained clearly shows that the performance of VSL-OFDM varies with data rates, the performance degrades as the rate increases. Even the performance of lowest rate (4R) VSL-OFDM is considerably poor than all rates of spread-OFDM. Around 7.5 dB of SNR gain is achieved by spread-OFDM over the lowest rate VSL-OFDM. This gain is even greater when compared to higher rate VSL-OFDM.

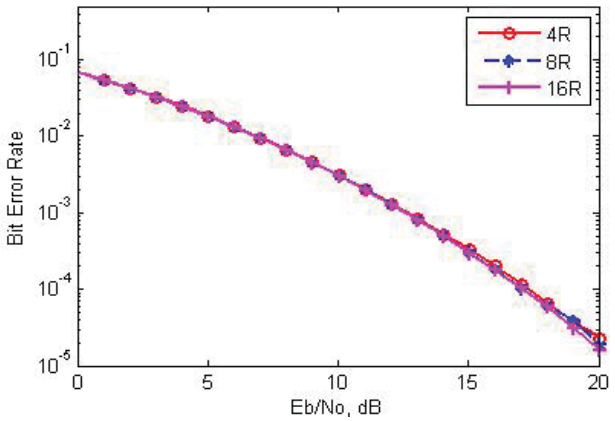

Figure 4: BER Performance of spread-OFDM over Pedestrian Channel

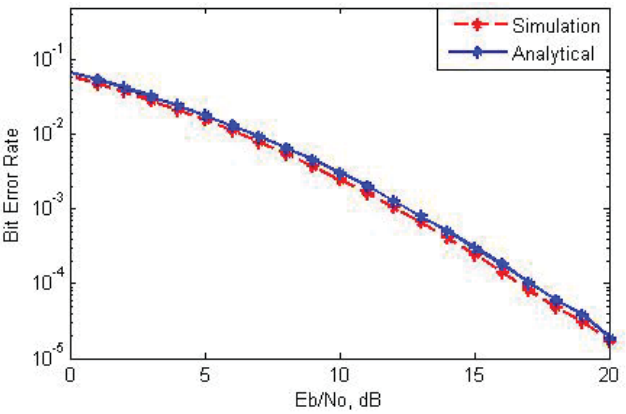

Figure 5: BER Performance of spread-OFDM for all rates over Pedestrian Channel

The maximum rate which spread-OFDM can support depends on the number of available subcarriers N and is equal to NR. For example, in this paper the number of available

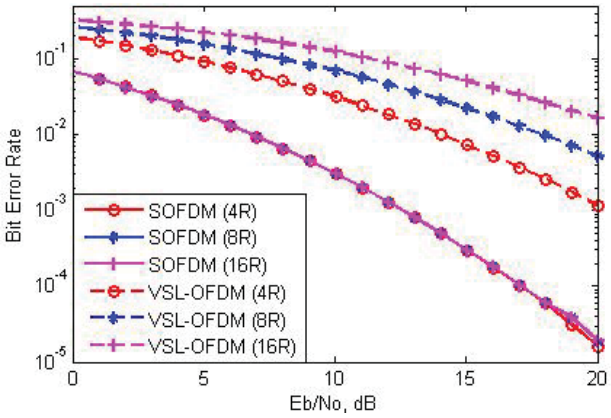

Figure 6: BER Performance comparison of spread-OFDM with VSL-OFDM over Pedestrian Channel

subcarriers are 64. Therefore, spread-OFDM can support maximum rate up to 64R. Moreover any rate can be supported by spread-OFDM which is not possible in case of VSL-OFDM due to the design constraint. Maximum rate supported by spread-OFDM can even increase by using higher modulation order. For example, in QPSK modulated maximum rate spread-OFDM, the will be double (128R). But as the modulation order increases the performance of spread-OFDM also degrades, as shown in Fig. 7. So there exists a trade-off between the date rate and the modulation order.

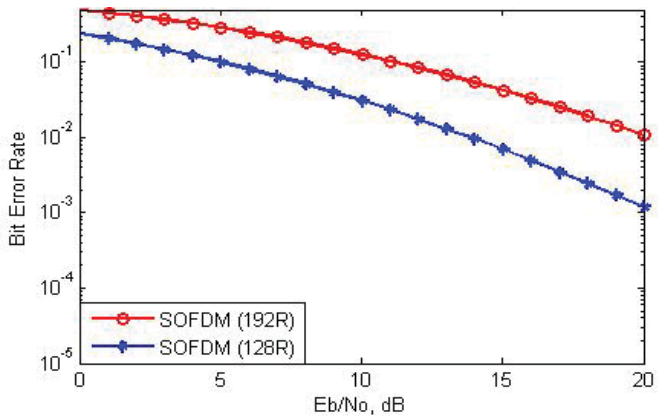

Figure 7: BER Performance of spread-OFDM with different modulation order

V. Conclusion

In this paper, the rate-independent spread-OFDM scheme has been discussed. Detailed analysis of the proposed scheme has been presented over AWGN and frequency selective channel. Further, simulation results match with the analytical results. Spread-OFDM is then compared with the VSL-OFDM and the results obtained clearly shows the performance improvement of spread-OFDM over VSL-OFDM. BER performance is independent of the transmission rate in case of spread-OFDM, while for VSL-OFDM the performance degrades as the rate increases. For spread-OFDM, SNR gain of about 7.5 dB is observed over the lowest rate VSL-OFDM.

The gain is even higher when compared with the higher rate VSL-OFDM. Later, for SOFDM, a trade-off between the transmission rate and modulation order is highlighted. These results clearly indicate that spread-OFDM can be a potential bandwidth efficient variable rate scheme for the wireless multipath environment.

ACKNOWLEDGMENT

This work is part of the project funded by DEITY, Government of India. We sincerely acknowledge the support of DEITY.

Abstract: Man has explored less than 5% of three-fourths of the water on Earth [1]. This is mostly due to lack of cheap and effective under-water transportation. Submarines and other deep sea modules have a wide range of problems and have limited our exploration capabilities and reach. After recent disasters requiring a wide range of under water rescue operations, it has become clear that we do not possess the means to efficient and effective under water travel. The Deep Sea Exploration Recovery and Transport (DESERT) Vehicle is an attempt to bridge that gap. Modeled on sharks, the fastest and most aerodynamic creatures in the seas, the underwater vehicle takes cues from nature and uses to its advantage. Deep and long ranged underwater travel and communication, using an engine and propeller system which uses sea water as a fuel [2], are the main points of discussion in this paper.

This study mainly focuses on the theoretical framework and design of DESERT, a undersea vehicle and the difficulties in attempting to do so. The ideas behind its mode of communication under-water have also been put forward and explored. Using new technological advancements, a first-of-its-kind model has been put forward with an inclination towards making it feasible.

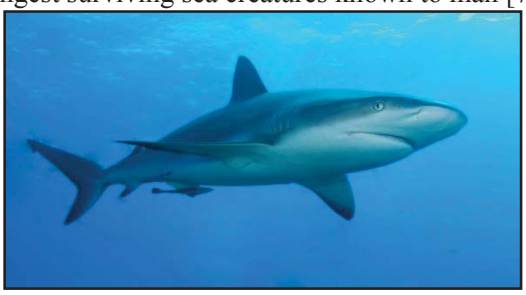
Keywords: Aerodynamic, AUV, DESERT, Flapping flight, ROV, Sharks, SWIPE, Under Water Acoustic Communication, UUV

1. Introduction

In the present, underwater travel has expanded beyond submarines to personal submarines, *Unmanned Underwater Vehicles (UUV), Autonomous Underwater Vehicles (AUV), Remotely Operated Vehicles (ROV)* and many more such robotic submersibles [3]. A variety of creative uses of these high-tech vehicles has been found, which works as an alternative to sending humans down into the depths. Hundreds of different AUVs have been designed over the past 50 or so years [4]. Large vehicle have advantages in terms of endurance and sensor payload capacity; smaller vehicles benefit significantly from lower logistics [5]. The future of AUV is evolving and changes in design are expected. These include hover-capable AUVs, ultra-low-power, long-range variants such as underwater gliders [6] or hybrid AUV/ROV design that switch between roles as part of their mission profile.

However, bionic AUVs are best suited for under water travel. These vehicles are able to achieve higher degrees of efficiency in propulsion and maneuverability by copying successful designs in nature. The DESERT is a first venture into combining the best of both bionic AUVs and underwater gliders.

Fig 1: Sharks are the most aerodynamic, fast and longest surviving sea creatures known to man [7]



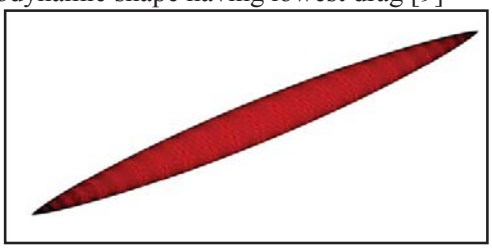
DESERT is an aerodynamic vehicle which is built on the model of sharks and mimic shark

movements. It has fins which work by providing flapping movement thus helping in movement. Propulsion is provided by an underwater engine, which works primarily using sea water as a fuel [2]. It is a green engine as is the technology. Newer technologies have helped in making design changes to existing AUVs and ROVs, thereby making way for DESERT and other future underwater vehicles.

2. Theory

The DESERT is shaped like sharks and uses their streamlined shape. This shape is known as the *Sears – Haack* body. The *Sears–Haack* body is the shape with the lowest theoretical wave drag in supersonic flow, for a given body length and given volume. Sharks have a body shape and skin type to have minimum pressure drag in supersonic flow [8].

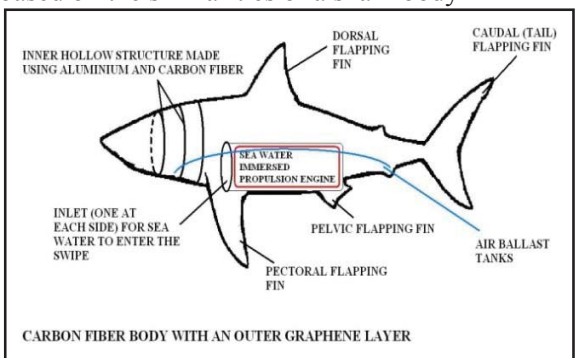
Fig 2: The Sears – Haack body shape. The most aerodynamic shape having lowest drag [9]



3. Design

DESERT features all the equipments and modern sensors found in any AUVs, UUVs or ROVs. It will host a collection of new systems for underwater communication under both manned and unmanned conditions. The design of DESERT has been divided into a number of individual components. The figure 3 below shows a rough outline of the DESERT. It is powered and propelled by the Sea Water Immersed Propulsion Engine (SWIPE) [2]. The entire underbelly of the vehicle has ballast tanks, like in a submarine, and for the same purpose. The entire outer skeleton is made by carbon fiber reinforced polymer and also uses carbon fiber and Aluminum. In addition, the outermost skin of the vehicle is covered with a graphene lacquer.

Fig 3: Rough outline of the DESERT model based on the similarities of a shark body



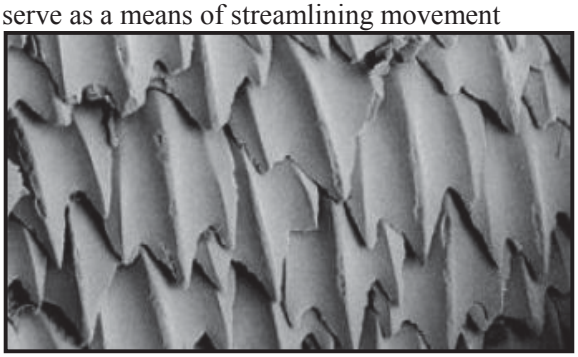
The theoretical design of each component has been elaborated under each section.

3.1 Outermost skin

The outer skin of the DESERT has a graphene layer which can generate electricity when salty sea water flows over it [10]. The electricity generated from the flowing sea water over this Graphene layer is collected by the engine SWIPE or any internal storage unit inside the DESERT. Although the amount of electricity generated is small, it can be harnessed to run any medium or small system within the vehicle.

The graphene coating will be present on the DESERT as a scaly skin coating, which resembles the shark scales and are known as *placoids* (slate-like) as in fig 4. The tiny ridges arranged parallel to the swimming direction - known as *riblets* - decrease drag in water, explaining the amazing speed that some sharks reach with minimal effort [11].

Fig 4: The scaly shark skin known as placoids serve as a means of streamlining movement



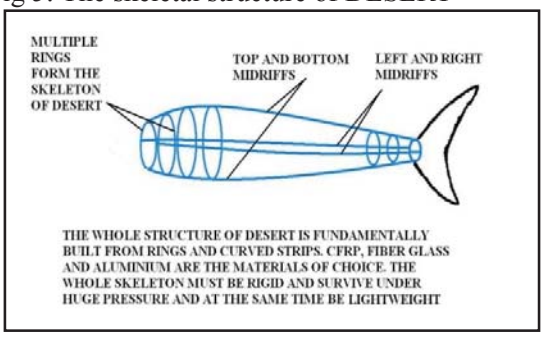
This scaly hide will serve as both a suit of armor and a means of streamlining movement. A new coating system to imitate this riblet effect has been tried and used by researchers and is a new prototype that combines a suitable lacquer and the technology for applying it [11]. The graphene layer applied must be present in that lacquer.

3.2 Exterior and Interior Framework of DESERT

The exterior and interior framework of the vehicle is made of Carbon Fiber Reinforced Polymer (CFRP) and Aluminum. CFRP is strong and light and is used where high strength-to-weight ratio and rigidity are required. Aluminum is lightweight and moldable. Before using these materials, they must be tested for high pressure conditions [12]. So the use of Kevlar or Fiber Glass can also be possible.

CFRP finds an excellent use in the fins of DESERT. It is a flapping wing or fin [14] and is used to impart motion and direction to the vehicle while underwater. Research is ongoing to make the effective and optimum flapping wings. The flapping fins move in all three axes to provide motion. These fins propel and guide DESERT. The outer wings/fins, attached to the body can function as a mechanism to impart a flapping movement to the vehicle.

Fig 5: The skeletal structure of DESERT



The whole inner skeleton of the DESERT will be constructed of thick rings as shown in fig 5. They will be well connected by a central midriff on the top, bottom, left and right, to provide rigidity to the structure. Multiple midriffs can be made as per design criteria. Inside the vehicle, the wall is CFRP.

The outer diameter of DESERT will be limited to 500-1000 mm. This impacts its towing capacity and speed. The aim will be to reduce the payload and increase speed. The provision of air ballast tanks, occupying a small area of the underbelly of the vehicle is beneficial. One or more air ballast tanks must be present to lift or sink the vehicle when pressurized air is forced into or out of it.

3.3 External Flapping Fins

The five flapping fins comprise of a Dorsal Fin, a Pelvic Fin, two Pectoral Fins on two lower sides and a Tail Fin. Fig 3 outlines the wings/fins. The fins must be carefully designed and behave like that of a shark fin and each fin must function independently. To propel the DESERT, the tail will swing back and forth to move forward. Much like an airplane, this forward movement pushes water around the fins to create lift. This is the same principle used by sharks. The tail fin must be built to create this movement of flapping.

DESERT also has two sets of paired fins on the sides, similar to the pectoral fins of sharks. The shark can position these fins at different angles, changing the path of the water moving around them. When the shark tilts a fin up, the water flows so there is greater pressure below the fin than above it. This creates upward lift. When the shark tilts the fin down, there is greater pressure above the fin than below it. This pushes the shark downward. This is the same method the DESERT must use. The DESERT also has one or two vertical dorsal fins on its back and a vertical anal fin on its underside, just like in a shark. These fins are flapping in nature and work like the vertical stabilizer wing on an airplane. They help the shark keep its balance as it moves through the water. They can be moved from side to side to help turn the vehicle left and right. The fin arrangements give sharks amazing speed and maneuverability. They can cruise or stop suddenly and make sharp turns in every direction. The same must be expected from DESERT.

3.4 Propulsion and Power

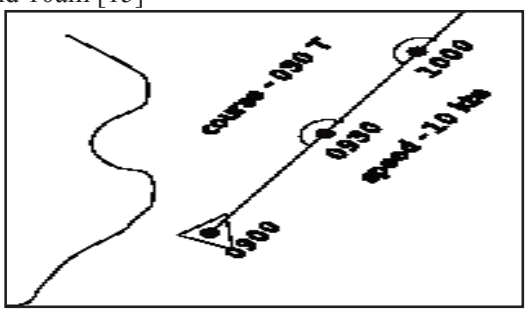
The vehicle is driven by an engine and propeller system known as the Sea Water Immersed Propulsion Engine (SWIPE) [2]. The power

produced by the SWIPE is not huge. This is why two of such engines must be carried by the vehicle. Although it makes the vehicle bulky, the benefit of added power is required. In addition, the engine uses sea or salt water as fuel and does not require surfacing at all. It is also a green technology and causes no form of pollution. The DESERT has been built using the benefits of both AUV and underwater gliders. It has got external flapping fins and an engine with propeller system and together it serves to cover all aspects of propulsion and power.

4. Communication and Navigation

Above the sea, the DESERT must be equipped with radio wave transmission system and GPS. Below the sea however, radio and GPS do not work effectively so DESERT can rely on Dead Reckoning (Dead reckoning is the process of calculating the current position by using a previously determined position, in our case by GPS, and advancing that position based upon known or estimated speeds over elapsed time and course.)

Fig 6: The navigator plots their 9am position, indicated by the triangle, and using their course and speed, estimates their own position at 9:30am and 10am [15]

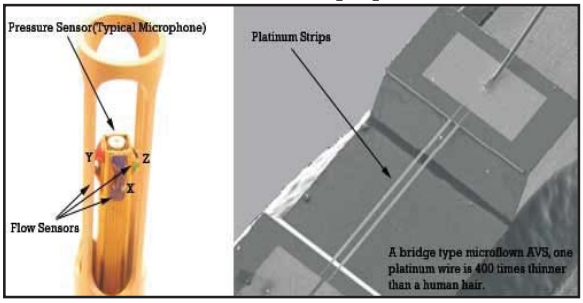


DESERT can also use LBL navigation wherein, when a ship is available over the surface, ultra-short baseline or short-baseline positioning can be used to calculate where the DESERT is, relative to the earlier known position. For fixing the position more accurately, an Inertial Navigation System on DESERT will calculate its position and velocity, and these estimates can be improved by adding acoustic Doppler current profiler - ADCP (this is a hydro-acoustic current meter which measures the velocity of water over a range using the Doppler effect, within that column of water, the device contains piezoelectric oscillators to be used as a trans-receiver but in addition we need to use an ADC and digital signal processing to measure the Doppler's shift and a microprocessor need to be used to determine the sound velocity). The vehicles can intercommunicate with each other through under water acoustic network using hydrophones arranged in array, and FSK modulation can be used for further signal processing. The DESERT can also use vector sensors with a specific signal processing algorithm, for better perception of sound.

Under water acoustics network is a process of transmitting and receiving messages under the water [16]. Among several ways the DESERT can use hydrophones as it has acoustic impedance match with water and the hydrophones can be set up in three dimensional arrays wherein spatial filtering can be used to achieve spatial selectivity (in this arrangement the hydrophones are arranged in such an angle that some of the signal interfere constructively and some destructively and this arrangement can be implemented at the transmitter and receiver to obtain directional signal transmission).

FSK (Frequency shift key) is a form of modulation where digital information is transmitted through the change of frequency and DESERT can use the simplest form of FSK, the binary FSK, wherein we have two frequency sets, each representing 0's and 1's and at the receiving end there can be filter and a level detector to detect whether a 0 or 1 has been sent. Another emerging method is through vector sensors.

Fig 7: The vector sensor indicating the pressure sensors and the flow sensors [17]



A vector sensor, if employed in DESERT, would help to measure the wave velocity which cannot be done by the pressure sensor. These types of sensors can measure both the scalar and the vector components of the field at a single point in the water. DESERT could use the inertial vector sensors which measures the velocity by acoustic medium motion.

4. Conclusion

Like AUVs, the DESERT must show capability to collect data for scientific and military purposes. To reduce the overall time and cost of acquiring data over large areas, multiple vehicles must be used. Through recent research, AUVs were capable of communication and cooperation without the intervention of an above-water operator. The DESERT having the same features must be able to do so too. The vehicles must perform cooperative operations autonomously i.e. without intervention by an external operator.

Flying in formation, deployment, replacement of missing vehicles, divert of a single vehicle from a formation to a position of interest, and replacement of the formation leader can all be done by DESERT, co-operating with other vehicles. In such missions, inter-vehicle communication is an important requirement upon which co-ordination strategy and intelligence decision making functions can be built, similar to AUVs.

***Abstract*—The work proposed in this paper deals with secret wireless transmission of sensitive data or message using a digital audio signal as carrier with reduced distortion in the modulated audio signal for enhanced imperceptibility of the added noise. This algorithm decomposes the carrier audio samples into small non-overlapping frames and uses Discrete Fourier Transform (DFT) to convert them into frequency domain. Payload data bits are inserted in transformed frequency coefficients at pseudo-random bit positions, generated by an unique generator function, to protect the secret data from any potential hacking attempt as the bits can only be retrieved accurately by reproducing the exact sequence of bit positions at extraction time with the help of the same pseudo-random number generator. Also a 160 bit message digest of the hidden message is inserted into the carrier to verify the integrity of the extracted message at the receiving end. The proposed algorithm has been experimented with various types of carrier audio signal and message data. Test results, compared with the previous version of this algorithm, show significant performance improvement in terms of both subjective and objective metrics.**

Keywords—Data security; Audio Steganography; Wireless Transmission; DFT; HAS; MSE; SNR; PSNR; MOS

I. INTRODUCTION

In the last decade we have noticed a major boost in the segment of wireless communication technologies which has become a widely accepted platform for transmission of digital data of all types across the globe. But, at the same time secured transmission of sensitive data has also become a prime concern for every organization. Secured data transmission involves consideration of three influencing factors of data security. These are, 1) confidentiality, which ensures the secrecy of data that must not be revealed to anybody except the intended parties, 2) integrity, which guarantees that the data is not modified during transmission or storage and 3) authenticity, which assures that the received data has been sent by a legitimate sender.

Till date secured data transmission is mainly achieved through cryptographic techniques, which are based on presenting the content of a message garbled to unauthorized people. But these techniques are unable to avoid the suspicion of any third party about the existence of the sensitive data or message being transmitted. So, to explore better or complementary new techniques, researchers has focused on techniques based on steganography, which hide sensitive data in another innocent looking cover medium, e.g. digital audio signal, in an attempt to completely avoid any suspicion about the existence of the hidden data along with the information of its sender and receiver as well. As a result, digital audio steganography has emerged as a prominent source of data hiding across novel telecommunication technologies such as covered voice-over-IP, audio conferencing, etc.

Hiding data in audio signals is more challenging compared to the techniques involving images or video sequences. This is due to the wider dynamic range of human auditory system (HAS) in comparison to human visual system (HVS) [1]. Audio-based steganography exploits the property of masking effect of HAS [2]. HAS perceives sounds over a range of power greater than 109:1 and a range of frequencies greater than 103:1. The sensitivity of HAS to the additive white Gaussian noise (AWGN) is high as well. White Gaussian Noise in a sound file can be detected as low as 70 dB below ambient level [3].

The quality of audio steganographic methods are influenced by various factors [4]. The importance and the impact of each factor depend on the application area and the transmission environment. The most influencing factors are, imperceptibility, robustness to noise, compression, security and hiding capacity. Generally, robustness and hiding capacity hardly coexist in the same steganographic system. This is due to the tradeoffs imbalance between these two criteria i.e. increase in robustness results in decrease in data hiding capacity [2].

Primarily data hiding in audio signals can be performed in three ways, a) using time domain techniques [5, 6], b) using frequency-transform domain techniques [7, 8] and c) using a combination of both [9]. Performance of these techniques varies with respect to the robustness and imperceptibility (inaudibility) of the added noise. Time-domain techniques include the Least Significant Bit (LSB) substitution, echo

hiding techniques and many others. Frequency domain techniques employ human perceptual properties and frequency masking characteristics of the human auditory system. The phase and magnitude of the transform domain coefficients are modified to embed the secret message. This procedure [15, 16] offers high level of robustness i.e. attempt to remove the watermark results in introduction of serious distortion in the original audio signal fidelity. To get back the payload, inverse frequency transform is applied. Popular transforms include Discrete Fourier Transform (DFT) [10, 11, 12], Discrete Cosine Transform (DCT) [13] and Discrete Wavelet Transform (DWT) [14].

II. THE TECHNIQUE

The proposed algorithm uses one dimensional Discrete Fourier transform and is a combination of two main procedures: insertion of the payload and extraction of the payload. In the context of this algorithm payload consists of three types of data, which are, 1) size of the actual message in bytes (length: 32 bit), 2) SHA-1 message digest of the message data (length: 160 bit) and 3) message data itself.

The algorithm is capable of hiding any form of message, be it a text, image, audio or any other file type into the uncompressed cover audio signal and produces the corresponding stego audio, which has the same size as that of the original audio.

In the insertion process the payload is treated as a sequence of bits $b_1, b_2, ..., b_N$, where N is the total length of the bit sequence, $b_k \epsilon (0,1)$ and $k = 1$ to N. The original cover audio signal is decomposed into non-overlapping equal sized frames each consisting of two audio samples. Due to non-stationary behaviour of audio signals it is necessary to analyse them in short time intervals (frames) in order to apply signal-processing rules [17, 18]. To convert each of these frames into transform domain one dimensional discrete Fourier transform is applied, resulting in two corresponding DFT coefficients. Out of them only the second coefficient value is considered for embedding as embedding in the first coefficient value results in perceptible noise in the final stego audio.

A payload data bit is inserted into the binary converted value of the integer part of the real component of the frequency coefficients. The insertion position is generated pseudo-randomly in the range of 0 and 3 i.e. the 1st LSB layer to 4th LSB layer. After replacing the target bit t_p in the target binary sequence T at position p by a payload bit b_k some or all of the bits on the left and/or right (depending on the magnitude of T) of the target position p in T are flipped to minimise the difference in the magnitude of the resulting binary sequence T'. Thus the value of T' remains closest to the original value of T. For example, if $T = 00001000_2 = 8_{10}$, and if we embed 0 into 4th LSB layer, result will be $T' = 00000000_2 = 0_{10}$, making the difference huge, which is $T - T' = 8$. To minimise the difference between T and T' we use our proposed method and then the modified value of T' becomes $00000111_2 = 7_{10}$, which is closer to the original value T, with a difference of only 1. To get back the corresponding time domain values when inverse DFT is applied on the modified frequency component frames consisting of resultant binary sequence T' this technique greatly reduces the distortion (due to the added noise component in the form of payload) in the final stego audio.

The extraction process is pretty straight-forward, which involves DFT transformation of the stego audio samples to frequency domain. Payload bits are then extracted from the integer part of the real frequency components by reproducing the same pseudo-random number sequence used in the insertion process. The extracted sequence of bits are reconstructed sequentially to get the three components of the payload i.e. message size, message digest and message data. The extracted message digest is then compared with the message digest generated from the extracted message at receiving end to ensure the integrity and authenticity of the received message. The extraction process is completely blind as it does not require the original cover audio for the purpose of extraction. The overall process of the proposed technique is graphically illustrated in Fig. 1 below.

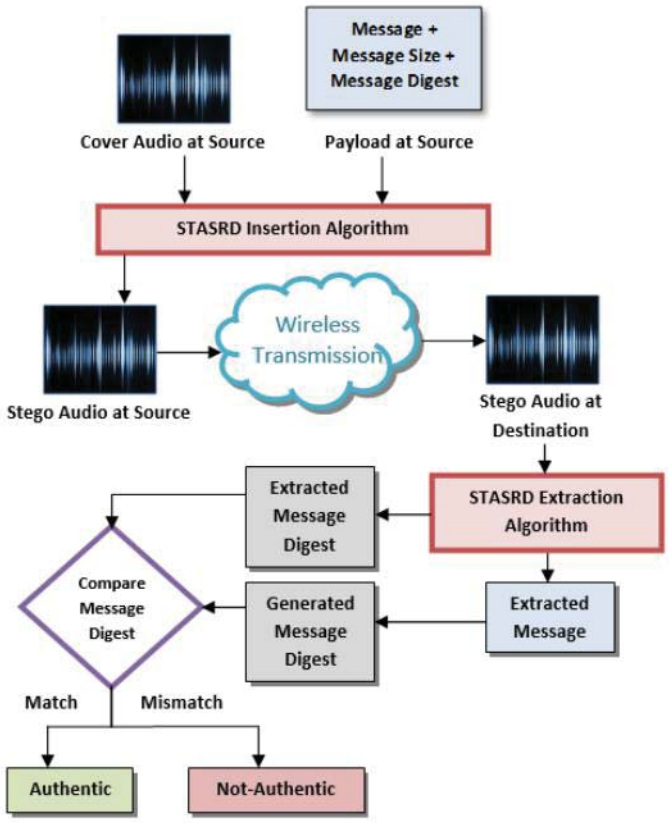

Fig. 1. Insertion and Extraction Process of STASRD

A. Insertion Algorithm

Input: A PCM WAVE cover audio and a message file of any type.

Output: A stego PCM WAVE audio.

Steps:

1. Copy the header information from the input cover audio into the output audio.

2. Generate a 160-bit message digest (SHA-1) of the message file.
3. Repeat the following steps until all the bits of the payload are embedded,
   3.1. Read a pair of sample amplitude values from the input audio into a two element frame.
   3.2. Apply 1-D Discrete Fourier Transformation on the frame to get the corresponding frequency coefficients.
   3.3. Generate a number (between 0 and 3) using a pseudo-random function to determine the insertion position of the payload bit.
   3.4. Replace the original bit, at the position obtained in the previous step, of the binary counterpart of real integer part of the 2nd frequency coefficient with the payload bit.
   3.5. Flip the bits on the left and/or right of the replaced bit to make the magnitude of the modified frequency component closest to the original value, which reduces distortion in the final stego component.
   3.6. Apply Inverse Discrete Fourier Transformation on the modified frame to get the corresponding amplitude values in time domain.
   3.7. Write the new sample values into the output audio in the same sequence as they have been read.
4. Copy rest of the samples from the input audio (if any) into the output audio.
5. Stop.

B. Extraction Algorithm

Input: A stego PCM WAVE audio.

Output: The extracted payload.

Steps:

1. Repeat steps 1.1 to 1.5 until all the bits of the payload are extracted,
   1.1. Read a pair of sample amplitude values from the input audio into a two element frame.
   1.2. Apply 1-D Discrete Fourier Transformation on the frame to get the corresponding frequency coefficients.
   1.3. Generate a number (between 0 and 3) using the same pseudo-random function to determine the insertion position of the payload bit.
   1.4. Extract a payload bit from the real integer part of the 2nd frequency coefficient using the bit position obtained in the previous step.
   1.5. Construct a byte of the payload data by eight consecutive extracted bits to form the payload data incrementally.
2. Generate a 160-bit message digest (SHA-1) of the extracted message.
3. Compare the generated message digest with the one extracted as part of the payload to verify the integrity and determine the authenticity of the extracted message.
4. Stop.

III. Experimental Results and Discussion

Thorough experimentation has been done using the proposed algorithm taking various types of cover audio as well as message to test the performance in different scenarios. After performing the insertion algorithm on each set of cover audio and message file type the quality of the resulting stego audio is examined using various objective and subjective metrics [19, 20], which are briefly discussed below.

A. Objective Metrics

1) Mean Squared Error (MSE): Computes an error signal by subtracting the test signal from the reference, and then computing the average energy of the error signal.

2) Signal to Noise Ratio (SNR): It is a measure that compares the level of a desired signal to the level of background noise. It is defined as the ratio of signal power to the noise power and a ratio higher than 1:1 indicates more signal than noise.

3) Peak Signal to Noise Ratio (PSNR): Defined as the ratio between the maximum possible power of a signal and the power of corrupting noise that affects the fidelity of its representation.

B. Subjective Metric

Objective metrics are considered as the most common procedure for the measurement of noise difference between the original and stego audio signals, but one drawback is that they do not prove authentic during consideration of some specific characteristics of HAS. So a different metric named Mean Opinion Score (MOS) is used as the subjective measure of the quality of audio signals. To determine MOS, a number of listeners listen to both the original and stego audio signals and rate them according to the grades shown in table 1.

TABLE I. MOS Grading Scale

MOS Grade	1	2	3	4	5
Remarks	Very Annoying	Annoying	Slightly Annoying	Perceptible, Not Annoying	Imperceptible

The final MOS is the arithmetic mean of all the individual scores, and may range from 1 (worst) to 5 (best).

C. Results

A variety of CD quality stereo audio signals with 16 bits/sample resolution have been used in the test phase. Three types of message, text, image and audio were separately inserted in each of the four types of cover audio signals i.e. instrumental, pop, rock and speech. Some example audio

signals and messages involved in the experimentation are visualised in Fig. 2.

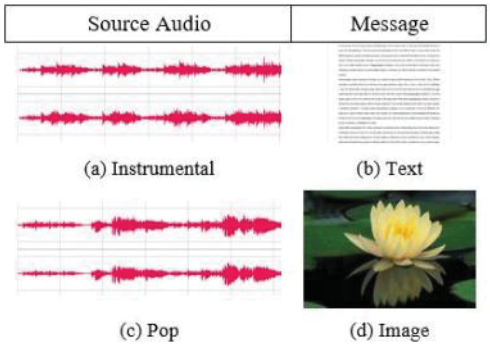

Fig. 2. Source Audio Signals and Messages used in STASRD

The results obtained in various objective tests as well as the subjective test are discussed in the following sub-sections.

1) Objective Tests – Table 2 shows the maximum hiding capacity of each type of cover audio and actual number of bytes embedded for each type of message along with test results of STASRD in terms of MSE, SNR and PSNR.

TABLE II. RESULTS OBTAINED USING STASRD

Cover Audio	Capacity (Bytes)	Message Type - Size	MSE	SNR (dB)	PSNR (dB)
Instrumental	166472	Text - 159464 Bytes	0.4996	73.4605	93.3221
Pop	170492		0.4719	74.0745	93.5699
Rock	165455		0.5005	78.7894	93.3142

Speech	160117		0.4579	74.0506	93.7006
Average		**157002 Bytes**	**0.4799**	**75.1173**	**93.5002**

It can be observed from the above results that despite of embedding a substantial amount of message data (1,57,002 bytes in average) the proposed algorithm shows an impressive performance with an average SNR value of 75.1173 dB and PSNR value of 93.5002 dB.

Moreover, the comparison presented in the following table exhibits the superiority of STASRD in terms of imperceptibility over the previous algorithm Secured Data Transmission Through Audio Signal (SDTAS) [21], which has no mechanism to reduce the distortion level in resulting stego audio signals. Thus, STASRD is quite appropriate in wireless transmission of secret data with reduced distortion level.

TABLE III. COMPARISON OF RESULTS OBTAINED USING SDTAS AND STASRD

Parameters (Average)	SDTAS	STASRD
Embedded Bytes	157002	157002
MSE	2.5442	0.4799
SNR (dB)	67.8725	75.1173
PSNR (dB)	86.2554	93.5002

2) Subjective Test – Twenty five pairs of source and stego audio, produced by the proposed algorithm, were put to tests and more than 35 listeners were involved to test the resulting audio signal pairs (Original and Stego). The listeners were requested to listen to the pairs very attentively. The final grades for the respective pairs are shown in table 3 and reveal high imperceptibility of the inserted noise (message) in the cover audio signals.

TABLE IV. SUBJECTIVE MEASURE OF AUDIO SIGNALS USING STASRD

Cover Audio	Message Type	MOS Grade
Instrumental	Text	5
Pop		5
Rock		5
Speech		5
Instrumental	Image	5
Pop		5
Rock		5
Speech		5
Instrumental	Audio	5
Pop		5
Rock		5
Speech		5

The values in the above table exhibit the subjective quality of the stego audio signals where there is no perceptible distortion in the resulting cover audio after embedding the payload data. This result is achieved due to the treatment done on the modified frequency components at the time of insertion of payload bits to keep the impact of the inserted noise negligible. And this is also evident from the above comparison in table 3.

IV. CONCLUSION

The proposed algorithm STASRD greatly enhances the imperceptibility of the transmitting secret data of any form, text, image or audio using an audio signal as cover. It adds a bit adjustment mechanism to reduce the distortion level of the resultant stego audio signal at the time of inserting the payload. The extraction process is also very straight-forward and blind. Performance of the algorithm has been evaluated by both objective and subjective metrics and the results show significant improvement in comparison with the previously proposed technique by the authors. Thus, this novel algorithm proves to be quite appropriate for secret transmission of data over the wireless domain.

ACKNOWLEDGMENT

The authors express their deep sense of gratitude to the faculty members of the Dept. of Engineering and Technological Studies, University of Kalyani, West Bengal, India, where the work has been carried out.

The increasing role of spoken language interfaces in human-computer interaction applications has created conditions to facilitate a new area of research - namely recognizing the emotional state of the speaker through speech signals. This paper proposes a text independent method for emotion classification of speech signals used for the recognition of the emotional state of the speaker. Different feature selection criteria are explored and analysed, namely Mutual Information Maximization (MIM) feature scoring criterion and its derivatives, to measure how potentially useful a feature or feature subset may be when used in a classifier. The proposed method employs different groups of low-level features, such as energy, zero-crossing rate, frequency bands in Mel scale, fundamental frequency or pitch, the delta- and delta-delta regression and statistical functions such as regression coefficients, extremums, moments etc., to represent the speech signals and a Neural Network classifier for the classification task. For the experiments the EMO-DB dataset is used with seven primary emotions including neutral. Results show that the proposed system yields an average accuracy of over 85% for recognizing 7 emotions with 5 of the best performing feature selection algorithms.

***Index Terms*—speech emotion recognition, feature selection, affective space, human-computer interaction, neural network classifier**

I. Introduction

SPEECH is the fastest and most natural method of communication between people. For this reason, researchers define it as being an efficient way to interact with machines. For this to be fulfilled, however, computers must possess sufficient knowledge and intelligence to separate the content from the human voice and speech. Speech recognition or the process of converting human speech into a series of words is the basic discipline in this area, where the success achieved so far is greatest. Information about emotional state is expressed via speech through numerous cues, ranging from low level acoustic ones to high level linguistic content. Several approaches to speech based automatic emotion recognition, each taking advantage of few of these cues have been explored [1]–[4]. It is believed that this would help to extract additional semantic aspects of speech that would improve work systems and speech recognition.

The main goal of this paper is to present the results of an extensive study and comparative analysis of different methods for voice feature selection criteria and to measure how potentially useful a feature or feature subsets may be when used in a classifier for emotion classification.

The rest of the paper is organized as follows: the next section describes the state of the art for the problem of recognizing the emotional state of the speaker through speech signals. Section III introduces the EMO-DB dataset used for research purposes in this paper. Then in Section IV a description of the proposed algorithm is given. In the following section the experimental results are illustrated. The final section draws the conclusion and suggests the scope of future work.

II. State of the art

A. Models of affective space

The selection of induced emotions is a crucial design feature of any human-computer interactive system dealing with voice recognition, and should be guided by a clearly specified theoretical model of the affective space. These models generally fall into one of three categories: categorical, dimensional and appraisal-based.

Categorical models focus on universal set of primary emotions (e.g. *fear, anger* or *disgust, happiness, sadness, surprise*), which are typically seen in terms of their evolutionary adaptive value [5]. These models are more easily understood and better suited for research purposes because they can be combined with facial expression for multi-modal recognition.

The more natural model is the dimensional [6] because a single label might not describe the complexity of an affective state very well. So to represent emotional signals in a more natural way a continuous rather than a categorical view of emotions is used. This way the emotion is modeled as a point in a multidimensional space describing emotionally relevant dimensions like arousal or activation, pleasantness or valence and dominance.

The appraisal-based model is based on the emotion being quantified with different evaluation checks, such as the novelty, intrinsic pleasantness, goal-based significance, coping potential and compatibility with standards [6].

Each model, categorical, dimensional or appraisal has its advantages and disadvantages [7]. In the categorical approach, mixed emotions cannot adequately be described with one label. In the dimensional approach, the reduction of emotion space to two or three dimensions may be not suitable for classification purposes because of the loss of information. The appraisal-based approach requires complex, multi-componential and sophisticated measurements with a panel of experts.

Even though neither model is not claimed to be sufficient for differentiating all possible emotions, we have chosen to

use in our research the categorical model and we try to classify emotions in the 7 basic categories mentioned above. In our context, the object of analysis will be a short phrase, digitally encoded and stored in an appropriate audio format. The phrases are segmented and separated into separate files according to certain criteria ergo specific emotional class.

B. Feature description

An important problem in systems for recognizing emotion in speech is the selection of features that effectively provide differences between affective classes, but also this process must not dependent on the speaker or lexical content of the speech. Although many have studied such features in the scientific community there is no agreement on which are the best ones.

Audio signals carrying speech are not fixed, often during processing speech there is a need to divide the signal into small segments called frames. The aim is to explore small enough areas where the signal is assumed to be stationary. Prosodial speech features such as the fundamental frequency or pitch (F_0) and energy of the signal are extracted from each frame and are called local features. On the other hand, the use of statistical analysis for the whole phrase gives the global features of the signal. There are disputes about which of the two types is more effective in these systems. Most scientists agree that global features outperform local in terms of training time of the classifier and the total accuracy of classification [8]. One of the reasons for that is global features being much fewer in number than the local. However, the researchers argue that global features are only effective in separating the classes with high activation [9] such as *anger, fear, joy* and classes with low activation as *sadness*. It is argued that global features do not do well between classes with a similar level of activation, for example anger against joy. Another problem with global features is that the timing information contained in the speech signal is completely lost in this presentation. An alternative solution in the same direction is to obtain feature vectors for sections with voice activity. Using only these selected parts of the signal the features of speech can be grouped into four main categories: continuous, voice quality-based, spectral and features based on Teager Energy Operator (TEO-based). Continuous features are used very frequently in recognition of emotion. According to [10] these features can be further classified into the following sub-categories: 1) pitch-related features; 2) formant frequencies; 3) timing features; 4) voice-quality parameters; 5) articulation parameters.

The voice quality is a special feature, because the human perception is subjective and its affected by many variables. According extensive study done in [11], acoustic correlates associated with voice quality, are grouped into the following categories: 1) voice level: signal amplitude, energy and duration; 2) voice pitch; 3) phrase, word, phoneme, and feature boundaries; 4) temporal structure which refers to measures at the pitch contour level and related structures in the intensity domain.

Besides the acoustic features in the time domain such as fundamental frequency and energy of the signal there are also discriminative features that can be selected in the frequency domain such as the spectral distribution, the speaking rate and the fundamental frequency contour. It has been found that the emotional impact of a phrase has an impact on the distribution of energy in the frequency spectrum of a signal [9]. Examples are: happiness sections have high energy values for the range, treble, while those with sadness have low levels of the same range [12]. Spectral features can be extracted in several different ways such as through Fourier transform, but also through the following methods: Linear Predictive Coding (LPC), one-sided autocorrelation LPC (OSALPC) [13], Short- time coherence method (SCM) or least-squares modified Yule- Walker equations (LSMYWE) [14]. There are also the cepstral-based features derived from appropriate transformations of linear features such as cepstral-based OSALPC (OSALPCC) and cepstral-based LPC and mel-frequency scale coefficients (MFCC) [13].

The current most commonly used short-term spectral features are the LPC-derived cepstral coefficients and their regression coefficients. As for the regression coefficients, typically the first- and second-order coefficients, that is, derivatives of the time functions of cepstral coefficients are extracted at every frame period to represent spectral dynamics (the delta- and delta-delta-cepstral coefficients). In [13] is noted that the addition of delta-cepstral features strongly improves speech recognition accuracy, and a further but smaller improvement is provided by the addition of double- delta cepstral features. For these reasons some form of delta and double-delta cepstral features are part of nearly all speech recognition systems.

C. Feature extraction

In [15] the authors have proved that the right choice of features for recognizing emotion in speech strongly depends on the nature of the specific classification task, which is considered. For example if we consider the classification of affective states with high levels of activation against such with low level, generally continuous features based on the voice tone or pitch are used for description. It is believed that more complex tasks require an approach build on a combination of different types of features. Also, there are certain interrelationships between the aforementioned types of features, for example spectral features are related to voice quality and the spectral envelope show patterns of evolution of speech articulation.

During feature selection the primary objective is to determine a subset of all extracted features that can provide the best classification results. An appropriate subset is typically evaluated using a feature selection criterion such as cross-validation error and mutual information between annotation class and the specific descriptor [16]. On the other hand, feature transformation, is finding a suitable uniquely linear or non-linear transformation of the original feature vector space into another abstract space with a small number of dimensions. This must be achieved so that useful information is preserved. Feature extraction algorithms are one of the main components of the emotion detection system.

The methods for feature selection can be associated into two broad groups in terms of their dependence on the classifier:

classifier-dependent - ”wrapper” and ”embedded” methods, and classifier-independent called filter methods. For the purpose of this work the latter approach will be used. The filter methods [16] separate the classification and feature selection components, and define a heuristic scoring criterion to act as a proxy measure of the classification accuracy. Intuitively, such a criterion may be selected on the basis of the determination of the correlation between the attribute and the label of the class on the assumption that a better correlation would be associated with a better recognition. In our case we use but not limit ourselves with the Mutual Information Maximization (MIM) feature scoring criterion to measure how potentially useful a feature or feature subset may be when used in a classifier. An extended description of this criterion is given in [16] along with different derivatives of the algorithm. The different criteria, compared in this research, are mentioned in Table I, section IV.

III. Database

In the design of an emotion recognition system, one important factor upon which the performance of emotion recognition system depends is the emotional database used to build its representation of human emotions.

Emotional behavior databases have been recorded for investigation of emotion, where some are natural while others are acted or elicited. For the analysis of vocal expressions of emotions, audio databases such as Belfast naturalistic database, Berlin Database of Emotional Speech (EMO-DB) [17], and Montreal Affective Voices have been researched [15].

The EMO-DB chosen for the current research purposes is a German acted database, which consists of recordings from 10 actors (5 male, 5 female). The data consist of 10 German sentences recorded in *anger, boredom, disgust, fear, happiness, sadness* and *neutral*. The final database consists of 535 utterances after listeners' judgement. The phrases have a length of 1-2 seconds and they are approximately equally divided between the key emotional classes, gender of the actor, text the phrase and etc. This dataset was chosen because of the nature of the annotation done on the entire phrase, i.e. the phrase is the smallest discrete unit of meaningful research. This allows the use of global features for the whole phrase.

IV. Description of the algorithm

The block diagram on Fig.1 represents the idea of the general algorithm for solving the classification problem using the selected dataset. Illustrated are all key phases in the processing of the signal information. In each of the major phases are presented various processes grouped by the software used for this research.

All the software applications used for the development of the proposed algorithm are open source platforms. The experimental environment chosen for this research is GNU Octave version 3.8.1. openSMILE (an abbreviation of The Munich open Speech and Music Interpretation by Large Space Extraction - http://www.audeering.com/research/opensmile) is a modular tool for extracting features for applications in digital signal processing and machine learning. The focus is on

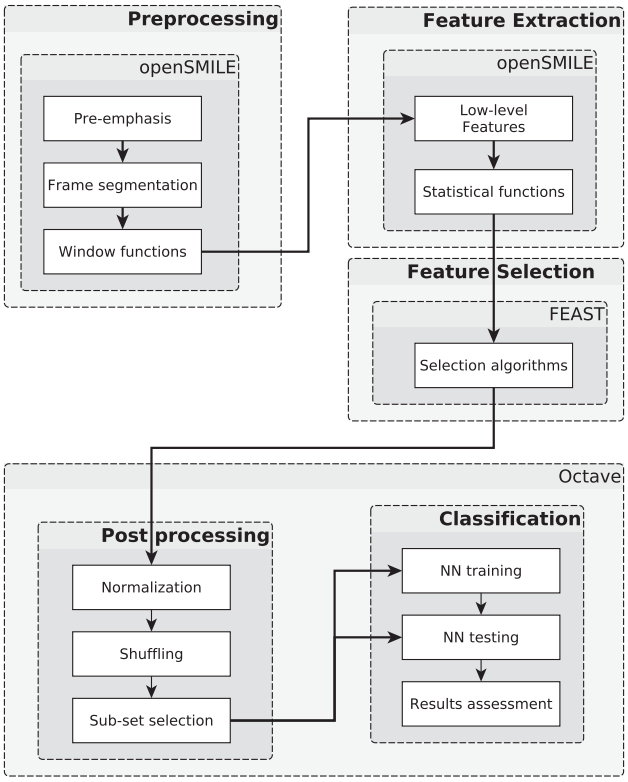

Fig. 1. Block diagram of the proposed algorithm

features associated with audio signals. We use openSMILE for the preprocessing step where different types of pre-emphasis algorithms are used to de-noise the signal, for calculating the frequency spectrum and for the extraction of the low level features such as energy, zero-crossing rate, frequency bands in Mel scale, pitch and 14 MFCC. Using these features the delta- and delta-delta regression are calculated together with the statistical functions such as regression coefficients, extremums, moments etc.

FEAST (http://www.cs.man.ac.uk/~gbrown/fstoolbox/) is freely redistributable software package capable of integrating in MATLAB/Octave and includes implementations of known algorithms for feature selection, namely those based on mutual information some of them are mentioned in Table I.

After the feature selection step for the classification we use the Neural Network (NN) classifier with different number of hidden layers and k-fold cross validation.

V. Experimental results

A. Analysis of the criteria for feature selection

Extensive testing is done for the parameters of the NN using feature vectors with 384 elements (16 low level features + their 16 delta coefficients * 12 statistical functions) as described in [2]. High accuracy is achieved primarily for networks with number of neurons in the hidden layer roughly between 30 and 50, while for larger networks with more than 100 neurons, the outcome in terms of recognition rate is very low.

TABLE I

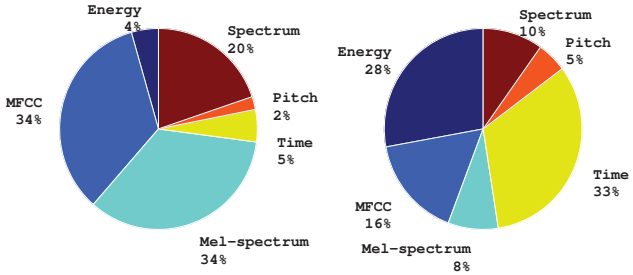
Spectrum	fband(0-250,0-650,250-650, 1000-4000,3010-9123); RollOff(25.0,50.0,75.0,90.0); Flux;Centroid MaxPos;MinPos	13	76	418

[a] For the single criterion yielding top recognition score (CMIM).
[b] For the criteria with the best results: CMIM, JMI, DISR, ICAP RELIEF.

After setting the optimal parameters for the NN classifier, the next phase is to compare the behavior of the feature selection criteria mentioned in Table I. The new feature vector is composed of 56 low-level features, delta coefficients of first and second order, all of them multiplied by 39 statistics functions. The final number is 6669 global attributes (large dataset). So the selection criterion must downsize the number of attributes to 384 - to compare the results with [2]. For each of the algorithms in FEAST we deploy 10 times 10-fold cross- validation. Highest accuracy is achieved with features selected by CMIM, JMI, ICAP, DISR and RELIEF, with very similar values - just under 86%. These results are comparable with the EMO-DB accuracy in the evaluation of annotation by an independent panel of experts [17] and with the published results in [18]. In other words, the resulting combined models (large number of features + selection + classification) reach the precision with which a person recognizes the emotional state of the actor.

We must note that the top 20 of the most common features used by the different criteria are belonging to almost all major groups. For this reason, further analysis was performed with respect to distribution groups shown in Table II. In it all low-level features used in the large dataset are accounted. Based on the results from the experiments described in the previous paragraph, was selected CMIM criterion for the subsequent experiments (the highest score in the cross-validation - 85.72% for all classes). Distribution groups are clearly shown in pie charts of Fig.2.



(a) (b)

Fig. 2. Pie charts of the shares of selected feature groups of CMIM criterion a) number selected features from a group; b) relative share of the group (obtained as the number of the selected features is divided by the number of the low-level features in the group before the selection).

B. Recognition accuracy

The previous sub-section discusses the results in terms of feature selection criteria, features and their main groups. At this point, we assess the feasibility of the models in terms of emotional categories for the selected dataset. In Table III are presented the recognition rate results for each class of emotion with cross validation. As expected, anger is the most accurately recognized class, followed by sadness (both with over 90% accuracy). Weaker recognition rate display those of boredom, fear, disgust and neutral, but still the accuracy is over 80%.

TABLE III
RECOGNITION RATE BY CLASSES

Criterion	Anger	Boredom	Disgust	Fear	Happiness	Sadness	Neutral
MIM	90.83	84.06	77.07	79.09	72.59	88.80	83.72
MRMR	84.49	71.57	53.97	60.09	47.88	83.42	75.26
MIFS	83.20	47.74	31.66	46.57	42.51	71.97	49.94
CMIM	93.34	88.71	79.83	80.03	74.89	91.72	83.70
JMI	92.38	89.28	83.30	82.34	68.61	89.87	86.06
DISR	92.52	89.76	83.88	82.99	70.19	87.81	85.73
CIFE	87.60	69.21	58.17	54.24	51.49	72.68	65.47
ICAP	92.82	87.84	79.87	80.38	75.99	92.01	82.63

The last stage of the current study was done in exploring fewer features based on the ordered lists returned by the selection criteria algorithms. From Fig.3 it is obvious that almost the same success in terms of recognition rate can be achieved with about 200 features.

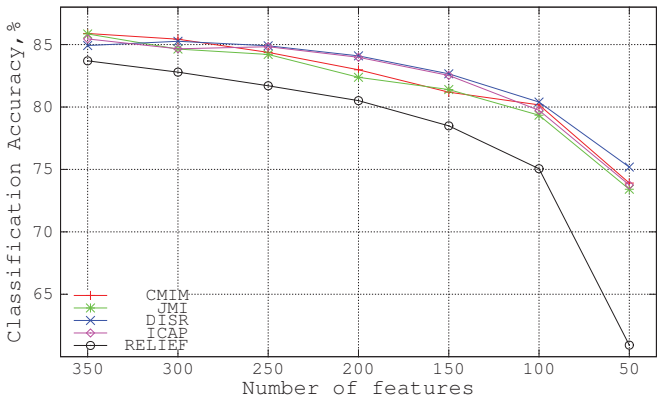

Fig. 3. Analysis of reducing the number of features

VI. CONCLUSION

This paper explores different feature selection criteria such as Mutual Information Maximization (MIM) feature scoring criterion and its derivatives to measure how potentially useful a feature or feature subset may be when used for classification purposes. A text independent method of emotion classification of speech is proposed in this paper. The proposed method employs different groups of low-level features and statistical functions, to represent the speech signals and a NN classifier for the classification task. For the experiments the EMO-DB dataset is used with seven primary emotions. Results show that the proposed system yields an average accuracy of over 85% for recognizing 7 emotions with 5 of the best performing feature selection algorithms.

We plan to expand our work by including in the classification step the Support Vector Classifier and to compare its recognition accuracy to the current NN classifier. The most important challenge remains the fusion between the two modalities speech and face emotion recognition. There are two way of fusion of the modalities: 1) at the feature level (before running the classifier) and 2) at the results level (combining results from classifier from each modality). By fusing the multimodal data we expect an increase in the recognition rates in comparison to the unimodal systems.

ACKNOWLEDGMENT

This work was supported by contract DFNI I02/1 for research project: "Intelligent man-machine interface for assistive medical systems in improving the independent living of motor disabled users" of the Bulgarian Research Fund of the Ministry of Education and Science.

***Abstract*— Web based learning plays a vital role in the global education since it can support learner from anywhere and anytime. The automatic assessment is required for web based learning to provide the individual support for each learner. The challenging is to serve the large numbers of learners with appropriate individual support. Therefore, there is the necessity to determine the effective automatic assessment so that the appropriate feedback can be given. This paper thus aims to determine the appropriate classification method for providing the automatic assessment for a large numbers of learners through web based learning. The interaction between the learners and the learning objects is used for classification. Two classification methods which are k-nearest neighbors and decision tree are studied and compared in this paper. The case study with 419 learners enrolling the course "Introduction to Information Technology", Mae Fah Luang University shows that both classification methods are suitable for employing as the automatic assessment classifiers because k-nearest neighbors provides 93.08% and decision tree provides 91.16% accuracy respectively.**

Keywords*— *automatic assessment; classification method; KNN; Decision Tree; web based learning

I. INTRODUCTION

The Information Communication Technology (ICT) establishes new strategy to achieve the learning objectives in education system. The ICT has created the major shift in education system, the roles of teacher, learner, curricula and new media in the past decades [1]. The integration of ICT in teaching and learning creates a possibility for learner to learn from anywhere and anytime with wired and wireless communications. The learning model that goes beyond classroom enhances the life-long and the effective of learning for both learners and teachers [2] for modern education system. Web based learning has been introduced for many years as the new delivery form of e-learning and become a common way for modern education systems nowadays. To promote effective learning of the web based learning, some issues need to be considered such as the effectiveness of knowledge transferring, learning lifestyle supporting, and learning efficiency evaluation.

Many outstanding theories such constructivism and situated cognition aim to design the learner-centered environment. These theories have the common assumption that the learners are active participants. They gain the knowledge from the relevant context and they also contribute or respond to learning objects [3] appropriately. Supporting the variety of learning theories in web based learning is even more important and challenging especially when it has to serve a large numbers of learners. Each learner has different learning abilities, personal interests, background knowledge and the ability to learn [4]. The learning styles of each individual in web based learning, such as how they interact with the learning objects and do their practice can be used to analyze learner's behavior in many areas [5] especially in implementation of web-based learning system[4]. Because the learning style affects learning outcome such as passing or failing the course, analyzing learning style could predict the learning achievement. The learners who have the difference background could have difference learning style [6]. Therefore, it will be an advantage, if the learners can be classified as who are going to pass or fail the course so that the assistant can be made appropriately on time. The classification of learners will enhance the learning efficiency of the learner and it is necessary for automatic assessment and feedback [7].

Therefore, the objective of this paper is to determine the appropriated methods for classifying the students who will potentially pass or fail the course. The interaction between students and learning objects is mainly used for classification in this paper. The k-nearest neighbor (KNN) and decision tree are examined and compared since they have been successfully applied in several classification problem domains [8]. The result from this paper will be useful in the improvement of the automatic assessment and feedback for web based learning.

II. LITERATURE REVIEWS

A. ICT for Education

ICT has affected the working process in many sectors, including the education sectors. It changes the way of teaching and learning [9]. It establishes the flexible learning strategies. The flexible learning strategies means that the flexible of time, place, content selection and delivery of instructions [1]. The ICT can enhance the teaching and learning process in higher education [10]. With the network, it makes possible for learners and teachers to access to the content in any place and time, which is also known as distributed learning. The key factor of the distributed learning is the web-based instruction [1]. There are a different types of learners and some learners might not be satisfied with the instruction or content that be provided. Even the ICT is a productivity tools in education system but to fulfill the different types of learner satisfaction, the learning software is the key competencies [1].

B. Automatic Assessment for Web Based Learning

The automatic feedback and assessment is the useful tools for self-learning and distance learning [7]. The advantages of the automatic feedback are enabling the instance feedback to the learner, consistency of evaluating assignment and reducing task and time for instructors [3]. The research found that the automatic assessment could enhance the learning result [11]. Moreover, the automatic assessment has applied many machine learning methods for many different purposes [12] including this paper.

C. K-Nearest Neighbor

K-Nearest Neighbor (KNN) is a method for data classification based on the similarity measure. It is used for measuring the distance among data attributes. Classification process consists of examining the features of a newly or unknown data and assigning it to one of the predefined set of class. The training dataset is the predefined set of class coming from the historical records. It is essential that the training dataset is big enough to cover all of the populations so that KNN is suitable for classification [13].

Generally, the KNN is suitable for numeric data. However, it can be applied with discrete data. There are two main operations commonly used for KNN including distance function and combination function. The distance function calculates the distance between two records to measure the similarity of data. The combination function combines the result of the distance then sorts the distance by ascending. The value of k identifies the numbers of the nearest neighbors. There are two main decision rules in KNN which are similarity voting and majority voting schema [14]. Many research has been used the KNN method in classification purpose. For example, Chang et al. purpose a mechanism for classifying learning style and identifying learners' learning styles. Some research goes further than applying the method because they also purpose the improvement the classification methods [14].

D. Decision Tree

Decision tree is a hierarchy data structure for using in decision support. It looks like a real tree model with the root node on the top and leaf node at the bottom of the tree. The decision tree diagram consists of node, branch, and leaf. Each node has its own attribute. The node at the top of the tree is called root node. Branch represents the possible attributes. Leaf is at the bottom of the tree which represents a class, or the result of prediction [13].

There are some famous versions of the decision tree methods such as ID3 and C4.5. The C4.5 method is suitable with an uncertain class label and can be applied pre-pruning and post-pruning to reduce the least reliable branches. Furthermore, the C4.5 applies the Information gain method as well as ID3 and the C4.5 can solve some disadvantages of ID3 [13]. There is Gain ratio criterion in the C4.5. The Gain ratio is used to decide which attribute should be selected and it helps reducing the bias for selecting attribute process by taking the number and size of branches into account when choosing an attribute [13]. Finally, the Split information of the attribute is applied to determine gain ratio [13].

Decision Tree has been adapted in many kinds or classification problems especially in web based learning. For example, the decision tree can be used to analyze learning profile from the data source such as web log to classify the learners' learning styles [15], analyzing the learners' activities [16], predicting learning effectiveness [16], enhancing learning outcome [17], etc.

III. RESEARCH METHODOLOGY

A. Data Gatheing

Mae Fah Luang University has been fully deployed the web based learning for "Introduction to Information Technology" course. This course is required as the general education course for every first-year student. There are more than 3,000 enrolling this course every year. The data used in this paper is collected from Web based learning course in 2013 academic year. The training dataset comes from 419 students. These students are from difference majors. These majors are categorized into two group, science (sc) and none science (nsc) majors. The training dataset is gathered from 2 parts. The first part is gathered from weblogging data which record the student's interactions with learning objects. The Introduction to Technology course consists of 6 modules. The spreadsheet module is selected for this paper, because there are a significant numbers of failure students. There are totally 18 learning objects in this module. The learning objects are available for students to access in any order and anytime. Finally, the second part data is the student assessment result which are passing or failing this module. This data is used for both the classifiers. TABLE I demonstrates the example of the training dataset.

TABLE I. EXAMPLE OF TRAINNING DATA

Std. no	**1**	**2**	**3**	**4**	**5**	**6**	**7**	**8**	**9**	**10**
Area	nsc	nsc	nsc	nsc	nsc	nsc	sc	sc	sc	sc
Grade	f	f	p	f	p	p	p	p	f	f
LO99	2	0	1	5	0	0	0	2	1	3
LO102	1	0	0	0	1	1	1	4	1	0
LO103	0	0	0	0	0	0	0	0	0	0
LO104	0	0	0	0	1	0	1	5	2	0
LO105	0	1	0	0	1	1	2	1	2	0
LO106	0	0	0	0	1	2	2	1	3	0
LO107 to LO113	0	0	0	0	0	0	0	0	0	0
LO114	0	0	0	0	0	1	1	2	2	0
LO115	0	0	0	0	1	1	0	2	2	1
LO116	0	0	1	0	0	0	1	2	1	0
LO120	0	0	1	2	0	0	0	2	2	0
LO121	7	1	1	7	0	0	0	3	2	0

The first-row "std. no" presents 10 examples. The second row presents the study areas which are science (sc) and none-science (nsc). The third row shows learning outcome of each student which are pass (p) or fail (f). The rows from LO99 – LO121 demonstrate the frequencies that the student interacts with these learning objects. For example, the first student who is student number 1 is from none-science major and did not pass the module. This student interacts with LO99, LO102 and LO121 two times, one time and seven times respectively.

B. *Accuracy of Correctly Classified*

The accuracy of the classifier method has to be tested. The formula for evaluating the total classification accuracy is defined as equation no. (1) [18].

$$\text{accuracy} = \frac{\text{no. of all correct classified samples}}{\text{no. of all examples}} \quad (1)$$

C. *KNN Classifier*

The Euclidean distance is applied in this KNN process. Euclidean distance calculates the difference between the sample data and training data. The Euclidean distance is defined as shown in equation no. 2 [19].

$$\left(d(x_m, x_n) = \sqrt{\sum_i (x_{m,i} - x_{n,i})^2} \right) \quad (2)$$

Where x is data for classifying which is defined as a vector x= (x1, x2, x3,….,xn), n is the number of the example's attributes, x1 is the example's attribute. "i" is from 1 to k. The smaller $d(x_{m,}x_{n)}$ means that these two examples are more similar [18].

TABLE II. EUCLIDEAN DISTANCE CALCULATION

Student No.	Major	Lo99	Lo102	Lo103	…	Distance
D(1,10)	0	1	1	0	…	1.73
D(2,10)	0	3	0	0	…	3.32
D(3,10)	0	2	0	0	…	2.24
D(4,10)	0	2	0	0	…	2.24
D(5,10)	0	3	1	0	…	3.74
D(6,10)	0	3	1	0	…	4.00
D(7,10)	1	3	1	0	…	4.36
D(8,10)	1	1	4	0	…	6.63
D(9,10)	1	2	1	0	…	4.69

TABLE II demonstrates how to calculate Euclidean distance of the testing data who is the student no.10 from other 9 students. According to TABLE II, the first column is the student no. 1-9. The second column is the student major. The column "99" to" …" are the learning objects which the Euclidean calculates in the process of $(x_{m,i} - x_{n,i})^2$. The distance column shows the result of the calculation. The value of k is the numbers of nearest neighbors for classification. This number identifies how many neighbors effect classification which will choose from the distance matrix. The k is usually an odd number. The number of k influences the accuracy of the result. If k is smaller, then the result will be higher variance or less stable. If k is larger, then the result will be higher biased and less stable. The lists below are the example results of KNN with different k values in this paper.

- If k value is 3, then the nearest neighbor is student no1 (fail), no3 (pass) and no4 (fail), so there are 1 pass and 2 fail, then student no. 10 is classified as fail the module.
- If k value is 5, then the nearest neighbor are student no 1(fail), no3 (pass), no4 (fail), no2 (fail) and no5 (pass), so there are 2 pass and 3 fail, then student no. 10 is classified as fail the module.

D. *The Decision Tree Classifier*

This paper has adapted the C4.5 method since there are 2 class types, "pass" and "not pass". From the training dataset, there are 419 instances. The students are categorized into two classes including, passing and not passing the course. The attributes for calculating the decision tree is a number of times accessing learning objects and the major of studying. There are total 19 attributes used in this paper. After running the decision tree, there are 9 attributes is accounted for classifying. Each attribute has 2 classes including pass and not pass statuses.

Fig. 1 demonstrates the decision tree results from the training data. The gain ratio is the criteria for selecting the split point. Each branch is created by comparing the value between the split point and split attribute. In this paper, the root node is LO104 which is selected because of its maximum gain ratio. From LO104, the dataset is divided into left and right branches. If split attribute value ≤ split point value (4.5), otherwise another branch which is LO121 becomes necessary. In another hand, if split attribute value split > point value (4.5), then the LO99 needs to be performed. The method will repeat the process to build a decision tree for the sub-dataset, until the dataset is empty or the terminated condition is satisfied.

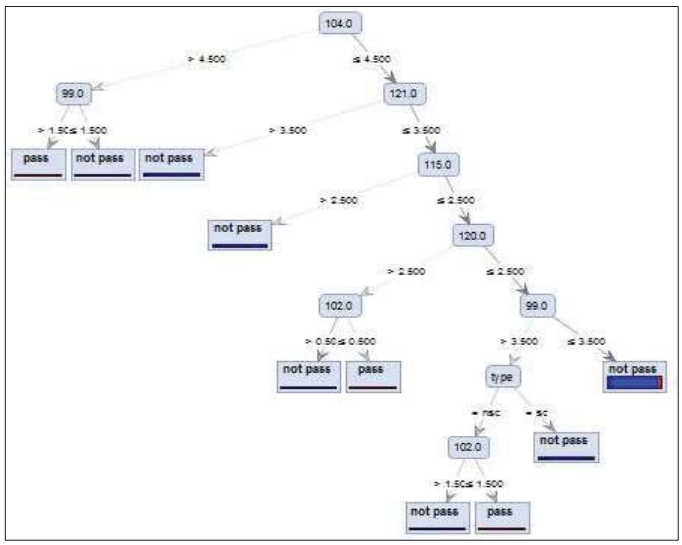

Fig. 1 Decision Tree Classification Results

IV. RESULTS AND DISCUSSION

A. *KNN Classification Accuracy*

In this paper, KNN classifier is tested for k = 1, k = 5, and k=9 respectively. According to the classification accuracy of KNN from TABLE III, k=9 has the highest accuracy which is 93.08% where k=1 and k=5 have 83.30% and 92.85% accuracies respectively.

TABLE III. CLASSFICATION ACCURACY

	K=1	K=5	K=9

Accuracy rate	83.30	92.85	93.08

TABLE IV demonstrates the classification result of KNN with k=9. The KNN predicts the failing student with 93.08% accuracy. However, 29 students who actually pass the course but they are classified as fail the course. For the pass, accuracy is 0.00%. The method could not predict 29 cases of pass students. Following equation (1), the accuracy of correctly classified examples is 93.08% and standard deviation is 1.04%.

TABLE IV. PRECISION OF KNN WITH K=9

	True fail	True pass	Class precision
Pred. fail	390	29	93.08%
Pred. pass	0	0	0.00%

B. Decision Tree Classifier Accuracy

TABLE V demonstrates the accuracy result of decision tree which is evaluated by the cross-validation evaluation technique. There are 382 students predicted as fail who actually fail the course. The 8 students are predicted to pass but they actually fail. There is no student has been classified as passing the course. However, 29 students who actually pass the course but they are classified as fail the course. Therefore the accuracy for predicting the failing student is 93.06%. The accuracy for predicting the passing student is 0.00%. There are 8 students who fail the module, but the method predicts as passing the module. Following equation (1), the accuracy of correctly classified examples is 91.16% and standard deviation is 1.91%.

TABLE V. PRECISION OF DECISION TREE

	True fail	True pass	Class precision
Pred. fail	382	29	93.06%
Pred. pass	8	0	0.00%

The result shows that both classification methods provide high classification accuracies although the accuracy of KNN is slightly higher than that of the decision tree. Therefore, both classifiers are potentially appropriate for automatic assessment in this paper. The training data composes of many examples for more numbers of failure than passing students. Therefore, this will probably lead the biasing for a classifier for the majority class. The future work will be improving the classification accuracy. In addition, the future study will also be focusing on protecting data security while retaining student's privacy.

V. CONCLUSION

This paper aims to determine the appropriate classification method for automatic assessment in web based learning by using the interaction between the learners and the learning objects. KNN and decision tree are studied in this paper for identifying the effective classifier. The case study is conducted with 419 learners enrolling the course "Introduction to Information Technology", Mae Fah Luang University, which is the web based learning course. The results shows that both classification methods are suitable for employing as the automatic assessment in web based learning by providing 93.08% and 91.16% accuracies for KNN and decision tree methods respectively.

***Abstract*—This paper presents a study on the bit error rate performance of cooperative diversity system under Ricean fading environment. Single-antenna nodes (relays) operate in variable-gain amplify-and-forward (VG AF) mode. Destination node receives two copies of information signals, from source and from relay, and combines them applying maximal ratio combining (MRC). We develop a novel analytical model for bit error rate performance, which is applicable to various fading scenarios described with different Ricean *K* factors and average signal to noise ratios (SNR). Finally, we determine the level of system performance improvement, or equivalently the signal-to-noise ratio gain, due to the existence of line of sight signal component between the network nodes and nodes cooperation. Numerical results show that the Ricean *K* factor have significant influence on overall system performance. Simulation results confirm the validity of the proposed analytical model.**

I. Introduction

In the previous years, the number of applications using wireless communication systems has remarkably increased. Such growth demands higher data rates and higher reliability of wireless systems. However, it is well known that wireless signal transmission imposes serious challenges in fulfilling these demands, due to the complex nature of wireless radio channel. To mitigate the negative effect of multipath signal propagation, various technical solutions for wireless networks are proposed. One of the most commonly used techniques for efficiently coping with the negative effects of multipath fading and for providing significant improvements in reliability and throughput is diversity. It is a relatively simple solution based on the usage of multiple antennas placed at the transmitter and/or receiver. However, the size, cost and hardware constraints in the use of multiple antennas may not always be feasible, especially in small portable devices. To overcome this problem, the concept of cooperative diversity became the focus of various research efforts, [1]. Such concept assumes that multiple (single antenna) nodes share their antennas in order to transfer the information from one to another. Through their cooperation, distributed antenna system is created, providing diversity gain without the necessity for multiple antennas.

Cooperative diversity has been in the research focus in recent years, since such concept offers significant performance benefits, including improved wireless link performance, increased spatial diversity, capacity and extended network coverage, [1]–[4]. In such wireless network infrastructure additional network nodes, called relays (R), are introduced in order to assist in signal transmission from source (S) to destination (D). Through cooperation among the network nodes, a virtual antenna array is created and by combining signals received through multiple signal paths certain diversity gain can be achieved. Such idea was first proposed by Meulen [5] and Cover [6].

Relay usually performs one of the two main relaying methods: Amplify-and-Forward (AF) or Decode-and-Forward (DF), [3]. AF relaying is a popular method for implementing in relay systems because of relatively simple processing of the received signal. Namely, the received signal from the source is amplified at the relay and then retransmitted towards the destination. Depending on the source-relay channel information, R can perform fixed gain (FG), also called average power scaling [3], or variable gain (VG), or instantaneous power scaling [7]. In this work we consider dual-hop variable gain AF cooperative relay system operating in an asymmetric Ricean fading environment, meaning that fading parameters (average SNRs and Ricean *K* factors) of the S-R and R-D channels are not necessary identical.

In order to determine performance of cooperative diversity systems, good knowledge of wireless channel is of the great importance. Thus, extensive studies are done assuming different communication scenarios and various fading statistics. Cooperative diversity systems operating in Rayleigh and more general Nakagami-*m* fading environment are studied in [8]–[12], having identical or non-identical fading channel parameters. At the same time, Ricean fading is also commonly used in the technical literature to model wireless propagation comprising a LoS (Line-of-Sight) component and multiple scattered components, [13]. However, despite the obvious practical importance of such Ricean channel model that is typical for micro/macro cellular communication, as well as indoor radio channels [14], only a few works have analyzed the performance of cooperative diversity systems in such LoS fading conditions, [15]–[21]. The lack of general model for performance analysis of such systems in an asymmetric Ricean fading environment represents the main motivation for the research presented in this paper. We propose appropriate analytical model which leads toward deriving the exact expression for system end-to-end bit error rate (BER) given in the form of infinite, but fast converging sum. We also compare the theoretical results with Monte Carlo simulations for different scenarios considered.

Section II describes the model of the analyzed system and associated channel distributions. In Section III we derive the BER expression for the received signal at destination, at the output of MRC combiner. The obtained results are showed in Section IV. Concluding remarks are given in Section V.

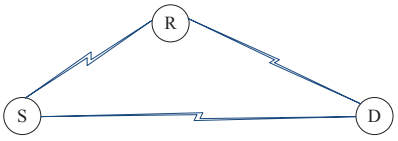

Fig. 1. Two hop cooperative relay system

II. System Model

A simple example of wireless cooperative diversity system is shown in Fig 1, in which source (S) sends the information to destination (D) using intermediate relay node (R). The destination will receive two copies of the information signal, one from source directly and the other from the relay. By proper combination of these two versions of the same signal, cooperative diversity can be achieved. The main advantages of cooperative communication are higher spatial diversity, reduced transmitted power, higher throughput and adaptability to network conditions, [22].

Each transmission period is divided into two time intervals. In the first time slot, S broadcasts the information signal to R and D. In the second time slot, R amplifies and forwards the scaled version of the signal to D, and the source keeps silent. Since D receives two versions of the same signal, one from S and the other from R, spatial diversity is achieved, with the received signals being combined by applying MRC.

It has been found in practice that by introducing the intermediate node (relay) between S and D, and by carefully planning its position, different links of a relay system could experience LoS fading conditions. In such circumstances, Ricean distribution is more suitable to describe statistical properties of the S-R and R-D fading channels, [13]. Furthermore, Ricean fading channels on the two hops are assumed to have different values of *K* factors and average received powers (or equivalently average SNRs). At the same time, the channel between S and D is assumed to follow Rayleigh fading distribution, because there are multiple paths due to buildings, trees and other objects and thus fading should be considered as more severe.

The instantaneous SNR of the signal received after maximal ratio combining done at the destination node can be written as:

$$\gamma_t = \gamma_0 + \frac{\gamma_1 \gamma_2}{\gamma_1 + \gamma_2 + c}. \quad (1)$$

γ_0 represent the instantaneous SNR of the direct S-D channel, while γ_1 and γ_2 represent the instantaneous SNRs of the first (S-R) and second (R-D) hop of the relaying channel, respectively, defined as $\gamma_i = \frac{|h_i|^2}{\Omega_i}$, $i = 0, 1, 2$. $\Omega_i = E[|h_i|^2]$, where h_i, $i = 0, 1, 2$ represent mutually independent complex channel gains of the S-D, S-R and R-D channel, respectively. Furthermore, it is assumed that additive white Gaussian noise (AWGN) has zero mean with respective noise powers N_0, N_1 and N_2 for S-R, R-D and S-D links. c is the constant which can have value 1, for the exact SNR of S-R-D link, or its good approximation for $c = 0$, [23]. Without loss of generality, in further analysis we consider automatic gain control (AGC), thus ignoring the noise at the relay, [24]. In that case $c = 0$.

Based on the above assumptions, the instantaneous SNR of direct link, γ_0, is distributed according to exponential distribution with the PDF (Probability Density Function), [14]:

$$p(\gamma_0) = \frac{1}{\overline{\gamma}_0} e^{-\frac{\gamma_0}{\overline{\gamma}_0}}. \quad (2)$$

For wireless links on the two hops experiencing Ricean fading, γ_i, $i = 1, 2$, are distributed according to non-central χ^2 distribution with two degrees of freedom, [25]. In that case PDF of the instantaneous SNR of *i*-th hop, $i = 1, 2$, is:

$$p(\gamma_i) = a_i e^{-K_i} e^{-a_i \gamma_i} I_0\left(2\sqrt{K_i a_i \gamma_i}\right). \quad (3)$$

In the above equation we put $a_i = (1 + K_i)/\overline{\gamma}_i$, where K_i is the Rician *K* factor of the *i*-th hop, $i = 1, 2$, and $I_0(\cdot)$ is the zero-th order modified Bessel function of the first kind. Ricean factor *K* represents the measure of the fading severity, and it is defined as the ratio of the LoS component power to the power of scattered components, [14]. For the special case of $K = 0$ (non LoS scenario), the Rician fading distribution becomes the Rayleigh fading distribution, while for $K \to \infty$, the distribution approximates that of an AWGN (no fading) channel. Typical values of the *K* factor in indoor/outdoor land mobile applications normally range from 0-12 dB, [13].

III. Performance Analysis

Average bit error rate (BER) is a useful criteria for evaluating performance of wireless communication systems. Traditionally, BER can be computed either using MGF (Moment Generating Function) based approach, or averaging the conditional bit error probability over the SNR distribution [14, Eq.(1.8)]. The latter (PDF-based) approach can be applied only if combined SNR per bit can be determined in a form feasible for further use. However, finding the PDF of the combined SNR in a tractable form is more difficult if the combined paths have different fading distributions and different fading parameters. Since the total SNR is given with (1), in this paper we will use the MGF based approach to determine BER of the analyzed cooperative diversity system operating in asymmetric Ricean fading environment.

To compute the average error probability, it is necessary to evaluate the following integral, [14]:

$$P_b(\gamma_t) = \int_0^\infty Q\left(\sqrt{2g\gamma_t}\right) p(\gamma_t)\, d\gamma_t, \quad (4)$$

where $Q(\cdot)$ is Gaussian Q function, defined as $Q(x) = 1/\sqrt{2\pi}\int_x^\infty e^{-t^2/2} dt$, while $p(\gamma_t)$ is PDF of the total received SNR. Parameter g is determined by the specific modulation scheme employed. If MPSK (M-ary phase shift keying) of the transmitted signal is assumed, $g = sin^2\pi/M$. Using the alternate representation of Gaussian Q function, defined as:

$$Q(x) = \frac{1}{\pi}\int_0^{\pi/2} \exp\left(-\frac{x^2}{2sin^2\theta}\right) d\theta, \quad (5)$$

BER can be represented over MGF of the total received SNR. Knowing the fact that MGF of the sum of two independent random variables is equal to the product of their MGFs, BER of the analyzed cooperative diversity system can be presented in a form of single, finite range integral:

$$P_b = \frac{1}{\pi}\int_0^{\frac{M-1}{M}\pi} M_{\gamma_0}\left(-\frac{g}{sin^2\theta}\right) M_{\gamma_{SRD}}\left(-\frac{g}{sin^2\theta}\right) d\theta. \quad (6)$$

In the case of Rayleigh fading, MGF is given in the following form, [14]:

$$M_{\gamma_0}(s) = \frac{1}{1 - s\bar{\gamma}_0}. \quad (7)$$

In order to proceed with the performance analysis of the considered cooperative diversity system, it is necessary to find SNR statistic of the S-R-D link. Previously, in [26] we derive statistical properties of the total received SNR at D, for the two-hop AF VG relay system operating in Ricean fading environment. We have shown that the PDF of the total received SNR of two hop AF VG relay system is given with (8). It is clear that (8) is presented in a form of infinite sum. However, it is dominated by the first few terms, and can be computed with sufficient accuracy with only few terms of a summation, as given in [26]. Calculating the Laplace transformation of the PDF, with the aid of [27, Eq. (6.621.3)], MGF can be also derived in a form of infinite but fast converging sum, given in (9). $F(\cdot,\cdot;\cdot;\cdot)$ denotes Gauss hypergeometric function [27, Eq. (9.100)], while $\Gamma(\cdot)$ is Gamma function. In the case when fadings on the two hops are characterized with Rayleigh distribution ($K_1 = K_2 = 0$), the infinite summation in (9) reduces to only one summation term, i.e. $n = m = 0$.

After deriving MGF of the total SNR at D, we can obtain the average BER for a variety of modulation types using the MGF based approach, by putting (9) and (7) in (6).

The above described analytical model for exact determination of the two-hop cooperative diversity systems BER performance in the chosen propagation scenario, to the best of authors knowledge, is new. There are some similar performance analyses of cooperative diversity systems operating under mixed Ricean/Rayleigh and Ricean/Nakagami-*m* fading channels, but the case of having Ricean fading on both hops of relaying channel is not considered. Model presented in this paper is general, and includes a whole range of fading severity, from non LoS ($K_1 = K_2 = 0$) to ideal case of no fading ($K_i \to \infty$).

IV. Results

This section presents the numerical and simulation BER results for the analyzed cooperative diversity system having arbitrary fading channels parameters.

In all considered scenarios we have assumed that the channel between S and R as well as the one between R and D have LoS communications, with arbitrary chosen Ricean *K* factors, and the channel between S and D experience multipath Rayleigh fading. That is why in the Monte Carlo simulations, three independent channel variables are created following Ricean and Rayleigh distribution. Signal at R is amplified and forwarded to D, where the signals from S and R are combined using MRC. The AWGN is modelled as complex Gaussian random variables having zero mean and variance N_i, $i = 0, 1, 2$.

The obtained BER performance curves are plotted versus the average SNR of S-R link. BPSK mapping of the information signal is assumed ($M = 2$). Analytical results are evaluated numerically and presented with lines, while the simulation results are shown by different markers.

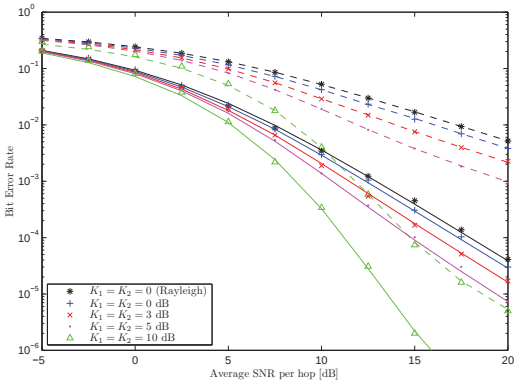

Fig. 2. BER versus average SNR per hop, identical channel parameters on S-R and R-D links; solid line - cooperative diversity; dashed line - relay system without cooperation

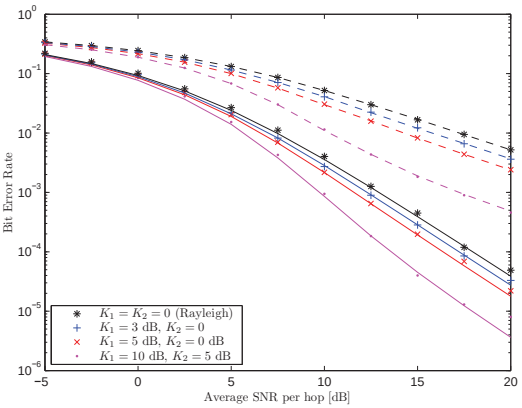

Fig. 3. BER versus average SNR per hop, non-identical *K* factors on S-R and R-D links, $\bar{\gamma}_0 = \bar{\gamma}_1 = \bar{\gamma}_2$; solid line - cooperative diversity; dashed line - relay system without cooperation

Fig. 2 presents BER values of the considered cooperative communication system in the case that fadings on S-R and R-D links have identical parameters. The average SNRs of all three links are assumed to be equal ($\bar{\gamma}_0 = \bar{\gamma}_1 = \bar{\gamma}_2$). BER results for the non-cooperative scenario (no direct communication between S and D) are also presented. It is observed from the figure that the existence of LoS between the S and R as well as R and D have significantly improves overall system performance. As *K* factors increase BER decreases. Furthermore, even if the direct channel is strongly influenced by multipath fading, its contribution in diversity combining is of great importance.

Fig. 3 illustrates the BER performance when the S-R link has different *K* factor than R-D link. Here we assume that the *K* factor of the first (S-R) link is greater thant the *K* factor of the second (R-D) link. However, knowing that γ_{SRD} is symmetrical to the SNRs of the individual hops, γ_1 and γ_2, the statistic of the total SNR, and thus the BER of the considered system will be the same as in the case when the *K* factor of the R-D link is greater than *K* factor of the S-R link.

Even in the case of different fading severities on the individual links, benefits of nodes cooperation is undoubted. The system with cooperative diversity offers significant gain

$$p(\gamma) = 2a_1a_2e^{-(K_1+K_2)}e^{-(a_1+a_2)\gamma}\sum_{n=0}^{\infty}\sum_{m=0}^{n}\frac{(a_1K_1)^m(a_2K_2)^{n-m}\gamma^{n+1}}{(m!(n-m)!)^2}\sum_{k=0}^{n+2}\binom{n+2}{k}\left(\frac{a_1}{a_2}\right)^{\frac{n-m-k+1}{2}}K_{n-m-k+1}\left(2\gamma\sqrt{a_1a_2}\right) \quad (8)$$

$$\begin{aligned}M_{\gamma_{SRD}}(s) = a_1a_2e^{-(K_1+K_2)}\sum_{n=0}^{\infty}\sum_{m=0}^{n}\frac{{K_1}^m(K_2a_2)^{n-m}}{(m!(n-m)!)^2}\sum_{k=0}^{n+2}\binom{n+2}{k}\frac{{a_1}^{n-k+1}\sqrt{\pi}2^{2n-2m-2k+3}}{\left(a_1+a_2+2\sqrt{a_1a_2}-s\right)^{2n-m-k+3}}\\ \times\frac{\Gamma(2n-m-k+3)\Gamma(m+k+1)}{\Gamma(n+5/2)}F\left(2n-m-k+3, n-m-k+\frac{3}{2}; n+\frac{5}{2}; \frac{a_1+a_2-2\sqrt{a_1a_2}-s}{a_1+a_2+2\sqrt{a_1a_2}-s}\right)\end{aligned} \quad (9)$$

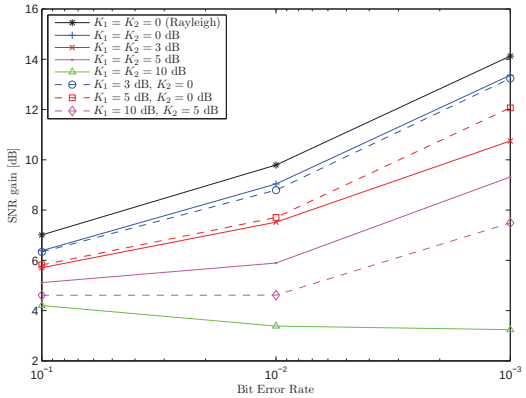

Fig. 4. SNR gain, $\bar{\gamma}_0 = \bar{\gamma}_1 = \bar{\gamma}_2$

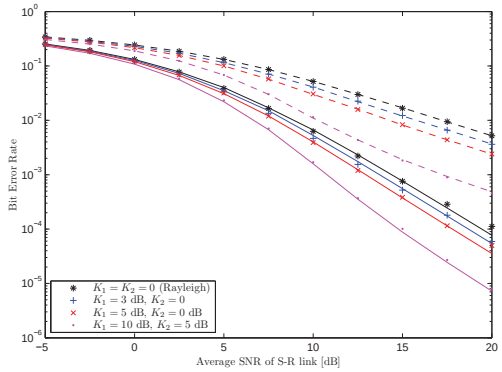

Fig. 5. BER versus average SNR of S-R link, $\bar{\gamma}_1 = \bar{\gamma}_2 = 2\bar{\gamma}_0$; solid line - cooperative diversity; dashed line - relay system without cooperation

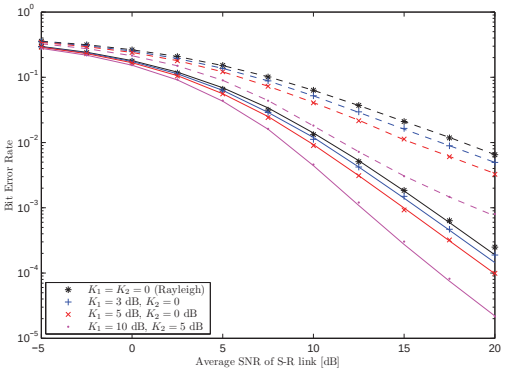

Fig. 6. BER versus average SNR of S-R link, $\bar{\gamma}_1 = 1.5\bar{\gamma}_2 = 4\bar{\gamma}_0$; solid line - cooperative diversity; dashed line - relay system without cooperation

compared to the system without cooperation. Fig. 4 presents the SNR gain, i.e the SNRs difference of cooperative and non-cooperative relay systems needed for achieving the same level of BER performance. The lowest SNR gain is obtained in the case of high K factors, because the contribution of direct (S-D) signal in the diversity combining, compared to the relay link is neglected. However, in the more severe fading conditions (lower K), as K factors of relay links decrease, the obtained gain increases, since the influence of direct link in diversity combining becomes greater.

When considering wireless cooperative diversity, the realistic assumption is that SNRs on the three links are not always equal. In particular, the S-D link is generally longer than S-R and R-D links, thus the signal power received at D from S, and equivalently the average SNR of the S-D link, is likely to be lower than the average SNRs of S-R and R-D link. Accordingly, in further analysis we assume that $\bar{\gamma}_1 = \bar{\gamma}_2 = 2\bar{\gamma}_0$ and $\bar{\gamma}_1 = 1.5\bar{\gamma}_2 = 4\bar{\gamma}_0$. The obtained BER results are presented in Fig. 5 and Fig. 6, as a function of $\bar{\gamma}_1$. BER results for the system with no cooperation are also presented. The appropriate SNR gains are shown in Fig. 7.

Presented results confirms the fact that in all the cases, even when the direct link is influenced by more severe fading than the relaying link, its contribution to diversity combining is not neglected. Even in the case that the average SNR of direct link is 4 time less than the average SNR of one of the relay links, for achieving the BER of 10^{-3} 6-12 dB less SNR is needed compared to non-cooperative scenario.

Furthermore, it can be seen that all the analytical results exactly match with the Monte Carlo simulations, confirming the accuracy of the presented analysis.

V. Conclusion

This paper presents novel analytical model for BER performance analysis of cooperative diversity system. Signals received at D directly from S, and from two hop variable gain AF relaying are combined using MRC. Signals transmitted over the S-D, S-R and R-D channels may experience different fadings. Thus, we assume that S-R and R-D channels are characterized with Ricean fading, while direct S-D link is under more severe fading and characterized with Rayleigh fading distribution. First we derive the MGF of the combined

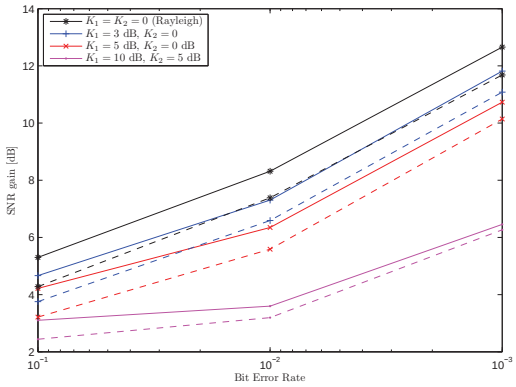

Fig. 7. SNR gain for non-identical channels; solid line - $\bar{\gamma}_1 = \bar{\gamma}_2 = 2\bar{\gamma}_0$; dashed line - $\bar{\gamma}_1 = 1.5\bar{\gamma}_2 = 4\bar{\gamma}_0$

SNR at D, in a form of infinite, but fast converging sum. Based on this expression, the average bit error rate of M-ary PSK signal is derived, using maximum 25 summation terms, for all the considered values of Ricean K factor.

The presented results clearly demonstrate that the considered system exhibits considerable improvements in system BER performance for various values of fading channels parameters, compared to the non-cooperative scenario. Furthermore, it has been shown that the existence of LoS between S and R and/or R and D influences the overall system performance. The obtained results can be useful to the system design engineers when planning the relay position.

Such system model is sufficiently general to encompass various fading channel conditions, as well as different communications scenarios which include both cooperative and non-cooperative communication. Furthermore, the generality of our analysis and numerical examples enables that the BER performance of a digital communications scheme using cooperative diversity can be also evaluated for other coherent modulation schemes and a variety of wireless fading channels. The performance of the proposed system may also be extended to other relaying schemes, such as FG-AF, or DF.

Digital door lock using fingerprint, webcam and GSM

A novel approach for smart homes

***Abstract*— This paper explains the design and implementation of an electronic door lock using microcontroller and suitable peripherals. Home security has gained a lot of significance in the present day world owing to increased crimes, nuclear families and busy lifestyles. The proposed system provides a secure setup consisting of a fingerprint detection module, a webcam, microcontroller AT89S52, a GSM module, an LCD display and a DC motor. Fingerprints of 4 to 5 family members are registered in the fingerprint device. A user who wishes to enter the home shall get his/her fingerprint authenticated. Unauthorized users are denied access and the GSM module interfaced to the microcontroller sends an SMS to a predefined mobile phone (preferably, of the family head). The novelty of this project which differentiates it from the existing solutions [1-6] is that the webcam captures the image/scene in both the cases, irrespective of whether access is granted or denied. This feature helps in capturing any attempts made by burglars to gain access into the home by forcing children or elderly family members to undergo the fingerprint authentication. The webcam is serially interfaced to a personal computer and captures the events at the door. An optional LCD module displays the status of authentication or denial of access as the case may be. Upon authentication, the motor rotates and the door opens.**

Keywords—Microcontroller; fingerprint recognition R305; intelligent door lock; secure homes; GSM module SIM900; webcam; Proteus software.

I. INTRODUCTION

Modern households need foolproof security measures to provide access into the home. Smart homes call for digital or electronic solutions which offer reliability, ease of access, correctness and affordability. A digital door lock offers secure access through electronic and electromechanical components.

This project uses the most reliable biometric technique; namely, the fingerprint verification method. Other forms of biometric recognition include Iris scan, face recognition, voice recognition etc., Fingerprint techniques are simple, reliable and provide non-invasive means for personal identification as the patterns are unique to each individual.

Any biometric technique consists of two basic procedures, namely *Enrollment* and *Authentication* [1]. As a starting point, fingerprints of the family members are registered (enrolled) into the fingerprint module which is interfaced to the microcontroller through serial communication UART (Universal Asynchronous receiver transmitter). The complete system consists of a webcam, an optional LCD display, GSM SIM900 modem and a DC motor. Legitimate users are granted access whereas imposters are denied access.

The system provides accurate results for fingerprint scanning as the R305 scanner has False Acceptance Rate (FAR) 0.0001% and False Rejection Rate (FRR) 0.1% which are quite reasonable. Details about FAR and FRR can be found in [1].

The system was first simulated in the Proteus ISIS software. Since all the hardware components are not supported in the software, a keypad module was used instead of the fingerprint scanner and a virtual terminal was used in place of the GSM module just to ensure that the design and programming were correct. Once the desired functionality was achieved through software simulation, hardware interfacing was carried out.

II. EXISTING METHODS OF SECURE ACCESS

Authors in [2] propose a similar thought of biometric access using fingerprints but use an MMS mechanism to notify the house owner about imposters. Authors in [3-4] propose multi-factor authentication using fingerprint, RFIDs and one-time passwords (OTP) for secure ATM booth access. Authors in [5] and the references therein propose secure home access using the face recognition technology.

Other systems such as the traditional mechanical lock and key were replaced by electronic microcontroller locks which have passwords. These have been superseded by the use of smart cards (ID cards, RFID tags). Different modes of providing access are discussed in [6].

III. PRESENT PROJECT OR PROPOSED METHOD

The proposed system is built by interfacing suitable peripherals such as the fingerprint sensor (R305), webcam, 16x2 LCD display (optional), DC motor (with relay) and GSM modem with the microcontroller AT89S52. Users who wish to enter the home, have to clear the authentication procedure at

the fingerprint module (R305 optical fingerprint sensor) upon which, the microcontroller turns the motor ON and opens the door. In case of unauthenticated users, the access is denied, microcontroller sends an SMS to the house owner's mobile phone using the SIM900 modem. The optional LCD display shows 'Authenticated Door Opening' in case of authorized users and 'Access Denied' when the authentication fails. The webcam captures pictures at all instances of fingerprint access.

A. *Merits*

Our system is simpler than the one proposed in [2] as it uses SMS feature and eliminates the need of sending MMS links which are quite awful for general public as they need internet connectivity and complex mobile configuration settings. SMS based systems do not need internet connectivity or high-end mobile handsets.

Multi-factor authentication systems proposed in [3-4] are slightly expensive as they need additional circuitry and 32-bit microcontrollers. The only advantage of these systems is that they provide foolproof security because of multi-factor authentication.

Our system offers an inexpensive solution and low power operation compared to the above solution.

It also overcomes the drawbacks of password based systems by eliminating the need for memorizing complex passwords and gives the freedom from stolen password/smart card crimes. Fingerprints are time invariant and are not vulnerable to memory loss/hacking attacks. They do not require complex image processing techniques which are used for face recognition such as in [5].

B. *Uniqueness*

The novelty or uniqueness of this project comes from the fact that the webcam captures the images in all cases i.e., access grant or denial and forms a powerful repository of images which may be useful in cases of burglary to identify the culprits. Incidences of forceful authentication at ATMs and other places have been reported in many countries and are common examples of crime where the accused force the victims to login by threatening or manhandling. The proposed system provides an edge by capturing the images during successful authentications too, thereby providing an option to track events of forced entry into the homes.

IV. DESIGN AND IMPLEMENTATION

The design of any Embedded system is carried out by following the design lifecycle which involves identifying the requirements of the system, laying down specifications regarding the usage of hardware and software tools, optimization, detailed design of hardware and software coding, integration of hardware and software modules, testing and manufacturing followed by maintenance and upgrade. We take the same approach to explain about this project though the last two steps may not be applicable in this context.

A. *Requirements*

The requirement of the system is a fingerprint scanner which authenticates or declines the user requests, a webcam which takes pictures, a provision to send SMS to a pre-defined mobile number and a motor which runs to open the door.

B. *Specifications*

Hardware specifications

- AT89S52
- Fingerprint scanner R305_V1.6
- GSM modem SIM 900A
- Webcam (Genius video cam model NB1)
- 16x2 LCD display (HD44780)
- DC motor (100 rpm)
- Power Supply for 5V
- Top win universal programmer

Software specifications

- Keil IDE
- Proteus ISIS Professional
- Express PCB or OrCAD

C. *Hardware and Software Design*

Hardware flow

Initially a block diagram of the entire system was made and then the circuit level schematic was designed.

The following Fig. 1, shows the block diagram

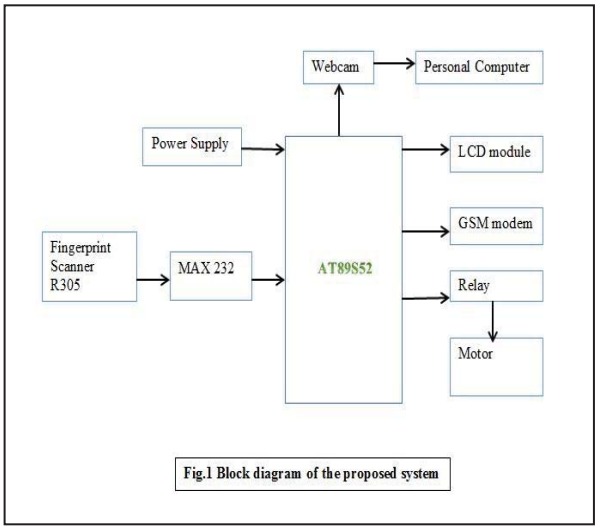

Fig.1 Block diagram of the proposed system

The fingerprint scanner operates with TTL logic. So a voltage level converter i.e., MAX 232 was used to interface. The LCD display unit is optional.

Software flow

A flowchart describing the sequence of operations was drawn and then the programming was done in Embedded C using the Keil IDE and the HEX code was generated.

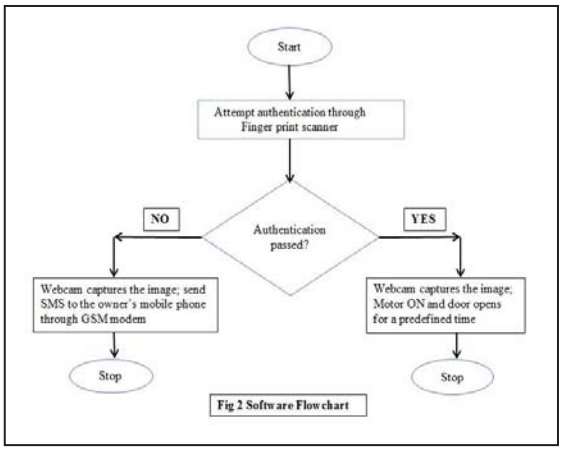

Fig 2 Software Flow chart

Hardware design

The circuit level design was implemented in the Proteus software. Keypad, virtual terminal were used in place of fingerprint scanner and GSM modem respectively. The Hex code which was generated through Keil was ported to the microcontroller in the Proteus environment. Simulation was carried out to verify the functionality of the concept.

The figures 3,4 below show the Proteus ISIS screenshots

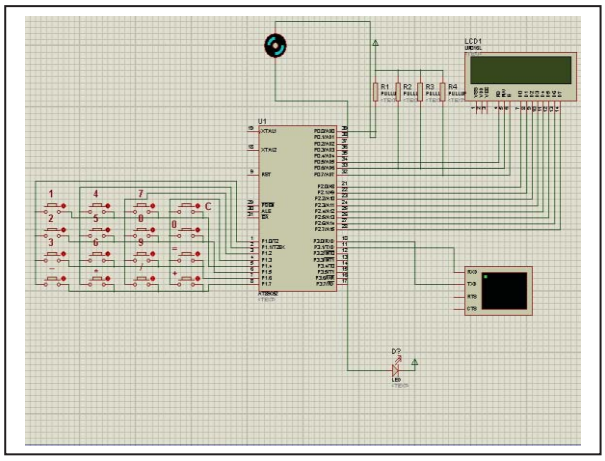

Fig 3. Circuit level schematic in Proteus ISIS

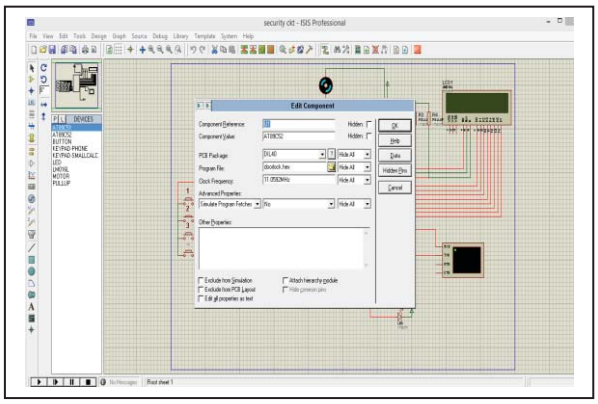

Fig 4. Porting HEX file into Proteus ISIS

After the simulation, the hardware prototype was implemented. All the required peripherals were procured and the interfacing was carried out.

Software design

The programming routines for the fingerprint module, webcam, LCD display and GSM module (using AT- attention commands) were being developed simultaneously.

D. Hardware software Integration

After successful code development and hardware interfacing, the hardware software integration was done by burning the HEX file into the microcontroller through the Top win programmer. An evaluation board for AT89S52 was made use of; to which the fingerprint, GSM and webcam were attached and the system prototype is shown in Fig 5.

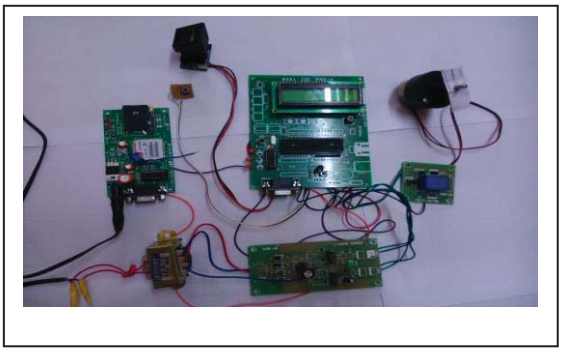

Fig 5. Hardware Prototype

E. Testing

The hardware model was tested by registering the fingerprints of different users. In case if the features are not registered properly, the device asks to undergo scanning once again. After the enrollment phase, the device was ready for operation. Figures 6-10 show that under different conditions, the circuit has functioned in the desired manner.

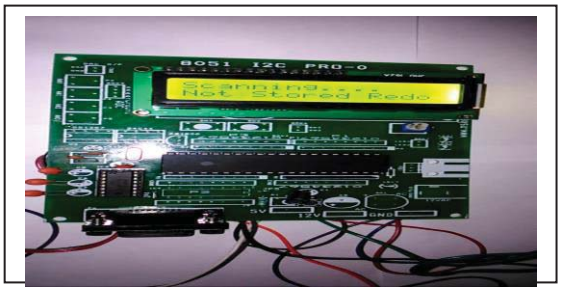

Fig 6. Circuit prompts the user to re-scan

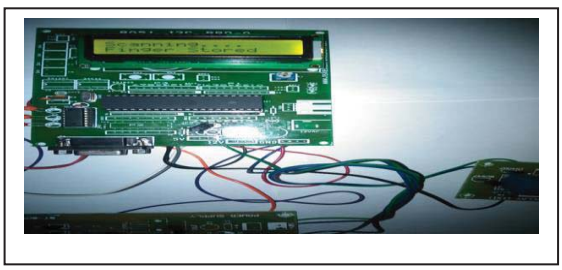

Fig 7. Scanning successful, fingerprint stored

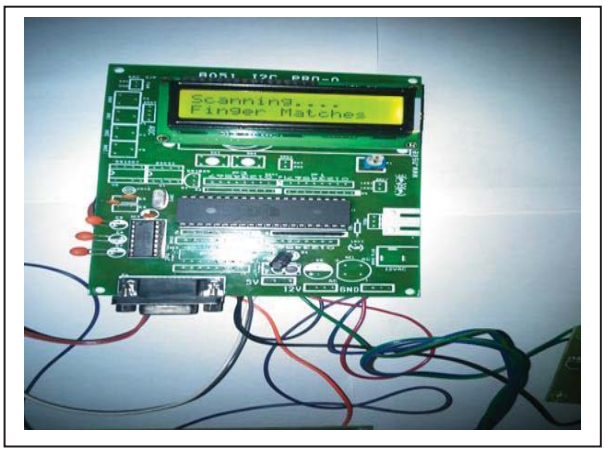

Fig 8. Authenticated user

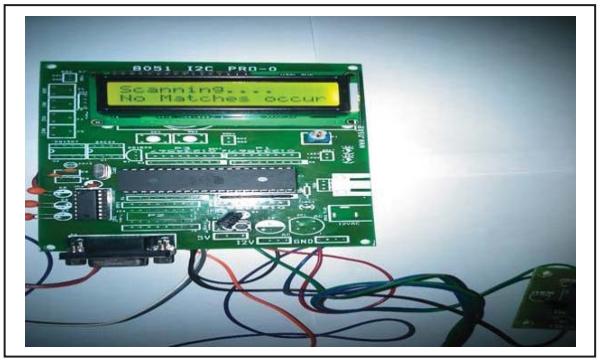

Fig 9. Authentication fails

Fig 10.SMS on owner's phone in case of imposters

Thus the desired functionality was obtained from the hardware prototype. After successful authentication, the microcontroller activates the DC motor through the ULN driver and relay circuit which opens the door for a predefined time of 30 seconds (which may be programmed as per the user's choice) and then closes the door. If the person misses out the entry during this time, he/she has to undergo the authentication test again.

The following Table I gives a brief description of the important hardware components used in this project.

TABLE I: KEY HARDWARE MODULES

Hardware module	**Specifications**		
	Description	***Product number***	***image***
Fingerprint sensor	Optical sensor, 500 dpi, can hold 250 fingerprints, 1:N matching	R305_V1.6	
GSM modem	Dual-band,GPRS capability, SIM holder, RS 232 serial communication, variable baud rate, AT commands	SIM 900A GSM/GPRS modem	
Webcam	Wired USB, 0.1MP, image recording BMP, JPEG format	Genius video cam model NB	

V. CONCLUSION AND FUTURE SCOPE

We would like to conclude that the digital door lock was designed and implemented using fingerprint, webcam and GSM modules. The working model was designed and tested. The system meets the desired requirements. The system offers a reliable and simple method to provide secure access to homes. It operates in real time and interacts with the real world. It ensures correctness and accuracy. The final product has to be manufactured by considering real world constraints such as the form factor, power consumption, cost, speed of operation etc.,

Future Scope

As discussed in [3], a mechanism of OTP authentication may also be used in addition to the fingerprint module. Other improvements such as interfacing a real-time clock (RTC) to the microcontroller to keep track of the events and corresponding calendar daytime. A pressure or vibration sensor may be interfaced such that the sensor can detect any event of tampering with the machine and raise an alarm using a sound buzzer. Using IoT (Internet of Things), the webcam can send email to the house owner's smartphone which is a viable option compared to the SMS or MMS techniques.

ACKNOWLEDGMENT

The authors would like to acknowledge the facilities and infrastructure available at the microcontroller lab and embedded systems lab in the School of Electronics Engineering, VIT University, Vellore. We would also like to appreciate the expertise and guidance obtained from the TIFAC core, VIT Vellore.

Mesh IP Video Surveillance Systems Model Design and Performance Evaluation

C. S. Lubobya , M .E. Dlodlo, G. De Jager and A. Zulu, *Members, IEEE*

***Abstract*— This paper proposes a model for Internet Protocol (IP) mesh video surveillance systems and presents the performance evaluation of AODV and OSPF routing protocols in wireless mesh video surveillance system. A wireless mesh video surveillance network consists of IP cameras linked to mesh routers which are then linked to the mesh gateways. Local monitoring can be done by inserting a switch or router between the gateways and the Internet while remote monitoring can be done through the Internet. Routing provides selection, constructing and management of routes in order to maximise Throughput and minimise video Packet Losses, End-to-End delays and Jitter. Results show that the OSPF routing protocol outperformed the AODV in Throughput, Packet Loss, End-to-End delay and Jitter terms with a throughput advantage of 35%.**

***Index Terms*— Wireless Mesh Networks; Video Surveillance; Routing Protocols ; Throughput; End-to-End delay; Jitter.**

I. INTRODUCTION

There is an increased use of wireless mesh network (WMNs) in homes, industries and service organizations for data and voice applications. Wireless Mesh Networks are communication networks consisting of wireless devices, with single or multiple radio interfaces, for the purpose of receiving and transmitting defined information type. Video streaming, broadcasting and video surveillance applications are some of the applications in which wireless Mesh networks can be used. WMN have the advantage that they provide large coverage area, have low backhaul connection costs, prolong battery life for end-users and above all provide connectivity to users without line of sight[1]. The architectural design differs depending on application and number of source nodes connected or anticipated to be connected. Three common network architecture designs have been proposed in [1] [2]: infrastructure/backbone, client and hybrid infrastructure-client type. Devices making up the WMN architecture include a combination of: mesh clients (MCs) and /or non-mesh clients, Access Points (APs), Mesh Routers (MRs) and Mesh Gateways (MGs).

For the infrastructure/backbone based WMN, mesh clients and mesh routers connects to the Internet through mesh gateways using wired cables. Mesh routers relay information from mesh clients to the mesh gateways, which routes the information to the Internet. Both the mesh routers and gateways have multiple interfaces. Fig.1 illustrates the infrastructure based WMN.

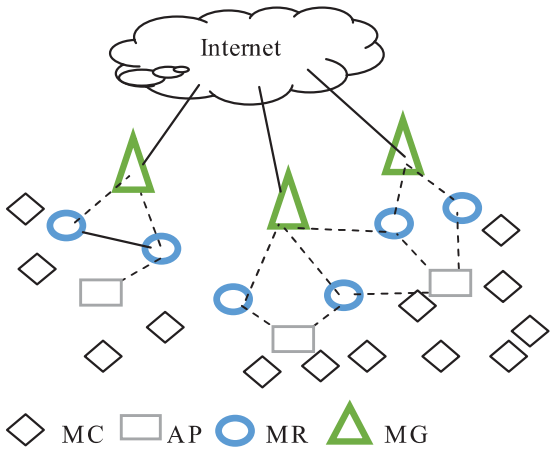

Fig. 1: Wireless Mesh Network Infrastructure

In client WMN, mesh clients connects to each other as peers. There are no wired connections, mesh routers and gateways as each mesh client is a standalone device with routing functions [3]. The hybrid WMN combines the infrastructure and client WMN whereby internet, Wi-Fi, sensor and connectivity is provided by the infrastructure component while the client WMN part provides routing and configuration functions.

Routing protocols provides selection, construction and management of routes. It also maximises throughput and minimises video packet delays[2]. Additionally, Jun and Sichitiu suggested that general Mobile Ad-hoc Networks (MANET) routing protocols can be used in WMN[4].

This paper proposes a model for IP mesh video surveillance system and presents the performance comparison of AODV and OSPF routing protocols for a meshed video surveillance system operating in the Meshed Wi-Fi environment. The next section gives related work on routing in mesh networks. Section III, discusses the wireless mesh IP video surveillance system in detail and explains the functions of each unit. The detailed description of the ad-hoc and dynamic routing

protocols is given in section IV. Section V describes the simulation set up in details while section VI discusses the results obtained in simulations. The conclusion is given in section VII.

II. RELATED WORK

A new Mesh Routing Protocols (MRP) was proposed and its performance evaluated and compared to the traditional mobile ad-hoc network routing protocols in the work by Jun and Sichilui [4]. MRP outperformed the general purpose MANET protocols in terms of routing overhead, packet delivery ratio, network throughput, end-to-end delay, and average hop-count [4]. Broch et al.[5] did a performance comparison study of multi-hop wireless ad hoc network routing protocols. They configured 50 mobile nodes connected in multi-hop fashion and observed that the Dynamic Source Routing (DSR) and Ad-hoc On-demand Distance Vector (AODV) performed particularly well, delivering over 95% of the data packets regardless of mobility rate compared to Temporarily Ordered Routing Algorithm (TORA) and Destination-Sequenced Distance Vector (DSDV) protocols. Shubat and Essied [6] compared the performance of the AODV protocol for single and multi-radio scenarios. They observed that the AODV performed well in a multi radio in terms of throughput, end to end delay and packet loss. Campista et al.[7] evaluated the performance of different WMN routing metrics; Hop count, Expected Transmission Count (ETX), Expected Transmission Time (ETT), and ML metrics. They implemented and assessed them using the OLSR routing protocol. Chissungo and Blake [8] in their review on ad hoc routing protocols categorised and discussed the inner workings of proactive, reactive and hybrid ad- hoc routing protocols.

This paper makes the following contribution: firstly it proposes a network model for wireless mesh IP video surveillance by exploiting the advantages of mesh networks discussed in section I. Secondly, the paper investigates the performance of OSPF and AODV routing protocols for such a model in terms of throughput, jitter, packet loss and delay.

III. WMN VIDEO SURVEILLANCE MODEL

Fig.2 shows a wireless mesh video surveillance model. It consists of several Wi-Fi IP cameras; wireless Mesh Routers (MRs) and Mesh Gateways (MGs) to form an infrastructure based video surveillance system. The IP cameras are not meshed clients, that is, they do not send surveillance video from one IP camera to the other. The cameras connect directly to the mesh routers. This way the hop count is minimized as Video surveillance information routed to the MRs only hops from IP cameras to each of the MRs and the MGs. Hop count is the number of hops between the IP cameras and the MGs [1]. A detailed description of each unit in the model now follows.

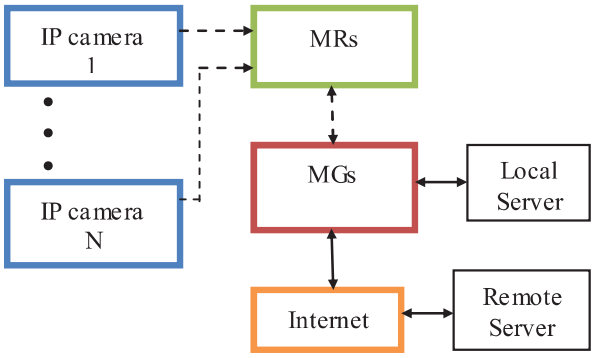

Fig. 2: Block Diagram of a Mesh IP Video Surveillance System

A. IP cameras

An IP camera or network camera , is a device that digitizes and processes analog images or videos, encodes them internally and then transmits the video information digitally over a wired or wireless connection to a computer or similar device [9].The Wi-Fi video surveillance IP cameras consists among other components the lens, the Charge Coupled Device (CCD) or the Complementary Metal Oxide Semiconductor (CMOS), the analogue to digital converter (A/D) and the Digital Signal Processor (DSP). There are various types of IP cameras: dome, box, bullet, covert, Pan Tilt Zoom and the like cameras. Some of these camera types have Wi-Fi functionality.

In general, the network bandwidth (B) can be calculated from the knowledge of number of IP cameras, frame size and frame rate as:

$$B = \frac{FS \times FR \times N \times 8}{1024} \quad (1)$$

Where the frame size in Kilobytes is, is the frame rate and is the number of IP cameras. The constant 8 is included since there are eight bits per byte. However, the actual bandwidth consumed by each router in the network can be measured and is called the flow throughput. Flow throughput (T_{flow}) is the summation of the traffic sent by MRs and received by the MGs over the observation period [10]. It is a measure of the bandwidth consumed by each router in the network.

$$T_{flow} = \frac{\sum_{k \in K} \left| \, rec.bits(n \to k) \, \right|}{t} \quad (2)$$

B. Mesh Routers and Gateways

These are wireless multi-interface devices operating in the ISM band of frequencies. Typically, in this model we used 2.4GHz unlicensed frequency. Mesh routers provides the first access or contact point for the IP cameras. They then relay the surveillance information to the mesh gateway routers. The mesh gateway has Ethernet connectivity to the internet. This

1570211897

work involved creating custom mesh routers and mesh gateways. We created multiple radio interfaces and configured the new devices for video surveillance use.

C. Internet

Surveillance information can be routed to the local storage servers and monitoring displays or to the remote monitoring devices via the internet. A category 5 or 6 Ethernet cable is recommended for the MG-switch-Internet link connectivity. The Internet can be accessed anywhere using web connectivity and therefore it provides a link for remote monitoring.

D. Local and Remote Monitoring

Local monitoring can be placed anywhere between the mesh gateways and the internet. Practically, that would mean inserting a switch or router (not shown) between the mesh gateways and the internet. The local and remote monitoring consists of video servers, one or several display units and/or personal computers. Some modern, Wi-Fi IP cameras do have provisions for a memory card through which surveillance information can be stored before transmission to the nearest mesh router."

IV. AD-HOC AND DYNAMIC ROUTING PROTOCOLS

In this section, a detailed discussion of ad-hoc and dynamic routings protocols is done in order to determine the possibility of use in WMN video surveillance systems.

A. Ad-hoc Routing Protocols

Ad-hoc networks are infrastructure-less networks in which every node in the network can communicate to the next node via a wireless link. Ad-hoc routing protocols are primarily employed in Ad-hoc networks. We investigate their performance in this work considering that part of WMN design is infrastructure-less. These protocols are broadly classified as proactive, reactive and hybrid ad-hoc routing protocols.

In proactive or table-driven routing protocols, each node continuously updates it routes to every other node in the network and keeps at least one route to any destination in the network[7][10]. Routers periodically transmit routing information throughout the network and maintain a consistency routing table. Examples of proactive ad-hoc routing protocols includes: DSDV, Wireless Routing Protocol (WRP), Global State Routing (GSR) and Cluster-head Gateway Switch Routing (CGSR). One major drawback of these type of ad hoc routing protocols in highly dynamic network topology is that a large amount of resources is needed to keep routing information up to date [11].

With Reactive or On-Demand Routing protocols, a node only requests the route to the destination if it has a packet to send [7] [11]. The major advantage of on-demand protocols is that communications overheads are reduced as requests are only send when there is a packet to transmit. However, that potentially increases delay during transmission due to route research process. Examples of reactive protocols include AODV, DSR, Cluster Based Routing Protocol (CBRP), Temporally Ordered Routing Algorithm (TORA), Associativity-Based Routing (ABR), Location Aided Routing (LAR) and Signal Stability Routing (SSR).

Alternatively, they can be classified as source initiated, power aware, hybrid, location aware, multicast and the like as categorised by Boukerche *et al* [12]. Hybrid protocols combine features of proactive and reactive protocols. The fundamental roles of these protocols are essentially the same: increasing or maximising throughput while reducing packet loss, control overhead and energy usage [12].

B. Dynamic Routing Protocols

Dynamic routing protocol are a class of routing protocols in which a router learns about the network topology by announcing its presence and sharing its available routes with other routers on the network [13]. Existing routers update their routing tables every time there is new router addition on the network; thus routers learn about each other on the network. Dynamic routing protocols have two major advantages over static routing protocols: scalability and adaptability [13]. As Scalable routing protocols they enable network to grow more quickly and in a large way, and adapts well to network topology growth or failure of one or more network components[13]. Other advantages are that configurations are less prone to error and consume less time to configure and maintain.

Dynamic routing protocols are divided into interior and exterior gateway protocols. Interior gateway protocols are used for routing inside an autonomous system.ie within the network systems. Exterior routing protocols are used for routing between autonomous systems and example is the BGPv4 routing protocols. Interior gateway protocols are further divided into Link State Protocols and distance vector protocols.

Link state protocols selects the best routing path by calculating the state of each link in a path and finding the path that has the lowest total metric to reach the destination [13]. The best route for data is calculated based on cost. Once convergence occurs, protocol traffic is limited to changes in specific links. Examples include: Intermediate-System to Intermediate-System (IS-IS), Open Shortest Path First (OSPF), etc. With OSPF a complete topological database of all connections in the local network is maintained and each router calculates from its data structure the shortest path tree. This path tree describes the shortest path to each destination address and specifies the nearby router to send to for each communication [13].

Distance Vector Protocols selects the best routing path based on a distance metric and an interface [13]. It uses a distance calculation plus an on-going network interface to choose the best path to the destinations network. Examples of distance vector protocols are Routing Information Protocol (RIP) versions one and two, Interior Gateway Routing Protocol (IGRP) and Enhanced Interior Gateway Routing Protocol (EIGRP). When a change occurs in the network, the router with the change informs other routers.

V. PERFORMANCE EVALUATION METHODOLOGY

For evaluating the performance of the model under varying routing protocols and channels assignment schemes, we used an H.264/AVC CIF video with 352x268 resolutions,

1570211897

10 frame per second video and having a payload of 3216 bytes. OPNET Modeller 14.5 network simulator tool was used in simulations.

Two scenarios were adopted in our simulation based on the model of Fig.2. Scenario one consists of a mesh video surveillance system with 28 IP cameras with half of the cameras clustered around and linked to MR1 and the other half around MR2. All IP cameras are single mode, consisting of one wireless LAN interface in the IEEE 802.11g, 2.4GHz unlicensed ISM frequency band. The two mesh router MR1 and MR2 are also wirelessly linked to the two mesh gateways, MG1 and MG2. Like the IP cameras, mesh routers and mesh gateways are all operated in the IEEE 802.11g and the buffer size set to 1,024,000 bits. Further, the MR and MG have all been custom created with multiple wireless interfaces and have been configured as illustrated in Table 1. Care has been made to disable wireless access functionality on the IP cameras since the intention is to transmit video surveillance information in one direction, typical of surveillance systems. We then configure OSPF routing protocols and IP addresses on the mesh and non-mesh device interfaces. The system is run for 20 minutes and throughput, end to end and jitter values plotted and compared to the second scenario.

TABLE 1: CONFIGURATION OF MESH DEVICES

Mesh device	Interface	channel	Frequency (MHz)
IP camera cluster 1	1	1	2412
IP Camera cluster 2	1	2	2417
MR1	3	1 4 6	2412 2427 2437
MR 2	3	2 5 7	2417 2432 2442
MG1	2	5 6	2432 2437
MG2	2	4 7	2427 2442

The second scenario is duplicated, retaining the IP cameras and mesh devices parameters setup, including geographical position of all devices. The only change made is the type of routing protocol; the AODV ad-hoc routing protocols is now configured. The start time for all simulations was 100s and end time was 1200s.

For a valid video transmission packet loss should not exceed 1% [14], otherwise throughput needs would not be satisfied. End to end delay should be less than between 150ms and 200ms [14] [15] while jitter delay for one way traffic should be less 60ms [14]. The two scenarios are run under strict assumptions that: no other programme is running during simulations, including web browsing. Simulating devices are assumed not to have any external interfering signals.

VI. RESULTS AND DISCUSSION

Fig.3 shows the results of the throughput measurement over the simulation time of 1200s or 20minutes based on (2) for 28 cameras. As seen from the figure when the mesh surveillance system was configured with OSPF routing protocol, an average throughput of 6.63Mbps was measured in contrast with 4.31Mbps for the AODV routing protocol. That represents a 35% throughput increase for OSPF under similar conditions. This can be attributed to the fact that with AODV protocol, Mesh routers gets flooded with surveillance video information bits. Flooding tends to make the network inefficient since connections happen on nodes that are close to each other, in this case IP cameras and mesh routers. OSPF controls flooding of mesh devices. Control packets should be sent to close nodes in order to make the network efficient thereby improving capacity.

The throughput versus number of IP cameras is shown in fig. 4. The throughput under OSPF routing protocol increases linearly with increase in number of IP cameras upto 28 cameras. Beyond 28 cameras the throughput maintains a constant value of 6.62Mps. With AODV protocol, throughput too increases with increase in number of IP cameras. However, beyond 28 cameras throughput begins to drop. OSPF performs better than AODV regardless of the number of IP cameras. Throughput for either routing protocols type does not exceed the calculated capacity (B) plot based on (1).

In fig. 5, we show the packet/bit loss comparison between the two routing protocols for the two scenarios. Both scenarios are loaded with 6.63Mbps. A bit loss of 0.44mbps was recorded for the AODV and none for the OSPF. AODV packet loss percentage of the total load was 6.58% which is above the accepted percentage of below 1%. These bit loss results when compared to results of fig. 4, further explains why throughput is low.

Fig. 6 shows the measured results for End-to-end delay. The OSPF routing protocol outperformed AODV with 0.31ms End-to-end delay compared to the 6.24ms measured for the AODV. The AODV and OSPF performance are all within the acceptable limit of 150ms. However, increasing the number of IP cameras, frame size and frame rate could possibly make AODV End- to- End delay values exceed the 150ms limit.

The average jitter variations measured results is shown in fig. 7. For easy comparison, a logarithmic scale has been used. AODV has a high log average jitter value than the OSPF. In time terms this represents an average jitter of 18ms for AODV compared to 5.34 μs for OSPF with both values within recommended limit of less 60ms for video transmission. The good performance of the OSPF can be attributed to the shorter hop network formed thus reducing the size of the mesh topology and creating sub-optimal routes. AODV Queues video packets when discovering new routes causing packets to be dropped, minimising throughput and increasing latency.

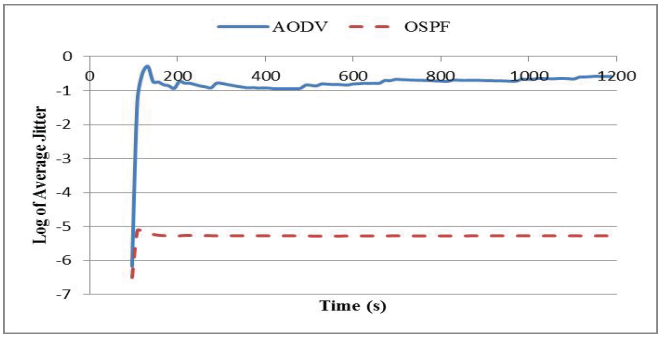

Fig.7: Jitter measurements for the two scenarios

VII. CONCLUSION

This paper has proposed a mesh IP video surveillance model and presented the performance comparison between OSPF and AODV routing protocols in the IEEE 802.11g, 2.4GHz mesh environment. The OSPF routing protocols outperformed the AODV routing protocols in throughput by 35% for 28 cameras; OSPF performs better than AODV regardless of the number of IP cameras. The OSPF routing protocols also has better packet loss, End-to-End delay and jitter values than the AODV, making OSPF a better routing protocol for video surveillance applications. Going forward, an investigation on effect of mesh topologies and routing algorithms on throughput, packet loss and jitter is suggested.

***Abstract* - The paper presents a novel color image authentication scheme by variably watermarking bits of four secret images within the carrier image imparting multi verification criteria applicable for the wireless platform. Secret bits are hidden into all the pixel bytes of the sub image block using distinctly different dynamically variable bit insertion approaches on each of them within the spatial domain values. Additionally bits are also inserted with different sequencing patterns on the pixel bytes of the sub blocks involving the bits of the same or the different secret images injecting robustness and reliable authentication. Apart from that secret bits are randomly rotated on these pixel bytes ensuring strong security and resistance against the image processing attacks. Threshold based highly variable and randomized coding ranges are further adopted on these pixel bytes eventually strengthening the robustness against the attacks in combination with the secure bit insertion policies needed for the wireless domain. Delicate noise adjustment on these bit embedded pixel bytes optimizes the distortions against the attack fragility limits and ultimately improving the watermarked image quality even with very high data pay load capacity. This dynamically randomized separate encoding strategies for the different multi-image secret bits actually enhancing the watermark sustainability as well as secure authentication scenarios. Experimental results have confirmed outstanding watermark imperceptibility by far as compare to the other existing schemes while pretty decent robustness is also achieved against the image processing operations with the multi watermark insertion concept encouraging utilization of the approach under the public wireless environments.**

Keywords—Steganography;Multiple-Image-Hiding;Image Authentication;Multi-Image-Watermarking;Variable-Bit-Hiding–Sequence;Variable-coded-watermarks.

I. INTRODUCTION

Advancement in digital transmission demands secure communication as well as strong authentication scenarios where Steganographic approaches are often utilized for hiding the secret images within the carrier image authenticating its ownership. In this context color image authentication can be considered more suitable due to their wider ranges of color variations and having enough redundant information for hiding the secret bits [2-4]. In extension of this multiple image watermarking is further explored in recent times involving multiple verification phases and they are relatively robust as compare to the single image watermarking concept [5,6]. This idea actually encourages reasonable recovery of at least one of the hidden images under the common image processing operations [7-10] and is quite useful for synchronously embedding the watermarks for the multiple users [5-15].

In the present scenario image authentication with multiple watermarks can be considered very vital in the wireless domain in order to reliably and efficiently validating the transmission of digital e-documents. Wireless environment is basically susceptible to illegal unauthorized access and its signal transmission also suffers from severe distortions due to the heavy noise inclusion within the host signal [17]. So multi image watermarking within the transmitted host image not only resists the total destruction of the hidden watermarks but also introduces strong authentication for this domain [5-9,17].

A. Related Works

Among the existing works [3], in 2009 divided and encrypted multiple parts of a binary watermark image and embedded them into the blue components of the host color image for achieving robustness but the process is somewhat non blind in nature. Then [4], in 2010, watermarked three small grey-scale images in the Red, Green, and Blue channel with their respective encryption keys using a chaotic map based technique where embedding positions and the watermark bits are encrypted using the pair coupled maps. The approach reflects marginal watermarked image quality while the authenticating images are mostly affected by attacks. Reference [5], in 2010 embedded 24 binary images within the mid frequency components of the DCT as the RGB watermark and also inserted 12 binary images using the different LSB substitution techniques while the watermark images are

differently scrambled for different domains before embedding. Then [6], in 2011 suggested a multiple grey-scale based watermarking scheme for medical images using DWT and repetitive BCH encoded watermarks which are destroyed under the cropping and contrast attacks. Reference [7], in 2013, developed a technique using DWT where two small watermarks are embedded successively one after the other and also they are segmented between the odd rows and the even rows but the qualities of the images were affected to an extent even with the small watermarks. Then [8], in the same year proposed a technique for embedding multiple gray scale watermarks in the DCT and spatial domains separately with fuzzy-c means clustering that identifies the small zones of watermark embedding. Although the approach shows robustness but the watermark imperceptibility is not very high. Reference [9], in 2013 added multiple grey scale watermarks by segmenting the host image into non overlapping blocks by means of space filling curve and block DCT energy. Watermarks are added by modifying the respective block singular values but 3-level ENOPVD decomposition introduces greater overhead with increasing distortions also. On recent concepts [10] in 2014 showed binary double image watermarking based on the position property of the grey scale cover image although it has not resulted relatively good quality of the extracted images. Reference [11] in 2014 also highlighted watermarking of four binary images where DWT is applied on the non-overlapping sub blocks while the most densely packed information blocks are identified based on the texture for watermark insertion. Reference [12], in the same year demonstrated gray scale based invisible multiple biometric watermarking approach in the different frequency bands with re-watermarking concept where the interference of the different watermarks are to be reduced considerably. Reference [13] in the same year embedded two watermarks one after the other on the host image with different embedding methods like additive, multiplicative and hybrid using the DWT but the quality of the extracted images under the noise attacks are not that great. Then [14], in 2015 proposed a technique where three combined binary watermarks in a 3-D watermarking sequence were added into the sub image blocks with best abundant texture information and the approach shows at least one watermark recovery against the common image processing attacks. Reference [15], in 2015 introduced two level watermarking for biometric images where the sparse measurement information on fingerprinting while the iris bio-metric template using CS theory was generated for secure watermarking but the watermarked image quality was low.

B. Motivation

Existing works [3-15] are mainly focused on binary or gray scale images supporting very little data pay load capacity while every pixel bytes of a sub image block are not considered for watermarking that would have eventually increased the availability or robustness aspects of the secret bits. In addition these works have very rarely highlighted the different bit sequencing patterns on the sub block pixel bytes involving the secret bits of the same or the different images for further tackling the robustness issues. Although some approaches have adopted different bit insertion techniques for embedding successive watermarks but hardly any work that proposes distinctly different dynamically variable bit insertion policies on each of the different pixel bytes of the sub image blocks. In fact this successive watermark insertion does not guarantee the quality of the watermarked image while they are destroyed with severe cropping attacks.

In view of these unaddressed issues especially for the wireless domain the work adopts distinctly different dynamically variable secret bit insertion strategy for each of the pixel bytes of the sub image block with extreme randomization. Also multi-watermark bit embedding is done sequentially through the threshold based variable range driven bit insertion approach that somewhat enhances the robustness as compare to the successive watermark embedding policy. Additionally different secret bit sequencing patterns involving the bits of same or the different watermark images are incorporated in a more randomized manner onto the separate pixel bytes of the sub image blocks. This idea basically strengthens the availability cum robustness aspects of the secret bits and even adding an extra layer of security on the authentication scenarios apart from the secure bit insertion criteria. Avove all partial noise adjustment on the bit inserted pixel bytes not only optimizes the distortions against the robustness but actually imparts further randomizations as well.

The paper is organized as follows; sec.2 describes the bit insertion and extraction process, sec.3 shows the experimental results, sec.4 presents the social application, sec.5 gives the conclusion followed by acknowledgement and references.

II. The Technique

A. Bit Insertion Algorithm

Input: One color cover image and four secret color images.
Output: One watermarked color image having hidden images.
Method: Cover image is divided into 2x2 non overlapping sub block of pixel bytes for inserting one secret bit into each pixel byte resulting four bit insertion per sub matrix block. These four bits are hidden on a random rotational sequence starting from the pixel byte position 'I' of the sub matrix decided from the matrix number 'Mat' as I=[sum of the digits of Mat+Digit reverse value of Mat+(Mat+digit reverse value of Mat)%4]%4
Steps:
1. Secret Bit Insertion for the First matrix Element-
1.1 Last two digits of the matrix number D2D1 written in a reverse manner and the resultant decimal number is then modulo with 4, while the mod value resulted between 0-3 is added with 3 to obtain the range value M as M=(D2D1)%4+3.
1.2 The upper(U) and lower(L) multiple value of M with respect to the first matrix element number is then considered and the respective reference point R of the range is calculated as the round off value for the expression R=(L+U)/2.
1.3 Now for inserting the secret bit '1' or '0', the output coding C will be performed as – for inserting '1', if M=3, then C=R, otherwise C=R+1, but for inserting '0', C=R-1 always.
1.4 The coded value C thus obtained will be written in the first element position of the sub matrix block as the output value.
2. Secret Bit Insertion for the Second matrix Element-

2.1 Lower (L) and upper (U) multiple number of 6 with respect to the second element value is considered. **2.2** Matrix number (Mat) is then modulo with L and the resultant value is again modulo with 3 to obtain value v1(0-2). **2.3** The value v1 is then added with 2 to generate v2 (2,3,4) **2.4** Now add the value of v2 with L to obtain the reference R. **2.5** For inserting bit '1' coding C=R+1, and for inserting '0' coding C=R-1, and C is written in the second element place.
3. Secret Bit Insertion for the Third matrix Element-
3.1 Lower (L) and upper (U) multiple number of 6 with respect to the third element value is considered. **3.2** Matrix number (Mat) is then modulo with U and the resultant value is again modulo with 3 to obtain value v1(0-2). **3.3** The value v1 is then added with 2 to generate v2 (2,3,4). **3.4** Now add the value of v2 with L to obtain the reference R. **3.5** For inserting bits '1' coding C=R+1, and for inserting '0' coding C=R-1, and C is written in the third element place.
4. Secret Bit Insertion for the Forth matrix Element-
4.1. Lower (L) and upper (U) multiple number of 4 with respect to the fourth element is considered and the average of these two values are taken for identifying the reference point. **4.2** For inserting bits '1' coding C=R+1, and for inserting '0' coding C=R-1, and C is written in the fourth element place.
5. Step 1 to 4 is repeated until all the secret bits are finished.
Bit Insertion Example- Let the matrix number N=24 with its pixel byte elements are [21,19,23,15] and the secret bits are to be inserted as (1,0,1,0) in the given element sequences. Now for the first element M=[(42)%4+3]=5, L=20,U=25, and R=Round[(20+25)/2]=23, hence C=(R+1)=24. Then for the second element L=12, U=18, gives v2=[(24%12)%3+2]=2, and R=12+2=14, hence C=R-1=13. Now for the third element L=18, U=24, so v2=[(24%24)%3+2]=2, and R=18+2=20, hence C=R+1=21. For the fourth element L=12, U=16, so R=(12+16)/2=14, produces C=R-1=13. So the final secret bit inserted matrix is [24,13,21,13] which will be transmitted.

B. Bit Extraction Algorithm

First of all the correct random circular sequence of inserted bits are identified through the derivation of starting index number I, as it was computed in the sender side part since the concerned matrix number 'Mat' is known to the receiver also.
1. Bit Extraction from the First Matrix Element-
1.1 Repeat step 1.1 and 1.2 as defined in the bit insertion process where the upper and lower multiple number values are determined with respect to the received coded value C for computing the same reference point R since the concerned matrix number is known to the receiving end also. **1.2** If code C≥R, then 1 is extracted; otherwise '0' is extracted.
2. Bit Extraction from the Second Matrix Element -
2.1 Identify upper and lower multiple value of 6 with respect to the received coded value 'C' as it lies within this range. **2.2** Repeat steps 2.2 to 2.4 as defined in the bit insertion process for computing the same reference point R since the concerned matrix number is also known at the receiving end. **2.3** If code C≥R, then 1 is extracted; otherwise '0' is extracted.
3. Bit Extraction from the Third Matrix Element-
3.1 Identify upper and lower multiple value of 6 with respect to the received coded value 'C' as it lies within this range. **3.2** Repeat steps 3.2 to 3.4 as defined in the bit insertion process for computing the same reference point R since the concerned matrix number is also known at the receiving end. **3.3** If code C≥R, then 1 is extracted; otherwise '0' is extracted.
4. Bit Extraction from the Fourth Matrix Element-
4.1 Identify immediate upper and lower multiple value of 4 with respect to the received code 'C' as it lies in this range. **4.2** Compute the average of these two values as obtained in step 4.1 to obtain the same sender side reference point R. **4.3** If code C≥R, then 1 is extracted; otherwise '0' is extracted.
Bit Extraction Example- The received matrix [24,13,21,13] is used for extraction of four hidden bits with its elements are coded C values. For the first element L=20, U=25, based on C value, so R=23 as computed like the sender side, and Since C>R, hence '1' will be extracted. For the second element L=12, U=18 based on the C value, and R=14 calculated like the sender side. Now C<R implies '0' will be extracted here. For the third element L=18, U=24 based on the C value, and R=20 determined just like the sender side. As C>R so '1' will be extracted. Then for the fourth element L=12, U=16, based on C value, gives R=14 just like the sender side. Here C<R extracts '0' and the whole extracted secret bit set are (1010).

C. Bit Insertion Sequences

Three different cases of secret bit sequncing patterns are considered in Fig1. where the first case shows embedding of each secret image within one of the four equally partitioned non overlapping region of the cover image and hence the four pixel bytes of the sub-matrix belonging to a partcular region will hold secret bits of the same image. Another option is to embed the secret images one after the other where secret bits of the same image is actually hosted by the consecutive set of submatrices. Alternatively four different secret image bits can be inserted into the four different pixel bytes of the submatrix block satisfying the parallel bit embedding concept which actually takes care of the noise related attacks while sequntial bit insertion policy performs well under the cropping attack.

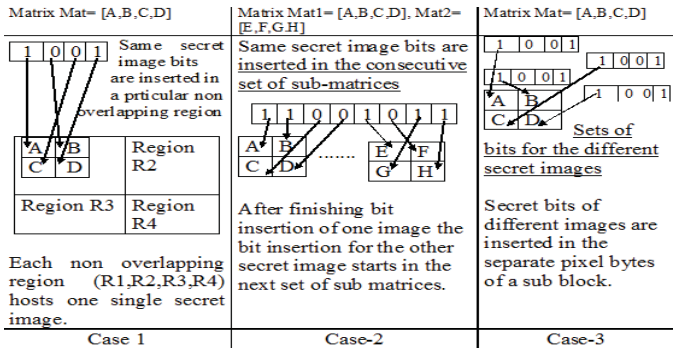

Fig.1 Different pattern of bit insertion sequences on the pixel bytes.

III. EXPERIMENTAL RESULTS

Four equal sized secret color images are watermarked within the host color image of size 512x512 maintaining its identical visual qualities as shown in Table-I. Systems are developed under LINUX using the PPM images and tested in the public wireless network platform (Wi-Fi) with Table-II reflecting excellent watermark imperceptibility in terms of higher PSNR (db), SSIM, CC and Similarity Factor (SF)[1-15] values.

TABLE I. VISUAL QUALITIES OF WATERMARKED IMAGES [16]

Original Image with Bit Insertion sequences used	Embedded image sizes 32x32	Embedded image sizes 64x64	Embedded image sizes 80x80
 Case1-(Lena)			 Case2-(airplane)			
Case3- (baboon)			

Identical histograms for the watermarked images are given in Table IV whereas Table V shows the secret watermark images used in this experiment. Since the coded pixel byte values are maintained close to their original values in several cases randomly with smaller variable coding ranges so the resulting PSNR and the other similarity parameter values are relatively higher or better than the other related existing approaches. This observation was thoroughly confirmed in Table-III which actually establishes far superior watermark imperceptibility of this scheme basically supporting very high data pay load embedding capacity as compare to most of the other recent existing works. Overall the approach has definitely guaranteed outstanding watermarked image quality and hence it is free from any kind of visual, statistical or copy attack making the scheme perfectly suitable for the vulnerable wireless domain applications. The watermarking strength in the public wireless domain is explored in Table-VI under the attacks and noise integration by studying the qualities of the extracted images.

TABLE II. WATERMARKED IMAGE QUALITY ASSEMENT

Image	Secret image sizes 32x32 (total 12288 bytes of data embedding)	Secret image sizes 64x64 (total 49,152 bytes of data embedding)	Secret image sizes 80x80 (total 76,800 bytes of data embedding)	Bit pattern sequence used

	Baboon image watermarked with secret bit insertion policy 3	

TABLE V. SECRET WATERMARK IMAGES USED AS PAY LOAD [16]

Map	Oakland	Ocean	Earth

TABLE VI. PERFOMANCE AGAINST IMAGE PROCESSING ATTACKS

Extracted secret hidden images[16] of size 80x80				
Attacked Lena (with bit sequence)	Map	Oakland	Ocean	Earth
case=1				
Cropping- 200x300 block cut from the upper right corner	SF=1.0, CC=0.99	SF=0.12, CC=0.15,	SF=1.0, CC=1.0	SF=1.0, CC=0.99
case=2				Pick noise-random speed=12, randomize=22%, Repeat=1.	PSNR= 16.75db, SF=0.33, CC=0.70	PSNR= 14.82db, SF=0.29,C C=0.69	PSNR= 18.25db, SF=0.35, CC=0.75	PSNR= 17.92db, SF=0.31, CC=0.72
case=3				
Gaussian random noise- speed=7%, randomization=9%	PSNR= 19.85 db, SF=0.38, CC=0.76	PSNR= 18.25db, SF=0.35,C C=0.74	PSNR= 19.17db, SF=0.33, CC=0.79	PSNR= 23.72db, SF=0.49, CC=0.81

Due to the dynamically variable ranges of bit encoding concept the scheme is mostly robust against the noise attacks while the region based embedding performs well under the cropping attack as shown in Table-VI. The approach encourages partial recovery of at least one of the secret images under sustainable randomized attacks maintaining sufficient visual quality of the watermarked image during transmission.

IV. Application In Wireles Platform

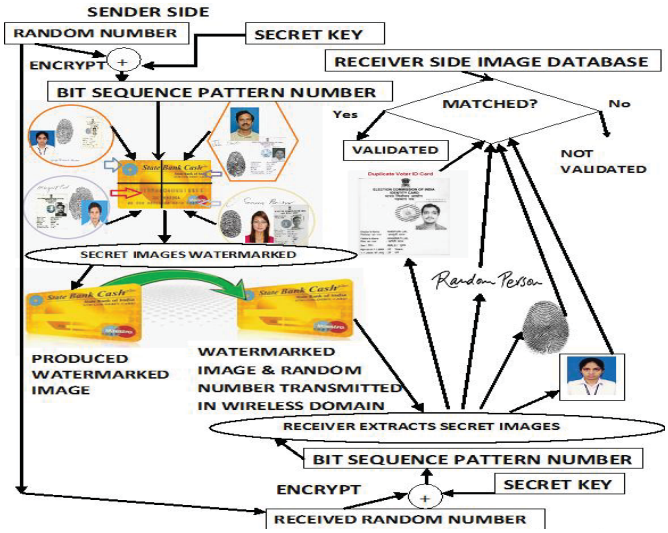

Fig2. Authenticating Digital Documents in Wireless Domain

The proposed concept can be effectively utilized for authenticating the transmitted digital documents within the wireless environment as shown in Fig2. The idea is to transmit a random number along with the watermarked image containing hidden secret images of biometric features of its owner. This random number is used to encrypt the secret key of the owner for generating the secret bit insertion sequence number used during the watermarking. These secret key and secret images are also available at the receiver side Data Base (DB) against a particular user where the received random number is again encrypted with the concerned secret key in order to identify the appropriate secret bit sequencing pattern. Using this pattern the hidden secret images are extracted from the watermarked image and then matched properly with the respective images stored in the DB to judge the authenticity.

V. Conclusion

The proposed work focuses on a secure and reliable color image authentication scheme for the wireless domain by watermarking different secret image bits with dynamically variable encoding strategies and also using different randomized secret bit sequencing patterns. Variably coded values has in fact established superior watermark imperceptibility as compare to the other approaches while the robustness is also achieved against the image processing operations promoting partial recovery of at least one of the secretly hidden images. Additionally different secret image bit sequencing patterns are quite useful for strongly authenticating the cover image under the wireless environment where the security is often compromised. So this enhanced form of color image authentication scheme for the wireless systems capable of resisting the brute force attack while also maintaining the better watermarking strength under the signal interference.

Acknowledgment

The author(s) expresses the deep sense of gratitude to all the associated staff members of the Dept. of Engineering and Technological Studies (DETS), University of Kalyani, West Bengal, India, where the work has been carried out.

***Abstract*— Video streaming is considered as one of the best compelling sources of information for several applications ranging from vehicular technology, security systems, biomedical systems to aerospace applications. Video streaming using wireless network is quite challenging and a lot of research is in progress. In this paper, design and development of a low-cost real-time wireless video streaming mote is proposed which is an outcome of a funded project. Two different variants of the proposed system are designed and tested. One uses an Arduino YUN board and the other uses a Raspberry PI board. The proposed wireless video streaming mote is aimed at moving around an area under surveillance, gathering images and transferring the same to control station. The proposed system has potential applications including assistance to vehicle drivers during reversing, parking, autonomous driving of the vehicles, driving vehicles using mobile application etc. The proposed system designed has a myriad of real-time applications for domestic requirements with social cause too.**

Keywords- Electronic Systems; Vehicles; Video Streaming; Wireless.

I. INTRODUCTION

Videos in the form of recorded videos, off-line videos and real-time video streaming are considered as the best sources of information for various applications ranging from rear-end collision warning system for cars in [1], surveillance and home security in [2], personal protection and kidnapping detection in [3], automatic detection of crimes in [4], Helmet Mounted Display Systems (HMDS) in [5], to Curiosity rover landing event from Mars in [6]. Live video streaming using wireless network is quite challenging and a lot of research is in progress.

In this paper, design of a low-cost wireless mote is proposed as shown in Fig. 1, which is capable of moving around an area under surveillance and can perform live video streaming of its path onto a mobile phone as well as laptop using Wi-fi network. This can be widely used for security purposes such as around VIP buildings and high-alert zones/ offices, wherein the mobile mote would be continuously roaming around these zones and performing live video streaming. These mobile motes can also be programmed to roam around and collect data from stationary access points in a wireless sensor network area as shown in Fig. 1.

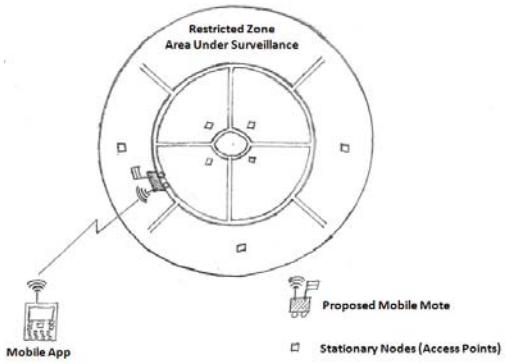

Fig. 1. Working of proposed Mobile Mote

The organization of the paper is as follows: Section II explains the design of the proposed mote using Raspberry Pi board and Section III explains the design of the system using Arduino Yun board. Experimental results and comparison between the two systems is reported in Section IV followed by conclusion, acknowledgement and references.

II. DESIGN OF PROPOSED MOTE USING RASPBERRY PI

Raspberry Pi [7] is a credit-card sized single board computer, running open-source Linux as operating system, which is designed and developed by the non-profit charitable Raspberry Pi foundation, UK. The board is designed using Broadcom BCM2835 system on a chip processor which includes an ARM1176 processor with an operating speed of 700MHz. Different models and variants of Raspberry are available in the market with the Raspberry Pi Model B+ being the latest version and the details about the comparison between different Raspberry models (Model A, Model B, Model A+, Model B+, Pi 2 and Compute) are reported in [8]. Raspberry Pi boards are being used for various applications such as design of miniaturized cloud data center in [9], novel education platform in [10], interactive home automation in [11] and many more. Considering the capabilities and features of Raspberry board, the same is employed for the proposed work.

A. Hardware Design

The block diagram of proposed wireless mote designed using Raspberry Pi with live video streaming capability is shown in Fig. 2. The Raspberry Pi board is powered using a 6600mAh power bank and the motors are powered using a 12V 1.3Ah battery to establish a complete wireless mote which is capable of moving in an area under surveillance. A Logitech make C170 USB camera is connected to the board for capturing video and an Edimax make EW-7811 wireless adaptor is used to establish wireless connectivity to other wireless nodes including phone and laptop. Texas Instruments make L293D based motor driver circuitry is designed to power the 12V DC motors for the mobility of the proposed wireless mote. Fig. 3 shows the snapshot of the hardware designed as per the block diagram shown in Fig. 2.

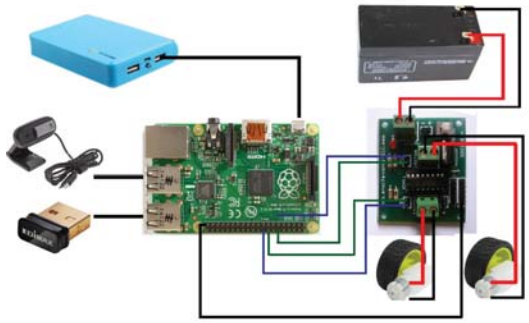

Fig. 2. Block diagram of proposed Mobile Wireless Mote

Fig. 3. Snapshot of the Mobile Wireless Mote designed

B. Software Design

Once the hardware is designed as shown in Fig. 3, the software design is initiated as per the design flow explained below. The first step is to install an operating system for the Raspberry board. Raspbian OS is downloaded from [12] and installed for the proposed work. In order to install drivers and write python script for Raspberry Pi board, the board should be connected to a monitor. The two alternative approaches for doing the same are connecting the board to a HDMI monitor or by using putty software to get remotely connected to the board. Once OS is installed on the Pi board, two libraries/frameworks are installed for the proposed design. One is the WebIOPi, which is a fully integrated Internet of Things framework for the Raspberry Pi and is considered as the perfect Swiss-knife to control, debug and use Raspberry Pi's GPIO locally or remotely from a browser or any app. In the proposed work, communication between android smartphone and Pi board based mobile mote is established through this library using HTTP client services. The WebIOPi library is downloaded from [13] and the following commands are used to install the WebIOPi library in the Pi.

pi@raspberrypi ~ $ wget webiopi.googlecode.com/files/WebIOPi-0.6.3.tar.gz
pi@raspberrypi ~ $ tar xvzf WebIOPi-0.6.3.tar.gz
pi@raspberrypi ~ $ cd WebIOPi-0.6.3
pi@raspberrypi ~ $. /setup.sh

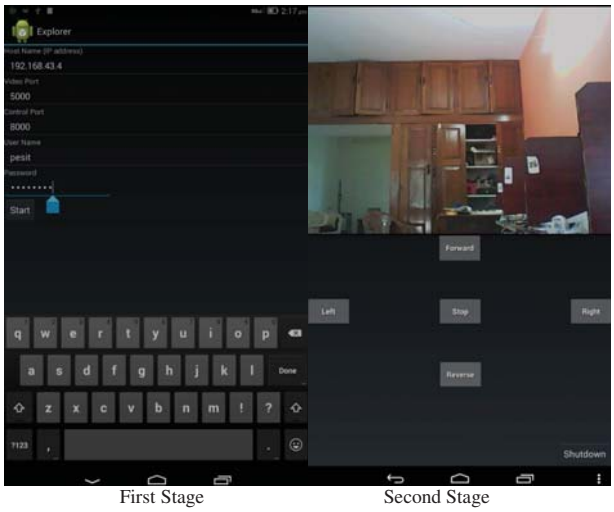
The second framework is Gstreamer, which is a pipeline based multimedia framework that allows programmer to create a variety of media-handling components. The Gstreamer framework is used in the proposed work to decode the video information from USB webcam connected to Raspberry Pi board. Before installing the Gstreamer library/packages, the Raspbian OS should be updated using the following commands

pi@raspberrypi ~ $ sudo apt-get update
pi@raspberrypi ~ $ sudo apt-get upgrade

Once the OS is updated the Gstreamer packages are installed using the following command

pi@raspberrypi ~ $ sudo apt-get install gstreamer-tools gstreamer0.10-plugins-bad gstreamer0.10-plugins-good v4l-utils

After installing the packages, a python script is written which serves as the main program residing on the Raspberry Pi board to perform the functional requirements of a mobile mote with wireless video streaming capability. This is followed by a shell script written for video streaming and commands are given to run both the scripts on boot.



First Stage Second Stage

Fig. 4. Android App designed for the proposed mobile mote

An android application using Eclipse IDE [14] is designed as shown in Fig. 4 for the proposed work which has two stages of operation. The first stage demands the user authentication and successful authentication leads to the second stage for navigating the mobile mote towards a desired direction using buttons and live video streaming as shown in Fig. 4.

III. Design of Proposed Mote using Arduino Yun

Arduino Yun [15] is a microcontroller board based on the ATmega32u4 microcontroller and the Atheros AR9331 processor. The Atheros processor onboard operates at 400MHz and supports OpenWrt-Yun linux distribution. The board has built-in Ethernet and WiFi support. Arduino boards including Arduino Yun are being used for various real time applications such as design of portable wireless indoor air monitoring system in [16], wireless sensor node for outdoor pollution monitoring in [17], Human-Computer Interface for Users with disabilities in [18] and many more. Both, Arduino and Raspberry Pi boards are considered as two powerful devices in the market with each one having its own followers and supporters and hence a mobile mote with video streaming is developed using Arduino Yun too and the performances are evaluated in the proposed work.

A. Hardware Design

The block diagram of proposed wireless mote designed using Arduino Yun with video streaming capability is same as shown in Fig. 2 where Raspberry Pi board is replaced by an Arduino Yun board and the USB Wifi adaptor is replaced by the Wifi available on-board. The other interfaces and functionalities are same as mentioned for Raspberry Pi based mobile mote.

B. Software Design

Once the hardware is designed using Arduino Yun board, the software design is initiated as per the design flow given below. Two approaches of video streaming are explored in this work. The first approach discusses video streaming using both python script (for Atheron processor) as well as arduino sketch (for ATmega32u4 microcontroller). The Yun board runs a distribution of Linux for embedded systems named OpnWrt-Yun based on OpenWrt and a full install of Python 2.7 is included as well. In order to install few drivers required for the proposed work, the Yun board is connected via secure shell (SSH) as shown in Fig. 5 after giving following command in the terminal.

ssh root@yourYunName.local

An Open PacKaGe Management (opkg) considered as a lightweight package management system based upon ipkg is written in C, which is intended for use on embedded Linux devices such as Arduino Yun. The package manager is first updated using the following command

opkg update

Fig. 5. Snapshot of the OpenWrt Terminal for Arduino Yun board.

The USB video class (UVC) drivers provide driver support for video streaming functionality on the USB such as webcams, video recorders etc. These drivers are installed using the following command

opkg install kmod-video-uvc

The fswebcam utility is required to take pictures from the terminal and the same is installed using the following command

opkg install fswebcam

In order to stream videos online, mjpg streaming library is installed using the following command

opkg install mjpg-streamer

The final software comprises of two parts. The first one is a python script that will upload the pictures captured using camera onto the Dropbox from micro SD card. Second part of the code is an arduino sketch which calls the python script to take pictures via the bridge library of the Yun. The video streaming requirement is met by initially streaming the video locally and then transmitting it to Youtube using Wirecast software.

The second approach discusses video streaming handled using Arduino sketch (for ATmega32u4 microcontroller) and libraries for Atheron process that can be used along with arduino sketch. This avoids the need of python script. The Bridge library's Process class is used to run Linux processes on the Atheron AR9331 processor. The first step of this approach demands the configuration of the Wifi network on the Arduino Yun board, which includes establishing Wifi connection between Arduino Yun and smartphone/tablet/ laptop. Google chrome browser is used to monitor the video streaming onto a PC/laptop and an easy auto refresh plug-in for Google chrome is installed for auto refresh of the screen. Similarly Dolphin browser is used to monitor the video streaming onto android phones with auto tab reload plug-in.

IV. Results and Observations

A rough breakup of the budget required to develop the proposed system using Raspberry Pi and Arduino Yun is reported in Table I. It may be observed from Table I that the

design using Arduino Yun is expensive over the system designed using Raspberry Pi board and hence the final mobile mote with wireless video streaming and control prototype is designed using Raspberry Pi board. Snapshot of the working of mobile mote using Raspberry Pi board is shown in Fig. 6. It may be observed that the video in front of the mobile mote is displayed on the android app. Also the mobile mote is successfully controlled using the four buttons visible on the mobile application for navigating the robot in all four directions and halt. Snapshot of the wireless video streaming from Arduino Yun onto a mobile phone as well as laptop is shown in Fig. 7. In Fig. 7, the USB cable connected to laptop is only for powering the Arduino Yun board and video streaming onto mobile phone and laptop is achieved using Wifi network.

TABLE I. EXPENSES INCURRED FOR THE PROPOSED SYSTEM

Hardwares ↓	Raspberry Pi Based System	Arduino Yun based System
Raspberry Pi	$40	NA
Arduino Yun	NA	$75
USB Webcam	$15	$15
12V Battery	$10	$10
6600mAh Power Bank	$15	$15
WiFi Adaptor	$10	NA
Robot Chassis and Misc.	$10	$10
Total	**$100**	**$125**

V. CONCLUSION

In this paper, design of mobile motes with live video streaming capabilities is discussed using two recent boards, Raspberry Pi board and Arduino Yun board. Details about the hardware and software design for both these variants are discussed. It is concluded that the design using Raspberry Pi board is economical over the design using Arduino Yun board. The proposed system has huge potential in vehicular technology and automotive industry towards designing an autonomous and mobile application based vehicle driving assistance for specially challenged. The system can also be used for assistance towards reverse parking the vehicles and for use of rear-end anti-collision warning. The proposed design can be easily adapted for designing home-security systems, industrial applications related to long-armed pick and place robots with video capability and many more applications.

***Abstract*—In this paper, the bit error rate(BER) performance of downlink multiuser scheduling (MUS) for multiple-input-multiple-output (MIMO) transceiving systems is analysed with imperfect channel state information (CSI) caused by feedback delay over Rayleigh fading channel. Two transceiving schemes, i.e., space time block codes (STBC) and selective transmission maximum ratio combining (ST/MRC) has been studied with normalized signal-to-noise ratio (SNR) based scheduling in heterogeneous environment and serving M number of users at a time, where M is the number of transmit antennas. Also the performance under perfect and imperfect CSI is studied for the two transceiving schemes which shows different performances for different schemes. In frequency selective channel, orthogonal frequency division multiplexing (OFDM) performs well to transform it from frequency selective to frequency flat. Therefore error rate performance of MUS-MIMO downlink system integrated with OFDM is studied in heterogeneous user environment with imperfect CSI and STBC transceiving scheme and a considerable gain in error rate performance is observed.**

I. Introduction

Single antenna systems do not utilize the channel efficiently as single user is being served by the base station (BS). Hence, multiple antenna systems have gained momentum as they ensure efficient spectrum utilization. In fading channels, multiuser diversity (MUD) and antenna diversity results in both higher spectral efficiency and better bit error rate (BER) performance [1]. In multiuser (MU) enviornment, MUD can be exploited in case of channel state information (CSI) feedback by receivers to BS. According to multiuser scheduling (MUS), the spectral efficiency of broadcast channel (BC) can be maximized by sending real data to users with the best channel conditions [1].

Dirty paper coding (DPC) and zero-forcing (ZF) precoder in multiuser multiple-input multiple-output (MU-MIMO) environment result in optimal usage of channel by pre-cancelling the interference at users. However, these schemes are not implementable in real time as perfect CSI at transmitter (CSIT) is required. In literature limited feedback scheduling schemes are discussed [2]–[4]. In recent past, soft computing techniques are also used for scheduling [5], [6]. The bit error rate (BER) performance of user scheduling for MU MIMO broadcast system with heterogeneous users is less studied in past. Hence, in this paper, the BER performance of MIMO MUS is studied for imperfect CSI caused due to feedback delay is considered where BS serves multiple users (equal to the number of transmit antennas at BS) simultaneously.

MUD gain with opportunistic scheduler is analysed in [7], [8]. Wong [9] investigated the performance analysis of both single and multiuser MIMO diversity channels using Nakagami-m distribution. Antenna diversity and MUS is jointly investigated for the generalized Nakagami fading channels along with the derivation of unified capacity formula for MUS with different transceiving schemes in [10]. BER and capacity expressions with MUS for heterogeneous and homogeneous users are presented in [11], [12]. MUS system capacity is analysed in [13], [14] by taking delayed CSI into account. BER performance analysis for MUS-MIMO system with imperfect CSI and heterogeneous network is presented in [15] with space time block code (STBC), selective transmission maximum ratio combining (ST/MRC) and selective transmission selective combining (ST/SC) combining schemes. However, only the user with highest SNR is being served at a time using time division multiplexing (TDMA) technique. This results in inefficient spectrum utilization by not exploiting the advantage of spatial multiplexing gain, where the capacity of the wireless channel can be increased linearly by a factor of $min\{M, N\}$. M and N are the number of transmit and receive antennas respectively.

Hence, it will be interesting to observe the performance of the MUS-MIMO downlink system with imperfect CSI and heterogeneous users when M users are served simultaneously according to DPC. Moreover, integrating orthogonal frequency division multiplexing (OFDM) with MIMO can convert a frequency selective channel into a frequency flat channel. This can result in better BER performance of the MU MIMO-OFDM BC. Here, BER performance of MUS-MIMO-OFDM downlink system with frequency selective channel and heterogeneous users is analysed for various transceiving schemes like STBC, and ST/MRC for perfect and imperfect CSI through extensive simulation resuls.

Section II describes the system model along with the MUS scheme. Simulation results are presented and discussed in Section III. Finally, Section IV concludes the paper.

II. System Model and Multiuser Scheduling Scheme

A. MUS-MIMO downlink system

Consider multiuser scheduling for MU MIMO downlink system. It consists of one BS with M number of transmitting antennas. There are K number of users each one having N number of receiving antennas. The wireless channel between

BS and users is assumed to be flat Rayleigh fading channel. The users feed back the CSI to the BS. Depending upon this feedback the transmitter schedules the users for transmitting data. The channel between the transmitter and receiver is represented by an $N \times M$ channel matrix $H^k = h_{ij}^{(k)}$, where the complex element $h_{ij}^{(k)}$ is the gain between the jth transmit and the ith receive antenna for the kth user. The channel elements are independent and identically distributed ($i.i.d.$) complex Gaussian random variables (RVs) with zero mean and 0.5 variance per dimension. The MIMO transceiving scheme namely STBC and ST/MRC has been used for multiuser scheduling. It has been assumed that the channel is quasi static, i.e., the channel parameters do not change for one STBC frame but varies from one frame to another. For the STBC scheme the received SNR per symbol of the kth user can be expressed as below [16], [17]:

$$\begin{aligned}\gamma_{STBC}^k &= (P_t^k/rM\sigma_n^2) \times \sum_{j=1}^{M}\sum_{i=1}^{N} \left|h_{ij}^k\right|^2 \\ &= \frac{\bar{\gamma}^k}{rM}\sum_{j=1}^{M}\sum_{i=1}^{N}\left|h_{ij}^k\right|^2 = \frac{\bar{\gamma}^k}{rM}\left\|H^k\right\|_F^2, \quad (1)\end{aligned}$$

Where r is the code rate, P_t^k is the total transmit power, $\sigma_n^2$is the noise variance, $\bar{\gamma}^k$ is the average SNR at the kth user, and $\left\|H^k\right\|_F^2$ is the square of the Frobenious norm of $\{h_{ij}^k\}$. According to this scheme, all transmit antennas are utilized for transmitting data.

For the ST/MRC case the received SNR per symbol of the kth user is given by:

$$\begin{aligned}\gamma_{ST/MRC}^k &= max(P_t^k/\sigma_n^2 \sum_{i=1}^{N}|h_{ij}|^2) \ \forall\ j = 1, 2, ...M \\ &= max\left(\bar{\gamma}^k \sum_{i=1}^{N}|h_{ij}|^2\right) \\ &= max\left(\bar{\gamma}^k \left\|h_j^k\right\|_F^2\right) \ \forall\ j = 1, 2, ...M, \quad (2)\end{aligned}$$

where $\left\|h_j^k\right\|_F^2$ is the Frobenious norm of jth column of H^k. According to this scheme, the BS selects the transmit antenna which results in $max\left\|h_j\right\|_F^2 \forall j$ = 1, . . ., M.

The received SNR (γ^k) may be expressed as the largest order statistic of LQ scheme of L *i.i.d.* received SNRs as discussed in [15]

$$\gamma^k = \max_{m=1,\ldots,L}\{r_m^k\}, \quad (3)$$

where

$$r_m^k = \begin{cases} \rho^k \left\|H^k\right\|_F^2, & \text{L = 1, Q = MN for STBC} \\ \rho^k \left\|h_j^k\right\|_F^2, & \text{L = M, Q = N for ST/MRC} \end{cases}$$

where the average receive SNR, i.e., ρ^k will be expressed for different transceiving schemes as $\rho^k = \frac{\bar{\gamma}^k}{rN}$ for STBC, and $\rho^k = \bar{\gamma}^k$ for ST/MRC.

Here complete knowledge of the channel is considered based on the CSI received from the receiver. Also the feedback channel is assumed to be error free but there is delay in received CSI value. In multiuser scheduling each user feeds back its maximum SNR value along with the corresponding transmit antenna index to the BS. After attaining the complete feedback from all users, BS schedules M distinct users with highest SNR values corresponding to each transmit antenna. However, in case of STBC, users do not send the index of the transmit antenna (which is not required). The BS will perform multi-user scheduling using delayed CSI denoted as $\hat{\gamma}^k = \max_{m=1,\ldots,L}\{\hat{r}_m^k\}$, where $\hat{r}_m^k = \hat{\rho}^k \left\|\hat{H}^k\right\|_F^2$ for STBC, and $\hat{r}_m^k = \hat{\rho}^k \left\|\hat{h}_j^k\right\|_F^2$ for ST/MRC. $\hat{H}^k$ is the τ delayed form of H^k having same Gaussian distribution as H^k and the correlation coefficient between their elements is $c_k = J_0(2\pi f_d^k \tau_k)$ where J_0 is first order Bessel function of the first kind. τ_k, and f_d^k are feedback delay and the maximum Doppler frequency of user k respectively. Also, the relationship between the actual channel and its delayed form as discussed in [18] can be expressed as below:

$$H^k = c_k\hat{H}^k + \sqrt{(1-c_k^2)}E^k, \quad (4)$$

where E^k is the channel error matrix which is independent of $\hat{H}^k$, and its entries are $i.i.d.$ complex Gaussian RVs with zero mean and variance $\sigma_k^2 = 1 - c_k^2$. The signal received at each user k is given as below:

$$y^k = H^k s + n^k. \quad (5)$$

In this paper, BER performance is compared through simulation for the below mentioned two scenarios as:

- The user with the best received SNR is being served by the BS. and
- The M users with the M best received SNRs are being served simultaneously by the BS.

Moreover, the BER performance for heterogeneous network is compared for both perfect and imperfect CSI at BS.

B. MUS-MIMO-OFDM downlink system

In a multiuser MIMO−OFDM downlink system, a single cell has been considered where the transmitter is furnished with M transmitting antennas and there are K heterogeneous users each having N antennas as receiver. The scheduling process for users at the BS allots a sub-carrier to a particular user at the initialization of each frame for which the user has reported the highest received SNR value. The BS then selects the best M users, who have reported the highest M SNR values. The signal is then transmitted to that M users over their l_{th} subcarrier on which they have reported highest SNR. The SNR value of the k^{th} user over the l_{th} subcarrier is shown below in (6) for STBC transceiving scheme:

$$\begin{aligned}\gamma_l^k &= (P_t^k/rM\sigma_n^2) \times \sum_{j=1}^{M}\sum_{i=1}^{N}\left|h_{ij}^{k,l}\right|^2 \\ &= \frac{\bar{\gamma}^k}{rM}\sum_{j=1}^{M}\sum_{i=1}^{N}\left|h_{ij}^{k,l}\right|^2. \quad (6)\end{aligned}$$

A mobile user will be able to detect the signal forwarded to it by utilizing point-to-point MIMO spatial multiplexing, if and only if N is equal to or larger than M as discussed in [20]. The channel has been considered to be frequency selective and has been modelled as a length P finite− impulse response (FIR) filter as described in [19]. The space frequency channel at the l_{th} tone for the kth user can be written as below as described in [20]:

$$H_l^k = \sum_{p=0}^{P-1} \sigma_p F[k,p] exp(-j2\pi \times p), \tag{7}$$

where $F[k,p]$ is $M \times M$ square matrix and MIMO channel impulse responses of the kth user with each $F[k,p]$ contains independent $\mathcal{CN}(0,1)$ elements. σ_p^2 represents the channel power delay profile normalized by assuming $\sum_{p=0}^{P-1} \sigma_p^2 = 1$. The channel is expected to be quasi-static, which remains same for one coherence time duration. Here one coherence time is equal to the length of one OFDM frame. Also each frame consists of a number of OFDM symbols. Correlation coefficient between the channel elements on two arbitrary subcarriers r and s is given as in [21]

$$\begin{aligned} \beta_{r,s} &= E[(H_r^k)(H_s^k)^*_{i',j'}] \\ &= \sum_{p=0}^{P-1} \sigma_p^2 exp(-j2\pi(r-s)p/L)\delta[i-i'] \\ &\quad \times \delta[j-j']]. \end{aligned} \tag{8}$$

The received signal by kth user over the lth sub-carrier can be expressed as below:

$$y_l^k = H_l^k s_l + n_l^k, \tag{9}$$

where H_l^k is given by (7), x_l is signal vector transmitted over the lth sub-carrier and n_l^k is the normalized noise vector with $\mathcal{CN}(\iota, \infty)$ elements. The BS will perform multiuser scheduling by calculating the SNR values at each of the user and for each subcarrier given by (6).

III. Simulation Results and Discussions

In this section, BER performance of MUS for MIMO and MIMO-OFDM BC over quasi static Rayleigh flat fading channels is discussed. Monte-carlo method is used for simulation for various scenarios. An exponentially decaying profile expressed as $\{\bar{\gamma}^k = \bar{\gamma} e^{-\varepsilon(k-1)}, k = 1, \ldots, K\}$, is used for heterogeneous case to compute the average SNRs of users. Here ε is the power decaying factor [12], and its value has been taken as 0.2 for all the simulation results. For heterogeneous case normalized SNR based scheduling is used for user selection. The channel estimation and antenna selection time is set to be $190mus$ as used in [22] for all simulations presented in this paper. The correlation coefficient of any user k is given by relation as $c_k = J_0(2\pi f_d^k \tau_k)$. Here, we have considered a heterogeneous network consisting of four users. The Doppler frequencies for the these users are assumed to be $f_d^k = 200$, 300, 400, and $500Hz$ corresponding to their speed of 43.2 , 64.8 , 86.4, and $108Km/h$. The carrier frequency is assumed to be $5GHz$. Assuming τ_k value as $190mus$, the correlation coefficients are obtained as $c = \{0.98, 0.96, 0.94, \text{and } 0.91\}$ for these users. For this entire section the various simulations are performed for 2×3 MIMO system with four users as discussed earlier.

A. Numerical result for MUS-MIMO downlink system

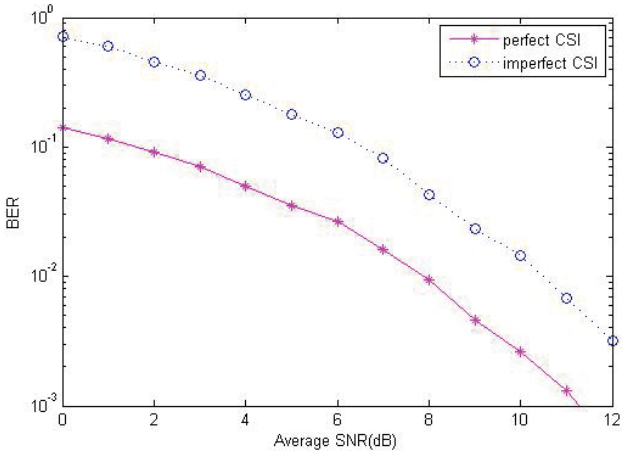

Fig. 1. Performance comparison for perfect and imperfect CSI

In Fig.1, performance comparison for perfect and imperfect CSI has been plotted, using binary phase shift keying (BPSK) modulation in MUS-MIMO environment and using the discussed scheduling algorithm. From the Fig.1 it is clear that the BER performance under imperfect CSI case is worse than that in case of perfect CSI.

In Fig.2, simulation results are plotted for BER performance comparison for the case when the BS serves single user with the maximum SNR and multiple users(equal to the number of transmit antennas) with imperfect CSI. BPSK is used as the modulation scheme. It is important to observe from this is that there is very less increment in BER, i.e., approximately 1 dB loss while we are serving to M users simultaneously. However it is observed that the capacity increases M-fold by serving M users simultaneously.

In Fig.3, performance comparison for STBC and ST/MRC transceiving schemes are given for imperfect CSI at the BS. For both the schemes BPSK modulation is used. For ST/MRC scheme performance is better because only user selection gets affected by delayed CSI in case of STBC however for ST/MRC both user and antenna selections are affected. However, for the case of perfect CSI at BS, the BER performance is as shown in Fig.4. In this case the performance of ST/MRC is better than STBC as more diversity gain is achieved by ST/MRC in the presence of perfect knowledge of channel condition at the transmitter.

B. Numerical result for MUS-MIMO-OFDM downlink system

The BER performance achieved by MUS for MIMO-OFDM frequency selective BC channel is shown in Fig.5. The exponential power delay profile σ_p^2 is used to model the channel

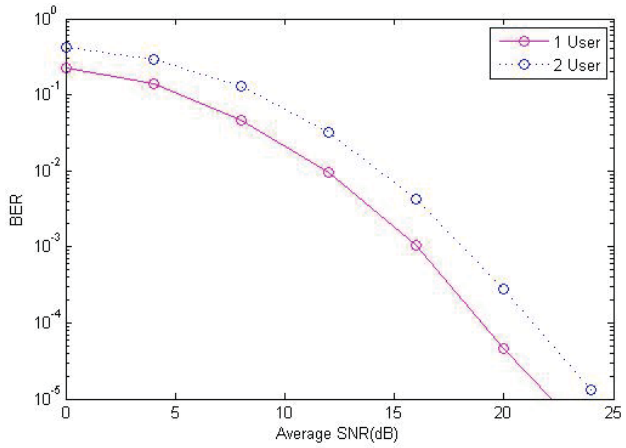

Fig. 2. Performance comparison for the case when the BS serve single user and multi users (depending on number of transmit antennas), With imperfect CSI.

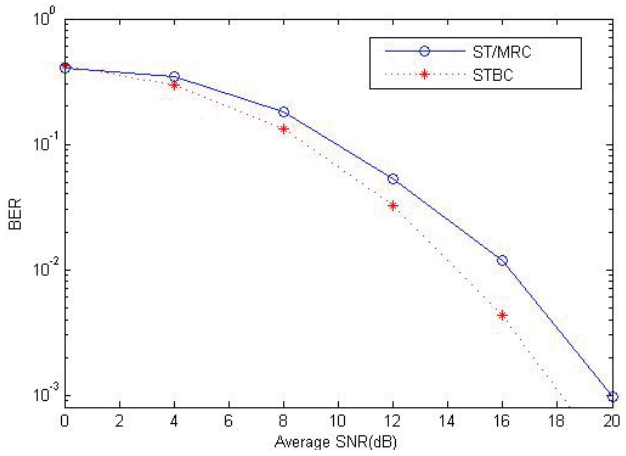

Fig. 3. Performance comparison for STBC and MRC with imperfect CSI

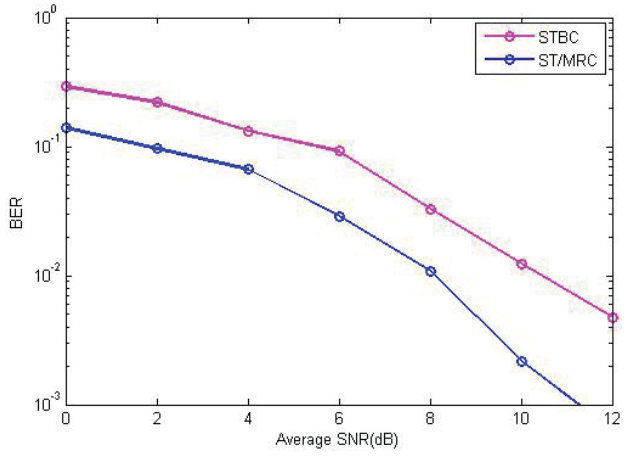

Fig. 4. Performance comparison for STBC and MRC with perfect CSI

for simulation results. It is given by (10) as discussed in [20]

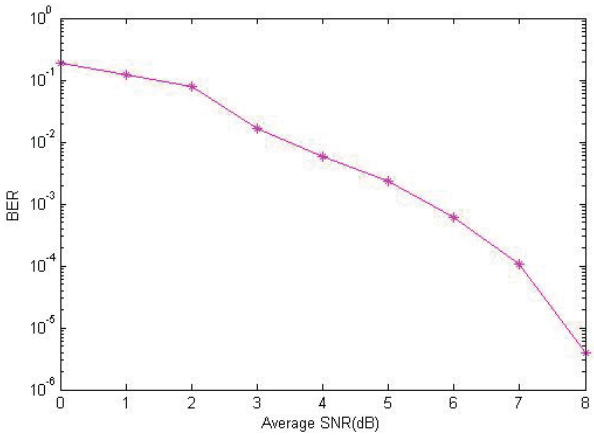

Fig. 5. Performance of MUS-MIMO-OFDM downlink system

as:

$$\sigma_p^2 = \frac{1 - exp(-1/D_{exp})}{1 - exp(-P/D_{exp})} exp(-p/D_{exp}),\ 0 \leq p \leq P-1, \tag{10}$$

where P is the number of resolvable paths which is taken as P = 4 and total sub-carriers are assumed to be 16, i.e., L = 16. Also the D_{exp} is considered to be 2 for the simulation purpose. STBC coding scheme is used with BPSK modulation over frequency selective channel for which the system model is provided in section II. It can be observed from the plot that a reasonably good BER performance of 10^{-6} is achieved at an SNR of 8 dB.

IV. Conclusion

In this paper, we have presented an error performance study of MUS for both MIMO, and MIMO-OFDM downlink system with imperfect CSI at the transmitter end. The BER performance by MUS for MIMO broadcast network over Rayleigh flat fading channel with heterogeneous users is studied with two transceiving schemes like STBC, and ST/MRC. BER performance is done for both the cases of perfect and imperfect CSI. The effect of serving multiple users simultaneously on BER performance is also observed. It is interesting to observe that the BER performance of serving M users with the M best SNRs degrades insignificantly (by approximately 1 dB) as compared with serving only the user with the highest SNR. It is observed for the case of perfect CSI that the BER performance of ST/MRC is better than STBC due to more diversity gain provided by ST/MRC. Moreover, it is observed for the case of imperfect CSI that the BER performance of STBC is better than ST/MRC because the delayed CSI affects only selection of user in case of STBC while in case of ST/MRC it affects both user and antenna selection. Later in the paper, the BER performance attained by MUS is studied for MIMO-OFDM downlink system over a frequency-selective channel. The performance is very intriguing in frequency-selective channel environment.

Evaluation of Channel Assembling Strategies with Single-Class Users in Cognitive Radio Networks

Esenogho Ebenezer and Tom Walingo
School of Electrical, Electronic and Computer Engineering
University of KwaZulu-Natal
213573292@stu.ukzn.ac.za

Abstract— **Channel assembling (CA) strategies which allows several Primary User (PU) idle or unused channel-slot to be aggregated into combinations of usable secondary user (SU) channels have been deployed in cognitive radio networks. However, many of these schemes have been implemented without considering the varying nature of a wireless link that incorporates adaptive modulation and coding (AMC). This paper develops and compares two channel assembling strategies which are the Immediate Blocking Strategy (IBS) and Readjustment Based Strategy (RBS) in single-class SU traffic on a dynamic wireless link. The performance is evaluated through extensive simulation and the results demonstrate that, in a single class SU traffic, capacity and throughput is improved with significant reduction in blocking and Forced Termination .**

Keywords—AMC, channel assembling, cognitive radio networks, homogeneous traffic.

I. INTRODUCTION

Radio spectrum is the most precious and scarce resources in wireless communication systems given the facts that the existing licensed band are almost exhausted as a result of exponential growth in wireless applications and services both in multimedia and voice services[1][2]. Studies have shown that busty Primary User (PU) behaviour has been characterized as ON/OFF (utilizing and non-utilizing) given rise to un-used spectrum in time domain and spatial domain as in the TV white space (TVWS). In a radio network comprising of PU and Secondary User (SU), the primary users have high priority to use their spectrum while SU periodically sense to identify un-used channels [4]. Based on the sensing outcome, SUs tune their transceivers to communicate among themselves without interfering with the PU. The un-used PU channels/time slots need some organization to meet the demand of the SUs hence, the need for channel assembling. An effective channel assembling strategy must take into account the PU behaviour models and several of them were investigated in [3]. Network traffic has evolved from simple to more dynamic scenario such that, each SU requires different Quality of Service (QoS) at different signal to noise ratio. Hence, the need to aggregate PU un-used channels/slots to improve SU throughput and capacity since the channel is opportunistically used. This paper develops and compares two channel assembling strategies which incorporate the dynamics of a wireless link with adaptive modulation and coding (AMC) against No-assembling strategy (NA) in a homogeneous SU traffic. Moreover, the number of the channel/slot to be assembled for a particular SU with corresponding assembling strategy dependents on their signal to noise ratio (SNR).

II. RELATED WORK

Significant research work on channel assembling strategies has been done so far and they are aimed at developing novel schemes that exploits the scarce resources. In [6]. Channel assembling (CA) strategies with different spectrum adaptation strategies were proposed. In their work, two strategies which dynamically adjust channel occupancy of ongoing traffic flows are developed. In [10] Two channel aggregation schemes for wideband cognitive radio networks were proposed which are, a Constant Channel Aggregation scheme (CCA) and a Variable Channel Aggregation scheme (VCA) are presented. In the variable channel aggregation scheme, the bandwidth of the cognitive user is aggregated with a probability distribution or aggregated on the basis of the number of the residual channels. [6] [7]. Implements a dynamic CA strategy designed for heterogeneous traffic environment and spectrum adaptation by employing channel sharing and spectrum assignment among elastic users (real time) and non-elastic (non-real time). In [11] The authors incorporate priority queuing in CA such that, real-time SU are queued and serviced before non-real SU if no resources are available with the aim of avoiding or minimizing instant blocking. Combined queuing based CA and channel fragmentation is proposed in [9]. The protocol work in such a way that in any event, of batch arrival of SU, a secondary user channel can be split and share amore other SUs to accommodate other SU which cannot tolerate delay. However, none of these strategies considered the varying nature of a wireless link that incorporates adaptive modulation and coding (AMC). This paper develops and compares through simulation study, two channel assembling strategies which are the Immediate Blocking Strategy (IBS) and Readjustment Based Strategy (RBS) in a similar SU traffic on a dynamic wireless link.

III. SYSTEM MODEL AND ASSUMPTIONS

Consider an infrastructure based network consisting of a PU base station (TV mast), a cognitive radio base station (CRBs) and its users of similar class operating in the same frequency band as shown in Fig.1. The PU has full priority to utilize the spectrum and can pre-empt the SUs at any time irrespective of the class. The SU traffic operates in a first come first serve (FIFO) model since they are all of equal class. However, the first SU has higher priority to in terms of channel access and can pre-empt others if need arise. SU opportunistically utilizes the PU channels by employing any of the channel assembling schemes (IBS or RBS).

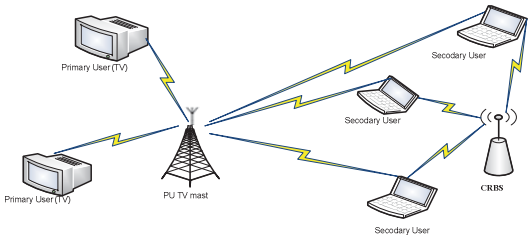

Fig. 1. Network Architecture

The licensed spectrum is divided into M frequency channels. Each channel frame consists of β slots and channel utilization per frame is on a slot basis. The PU utilizes one channel on an ON/OFF slot basis while SU can opportunistically assemble multiple adjacent or non-adjacent channels/slots, in frequency and time domain of the spectrum. The channel frame utilization map for a determined PU's ON/OFF behaviour is shown in Fig 2. The dynamic SU frame results in a heterogeneous system with variable frame channel/slot capacity and the SU traffic requires a particular transmission rate/number of channels. The CRBS decides to admit, block/ forcefully terminate the SU based on resources availability as dictated by channel assembly strategies deployed. The available capacity is determined by the conditions of the wireless link in terms of the SU SNR.

A. *Wireless Channel and AMC*

The Nakagami- m channel model is used to model the wireless link due to its versatility of spanning a wide range of fading channels [8].

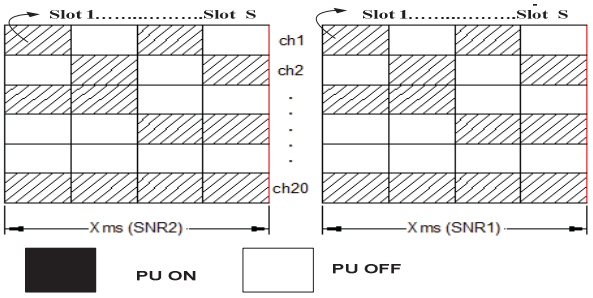

Fig. 2. Wireless frame utilization

The differing channel conditions are captured by the Finite State Markov Chain (*FSMC*) whose analysis for slow fading channel conditions is well known [9]. The entire SNR range is partitioned into Good, Moderate and Bad shown in Fig. 3. However, the specific modulation and coding modes for the AMC scheme as per IEEE 802.22 standard is adopted from [12]. The transition matrix of the FSMC, P is given by,

$$P = [p_{ij}]_{(N+1)\times(N+1)} \qquad (1)$$

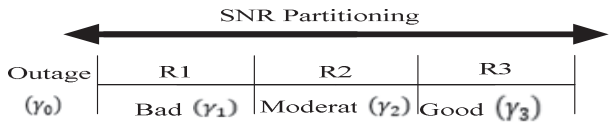

Fig. 3 SNR Partitioning

AMC is used in maximizing data rate with respect to the channel state thus, maintaining a prescribed packet error rate (PER) as adopted in [8]. The numbers of slot/channel a SU aggregate for data transmission decreases with increase in received SNR. [15]. Mode 1, Mode 2, Mode 3 Corresponds to QPSK, 16-QAM and 64-QAM representing assumed three states.

B. *Channel Slot Capacity*

Consider slot duration T_n in second as the minimum time to transmit a packet of length $\emptyset$ bits and R_n be the transmission mode in the slot while R_N is the highest transmission mode. The number of slots/channel in a fixed frame S is a variable function of the dynamic SNR with S being more when the SNR is good and less when bad. The number of slots of a frame in mode/state n, *(n=1, 2…)*, β_n, is given by,

$$\beta_n = \left(\frac{R_N \emptyset}{R_n \varepsilon_s R_1}\right) \qquad (2)$$

Where $\varepsilon_s$the constant channel is symbol rate per second and T_f is the frame duration in seconds. The channel state utilization is characterised by two-state Markov chain as shown in Fig. 4. Where ∂_i is the transitional probability from ON state to OFF state and σ_i be the transitional probability from the OFF state to the ON state for the i^{th} channel.

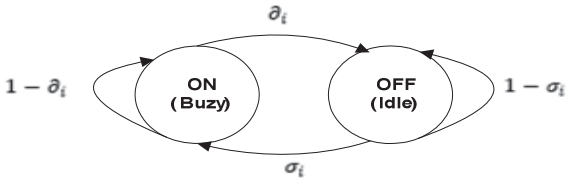

Fig. 4. The ON-OFF channel usage model for PU

The PUs slot/channel capacity, $\theta_{pu}$is given as,

$$\theta_{pu} = \beta_n \sum_{i=1}^{M} P_i \left(\frac{\sigma_i}{\sigma_i + \partial_i}\right) \qquad (3)$$

Where $P_i = \begin{cases} 1, & i \le N_{su} \le M \\ 0, & otherwise \end{cases}$, N_{su} is the number of frequency channel that have the presence of SU

Note that $\gamma_i = \sigma_i/(\sigma_i + \partial_i)$ is the channel utilization ratio. The SU system capacity (slot capacity/OFF capacity) $\theta_{su}(n)$, is given by,

$$\theta_{su} = (M * \beta_n) - \theta_{pu} \qquad (4)$$

IV. CHANNEL ASSEMBLING STRATEGIES

In this section, three strategies are presented. They are, the Immediate Blocking Strategy (IBS), the Readjustment Based Strategy (RBS) and the No-assembling scheme.

A. IBS ($\theta_{pu}, \theta_{su}, \theta_i, \theta_j$)

In this scheme, a SU which does not manage to assemble sufficient channels are immediately blocked. However, a SU that arrives first is given higher priority to the SU which arrives last. All the SUs are pre-empted by the arrival of a PU. Let Z be the total number of SUs in the system and the resource requirements for first $SU\ \ i$ be θ_i and next SU $\ j$ be $\ \theta_j$ respectively [13]. The assembly procedure is shown as Algorithm 1 below:

Algorithm I *for the CA using IBS*

CRBs check wireless link $\boldsymbol{\gamma_{su}}$;// cognitive radio base station checks wireless link state (SNR)

CRBs check $\boldsymbol{\theta_{su}}$;// cognitive radio base station checks available recourse for SUs

Access condition for i users

If ($\overbrace{\boldsymbol{\theta_{su} \geq \sum_{i=1}^{Z} \theta_i}}$); // resource assembly test as a function of SNR/mode pair.

$SU_{i,j}$_admit = true; // admit SU_s admit SU_i and assemble with a probability

else

$SU_{i,j}$_admit=false;//**block** the SU_s

if $[(\boldsymbol{\theta_{su} \geq \sum_{i=1}^{Z} \theta_i}) - \boldsymbol{\theta_{pu}}]$; // PU arrival, interrupts SU_i

$SU_{i,j}$_forced termination =true;//**forced-terminate** of ongoing SU_s

End If ;// terminate if no event

Go to start.

B. RBS ($\theta_{pu}, \theta_{su}, \theta^i_{min}, \theta_i, \theta^i_{max}$)

In this scheme, both SU_i and SU_j requires a minimum of $\theta^{min}_{i,j}(\theta^{min}_i, \theta^{min}_j)$ and maximum of $\theta^{max}_{i,j}(\theta^{max}_i, \theta^{max}_j)$ number of channels to commence or stop assembling respectively. When a SU_i require service, the assembling mechanism (CRBs) checks for resource availability similar to the IBS scheme. If the resources are available and sufficient, SU_i is admitted, otherwise, Readjustment Algorithm II is executed. However, because of the system is design in FIFO model, SU_i given preferential treatment.

Algorithm II *for the CA using RBS*

CRBs check wireless link $\boldsymbol{\gamma_{su}}$;// cognitive radio base station checks wireless link state (SNR)

CRBs check $\boldsymbol{\theta_{su}}$;// cognitive radio base station checks available recourse for SUs

condition for i user access

if ($\overbrace{\boldsymbol{\theta_{su} \geq \sum_{i=1}^{Z} \theta_i^{min}}}$); **);** // test for SU_{s1} resources

SU_i_admit = true; // admit SU_i

else

if $\left[\begin{array}{c}(\boldsymbol{\theta_{su} - \sum_{i=1}^{Z} \theta_n^{min}}) < \boldsymbol{\theta_{n,new}^{min}}) \\ \boldsymbol{or} \\ (\boldsymbol{\theta_{su} - \sum_{i=1}^{Z} \theta_n^{min}}) - (\boldsymbol{\omega})) \end{array}\right]$;// test for new SU arrival or PU arrival

Do $(\boldsymbol{\theta_i^{max} - 1})$, ++ *j:*// donation and iterate over i^{max} user resources

$SU_{i,j}$_admit = true; // admit $SU_{i,j}$ and assemble for both users

else

SU_i_admit =false; //**block** new SU_i no-free slot or insufficient

else

if all condition cannot be meet

$SU_{i_}$ FT=true;// force-terminate on going SU_i

End if; // start the process.

C. No-Assembling Strategy (NA)

This is the convectional communication system where transmitters and receivers communicate with each other without application of any special scheme or techniques. Even when enough idle channels are available, it is wasted.

V. SYSTEM MODEL PERFORMANCE MEASURES.

Let λ_p, λ_s be the arrival rates of the PU and SU respectively. Service time is exponentially distributed with the service rates defined as μ_p , μ_{su} for the PU and SU, respectively as in [10-11]. The total rate for a user is assumed to be the product of the users channel/slot service rate and the number of assembled channels/slot $\theta_i\mu_{si}$ or $\theta_j\mu_{sj}$ respectively.

A. The Performance Measures

a) *The blocking probability* P_b of SU traffic class is the probability that a new SU is denied access to the spectrum if it cannot meet the condition in the algorithms. If total SU blocked and arrived are Ω_{Ts} and λ_{Ts} respectively, then , It is expressed as,

$$P_b = \frac{Total\ \ SU\ blocked}{Total\ SU\ arrivals} = \frac{\Omega_{Ts}}{\lambda_{Ts}}$$

b) *The forced termination probability* P_f of traffic is the probability of an ongoing SU being pre-empted by a PU arrival however, in this paper, forced termination probability represents the fraction of the forced commenced SU services. Also, If total SU forced terminated and admitted are η_{Ts} and ζ_{Ts} respectively, then , It is expressed as,

$$P_f = \frac{Total\ SU\ forecd\ terminated}{Total\ \ admitted\ SUconnections} = \frac{\eta_{Ts}}{\zeta_{Ts}}$$

c) *Throughput* (T_P) is define as the fraction of SUs packet that successfully delivered (average service completion upon PU arrival), after meeting the necessary conditions in the algorithm. It can be given as,

$$T_P = \lambda_s(1 - P_b) \qquad (5)$$

d) *Capacity* ρ_{su}: The capacity of the homogeneous SU network is the average number of SUs service completion per unit time. Thus, ρ_{su} of admitted SUs at a particular time is a function of the SNRs/modes pair. It is expressed as,

$$\rho_{su} = \frac{Average\ number\ of\ SUs\ service\ completion}{Time(seconds)}$$

$$\rho_{su} = \{T_P = \lambda_s(1 - P_b)\}/T_n \qquad (6)$$

VI. NUMERICAL RESULTS AND DISCUSSIONS

To illustrate the performance evaluation of the CA strategies with AMC, the numerical results based on simulation are presented in this section for a homogeneous SU traffic. The parameters are configures as, $\lambda_p = 0.5$, $\lambda_s = 1.5\ \mu_s = 0.85$, $\mu_s = 0.6, Z = 6, P_b = 0.55$ $P_f = 0.65, T_P = 2.5, \rho_{su} = 2.2$ $\theta_i = 4$. MATLAB tool was used to run the simulations for each of the strategies. However, comparing the strategies of the RBS with the IBS strategies one can argue that there is a significant improvement of the RBS scheme over the IBS due to its flexibility. Precisely, the RBS scheme outperformed the IBS scheme in terms of SU capacity, throughput blocking and forced termination probability respectively.

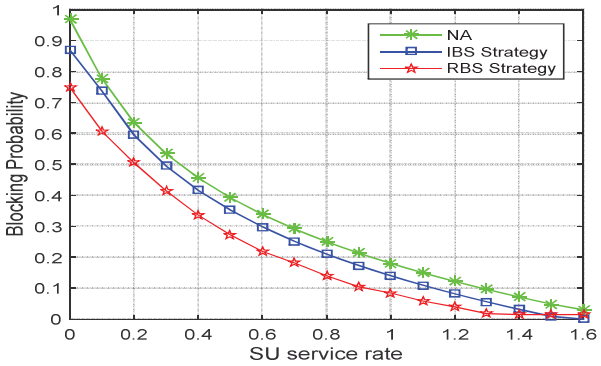

Fig.5a blocking probability P_b vs μ_{su}

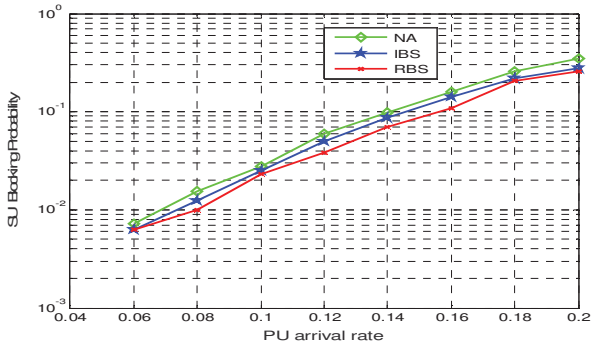

Fig.5b blocking probability of SU as a function of λ_p

Fig. 5a shows that, when the service rate μ_{su} of the SUs grows as a result of good channel condition, the blocking probabilities decreases since more SUs will be served. However, in both case (Fig. 5a and Fig. 5b), RBS scheme has a lower blocking probability as compared to the IBS while the NA strategy has a higher blocking probability. Moreover in Fig. 5b, as more PUs arrives, empty channel slot will not be available so, more SUs will not be given access.

In an event of batch arrivals of PUs, the SUs will experience decrease in throughput because very few slots will be available for the SUs to use and as such, not much will be sent by the SU as shown in Fig. 6a. Similarly, throughput improved as PU departs and more channels/slots are assembled by the SUs. However the RBS still shows better performance as compared to the two other strategies (IBS and NA) due it adaptability with respect to PU arrival as shown in Fig. 6a and 6b.

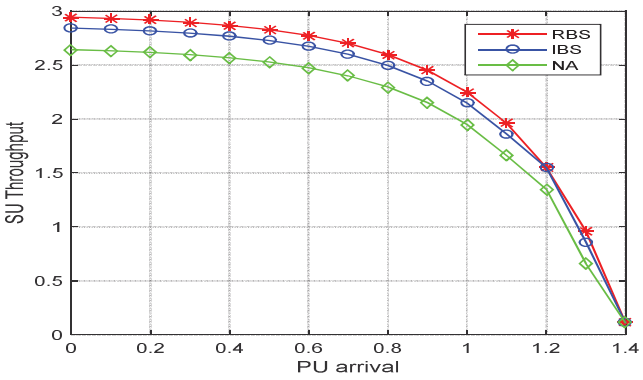

Fig.6a Throughput of SU as a function of λ_p

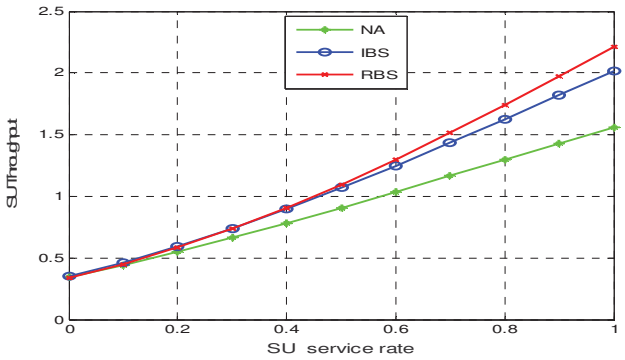

Fig.6b Throughput of SU as a function of λ_p

Fig.7a and Fig, 7b illustrates gradual increase in SU capacity with respect to the service rate and SNR irrespective of the scheme deployed. Incorporating AMC in channel assembling strategies helps improve service completion rate because more data will be sent as the SNR becomes better. However, in both results, the RBS showed a better characteristic due to its flexibility as compared to IBS and NA respectively.

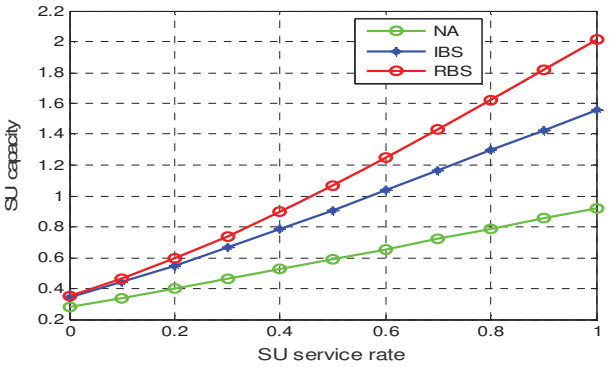

Fig.7a SU capacity as a function of μ_{su}

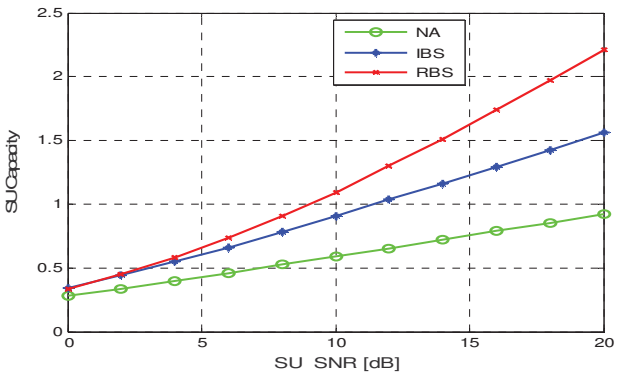

Fig.7b SU capacity as a function of SNR [dB]

In Fig.8a, PU activity has a significant effect on the behaviour of the SUs in terms of when to assemble channels and when to drop already assembled SU channels slot. When PUs arrives either in batch or individually, an ongoing SU must forcefully terminate its transmission if idle channel does not exist elsewhere within the network. Likewise in Fig.8b, when an SU arrives and enough channels exist, it is serviced and as such, the probability to force terminate these SU will drop. Moreover, the RBS scheme emerge a better scheme than the IBS and the NA as shown in the results.

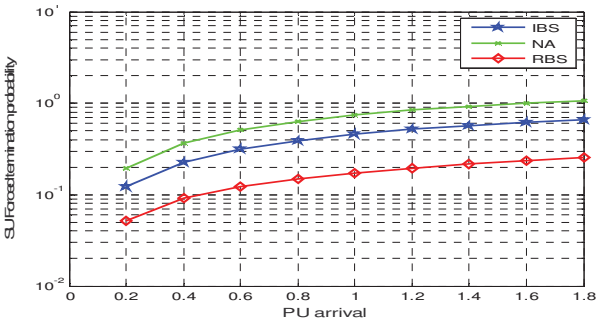

Fig.8a SU FT as a function of λ_p

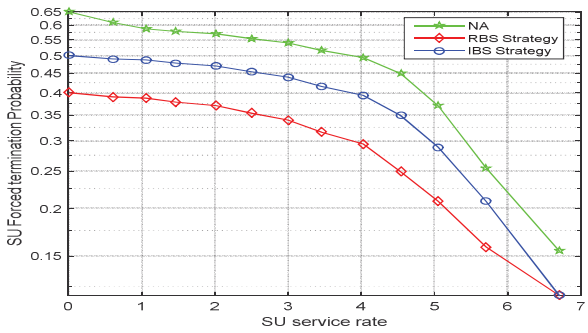

Fig.8a SU FT as a function of μ_{su}

VI. CONCLUSION

In this paper we have shown and compare through a simulation study, the performance measures of two channel assembling techniques for cognitive radio network, considering the dynamics of a wireless link with AMC against NA. The result obtained from our simulation shows that, the RBS techniques perform better than the IBS and the NA techniques in the sense that, it has lower blocking and force termination probabilities respectively. Also, it demonstrates that AMC is a robust technology in improving channel allocation schemes if incorporated. However, our future work will be focus in two folds: The selection of secondary users with two traffic running simultaneously.

***Abstract*—Cooperative communication is one of the emerging technologies that promise significantly higher reliability and spectral efficiency in wireless networks. It is a new form of diversity that allows users or nodes to share resources to create collaboration via distributed transmission and processing of messages. As candidate multiple access for future radio access, Non orthogonal multiple access (NOMA) over orthogonal multiple access (OMA) are adopted as downlink access scheme for future 5th generation mobile communication. In this paper, we compare user throughput when using orthogonal multiple access (OMA) and NOMA in macro femto network. We show through computer simulation the effect of imperfect interference cancellation on user throughput. We assist the performance of user selection when using fixed power allocation. Finally, we propose NOMA with COMP scenario whose performance improvement lead for user and cell throughput.**

Keywords—NOMA; JP; Heterogeneous.

I. INTRODUCTION

Heterogeneous Network (HeNet) is one of new technologies defined by 3GPP to improve LTE advanced network performance, it consists the deployment of macro cell with different cells such as microcells, femtocells, and picocells which enhance cellular network capacity [1].

Femtocells, also known as home eNodeB were first introduced in 3rd Generation Partnership Project (3GPP) Release 8, signaling that it had become a mainstream wireless access technology [2].

Femtocells promise improved indoor coverage and increased throughput for mobile data services while off-loading traffic from expensive macro radio access networks onto the low cost public Internet [3].

Femtocells access mode defines which user is allowed to use each femtocell. Two modes are defined, open access mode which every registered and unregistered user can access that femtocell but disadvantage of this mode is increased of signaling overhead. In the closed access mode only registered users are served by femtocell. Even femtocell provide higher signal quality than open access mode, the disadvantage of this type leads to high cross interference [4], [5].

Power control of HNB is interference management technique which mitigates interference to both macro user equipment (MUE) and home (femto) user equipment (HUE), it can be achieved by minimizing total transmission power of HeNB [6], [7]. The downlink transmission from HeNB will affect on nearby MUE when using co-channel deployment between macro and femto cell, strong interference from HNB may cause the received signal from macro to MUE degraded and unacceptable.

The enhanced Inter Cell Interference Coordination (eICIC) in heterogeneous networks is an efficient inter cell interference scheme compared to ICIC in LTE release 8 and 9 which that ICIC only consider data channels and didn't focus in interference between control channels [8], but in LTE release 10 solve this problem by two main solution, one in time domain multiplexing such as almost blank subframe (ABS), the other in frequency domain multiplexing such as carrier aggregation (CA).

The design of radio access technology (RAT) is one important aspect of improving system capacity. Radio access technology are characterized by multiple access scheme such as code division multiple access (CDMA), time division multiple access (TDMA), frequency division multiple access (FDMA), or orthogonal frequency multiple access (OFDMA), which indicate how multiple users access and share the system resources [10].

Non orthogonal access code division multiple access (CDMA) is widely used in the 3rd generation mobile communication system. Orthogonal frequency division multiple access (OFDMA) is adopted in 4th generation mobile communication system e.g., LTE and LTE-advanced for achieving good system throughput.

As candidate multiple access for future radio access, Non orthogonal multiple access (NOMA) over orthogonal multiple access (OMA) are adopted as downlink access scheme for future 5th generation mobile communication. In NOMA multiple users are multiplexed in power domain in base station (transmitter side) and in receiver side serial interference cancellation (SIC) are used to separate multiuser signals [11].

Cooperative MIMO (Co-MIMO) technique also referred to as coordinated multi-point transmission (CoMP) has emerged as a key enabling technique to improve system spectral efficiency and effectively mitigate inter cell interference (ICI). The cooperative transmission techniques involve two categories i.e. joint processing (JP) and coordinated beamforming (CB). Coordinated joint processing uses simultaneous transmissions of data from multiple transmission points to a single user in order to improve its received signal

quality and actively cancel the interference from other cells. It involves sharing of data and channel state information (CSI). In coordinated beamforming, data for a single user is instantaneously transmitted from one of the transmission points; however, coordinated beamforming/scheduling is performed to reduce the interference caused to other cells [12].

In this paper we showed the effect of imperfect interference cancellation on user throughput when using serial interference cancellation in receiver side. We compare through computer simulation between two users selection schemes when using fixed power multiplexing allocated to users in transmitting side using non orthogonal multiple access. We showed improvement of using NOMA over OMA in heterogeneous network downlink. Proposed Joint Processing with NOMA scenario will be shown as the method which improves user and cell throughput. The remainder of this paper is organized as follow: NOMA concept described in section II. Mitigation interference scheme and COMP are described in section III and section IV, respectively. Section V describes our proposed NOMA with Joint transmission. System simulation model are presented in section VI, followed by simulation results in section VII. Conclusion of paper is shown in section VIII.

II. NON ORTHOGONAL MULTIPLE ACCESS

NOMA is the one of the most promising technologies that it will play a central role in the 5th generation network. NOMA is a combination of OFDMA with superposition and interference cancellation techniques. It uses new path loss profile which utilizes pathloss difference for user multiplexing purposes and is proved more efficient than OFDMA.

A) NOMA Transmission

The basic concept of NOMA downlink as the eNB select two users have different channel gain and send two signals to each users but in different power allocation. For NOMA transmitter side, the total power for any multiplexed two users is the same. User whose channel gain is better condition than the another user is allocated less power, so power allocated to each user and selecting two pair users affect not only to user throughput but also other user due to inter-user interference.

B) NOMA Receiver

At the receiver side, where user 2 has a better channel than user 1 and hence can decode any data that user 1 can successfully decoded. Using superposition coding scheme, user 1 treats signal of user 2 as noise and decodes its data from y_1. User 2, which has better channel, performs successive interference cancellation (SIC): it decodes the data of user 1 (treats its data as interference) and then proceeds subtract signal of user 1 from y_2 and decode its data, with each possible split power $P=P_1 + P_2$, [12], [13]. The following throughput of two users as:

$$R_1 = log_2\left(1 + \frac{P_1|h_1|^2}{P_2|h_1|^2+N_{0,1}}\right) \quad (1)$$

$$R_2 = log_2\left(1 + \frac{P_2|h_2|^2}{N_{0,2}}\right) \quad (2)$$

Where P_1 and P_2 are transmitted power for users i=1,2. h_1 and h_2 are channel gain for two users, N is power of additive white Gaussian noise, R_1 and R_2 are throughput for two users.

C) Imperfect successive interference cancellation

In fact not all interference power is removed under cancellation; the parameter $\varepsilon \rightarrow [0, 1]$ gives the residual power of user after cancellation. The equation (2) after considering imperfect interference cancellation will be:

$$R_2 = log_2\left(1 + \frac{P_2|h_2|^2}{\varepsilon_1 P_1|h_2|^2 + N_{0,2}}\right) \quad (3)$$

Where ε is imperfect interference cancellation, $\varepsilon = 0$ for perfect interference cancellation. In simulation we show different values of ε.

D) Transmit power allocation

Due to power domain multi user multiplexing, the transmit power allocation (TPA) is important consideration in NOMA downlink, it affects the achievable throughput not only that user but throughput of system. In our simulation we compare between two transmit power allocated schemes, first used in [14], which called Pre defined user group and per group fixed power allocation (FPA) and our proposed scheme is user sorting power allocation (USPA). In first scheme, the users are divided into two different user groups according to their channel gains and pre defined threshold. In FPA, the users can be paired together only if they belong to different user groups. In the second scheme; the user sorting power allocation (USPA) is described as follow:

- PF scheduling calculates maximum priority for each user and sorts Users corresponding to their maximum priority.
- Users which will be selected by PF are sorted in descending order according to their signal to interference ratio (SIR), so high SIR users are the top of this list.
- The Scheduler Divides this list into two groups
- The users can paired together from different group (top of group 1 will be paired with top of group 2,etc)

III. MITIGATION INTERFERENCE SCHEME

In heterogeneous network, when macrocell network operates on the same carrier as HeNBs, HeNB-macrocell interference can result degrading performance in some scenario, indoor MUE which can't be associated to HeNB due to presence of CSG (closed subscriber group) nodes, MUEs are affected by interfering signal coming from HNB, also MUEs close to building (near outdoor) may experience to interference then may lead to degrade signal to interference ratio. Inter femto interference is other interference will be taken account in our simulation, since due HUE can be associated to HeNB in the same apartment or macrocell, the interference comes from HeNB neighbor apartment may be strong. Two mitigation interference schemes will be used in our simulation; Autonomous power control method and

enhanced ICIC in time domain which named as almost blank subframe (ABS).

A) Power control

To limit the impact interference of femtocell on existing heterogeneous network, it desired to limit transmission power control of CSG HeNBs; we used method which described in [15]. The following equation represents the power control algorithm for HeNB

$$P_{TX} = \max(P_{TX,min} , \min(P_{TX,max} , P_{RX} + PL - \lambda)) \quad (4)$$

Where P_{TX} is HeNB transmission power, $P_{TX,min}$, $P_{TX,max}$ are the minimum and maximum transmission powers which values are -10 dBm and 20 dBm, respectively. P_{RX} is the power received from the strongest macro (MNB), PL is the assumed pathloss in dB, and λ is the target minimum C/I value in dB. The target is to minimize interference to macro network, while the pathloss determines the desired HeNB coverage; it should be set to maximum pathloss for any link between HeNB and its HUE in same apartment (the value in our simulation is 60dB)

B) Almost Blank Subframe (ABS)

The basic idea is to have some subframe which femtocell is not allowed to transmit data. This scheme is called Almost blank subframe (ABS), ABS is TDM (time domain multiplexing) scheme for enhanced inter-cell-interference coordination (eICIC)[9]. To alleviate this issue, subframe resources are split among macrocell and femtocell to improve reliability [15], it means that macrocell can use all resources but femtocell can use only half of all subframe.

IV. Coordinated MultiPoint Transmission

Depending on whether the user data is shared among all the transmission points within a CoMP cluster, downlink CoMP transmission schemes can be divided into two main categories: coordinated scheduling/beamforming and joint processing.

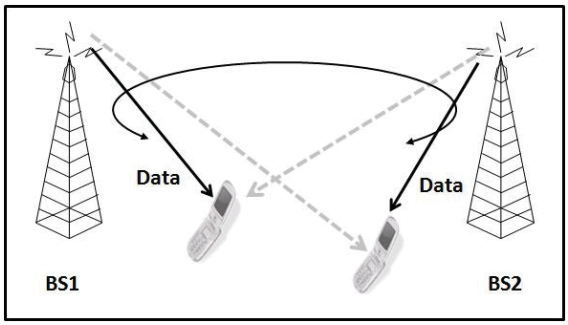

Fig. 4.Coordinated Scheduling/Beamforming Scheduling

A) Coordinated Scheduling/Beamforming Scheduling (CS/BS)

In CS/BS as shown in figure 4, user data is only available in one cell, and coordinated beamforming and scheduling is done between cells to reduce interference to other cells

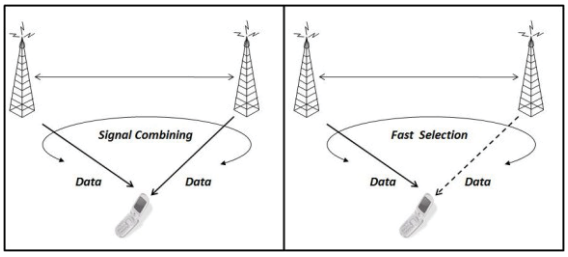
B) Joint Processing (JP)

In joint processing approach, user data is available simultaneously at all transmission cells. JP is further categorized into Joint Transmission (JT) and Dynamic Cell selection (DCS) as shown in figure 5a and 5b respectively.

In JT the same resource block (RB) of physical downlink shared channel (PDSCH) is transmitted from multiple cells among coordinated cells. In DCS, RB of PDSCH is transmitted from one cell among the coordinated cells. The unique cell is dynamically selected by fast scheduling where minimum pathloss is considered [16] and [17].

V. Proposed NOMA with Joint Transmission

We extend our simulation with NOMA to base station (BS) cooperative cellular downlink for future radio access. Since the MIMO capacity is increased as the numbers of transmitter and receiver antennas are increased, while the allowable numbers of these antennas per BS and user terminal are limited, employing a combination of BS cooperation and multiuser MIMO is an effective way to enhance the cellular system performance.



a) Joint Transmission b) Dynamic cell selection

Fig. 5.Joint Processing

For the proposed NOMA in a BS cooperative scenario, we employ NOMA with Joint transmission in this paper. We show that the proposed NOMA scheme with BS cooperation achieves better system-level throughput compared to OMA. We also show that the effect of the proposed NOMA scheme is more significant when BS cooperation is assumed since the BS cooperation improves the channel conditions of the cell-edge users, which are appropriate for obtaining a higher non-orthogonal user multiplexing gain. Figure 6 shows the flow chart of proposed NOMA with Joint Transmission.

VI. System Simulation Model

Simulation model is Macro-Femto cell deployment (heterogeneous network) which according to model described in [16] which some assumption and parameters used in simulation.

We employed 19-hexagonal macrocell with an inter site distance (ISD) of 500m; each macro node cell site includes three cells with antenna boresights pointing in the three horizontal directions separated by 120 degrees. The system bandwidth is 10 MHz, it means 50 RBs (Resource blocks).Macro transmission power in each cell equal to 46 dBm.25 macro UEs are dropped randomly following a uniform distribution in each cell dropped within the cell site

area. Dual strips model of HeNBs are randomly dropped in each cell, dual strips are composed of two building separated by one strip as shown in Figure. 5. A uniformly distributed is independently generated for each apartment.

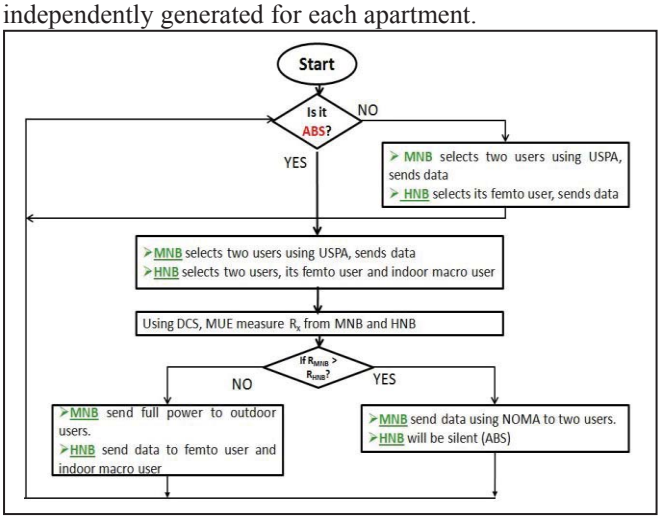


Fig. 6.The flow chart of proposed NOMA with Joint Transmission

HeNB and associated HUE are dropped in random location with minimum separation 3 m for each apartment, note that HeNB are assumed to be closed subscriber group (CSG) cells, we assume that both HeNBs and macro are synchronized in both time and frequency domain.

HUEs may associate to either its HeNB in its apartment or macrocell depending on received power, while MUE (macro user equipment) can only associate to MNB (macrocell), minimum distance between MNB and MUE is 35 m [15]. In our simulation we use 35% of MUEs are dropped indoor in random location. We assume two transmit antennas at the eNBs and two receive antennas at the UEs. UEs are assumed to be served using transmission mode 4 (TM4) as described in the LTE terminologies [6]. The maximum HeNB transmission power is 20 dBm. The deployment configuration channel is co-channel for both macro eNBs and HeNBs; they share the same spectrum. 5ms reporting periodicity is assumed while mobile speed is assumed to be 3m/s. Proportional fair is downlink scheduler in our simulation that at each Transmission Time Interval (TTI).

VII. System Results

We show in figure 8 comparison of cumulative distribution function for our heterogeneous network (macro and femto) model using orthogonal multiple access (OMA) and non orthogonal multiple access (NOMA) and see how NOMA boost user throughput comparing to OMA, this is because user throughput of orthogonal multiple access is limited by orthogonal bandwidth allocation. Figure 9 shows comparison between two schemes; Pre defined user group and per group fixed power allocation (FPA) and; user selection power allocated (USPA).Due to using high difference in channel gain USPA scheme lead improvement in user throughput than FPA. It shows that MUE throughput improve when using USPA, 90% of users in USPA are getting more than 0.5 Mbps versus 87% of users are getting more than 0.5 Mbps in FPA.

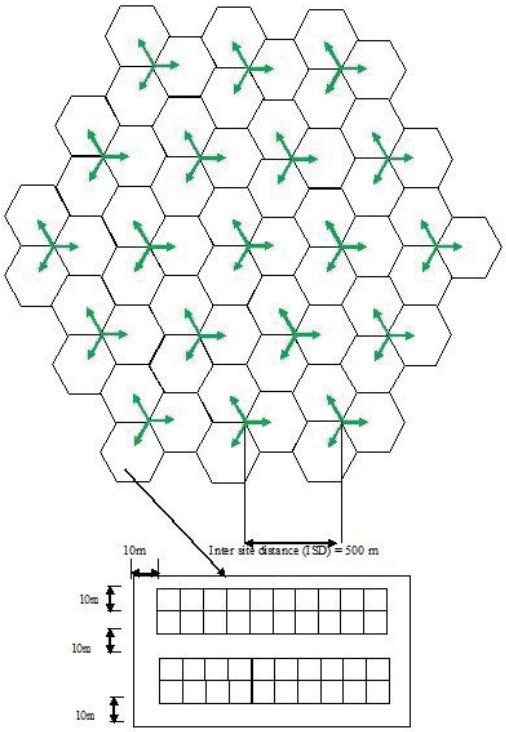

Fig. 7. System simulation model

In fact not all interference power is removed under cancellation; the parameter ε → [0, 1] gives the residual power of user after cancellation. ε =0 for perfect interference cancellation. Figure 10 compares between the effects of different imperfect interference cancellation on macro users throughput, it shows the throughput improves when imperfect interference cancellation decreases. Figure 11 shows the comparison between macro users throughput with COMP and without COMP, with COMP; only 40 percent are getting lower than 3 Mbps but without COMP, approximately 80% are getting lower than 3Mbps.

VIII. Conclusion

In this paper, we evaluate LTE heterogeneous network (macro femto network) with closed femto cells. We propose user selection with fixed power allocation scheme for NOMA downlink in heterogeneous network (USPA) and compare with FPA scheme. We propose Joint transmission as COMP techniques with NOMA in heterogeneous network and show how downlink Joint processing with NOMA improves average user throughput and cell throughput .

***Abstract*—Increasing demand for wireless services requires fast and robust broadband wireless communication for efficient utilisation of the scarce electromagnetic spectrum. Multi-carrier modulation and the use of multiple antennas coupled with multiple-access techniques have emerged as one of the promising solutions for high-speed future wireless communication. In this paper, we investigate the performance of a multi-antenna space-time block-coded (STBC) multi-carrier code-division multiple-access (MC-CDMA) system in a frequency-selective channel using Gold codes as spreading sequences. Results show that for a STBC CDMA system in a flat-fading channel at low signal-to-noise ratio, the coding gain provided by the codes surpasses the diversity advantage provided by the use of multiple antennas. The combination of diversity gain from the use of multiple antennas, coupled with coding gain provided by the Gold codes, plus the diversity gain resulting from frequency diversity of multi-carrier transmission and spectrum-spreading makes the composite STBC MC-CDMA system resilient to channel fading. This fact is particularly the case for long codes.**

Keywords— Space-time block coding, code-division multiple-access, orthogonal frequency-division multiplexing, multi-carrier transmission, Gold codes, spatial diversity, coding gain.

I. INTRODUCTION

The limited radio frequency spectrum, the harsh mobile environment, and the ever-increasing demand for wireless applications calls for advanced techniques for combatting the hostile environmental factors and for more efficient use of the scarce radio spectrum. One of the promising techniques for future wireless communication is the deployment of multi-input multi-output (MIMO) antenna system with orthogonal frequency division multiplexing (OFDM) coupled with multiple-access techniques. The combination of these techniques guarantees a much more reliable and robust transmission over the hostile wireless channel. This paper models the performance of a MIMO space-time block-coded (STBC) OFDM-CDMA system in a fading channel. The motivation for investigating space-time coded OFDM-CDMA system is because of the robustness of OFDM-CDMA against channel fading [1], and space-time coding in harnessing diversity and coding gain for improved system performance [2]. OFDM converts a frequency-selective channel to a flat-fading channel. Furthermore, the combination of OFDM and CDMA, as found in a multi-carrier (MC) CDMA, lowers the symbol rate in each subcarrier, the advantage being that a longer symbol duration makes it easier to quasi-synchronise the transmission. It also enables the use of a guard interval which helps in eliminating inter-symbol interference (ISI) [1-3].

Space-time coding (STC) is known to be an effective diversity technique for combating channel fading without bandwidth penalty. STC combines transmit diversity with coding scheme. In recent years, different types of space-time coding schemes, including space-time block codes (STBC), space-time trellis codes (STTC), concatenated STBC-STTC, and super-orthogonal STTC (SOSTTC), have been studied [4-6]. STBC, first proposed by Alamouti in 1998 [7], and later generalised by Tarokh [8, 9], provides diversity gain but no coding gain. However, the attractiveness in STBC includes its ability to achieve maximum possible diversity advantage, coupled with the simplicity of its implementation and decoding algorithm [10].

Although significant amount of work has been done on space-time-coded MC-CDMA systems, available literature shows that existing works have been largely limited to the use of Walsh-Hadamard codes as spreading sequences. Only a few reported works [11-14] involving the performance of Gold codes in such systems are available, and we seek to add to this small collection. In this paper, we investigate the performance of a series of Gold codes in a space-time coded CDMA system.

The rest of this paper is organised as follows. A description of the communication system is given in Section II. Results of software simulations are presented and discussed in Section III. The paper concludes with a summary of important results in Section IV.

II. SYSTEM MODEL

A space-time coded MC-CDMA system combines the positive advantages of space-time coding, multicarrier modulation with that of a CDMA system. Fig. 1 shows system block of a space-time coded MC-CDMA system for a single user. Here, the user source signal, represented by the vector $\boldsymbol{X}$, is first space-time coded by the STC encoder into parallel sub-streams. The CDMA encoder then encodes each sub-stream using a user's unique code. Each of the encoded sub-streams is placed on a subcarrier for onward transmission via the multiple transmit antennas through the wireless channel. The transmitted sub-streams convolves with the channel, and are then picked up by the receive antennas. At any time instant, the signal detected by each receive antenna is a summation of all the signals coming from the transmit antennas. To recover the original signal, the receiver carries out the reverse process on the detected signal.

Fig. 2 is another block diagram of the STC MC-CDMA system showing details of signal transformation through the communication system. This is described as follows. In the transmitter, the source signal is first space-time coded by the STC encoder into sub-streams. Each sub-stream is converted from serial to, say, N_p parallel symbol streams, having a symbol duration T_s. Each symbol stream is multiplied by the user code $c_k(t)$, after which the resulting signal for the pth

symbol stream modulates a subcarrier f_p. The subcarriers are orthogonal on the symbol duration and are given by $f_p = f_o+p/T_s$, where f_o is RF frequency. The multicarrier signal is obtained from addition of the different subcarrier signals. The resulting OFDM symbols are transmitted simultaneously from the individual transmit antennas. The received signal *r(t)* is a convolution of the multicarrier signal and the channel impulse response corrupted by noise. To recover the original data, the receiver carries out the reverse of what the transmitter does. In actual implementation, inverse fast Fourier transform (IFFT) and fast Fourier transform (FFT) are normally employed by the OFDM modulator at the transmit and the receive end respectively for improved system efficiency.

Starting from basic principles, we will now be developing a mathematical description of the communication system. The treatment begins by considering a simple direct-sequence (DS) CDMA system.For a multi-user DS-CDMA system comprising *K* users, the received signal *r(t)* at time *t* is a linear superposition of the signals for all users. We can show that the received signal *r(t)* is given by Equation (1), where user *k* is user index, c_k(t) is the code sequence for the user, $b_{k,t}$ is the user binary data, ω_c is carrier frequency, and θ_k is phase angle, $\beta_{kl,}$ is path gain for user *k* and path *l*, τ_{kl} is propagation delay, γ_{kl} *is* phase shift, *l* is path index, *L* is number of paths, and $n_{k,t}$ represents channel noise.

Now consider a space-time coded CDMA system with a transmit diversity scheme having n_T transmit antennas. Let $\boldsymbol{b_{k,t}}$ be the user data, space-time coded onto the n_T transmit antennas. The user data can be represented by a vector as

$$\begin{aligned} \boldsymbol{b_{k,t}} &= \left\{ b_{k,t}^{i} \right\}, \qquad i = 1, 2, \ldots, n_T \\ &= \left\{ b_{k,t}^{1}, b_{k,t}^{2}, \ldots, b_{k,t}^{n_T} \right\} \end{aligned} \tag{2}$$

where $b_{k,t}^{i}$ is the user data for antenna *i* at time *t.* For a multi-user system comprising *K* users, we can show that the received signal *r(t)* is a linear superposition of the signals for the users, and is given by Equation (3).

The space-time coded CDMA system above involves multiple transmit but single receive antenna. Now consider a space-time coded system with both transmit and receive diversity involving multiple antennas at both ends: multiple n_T transmit and n_R receive antennas. Received signal $r_{k,t}^{j}$ at j^{th} receive antenna and time *t* is a superposition of the signals

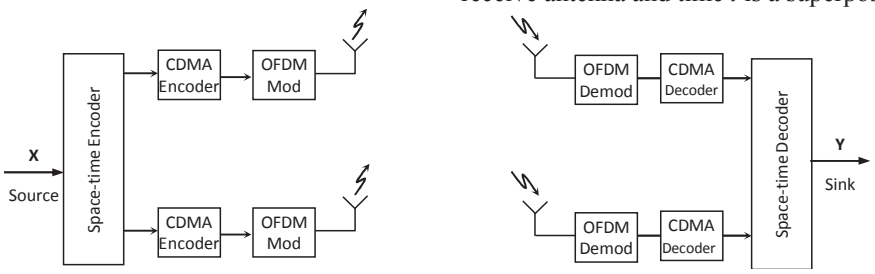

Fig. 1. Space-time coded MC-CDMA system.

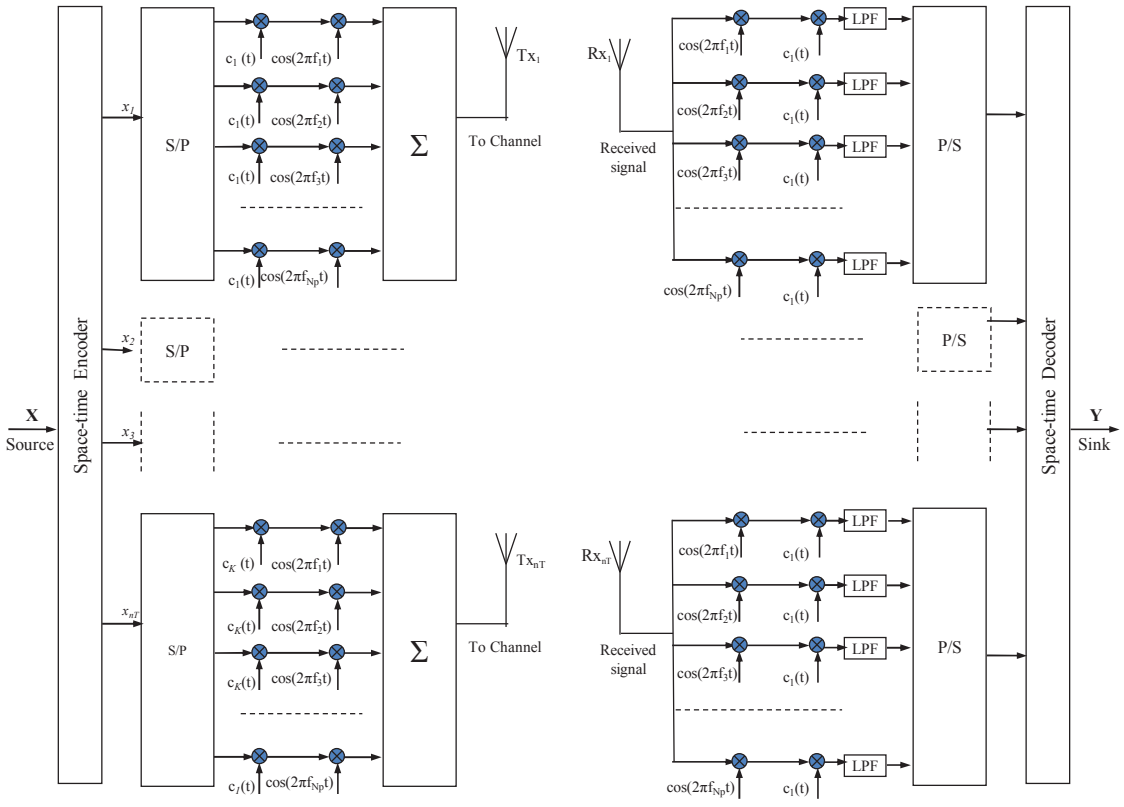

Fig. 2. Space-time coded MC-CDMA system showing details of signal transformation

coming from all the transmit antennas. Received signals for the all the receive antennas can be represented by

$$\begin{aligned} \boldsymbol{r}_{k,t} &= \left\{ r_{k,t}^{j} \right\}, \qquad j = 1, 2, \ldots n_R \\ &= \left\{ r_{k,t}^{1},\ r_{k,t}^{2}, \ldots, r_{k,t}^{n_R} \right\} \end{aligned} \tag{4}$$

Following a similar argument to that of the previous section, we can show that the signal received at the j^{th} receive antenna at time t for a multi-user system comprising K users is given by Equation (5). The array of signals $\left\{ r_{k,t}^{1},\ r_{k,t}^{2}, \ldots, r_{k,t}^{n_R} \right\}$ from the n_T transmit antennas can be combined using receive diversity technique such as maximal ratio combining, equal gain combining or selection combining.

Consider a space-time block code transmit diversity scheme involving two transmit antennas. Its generator matrix G for complex orthogonal design is given by [7, 8]:

$$G_2 = \begin{pmatrix} x_1 & x_2 \\ -x_2^* & x_1^* \end{pmatrix} \tag{6}$$

where columns signify transmit antennas and rows signify time instances. Thus, at time $t = 1$, x_1 and x_2 will be transmitted from antenna 1 and 2 respectively, while at time $t = 2$, $-x_2^*$ and $-x_1^*$ will be transmitted from antenna 1 and 2 respectively. Assuming a single receive antenna, and fading coefficient to be constant over two consecutive time slots, the received signal is given by

$$r_1 = h_1 x_1 + h_2 x_2 + \eta_1 \tag{7}$$

$$r_2 = -h_1 x_2^* + h_2 x_1^* + \eta_2, \tag{8}$$

where h_1 and h_2 signify the coefficients of the channel, and η_1 and η_2 the channel noise. For a space-time block code scheme involving four transmit antennas, transmission matrix G for real orthogonal design is given by [4, 5, 8]

$$G_4 = \begin{pmatrix} x_1 & x_2 & x_3 & x_4 \\ -x_2 & x_1 & -x_4 & x_3 \\ -x_3 & x_4 & x_1 & -x_2 \\ -x_4 & -x_3 & x_2 & x_1 \end{pmatrix} \tag{9}$$

Gold codes are a type of pseudo-noise (PN) sequences derived from combination of certain pairs of *m*-sequences called the *preferred sequences*, implemented using Linear Feedback Shift Registers (LFSR). A Gold code has a period $N = 2^n - 1$, where n is the length of the shift register.

III. Results and Discussion

Software simulations were carried out to investigate the performance of an OFDM-modulated as well as a STBC MC-CDMA system in a Rayleigh frequency-selective fading channel. The channel was assumed to be quasi-static, meaning that the fading process remained constant during transmission of each data frame.

A. STBC versus CDMA system

This section compares the performance of a transmit diversity system with that of a CDMA system for a 31-chip Gold code. Looking at Fig. 3, it can be seen that the Gold code provides a coding gain of about 14 dB, relative to the uncoded, no-diversity case. However, the code provides no diversity gain. Another look at this figure shows that in terms of bit-error-rate (BER), at low Eb/No the coding gain provided by the Gold code surpasses the diversity advantage provided by the use of the multiple antennas.

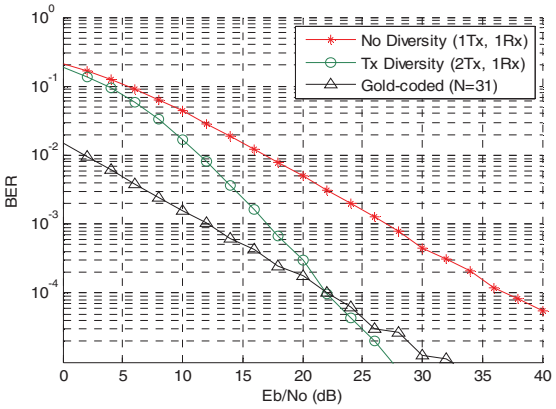

Fig. 3. Performance of a STBC system versus a Gold-coded system

B. STBC-CDMA system

This section presents the performance of a STBC CDMA system. Fig. 4a shows the results for a 31-chip Gold code. Looking at this figure, it can be seen that the STBC-CDMA system provides both diversity and coding gain. The curve for the plain 2x1 system is seen to be parallel to that of the STBC-CDMA system, which clearly shows that space-time coding is solely responsible for the diversity gain, while Gold code encoding is responsible for the coding gain. In the composite STBC-CDMA system, the diversity advantage of the STBC is complemented by the coding gain of the CDMA, giving better system performance. Diversity decreases the asymptotic error rate as a function of signal-to-noise ratio (SNR), while coding gain provides vertical shift of the error performance curve. At a BER of 10^{-3}, there exists about 12 dB difference between the coding gain of a CDMA-only system and its space-time-coded counterpart. This difference in coding gain grows with decent in BER. Apart from these, the figure also shows that the coding gain between the no-diversity link and its Gold-coded counterpart is the same as that between the transmit-diversity link and its Gold–coded counterpart.

$$r(t) = \sum_{k=1}^{K} \sum_{l=1}^{L} A \beta_{kl} e^{j\gamma_{kl}}\ c_k (t - \tau_{kl})\, b_k (t - \tau_{kl}) \cos\left(\omega_c (t - \tau_{kl}) - \theta_{kl}\right) + n_{k,t} \tag{1}$$

$$r(t) = \frac{1}{\sqrt{n_T}} \sum_{k=1}^{K} \sum_{i=1}^{n_T} \sum_{l=1}^{L_i} \beta_{kl}^{i} e^{j\gamma_{kl}^{i}}\ c_k \left(t - \tau_{kl}^{i}\right) b_k \left(t - \tau_{kl}^{i}\right) \cos\left(\omega_c \left(t - \tau_{kl}^{i}\right) - \theta_{kl}^{i}\right) + n_{k,t} \tag{3}$$

$$r^{j}(t) = \frac{1}{\sqrt{n_T}} \sum_{k=1}^{K} \sum_{i=1}^{n_T} \sum_{l=1}^{L_{i,j}} \beta_{kl}^{i,j} e^{j\gamma_{kl}^{i,j}}\ c_k \left(t - \tau_{kl}^{i,j}\right) b_k \left(t - \tau_{kl}^{i,j}\right) \cos\left(\omega_c \left(t - \tau_{kl}^{i,j}\right) - \theta_{kl}^{i,j}\right) + n_{k,t}^{j} \tag{5}$$

Fig. 4b shows simulation results for a 127-chip Gold code. It can be seen that this figure has similar features with Fig 4a of 31-chip Gold code. However, the 127-chip provides greater coding gain than the 31-chip Gold code. This is expected, consequent to difference in process gains of the codes.

C. *Performance in a frequency-selective channel*

We shall now be looking at results of the system performance in a frequency-selective Rayleigh fading channel. A four-path channel with fixed path delays and path gains were considered for a sample frequency of 10 kHz and a maximum Doppler shift of 83.3 Hz. Table 1 shows the simulation parameters. The performance of a space-time coded OFDM system as well as a MC-CDMA system were investigated for a single user. The number of subcarriers was kept fixed at 64. Cyclic prefix was added after IFFT at the transmitter, and removed at the receiver before FFT. The simulation results shall now be presented as follows.

D. *Space-time coded OFDM system*

Here, the performance of a space-time coded OFDM system in the frequency-selective channel is considered. For comparison, the results, Fig. 5, show the performance for a single-antenna, no-diversity (1x1) case for transmit diversity and MRC receive diversity. The water-fall region of this figure shows that the transmit and the receive diversity schemes provide the same diversity gain. This agrees with expectation, both being second-order diversity schemes. However, the figure shows that the receive diversity has a 3-dB advantage over the transmit diversity. This is because total transmitted power is modelled to be the same in both cases, such that the power transmitted from each transmit antenna of the latter is half that of the former. If the transmitted power is made to be the same in both cases, then the performance would be identical. It is noteworthy that these features are similar to those observed for a flat-fading channel.

Another important feature of Fig. 5 is the appearance of error floor. This error floor cannot be attributed to multi-user interference, as there is no interferer here. Rather, it originates from multi-paths characteristics of a frequency-selective channel. The figure shows that the receive diversity's 3-dB advantage is lost in the error floor region, such that both the transmit and the receive diversity schemes exhibit the same level of error floor. Compared to no-diversity scheme, the benefit of using multiple-antenna is obvious, as revealed by the lowering of error floor by the latter. A close look at the performance curves shows that whereas the error floor for no-diversity is about 0.1479, it is about 0.0740 for transmit diversity (see data tips). Dividing the former by the latter gives 1.9995, which indicates that the diversity scheme reduced the error floor by a factor of two.

TABLE I. SIMULATION PARAMETERS

Modulation type	QPSK
Frame size	64 QPSK symbols
No. of subcarriers	64
Cyclic extension (25%)	16 symbols

E. *Space-time block-coded MC-CDMA system*

This section presents results on the performance of a STBC MC-CDMA system in the frequency-selective channel. Results for STBC-OFDM are also included for the purpose of comparison. Simulations were carried out on the system performance for Gold codes of different lengths. Fig. 6 shows results for a 31-chip Gold code. It is obvious from this figure that a STBC MC-CDMA system has better performance than its STBC-OFDM counterpart. Comparing no-diversity transmission shows that at a BER of 10^{-1}, the use of the 31-chip Gold codes in the MC-CDMA system provides a coding gain of about 16.272 dB relative to the OFDM system (Fig. 5). For the transmit diversity scheme, the STBC MC-CDMA provides

a coding gain of about 15.516, relative to the OFDM system. Another look at the figure shows that the performance curves of STBC MC-CDMA and the STBC OFDM has similar slopes in the waterfall region. This indicates that the MC-CDMA provides no additional diversity gain to the STBC MC-CDMA system. That is, for the 31-chip Gold-coded STBC MC-CDMA system, diversity gain originates solely from the use of the multiple antennas, while coding gain comes from Gold codes.

Another important feature in this figure is the level of error floor. It is obvious from Fig. 6 that the STBC MC-CDMA system has lower error floor than the SBTC-OFDM system. For the no-diversity scheme, error floor is about 0.1479 (Fig. 5) for OFDM transmission, and 0.1271 for MC-CDMA. For transmit-diversity scheme, error floor is about 0.0738 for OFDM transmission, and 0.0591 for MC-CDMA. For the MC-CDMA system, the results show that the use of transmit diversity provides about 2.164 reduction in error floor.

We shall now consider simulation results for a 127-chip Gold code, as shown by Fig. 7. Looking at this figure, it is obvious that this longer code gives a better performance than its 31-chip counterpart in terms of BER, coding gain, diversity gain and level of error floor. For the no-diversity transmission at a BER of 0.2, the 127-chip Gold codes provides a coding gain of about 24.944 dB relative to the OFDM system. Looking at the results for the transmit diversity scheme shows that for the 127-chip code, the performance curve for the STBC MC-CDMA has steeper slope in the waterfall region than its STBC-OFDM counterpart. This implies that the former has a higher diversity gain than the latter. This can be compared to the results for 31-chip Gold code, for which the two systems have similar slopes in the waterfall region. The extra diversity gain observable in the 127-chip system could only be attributed as coming from MC-CDMA. For the 127-chip code, MC-CDMA provides not only coding gain, but also diversity gain.

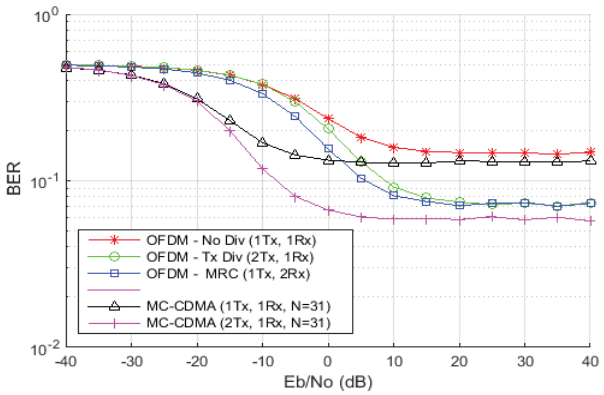

Fig. 6. Performance of a STBC MC-CDMA system for a 31-chip Gold code.

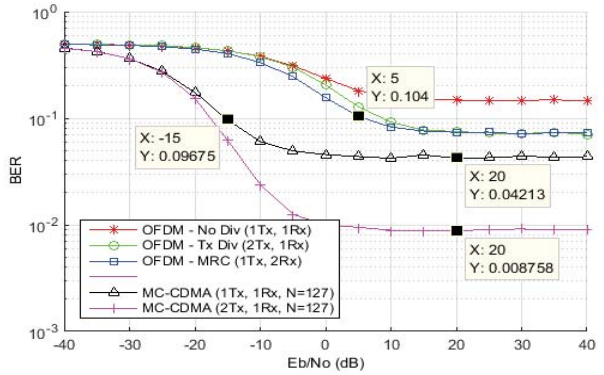

Fig. 7. Performance of a STBC MC-CDMA system for 127-chip Gold code

Now turning to the level of error floor, the results show that for the no-diversity case, error floor is about 0.04214 for 127-chip MC-CDMA system. With reference to the OFDM system, this is equivalent to a factor of about 3.51 reduction in error floor. For transmit-diversity scheme, error floor is about for 0.0088 for the 127-chip MC-CDMA, which is equivalent to a factor of about 8.4164 reduction in error floor

IV. Conclusion

This paper presented the performance of a space-time block-coded multi-carrier CDMA system using Gold codes as spreading sequences. Results on the performance of a space-time block-coded OFDM system in a frequency-selective channel showed that the receive diversity's 3-dB advantage over its transmit diversity counterpart was lost in the error floor region, such that both the transmit and the receive diversity schemes exhibited the same level of error floor. The results also showed that with reference to no-diversity transmission, the transmit diversity reduced the system error floor by a factor of two. The outcome of investigation of the performance of a space-time block-coded multi-carrier-CDMA system showed that the composite system is resilient to fading particularly for long codes, resulting in significant lowering of error floor.

***Abstract*— Vital signs (heart rate, respiratory rate, body temperature, and blood pressure) are features of physiological functions expressing the physical condition. The doctors use them during early diagnoses. The information about the heart rate is the primary vital sign which needed on a human approach in both emergency and clinical situations. Noncontact detection and monitoring of the human heart are well-accepted solutions for intensive care monitoring or home health care applications. This paper deals with the remote assessment of the heart (pulse) rate by facial color processing. The information is obtained by processing a certain color from the video signal. There is a maximum difference in spectral absorption of the colors for the two min components of the blood: oxy-hemoglobin and deoxy-hemoglobin. Biological signal was recorded from a video camera during 20 s, and it was associated with an important component of background noise. Results using variational mode decomposition (VMD) algorithm for determining heart rate (HR) of the facial color processing are presented and are compared with those obtained by using the empirical mode decomposition (EMD) algorithm. HR values are similar to those measured with a pulse oximeter in the same time period when the level of the signal to noise ratio is high. At small level of this ration, the EMD algorithm did not work properly.**

Keywords*— heart rate, facial expression, pattern recognition, computer vision, biomedical signal processing

I. INTRODUCTION

Status human health can be judged by measuring physiological parameters, which usually are interdependent. The most important common medical tests consist in verifying work of heart, respiratory system, and body's temperature. The accurate measurement and monitoring of these physiological parameters plays an important role in a wide variety of applications in healthcare, psycho-physiological examinations, sports training, and so forth. Abnormal levels of these parameters represent important risk factors for health.

Cardiovascular disease is the leading cause of death in almost all countries. Aging is another risk factor. The aging process involves various chemical and physical alterations which contribute to cognitive decline. There is a difference between natural cognitive decline and cognitive impairment [1]. Mild cognitive impairment (MCI), for example, is the earliest detectable stage. MCI may aggravate functioning daily life. For example, symptoms of memory loss and difficulty subtle in execution of complex cognitive tasks may occur [1, 2]. Early detection of these vulnerabilities could allow more successfully applying of preventive treatments. Pulse rate (PR) and heart rate variability (HRV) are important physiological markers to identify these higher risks [3].

The influences from many sources: physiological, behavioral, affective, cognitive, social, and environmental shape the heart activity under brain control. There are many studies in the literature that shows significant correlations between HR and cognition. Early HR control is important to reduce the development of cognitive symptoms in later life. A high HR suggests a major risk factor (especially midlife) [3, 4], and a low BP is more detrimental (particularly in older age) [5]. The brain is connected bidirectionally with the heart by the central autonomic network (CAN). The HR is the interplay between the parasympathetic (high frequency (HF)) and sympathetic (low frequency (LF)) branches. In the case of the short-term time series, the power spectrum contains two major components, a high (0.15–0.40 Hz) and low (0.01–0.15 Hz) frequency components. The poor cognition is linked to a low HR because the system autonomy is less reactive to changes in the external environment and is therefore less adaptable. The effects of the sympathetic nervous system neurotransmitters like norepinephrine are the slow time scale of seconds, while the parasympathetic nervous system effects using acetylcholine are fast, millisecond time scale.

Vital signs are parameters of physiological functions expressing the physical condition and are used for making initial diagnoses, and heart rate is considered as the primary vital sign information which is needed on a human approach in both emergency and clinical situations. There are many sensing principles and monitoring methods for HR evaluation, but the simplest method is palpation of some arteries. Traditional techniques for the HR measurement are contact-based and require sensors to be placed on certain positions on the body surface by finding certain points on the skin where the artery's pulsation is transmitted to the surface. The evaluation process of HR is a little bit difficult for certain people like premature neonates, infants at risk of sudden infant death syndrome, burn victims, and elderly. Sometimes, these methods may influence the underlying physiological parameters being measured.

Public compliance depends in part on the monitoring being contactless, non-obtrusive, and noninvasive. Based on working principle, in recent years four categories of contactless methods have been proposed for the heart monitoring: electromagnetic-based monitoring systems, laser-based monitoring systems, image-based monitoring systems, and other methods [6].

The two monitoring systems based on electromagnetic and laser can achieve high performances, but the price of equipment and mobility are limiting factors.

In the context of recent advances in video technology, the video cameras ability to measure physiological parameters, including HR, has been reported [6, 7]. The image-based methods for heart rate monitoring is based on the observation that the deflection of a human vessels due to heartbeats can be visually observed from the consequent deflection that the skin surrounding an important vase [8]. In [9] Takano reported the results of using the brightness data from a time-lapse image of a CCD camera. The data were measured for 30s. Chen et al. [10] investigated the Hilbert-Huang transform of the face reflectance for the HR measurement. Parra and Da Costa proposed to video acquire the deflections when the skin is illuminated by a 2 mW HeNe laser beam in the neighborhood of the vein [11]. McDuff et al. [12] used a DSLR camera capturing five color bands for remote HVR evaluation, Balakrishnan, et al. [13,14] have studied the subtle head oscillations accompanying the cardiac cycle from videos and performed the principal component analysis to decompose the trajectories into a set of mono-dimensional component motions, and identified the picks of the most periodic component for HR.

This paper addresses remote measurement of subtle changes in facial color due to HR by processing a certain color in the visible spectrum where there is the highest difference of skin color during a cardiac cycle.

In the remainder of this paper we will: 1) present materials and a novel numerical method for nonlinear processing of biosignals; 2) demonstrate that this method can allow remote evaluation of HR, and 3) compare our measurements with other results.

II. Materials and Methods

Many data about the skin morphology, composition or physiology could be obtained by investigation its optical properties. In vivo examination is noninvasive and widely used by clinicians for getting real time information about individual state of health. Light scattering and absorption properties of the skin are caused by various chromatophores, and hemoglobin in blood is one of the most important. Blood can reach up to 50 μm below skin surface. The pressure and the oxygen concentration of the blood are variable during heart cycle. Hemoglobin has two important components: oxy-hemoglobin, having a higher affinity for oxygen, and deoxy-hemoglobin that has a higher affinity for carbon dioxide. Their absorption spectra are shown in Fig. 1 [15, 16]. The biggest difference between the spectra of the two components of hemoglobin, oxygened and deoxygenated, occurs at about 560 nm. The amount of arterial blood (oxigened) to the skin surface varies over time due to the pressure generated by the heart rate. At the same time, the amount of deoxygenated blood from the superficial veins is constant. As a result, the reflected signal will contain information on the activity of the heart.

Unfortunately, the noise level is very high and the reflectance variation is small. Moreover, both the amplitude and frequency vary during investigation period, and filtering methods based on Fourier Transform cannot be used [17].

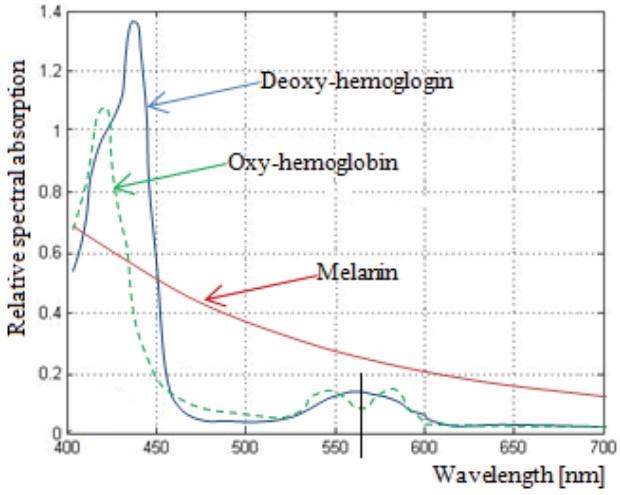

Fig. 1. Relative spectral absorption of melanin, oxy-hemoglobin, and deoxy-hemoglobin in the visible spectrum

New methods for nonlinear and nonstationary signals processing have been investigated in recent literature [17, 18]. They include time domain methods and frequency domain methods.

The Empirical Mode Decomposition (EMD) method is a novel and representative method for time signal analysis [17, 18, 19]. Nearly any signal can be decomposed into a finite set of intrinsic mode functions (IMF) whose Hilbert transforms give instantaneous values by their characteristic time scales in the data empirically [20, 21]. These intrinsic modes, obtained through a recursive process of sifting operations, have a limited bandwidth.

Dragomiretskiy has described a new method to decompose a signal in frequency domain, Variational Mode Decomposition (VMD) [22]. The problem was inspired by EMD algorithm and consists in signal decomposition into a small number of k modes (k imposed from the beginning design), that have a very limited bandwidth around their characteristic center frequency ω_k, which is to be determined along with the decomposition [22].

The bandwidth assessment of the u_k mode is realized in three steps: 1) the associated analytic signal is computed by means of the Hilbert transform in order to obtain a unilateral frequency spectrum; 2) the mode's frequency spectrum is shifted to "baseband" by mixing with an exponential tuned to the respective estimated center frequency; 3) the bandwidth is now estimated through the H^1 Gaussian smoothness of the demodulated signal, i.e. the squared L2-norm of the gradient. The variational problem can be formulated as follow [22]:

$$\min_{u_k,\omega_k}\left\{\sum_k\left\|\partial_t\left[\left(\delta(t)+\frac{j}{\pi t}\right)*u_k(t)\right]e^{-j\omega_k t}\right\|_2^2\right\}$$
$$\text{s.t.}\quad \sum_k u_k = f \tag{1}$$

where $*$ denotes convolution.

In [22] is presented the algorithm for the reconstruction constraint by using both a quadratic penalty term and Lagrangian multipliers. The augmented Lagrangian is as follows [22]:

$$\mathcal{L}(u_k,\omega_k,\lambda)=\alpha\sum_k\left\|\partial_t\left[\left(\delta(t)+\frac{j}{\pi t}\right)*u_k(t)\right]e^{-j\omega_k t}\right\|_2^2 + \left\|f-\sum u_k\right\|_2^2+\left\langle\lambda, f-\sum u_k\right\rangle. \tag{2}$$

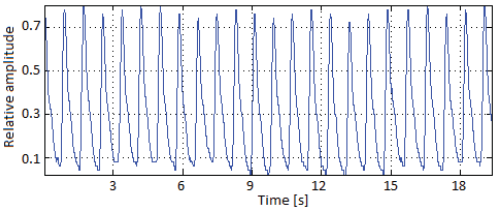
The minimization problem can be solved in spectral domain as follow [22]:

$$\hat{u}_k^{n+1}=\underset{\hat{u}_k,\hat{u}_k=\hat{u}_k^*}{\arg\min}\left\{\alpha\left\|j\omega\left[(1+\operatorname{sgn}(\omega+\omega_k))\hat{u}_k(\omega+\omega_k)\right]\right\|_2^2 + \left\|\hat{f}-\sum\hat{u}_i+\frac{\hat{\lambda}}{2}\right\|_2^2\right\}. \tag{3}$$

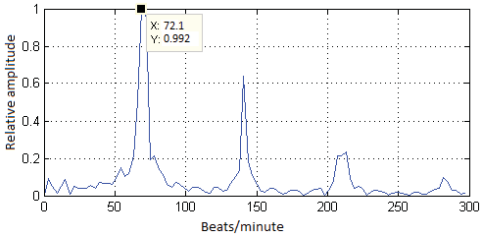
The role of the Lagrangian multiplier is to enforce the constraint, while the quadratic penalty improves convergence. In the case of signals that are both finite in time and resolution a certain window is necessary.

III. Experiment and Results

The input sensors were a video camera and a pulse oximeter. The same person has been investigated during about 20 seconds.



(a)



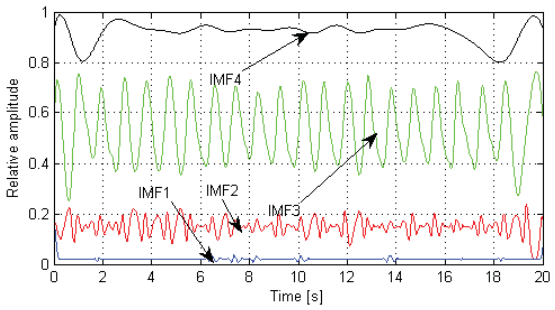
(b)

Fig. 2. The pulse oximeter output (a) and its Fourier Transform (b)

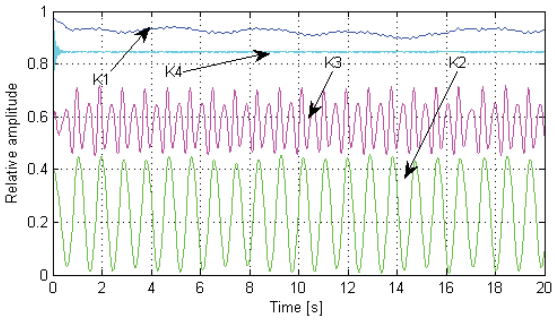
The output of the pulse oximeter was recorded to have a reference for the other sensor. The time evolution and its Fourier Transform of the signal from pulse oximeter are shown in Fig. 2a and 2b. The frequency value of about 72 beats /minute (from Fig. 2 b) represents the HR reference value. Also, the signal has still three important harmonics

Two methods were used to decompose this signal. In the first case, this signal was decomposed into 9 IMFs by using the EMD algorithm [17]. The time evolutions of the first 4 IMFs are shown in Fig. 3a. The first two IMFs are due to noise components. Their amplitudes are not too big. The IMF_3 looks like a clear harmonic of the input signal, and can be used to evaluate the HR.

The results of the signal decomposition in four oscillation modes by using VMD algorithm [22] are shown in Fig. 3 b. Harmonic structure of these modes is much more visible. The K2 oscillation mode looks like the IMF3 that was previously investigated by EMD algorithm. The assessment of the center frequencies of these modes is a recursive process, and after a number of iterations their values stabilize. In Fig. 4 is shown the variation of the central frequencies for the four oscillation modes using VMD.



(a)



(b)

Fig. 3. The mode decomposition of the signal with EMD (a) and VMD (b)

The iterative process may be stopped after about 70 iterations. HR value is about 72 beats / minute, the same as indicated by pulse oximeter.

The signal component from video stream having 560 nm is formed by using the following weighted mixing of the three colors: red (R), green (G) and blue (B) [8]:

$$I(x,y)=0.254*R(x,y)+0.659*G(x,y)+0.087*B(x,y) \quad (4)$$

The forehead area was selected by using the Viola Jones face detector from OpenCV 2.4.10 library in MATLAB [23].

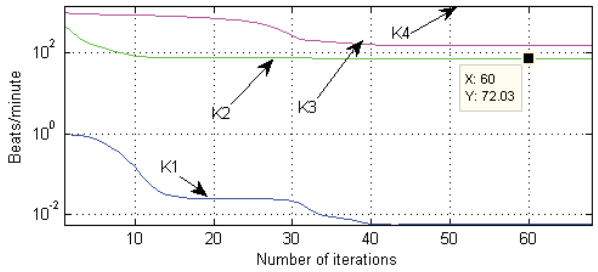


Fig. 4. The oscillation mode dependence versus number of iterations

The pixel having the biggest intensity value is chosen and the spatial position was maintained for the whole video stream of 20 s. This signal is shown in Fig. 5a. After applying a Hamming window [20], four oscillation modes were extracted by using VMD algorithm. Their time evolutions are shown in Fig. 5b, and their dependence on the number of iterations is shown in Fig. 5c. Iterative process stabilizes after a greater number of iterations (about 140).

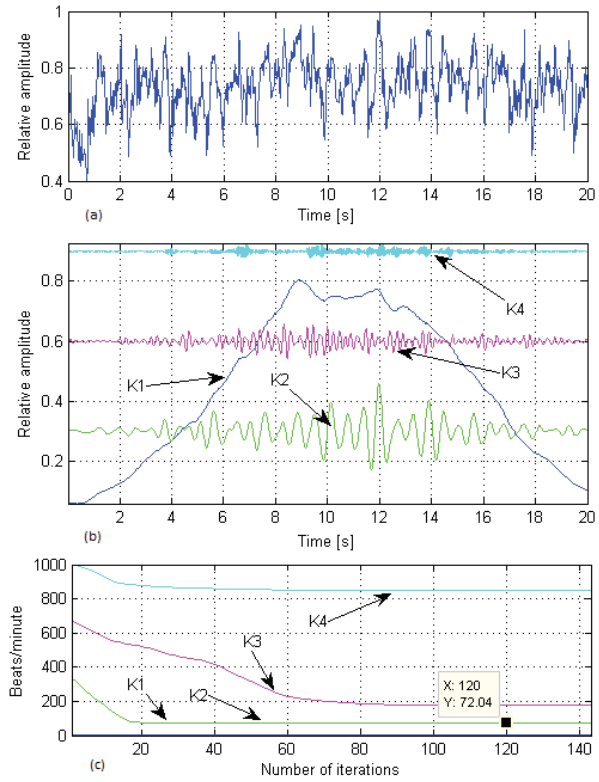

Fig. 5. Variational mode decomposition of the input video signal (a), the time variation of the four oscillation modes (b), and their evolution versus number of iterations.

The investigated signal is corrupted by noise, the signal to noise ratio is very low. K1 oscillation mode is very high and is due to application of Hamming window. The useful component is K2 and is seen that as its value (value corresponding HR of about 72 beats/minute) is identifiable even at this rapport signal to noise having a small value.

Unfortunately, EMD algorithm has not led to satisfactory results which may reveal a harmonic component to assess HR. 21 IMFs were obtained, but all were corrupted by noise. The EMD algorithm fails to extracts the harmonics accurately if the signal is affected with noises [24, 25].

IV. CONCLUSIONS

The remote evaluation of HR from face reflectance was investigated. The output RGB data from a video camera during 20 s have been converted in a mono-dimensional signal corresponding to the wavelength of 560 nm. In the same time the data from a pulse oximeter were recorded.

The two biosignals carrying information about HR were investigated using specific algorithms. EMD method provides decomposition into time domain components, and VMD method generates the signal components into frequency domain. The signal from the pulse oximeter had a high signal to noise ratio, and it was used to check the accuracy of the two methods. HR value displayed by the pulse oximeter was about the same as obtained by expansion the digital signal in Fourier series, 72 beats /minute. Also, this signal is composed of four distinct harmonics.

After that, the two methods have ensured an effective decomposition in several IMFs or oscillation modes of the pulse oximeter signal. Every decomposition was recovered the frequency components approximately the same as measured by pulse oximeter.

In the next step, mono-dimensional signal from the video camera, having a small level of the signal to noise ratio, was broken down into components using the two algorithms previously tested. The VMD algorithm has allowed the signal decomposition into four oscillation modes, one of them with frequency of about 72 beats / minute, after a double number of iterations. The EMD algorithm has allowed the signal decomposition into 21 IMFs, but no one contains the frequently noted by pulse oximeter.

Abstract— **Cognitive Radio (CR) technology enable nodes to use unutilized portions of the spectrum for communications. It increases the efficiency of spectrum usage. But CR introduces new challenges in design of protocols at different layers of the protocol stack. Use of clustering in Cognitive Radio Networks (CRNs) provides better network-wide performance. This paper introduces a new routing protocol for CRNs called Cluster based Cognitive Radio Routing Mechanism (C2R2M). In C2R2M, cluster formation is based on Low Energy Adaptive Clustering Hierarchy (LEACH) algorithm. LEACH is further modified to select more suitable Cluster Head (CH). The use of channel assignment algorithm and co-existence of Secondary Users (SUs) and Primary Users (PUs) in route decision improves the performance of C2R2M. Simulation results show that C2R2M achieves better network performance in terms of throughput, delay and routing overheads as compared with Ad-hoc On-demand Distance Vector (AODV) routing protocol in CRNs.**

Keywords—Cognitive Radio Network, Routing, Clustering, Cluster Head

I. INTRODUCTION

Regulation of today's wireless networks is carried out using a fixed spectrum assignment policy. Regulating authorities in respective countries distribute the spectrum to different license holders for specified duration and geographical areas. The license holders provide the services to end users which are called as the licensed users. This policy served well earlier.

While unlicensed spectrum bands are always crowded, the licensed spectrum remains underutilized or unutilized as the licensed users are not using it all the time. Thus, fixed spectrum assignment policy results in an inefficient usage of spectrum. According to Federal Communications Commission (FCC) the average usage of spectrum ranges in between 15% and 85% i.e. the spectrum utilization is not well [1]. On the other hand, due to tremendous increase in wireless devices and applications in recent years, the demand for spectrum is increasing rapidly.

To deal with spectrum scarcity and/or inefficient usage of spectrum, researchers introduced a device called as Cognitive Radio (CR). CRs can be networked to form the Cognitive Radio Networks (CRNs). In CRNs the CRs are known as the Secondary Users (SUs) and the licensed users are called as Primary Users (PUs). CR can sense the spectrum to find unused portions of it, known as white spaces. Also, CR can change its operating parameters to make use of these white spaces for its operation provided it is not interfering with the PUs. CR needs to switch to another white space if PU requires the same band of frequencies. This is called as the opportunistic use of the spectrum which increases spectrum utilization.

Research in CRNs has mainly focused at lower layers of the protocol stack even though the CR paradigm was introduced long back in 1999. Routing at network layer is one of the main issues in CRNs [2]. It is different and challenging than normal wireless networks due to variable nature of the available spectrum. Also, different sets of channels used by SUs increase the routing challenges. Tight coupling between the routing module(s) at network layer and the protocol(s) at lower layers is required. Use of clustering in CRNs provide network-wide performance enhancement. Clustering increases the scalability, stability of the CRNs and helps in balanced distribution of resources.

This paper proposes a Cluster-based Cognitive Radio Routing Mechanism (C2R2M) which finds out the efficient path form source node (PU or SU) to the destination sink node or Base Station (BS). Its working is divided in two parts. In first part it goes for Cluster Head (CH) selection and cluster formation. And in second part it carries out the channel assignment and discovers an efficient route from source to destination.

The remainder of the paper is organized as follows: Section II presents previous work in cluster based CRN routing. System model and assumptions are given in Section III. Section IV describes the proposed technique C2R2M. Performance evaluation of C2R2M is given in Section V and finally the conclusions are presented in Section VI.

II. RELATED WORK

Ghalib A. Shah et al. [3] introduced a spectrum-aware clustering for efficient multimedia routing in cognitive radio sensor networks. In this paper, CH selection is based on

the energy and relative spectrum awareness such that non-contiguous available spectrum bands are clustered and scheduled to provide continuous transmission opportunity. It uses a hybrid Medium Access Control (MAC) for data routing. Each node computes a joint energy spectrum rank in which a high rank node is elected as a CH that controls the spectrum access and data routing. Simultaneously it performs inter- and intra- cluster routing which exploits the performance. However, the use of hybrid MAC for data routing increases the routing overheads.

Rojin Tizvar et al. [4] proposed a collision and energy aware routing method for cognitive radio wireless sensor networks. It considers two main phases: next hop selection and channel selection. The routing is performed hop-by-hop with local information and decisions. Local reduction of collision probability leads to reduce in energy consumption. It also reduces the packet delay in terms of hop cost.

Anna Vizziello et al. [5] introduced a location based routing mechanism that combines location-based routing protocol and RSSI based localization algorithm. Routing consist of intra- and inter- cluster phase. It considers the existence of heterogeneous PUs and jointly selects spectrum and route. It also helps to reduce the interference to PUs. But it assumes similar spectral characteristics in different locations in a given cluster.

A cluster-based link recovery mechanism for spectrum aware on-demand routing in cognitive radio ad hoc networks projected by Chih-Chieh Tang et al. [6] recovers failed links locally and does not change the original routes. It uses buffer to cache the data packets during route recovery. SUs which are in the intersection area of all PUs' radio coverage form a cluster. CH chooses an available channel and assigns it as communication channel to all cluster members. Performance of this scheme is good particularly if there is an intersection area of all PUs' radio coverage in the network. It provides higher throughput in more congested environment. But route recovery mechanism adds the extra message overheads.

Nayyer Panahi, et al. [7] proposed adaptation of Low Energy Adaptive Clustering Hierarchy (LEACH) routing protocol to cognitive radio sensor networks. Here, by using the physical layer information and preserving the feature of random CH selection in LEACH, it has been tried to both move the position of CHs to appropriate locations and make their quantity optimal. Transfer of CHs to appropriate locations increases the network lifetime. However, it increases the network instability because of continuous transfer of CH location.

The cluster based control channel allocation in cognitive radio networks given by Sisi Liu et al. [8] uses an architecture that allocates different channels for control at various clusters in the network. It reduces the frequent need of re-clustering and takes into account the channel availability in deciding cluster memberships. Drawback of this technique is that it is limited only to cellular cognitive radio network. Also, it considers that CRN have same communication range for each channel.

United nodes, a cluster-based routing protocol for mobile cognitive radio networks proposed by A.C. Talay et al. [9] uses spectrum availability cost and interference metrics for route decision in cluster-based network. It uses router preservation method to repair the defective routes. It shows better adaptability with increased throughput and reduced data delivery latency. But it does not use any co-operation among the primary and secondary users during route decision, which may lead to inefficient routes.

Thus, clustering is a good solution to improve the performance of routing in CRN. The clustering helps to improve routing in terms of stability of route, route discovery and maintenance, rediscovery of route in case of link failure, reduction in routing overheads and improve the security.

III. SYSTEM MODEL

A. Assumptions

The proposed algorithm considers certain assumptions which are given in this section. Every node in the network has spectrum sensing capabilities [10, 11], which sense the available number of channels correctly. The whole network has network-wide Common Control Channel (CCC) [10, 11]. The network is divided into clusters, each cluster consist of CH, gateway nodes and member nodes. Every node in the network has distinctive identification (IDs). All nodes in a network are considered as homogeneous i.e. every node has same communication and data gathering capabilities. Every node in the network has same transmission and interference range. The network considers stationary PUs and SUs. The network considers the BS or sink node. It collects information from all nodes in the network. The sink node is considered as stationary.

B. System Model

Generalized system model is shown in figure 1 while intra- and inter- cluster communication is shown in figure 2.

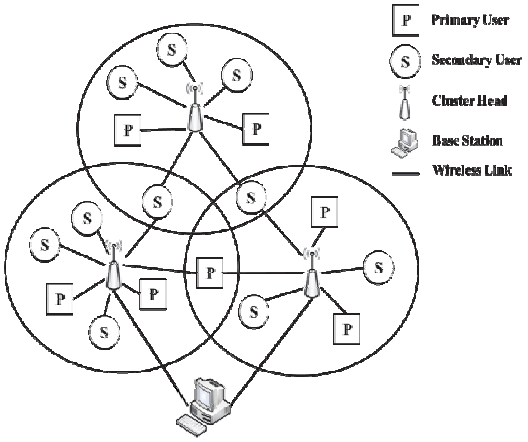

Figure 1. Generalized system model

Figure 1 shows the cluster-based [12] system model considered for the proposed routing algorithm. It considers *N* number of nodes randomly deployed in the specified area and collecting the information with some specific interval. The network consists of *C (C = {1,2,3,….})* data channels and one common control channel. The network considers the presence of both PUs and SUs. PU uses the licensed channel assigned to it. The mapping of licensed channel with number of PUs is one to one. PUs are in active state if they are using their own licensed channel. SUs can use this channel if PUs are not using it. The mapping of channel with SUs is one to many. Every SU node has spectrum sensing ability to know the available channels and it has capability to calculate the probability of PUs' presence on channel.

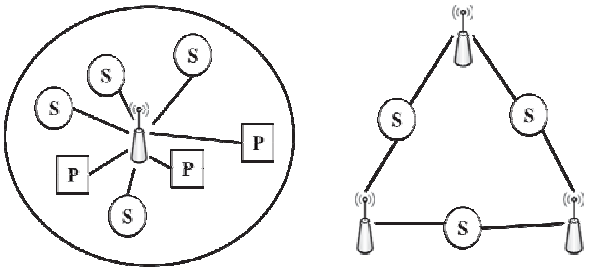

Figure 2. Intra-cluster and inter-cluster communication

Here, the network is divided into *n* clusters. Each cluster consists of CH, cluster members, and gateway nodes. The cluster members can directly communicate with CHs. The CH acts as the coordinator node for particular cluster. It gathers the information from cluster members. It also plays an important role in channel sensing decisions, which is required during routing. The member nodes like all PUs and SUs are associated with CHs. The communication between the members of a cluster is called as intra-cluster communication which is shown in figure 2 (a). The number of hops in between member nodes and CH is single. The gateway nodes are common nodes in between two or more clusters, they act as the bridge in between two clusters. They have capabilities two listen from both clusters. Hence, they are used during inter-cluster communication as shown in figure 2(b). The communication pathway from any CRN node to BS is,

$$Member\ node \rightarrow Local\ CH \rightarrow Gateway\ node \rightarrow Remote\ CH \rightarrow BS$$

IV. Cluster-based Cognitive Radio Routing Mechanism (C2R2M)

The aim of Cluster-based Cognitive Radio Routing Mechanism (C2R2M) is to find out the efficient path form source node (PU or SU) to the destination sink node or BS. To find out the efficient path, algorithm is divided into two phases. In first phase it goes for CH selection based on LEACH algorithm, node degree and available idle channels. It also completes cluster formation in this phase. In second phase it finds an efficient route from source to destination and also carries out channel assignment.

A. CH Selection and Cluster Formation

The proposed routing mechanism forms the clusters using LEACH clustering algorithm. According to the general LEACH [12, 13] algorithm, probability of *node i* to be a CH is denoted by $P_i(n)$. It is given as,

$$P_i(n) = \begin{cases} \dfrac{k_{CH}}{N - k_{CH} * \left(r \bmod \dfrac{N}{k_{CH}}\right)} & ; T_i(n) = 1 \\ 0 & ; T_i(n) = 0 \end{cases} \quad \ldots\ldots\ldots(1)$$

where, N is the number of nodes in a network, k_{CH} is the probable number of CHs per round, r signifies the present round number and is an indicator function which determines that either node i has been a CH for the most recent rounds or not. Most recent rounds are calculated by using following formula.

$$\left(r \bmod \frac{N}{k_{CH}}\right) \ldots\ldots\ldots(2)$$

This formula has probability to select each node as a CH once per cycle.

Here, the LEACH algorithm is used by considering number of available idle channels and the degree of each node. These two are used as extra factors for choosing the more appropriate CH in CRN environment. The probability of a node to become a CH is more which has higher number of available idle channels and has highest node degree in the available nodes. Let, c_i be the number of available idle channels on *node i* and d_i is the degree of *node i*. Therefore, new probability that node i to a be a CH is,

$$P_i(n) = \begin{cases} \dfrac{k_{CH} * c_i * d_i}{\left[N - k_{CH} * \left(r \bmod \dfrac{N}{k_{CH}}\right)\right] * \sum_{a=1}^{N} c_a d_a} & ; T_i(n) = 1 \\ 0 & ; T_i(n) = 0 \end{cases} \quad \ldots(3)$$

The calculated probabilities are useful to determine CHs according to the availability of channels and degree of node. This work considers the node with probability $P_i(n)$ greater than or equal to 0.5 as a CH. Once the CH decision is performed the nodes in the transmission range of CH will be considered as the cluster members.

B. Route Discovery

The route discovery phase finds the route from source node to destination node. It starts when any node (either PU or SU) want to transmit data to BS. As discussed in the system model path from cluster member to BS goes via CH. Therefore, route discovery phase is divided into two sub-phases: intra-cluster route discovery and inter-cluster route discovery. Intra-cluster route discovery finds the path from

source node to CH and inter-cluster route discovery finds the path from CH to BS. The basic procedure of both sub-phases is same; it only changes the source and destination node.

A sender node broadcast a request message through CCC. Request message consist of source node ID, receiver node ID, and the available channel information. The intermediate node who receives the request message updates its route table and forwards the request to the next intermediate node. Every time when node sends request to next intermediate node it also updates the reverse routing table. Here, route will be stored in route table only when both intermediate nodes have common communication channel. If there is no common communication channel in-between the two nodes then it will drop the request message, and route will not be stored in the route table. In this situation, intermediate node should rebroadcast the request message.

When the destination node will receive the request message transmitted via intermediate nodes, it will generate the reply message. The reply message will be unicast towards the node, which have generated the route request message. The reply message consists of ID of source node and destination with the channel information of destination node. The reply message goes through each intermediate node and stores and updates the forwards routing table of the intermediate nodes. Every intermediate node maintains the forward routing table and reverse routing table.

Now, the channel assignment will be done by using receiver channel list and the sender's channel list. The sender and receiver channel list is obtained from the route request and reply messages. The work selects a suitable common available channel from sender and receiver for transmission. The algorithm first makes the list of available common channels and then for improving the utilization of channel, the channel with low utilization will be given a high priority. Here, the channel with less than 50% utilization is given as high priority. If there is no single channel with less than 50% utilization then any one channel will be assigned randomly from available common channels.

V. SIMULATION RESULTS

The implementation is performed by using discrete event simulator NS-2 (Network Simulator-2) [14]. The parameters set during simulations are shown in Table 1. The simulation considers the area of network as 1000m * 1000m. The nodes are distributed uniform randomly in the given area. The simulation considers the following parameters for measurement,

- Average End-to-End Delay: The delay of one packet is time difference between packet's receive time at BS and packet's send time from source node. The total delay in the network is considered as sum of delays of all received packets. The average end-to-end delay is sum of delays of all received packets divided by total number of received packets.
- Average Throughput: Throughput is computed in terms of packet delivery ratio (PDR). PDR is the ratio of number of packets received by sink node divided by number of packets sent by source nodes. It is considered in percentage.

TABLE I. SIMULATION AND NODE PARAMETERS

Parameter Name	Setting Used
Network Interface type	Wireless Physical
Radio Propagation Model	Two-Ray Ground
Antenna	Omni-directional
Channel Type	Wireless Channel
Link Layer	Link Layer (LL)
Interface Queue	Priority Queue
Buffer size of IFq	50
MAC	CRMAC [14]
Routing Protocol	AODV [15], C2R2M
Transport Layer	UDP
Traffic Model	CBR
Number of Nodes	Varying from 50 to 200
Node Placement	Random
Size of Packet	100 bytes
Number of Packets	100
Number of Simulation Runs	10

The proposed algorithm addresses the open issues like scalability and route stability. Figures 3, 4, and 5 show the average end-to-end delay, average throughput, and routing overheads of Ad-Hoc On-demand Distance Vector (AODV) routing protocol and C2R2M respectively by varying number of nodes in the network. Here, the evaluation considers the nodes, which are varying from 50 to 200 with an interval of 50, number of channels considered is two (2), and packet time interval is one (1) second.

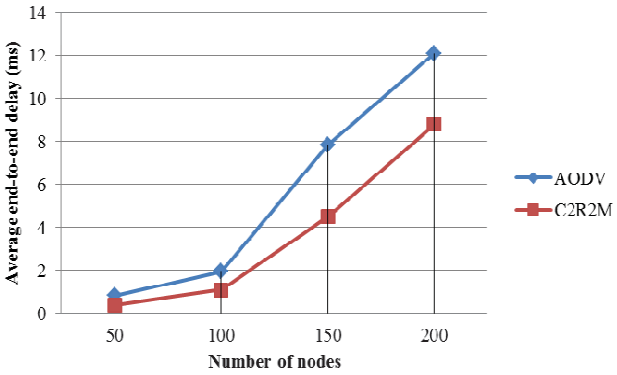

Figure 3. Number of nodes vs. average end-to-end delay

The result shows that the performance of C2R2M is better than the performance of AODV. The reasons for better performance of C2R2M than AODV are, the clustering algorithm used which decides the clusters according to the node degree and number of channels, co-existence of SUs and PUs during route decision, and channel assignment algorithm used. The reduction in routing overhead of C2R2M is because of local level (cluster-level) route decisions, which in turn helps to reduce the average end-to-end delay in the network.

The average throughput is also increased because of better selection of CHs and co-existence of SUs and PUs.

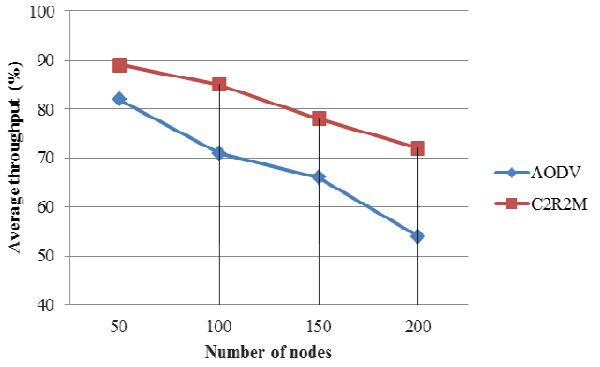

Figure 4. Number of nodes vs. average throughput

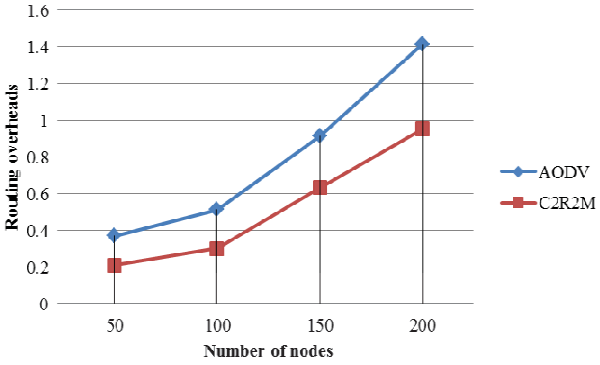

Figure 5. Number of nodes vs. routing overheads

VI. CONCLUSIONS

In this paper, a new routing technique called Cluster based Cognitive Radio Routing Mechanism (C2R2M) is proposed which improves network performance in terms of routing. This scheme utilizes LEACH algorithm to form clusters and modifies it to provide better CH. The impact of varying number of nodes on the operation of C2R2M in terms of throughput, delay and routing overheads is presented. Also the comparison of the performance of C2R2M with AODV is carried out and shown that the proposed C2R2M achieves better results than AODV for CRNs. It improves the route stability and supports scalability which is shown with the results. In the future the authors of the paper will explore the effect of varying number of available channels and the possibility of link failure due to mobility of nodes which will improve link stability.

***Abstract*—The IP Multimedia subsystem is a core network used with telephony services and multimedia. It has made it possible to use common standardized system for different multimedia services such as video conferencing, simultaneous media transfer etc. IMS represents a reusable way to integrate and deploy several voice and data services. This advanced technique of IMS is being widely used with LTE(Long Term Evolution) standardized by Third Generation Partnership Project(3GPP). It has been proposed in order to overcome the limitations of existing technologies 2G and 3G. LTE is an advanced technology but still it also uses IMS for multimedia delivery over LTE networks. This paper deals with integrating IMS with EPC (Evolved Packet Core) architecture to analyse different parameters based on Quality of Service(QoS). These parameters include call setup time, bandwidth usage, jitter, throughput and session management. To analyze the performance, a prototype of EPC was deployed. This has been further deployed on Linux test bed while carrying out the proposed approach. The results of this paper have been demonstrated in a different manner. Instead of inducing live traffic, It analyzes the usage of bandwidth reduction in long run.**

***Keywords*-IMS, EPC, LTE, VOIMS**

I. Introduction

Wireless cellular networks have been widely used for the past few years. People mostly relied on digital networks for different multimedia services. This technique has been quite successful in alternating among different active units and endpoints in the network. This path of wireless standards have been evolved focusing on building the next generation of all IP- network infrastructures[1][7]. The IMS and EPC were designed as an important steps towards the next generation networks to fulfil this need. It provides higher bandwidth, and lower operational costs of the whole network, and it also gives maximum convergence with the internet.

A. IP-Multimedia Subsystem

IMS is defined to be a mediator which enables the delivery of simultaneous multimedia services such as voice, data, video etc. Basically, it acts as an intermediate network which constitutes different entities to make this network functional. Few important features of IMS that separates it from others are:

- It maintains Quality of Service (QoS) by adopting several mechanisms.
- IMS has the ability to provide multimedia based new experience to its users.
- SIP signalling is provided by IMS network from one user end to another.
- It does not depend on access techniques.
- IMS has the inbuilt efficiency to offer both packaged and compound services.

B. Evolution of IMS

As mentioned in the earlier section, IMS standards have been maintained and written by the community related to next generation networks i.e. 3GPP. IMS was first introduced by the 3GPP in Release 5 for the standards of UMTS network. The initial phase concentrated on defining the entities which were considered as the core elements. Later on, various IMS protocols were defined for session control, management and authentication as well as for multimedia transfer and media processing. Release 6 by 3GPP included integration of WLAN(Wireless Local Area Network) and broadband networks to maintain the fact that voice call should be in continuation. It also enables the use of several multimedia related services like conferencing, push-to-talk, simultaneous video sharing etc. During Release 7, basis of specifications was provided to maintain the standards. Release 8 focused on defining the areas which were not addressed earlier such as Operations, Administration and Maintenance (OAM) and mainly works on optimization of IMS to overcome the limitations of 3rd generation networks[10][12]. The evolution of IMS network keeps the service providers more active and competitive.

C. The IMS Architecture

Architecture of IMS constitutes the entities or functional elements that enable it to act as an intermediate network. Defining architecture also includes the interaction process among these functional elements and the protocols need to carry out such interaction. With the associated functionality, these entities can also be viewed as layers or planes shown in fig.1. These entities have interfaces externally to the application, user and other networks[11].

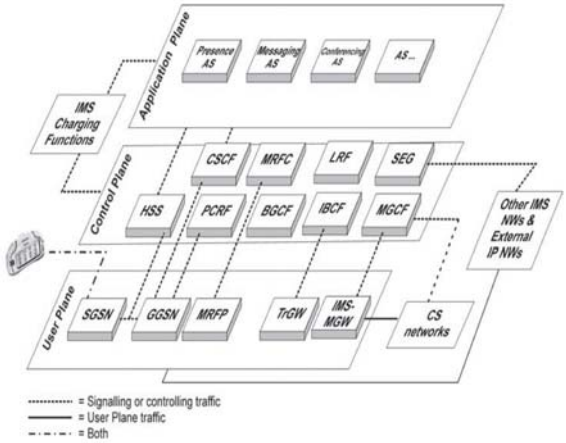

Fig. 1. IMS Architecture

1) Planes: There are certain protocols which make it possible to communicate among different entities. These packets have data flow which either takes the form of signals or media. The control plane consists of certain functional entities which have functions to perform related to signalling. They provide function for session establishment, maintenance and operation. The media planes contains the entities giving the resource and adaptation functions. Access to the application along with the service logic is given by service plane. Application and billing servers, Operational Support System (OSS) and service access functions are included in these entities[2].

D. EPC network Architecture

Fig.2 shows that Evolved Packet Core Architecture (EPC): EPC provides a converged data and voice networking frame work to provide LTE connections to the users. Main components of EPC consists of MME, S-GW, P-GW. The Signaling Gateway(S-GW):one of the main function it performs routing and forwarding Packets, and also it acts as a anchor point for inter e-node B handovers[3][13]. It offers a data path between the PDN gateway and enodeBs via S5 Interface, which supports either the GPRS tunneling protocol (GTP) or the proxy mobile(PMIPv6) protocol. Packet data interface termination point called PDN-GW:It performs anchoring functions of sessions for external packet data networks via SGi interface[5][6]. The main function of PDN-GW is to provide a packet filtering per user based and rate enforcement policies as well as service level charging[7].

II. Proposed Work

The proposed EPC with IMS Integration Architecture shown in fig.3. All-IP mobile core network for LTE is an EPC,

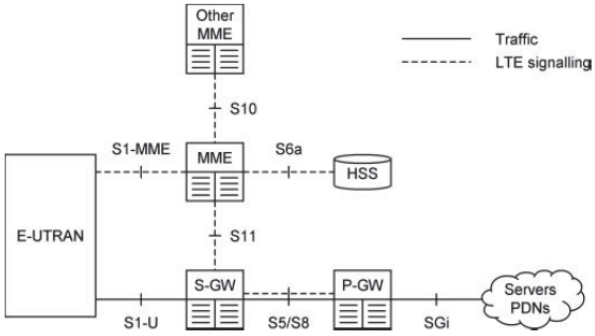

Fig. 2. EPC network Architecture

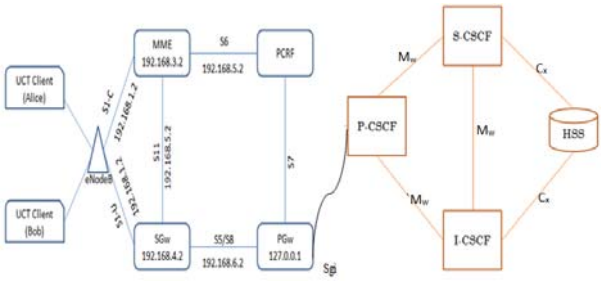

Fig. 3. EPC with IMS Integration Architecture

authorizing the mobile and fixed convergence of real time and non real time packet dependent services. The integration of Open IMS core with Evolved Packet Core is done in the steps by Running all the services of Open IMS core like P-CSCF, S-CSCF, I-CSCF and FHoSS using the terminal.

A. Methodology

Here,the IMS provides the delivery of voice services across the clients while the EPC provides the network framework for providing data packets at a high rate[9]. Therefore the interworking of both the networks can improve the existing QoS (Quality of Services) and support additional services that require high bandwidth. The integration approaches/methodologies for delivering voice services in EPC[8][14]:

- CS Fallback
- VoLGA
- VoIMS

B. Methodologies comparison

The comparison of all these methods is shown in table 1. VoIMS approach gives huge benefits of Internet and it is also capable to provide utilities related to mobile field. This helps us to choose the approach/methodology of VoIMS to deploy on the test bed along with the Evolved Packet Core (EPC) for delivering voice services.

Requirement	CS Fallback	VoLGA	VoIMSLTE
Network Requirement	None	VANC, Security gateway, AAA Server	IMS core,IP-SM-GW
Legacy Network upgrades	All MSCs overlaying Coverage	None	None
EPS/IMS Upgrades	E-UTRAN, MME	E-UTRAN, MME	HSS
Terminal changes	CS Fallback support	VoLGA SRVCC	IMS client

TABLE I
NETWORK IMPLEMENTATION UPGRADES

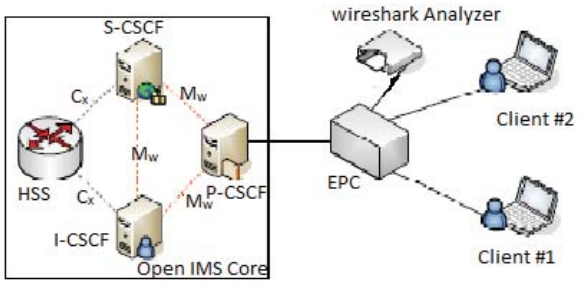

Fig. 4. Testbed setup with QoS Guarantees

C. Quality of Services (QoS) scenarios

We have designed a cloud computing environment which creates an environment of virtual servers and clients, eliminating the need of any physical resource. Further,a few open source tools were deployed in the Linux Virtual machine to consider the parameters related to QoS, by starting different configured profiles and evaluating the QoS parameter within the network[5].To measure the effect of various QoS scenarios, wire shark has been used to monitor the system traffic while observing the IP addresses and labelled PORT numbers.

III. EPC-IMS IMPLEMENTATION

The EPC-IMS implementation took place in four stages. Stage One: Configuration and Deploying of Open IMS core services in the test bed. Stage Two: Installation and Deploying of EPC components. Creating virtual IP addresses for integration of IMS with EPC[4][5]. Stage Three: Deploying the UCT IMS client and registering it with the core network. Stage Four: Deploying the wireshark for packet capture, Iperf and Jpref for measuring QoS parameters shown in fig.4. In the results we check the following parameter for the 6 QoS scenarios created by changing the Quality of Service required by the clients. given in table 3.

- Bandwidth usage
- SIP packets generated
- Call setup times and
- jitter

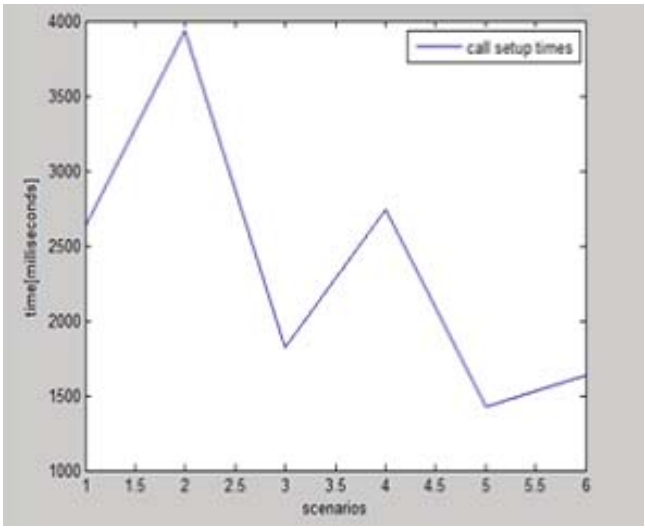

Fig. 5. Analysis of Call Setup Time

IV. SIMULATION RESULTS

A. Analysis of Call Setup Time

It is observed that in fig.5 the call setup time increases with additional QoS parameters induced, when we look at scenario 1 and scenario 2. But when we compare scenario 3 and scenario 5 the call setup time has decreased, this is because, as QoS has been chosen to be non-compulsory for one of the clients, therefore the sequence came to 3rd scenario. Due to this, call setup time drops critically low. however, the client having compulsory QoS, still transmits the additional messages.

B. Analysis of Bandwidth Usage

fig.6 shows that as the QoS requirement increases the bandwidth usage increase because of the additional messages sent by the client to compare scenario 1 and scenario 3 increase in the bandwidth usage.To compare scenario 3 and scenario 5 the bandwidth usage is decreased despite the additional messages sent by the client for which QoS is mandatory. Drop in bandwidth can also be observed with scenario 2 and scenario 4 although additional messages(SIP) still exists. The reason behind this, is that the segmented SIP messages, allowed by provisional ones that were used to enforce QoS. Due to this, the size of the SIP message and the total bandwidth used by the client gets reduced.

Parameter	Scenario 1	Scenario 2	Scenario 3	Scenario 4	Scenario 5	Scenario 6
Bandwidth usage [kbps]	10390367	10136722	10480340	10315013	10446540	11171559
Call Setup Time [milliseconds]	2636	3933	1824	2740	1426	638
SIP Jitter [milliseconds]	0.14	0.07	0.08	0.07	0.03	0.05
no.of Packets Generated	75	85	138	274	480	694
RTP Jitter [milliseconds]	1.53	1.85	2.05	1.89	1.93	3.27

TABLE II
COMPARISON OF ALL THE SCENARIOS

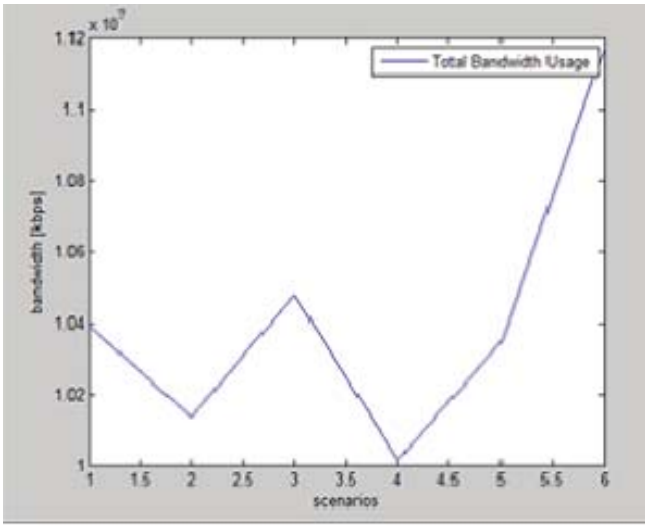

Fig. 6. Analysis of Bandwidth Usage

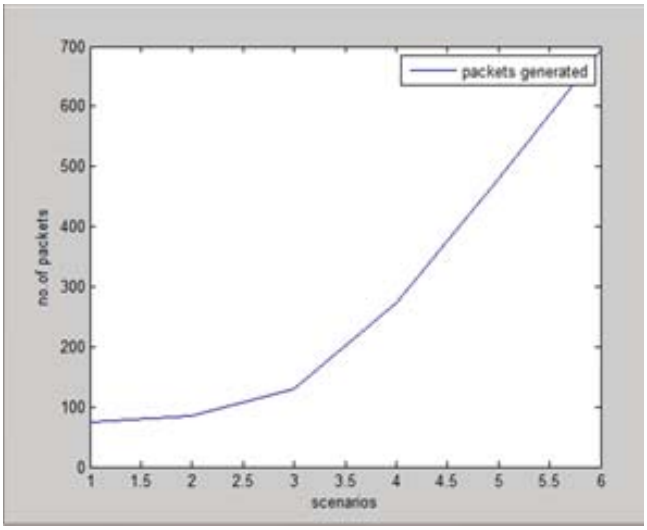

Fig. 7. Analysis of Packets Generation

C. Analysis of Packets Generation

The above fig.7 clearly indicates that the number of packets generated increases with the increase in the QoS enforcement priority. This is because additional messages were sent by client as the required QoS increases. So we can see a steady increase in number of packets generated as the scenarios rises and due to the different QoS parameter required by the clients of the particular scenario.

S.NO	Client#1 QoS	Client#2 QoS
1	Compulsory	Compulsory
2	Non-Compulsory	Non-Compulsory
3	Non-Compulsory	None
4	Compulsory	None
5	Compulsory	Non-Compulsory
6	None	None

EXPERIMENTAL QOS MATRIX

V. SUMMARY AND CONCULUSION

This paper has presented the experimental measurements for the IMS and the LTE/SAE integration. We have conducted experiments on three approaches on providing voice over LTE: CS Fallback, Voice over LTE Generic Access (VoLGA), and Voice over IMS (VoIMS). While, each approach has been associated with some advantages and disadvantages, it was concluded that VoIMS is the best suited approach for delivering voice over LTE network because of its less complexity, widely accepted delivery platform and also standardized by the 3GPP standards. The complete effect of QoS parameters on the IMS SIP signalling load has been observed, while negotiation takes place for IMS session between two users. Scenarios with no QoS, with non-compulsory QoS and with compulsory QoS have been considered for the analysis. From the experimental results, it has been observed that, the amount of data transferred by clients and the core network increases in which some QoS parameters present between 30% and 70%, But the amount of bandwidth usage reduces on the long run, Which could be used by some other clients or we can induce few services for the same client along with the voice services. So it is found that Evolved Packet Core (EPC) provides higher bandwidth, lower latency compared to other core networks. Based on this stsudy, It is suggested that LTE/SAE-EPC integrated with IMS is the best option for 4G telephony services.

***Abstract*— Massive number of web services are available, with a deployment of huge number of the Internet of Things (IoT) applications e.g. smart homes, smart cities, intelligent transport, e-health and many more. In the IoT paradigm, almost every device around us will be on the Internet to provide specific services to end users. A large number of services will be available to help end users however providing and selecting appropriate service from a massive number of available services is the challenge of IoT. Service discovery plays a vital role in web service architecture. Traditionally, keyword search has been used for service discovery. The traditional approaches of service discovery couldn't be applied as it is for web services in the IoT environment as devices providing, and accessing services are resource constrained in nature. E.g. limited size, limited energy source, limited computational capability and limited memory. Hence, there is need of a lightweight and semantic service discovery approach for the IoT. This work analyzes different service discovery approaches. This analysis will focus on the key requirements of service discovery mechanism needed for the IoT environment.**

***Keywords*— Internet of Things, Service Description, Service Discovery, Semantic Service Discovery, User Preference.**

I. INTRODUCTION

In the IoT environment devices around us are connected to the Internet to provide services to the end users. IoT devices could be anything around us. i.e. sensors, RFID tag, RFID reader, actuators. The different IoT devices may use different wireless/wired technology to transmit data to cluster head i.e. WLAN, ZigBee, NFC, Zwave, WiFi [1]. These devices may be different in sizes, computational capability hence heterogeneity will major challenge to design WS. IoT will be deployed in large number and almost in all application domains i.e. e-health, smart home, the smart city [2], intelligent transport, logistics and many more. Hence, large number of devices will be working with each other over the Internet to provide services to the end users. End users access a web service (WS) depending on their requirements hence selecting appropriate service from a large number of available services is essential design parameter for WS.

Remainder of this paper is structured as follows the motivation is discussed in the Section II, the detailed literature of service discovery mechanisms is discussed in Section III, comparative analysis of literature work is presented in Section IV and discussion is summarized in Section V.

II. MOTIVATION

Predicting and providing appropriate service depending on context and user preference is the necessity of IoT environment. User may be mobile and will require to access services via his/her Smartphone hence the lightweight WS discovery process is the important design parameter of WS architecture for IoT. In the IoT environment devices around us sense information and depending on this information services are built. Every IoT device is not capable of building and providing WS as IoT devices are resource constrained in nature. Hence, few devices are grouped together as a cluster, and one computationally strong device is selected as cluster head to perform complex task [3]. i.e. building and providing WS. The information senses by the IoT devices are raw and unstructured in nature, so there is need of describing services depending on the raw and unstructured information by converting it into structured format. The need of clustering IoT devices and lightweight WS discovery is shown in figure 1.

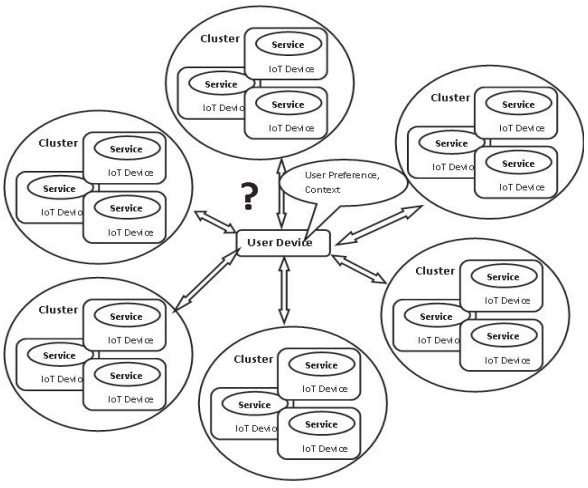

Figure 1. Requirement of service discovery mechanism for IoT environment

Traditional WS discovery methods are not applicable to IoT environment due to its different requirements, hence it is

important to review different WS discovery mechanisms. WS are the description of operations that perform a certain task. WS are language and platform independent. WS could perform a simple task or complex task. A WS has three components service provider, service registry, and service requestor. Service provider describes services using standard extensible markup language (XML) i.e. web service description language (WSDL). Services are advertised by publishing it to a registry. Universal Description Discovery and Integration (UDDI) is the registry used to publish web services. End users are the service requestor, requesting for web service using find operation. WS has four phases of the life cycle. i.e. Build, Deploy, Run, and Mange depicted in fig 2.

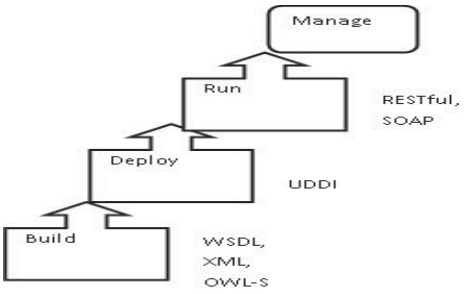

Fig.2. Life Cycle of WS

Build phase of life cycle plays very important role in the WS life cycle, to provide appropriate service to end user the description of WS is matched with requirements of the end user. WS uses the Simple Object Access Protocol (SOAP) to access WS, and it is not suitable for the WS architectures in the IoT environment as SOAP based approach are heavyweight in nature. Traditionally, syntactic service discovery mechanism is used to discover the WS. A syntactic service discovery mechanism result in a list of services among that user has to select appropriate service depending on his/her requirement, and this is not feasible approach for IoT environment. To provide appropriate service to end user, the service description should be done in the semantic way so that in the service discovery phase service could be searched very efficiently.

WSDL, SOAP and UDDI standards are used to build service architecture. However, the WSDL is not designed for semantic description. WSDL describes WS in the form of port, port type, and bindings. Hence, it is very difficult to specify semantic details about WS i.e. nonfunctional requirements, QoS requirements, availability, reliability, throughput, response time and mean time before failure. This invokes the need of a semantic description of services. To provide the semantic descriptions, different approaches are invoked i.e. OWL-S, WSDL-S. However these methods have few limitations i.e. huge number of services exists are described using WSDL format and it is not feasible to add semantic in the existing services, every new service can't have semantic description with it and service requestor may be unaware of terms related to the service. UDDI is used to publish a WS, however the runtime parameters cannot be stored in the UDDI and there is no universal registry for storing WS. Hence, it is very difficult to store runtime parameters to improve WS description [4].

Few challenges for WS architectures for IoT environment as follows:

- Information sensed by IoT device is heterogeneous, raw and unstructured
- IoT devices are resource constrained in nature i.e. limited energy source, limited computational capability, limited memory and limited size
- Traditional WS discovery mechanism is heavyweight and keyword search based
- User-centric approach is not considered in the traditional service discovery mechanisms
- The semantic service description is required for WS.

In the near future IoT devices around us offer a huge number of services to end users for betterment and comfortable life. The end user must get services depending on their requirement. However, IoT comes with challenges mentioned above. This invokes the need of a lightweight and semantic service architecture for IoT. In the next Section review of different approaches of service discovery is done. This analysis helps to find out design parameters of service architecture for IoT environment.

III. Related Work

The service description is the first and important step of service architecture as the efficiency of service discovery is dependent on the service description. In the literature, service description is done by three different approaches. i.e. functional, non-functional and data structural [5]. To provide appropriate service depending on user's requirement the need of betterment in a service description is invoked. The semantic service description is the step to fulfill the need mentioned above. The semantic service description can be done in two ways i.e. annotation based and semantic language based. The annotation based approach improves the expressivity of service description by providing an annototional description for data types, inputs and output of WS. In the IoT paradigm, devices around us will provide services to end users. A large number of services will be available as IoT applications will be deployed in all domains. To provide appropriate and useful service to the end user, efficient service discovery mechanisms are needed. Traditionally, services are registered in the UDDI registry then services are searched using the keyword search mechanism. The UDDI based service architecture faces the limitation due to a centralized approach, hence different ways of deploying service architectures are discussed by Demian et al. [6]. i.e. centralized and distributed. Centralized approach categorized into portal and UDDI based architecture. UDDI based architecture further categorized into hybrid and portal based. Distributed architecture approach categorized into three different ways. i.e. Agent based, Internet based and Point to

Point(P2P) based architecture. Among these different ways of WS architecture, appropriate architecture is used depending on the requirement of the application.

The ontology-based services discovery is proposed by Paliwal et al. [7]. Service discovery is achieved by functional level service categorization and semantic enhancement of service request. The service categorization is done at UDDI by performing two steps. i.e. parameter based service refinement and semantic similarity based matching. Service refinement is done by combining semantic characteristics with syntactic characteristics in WSDL description. In this approach, each service is represented as vector i.e. Service Description Vector (SVD). Service refinement is done by improving semantic contents of the SVD. Services having similar functionality may be grouped in different categories at UDDI, such services from different categories are grouped together in the cluster. These clusters are labeled depending on their functionality for efficient service discovery. To label the cluster, an ontology concept is used. Services from cluster are mined to find the pattern to satisfy the user's request. Hyperclique patterns are used for this purpose. User's request is enhanced using Latent Semantic Indexing (LSI) technique. In this approach, the service refinement and discovery is dependent on the WSDL file. It is impractical that every existing service will have a semantic description with WSDL file.

Logic-based and knowledge based service search and discovery are proposed by Cassar et al. [8]. The latent factor based approach is used to describe the service. Latent factors are recovered from service description by probabilistic machine learning approach. A latent factor is related to the semantic description of web service and can be expressed as probability distribution function. In this Ontology web language for services (OWL-S) is used for service description. To retrieve latent factor from the description, it is converted into Service Transaction Matrix (STM). STM provide a training set, and it is served as input to probabilistic machine learning technique to extract latent factors. Clustering of relevant services is done on the basis of latent factors using Latent Drichlet Allocation (LDA). Service discovery process works efficiently on clustered services.

Meditskos et al. [9] proposed service profile ontology-based service description. Object-based structural matching technique and logic reasoning methods are used for match making process of service discovery. Ontology roles are combined with description logic reasoning for improved service discovery process. The comparison between the complex concept (CC) and service profile (SP) description of WS description is proposed in this wok. The four ontology levels are used to describe WS i.e. Service, Service Profile, Service Process and Service Grounding. In the profile based discovery mechanisms, the service request and service advertisement both represented as the profile. Profile based discovery gives discovery results very efficiently.

Bootstrapping Ontology mechanism for service discovery is proposed by Segev et al. [10]. Term Frequency and Inverse Document Frequency (TF/IDF) methods are used to evaluate WSDL description. These methods review the service description from internal and external perspective. Lastly, free text description method is used to resolve the inconsistencies in the service description ontology. It works in four steps. i.e. token extraction, token evaluation, concept evocation and ontology evolution. Initial filtering and extraction of the labels from WSDL document is done in the token extraction step. In the second step the tokens are evaluated by TF/IDF and web context extraction (WCE) method. TF/IDF method searches for the token that present most frequently in its WSDL document but least present in other service's WSDL documents i.e. token that can represent service in a unique way. In a WCE method group of tokens are extracted from WSDL file of service that can represent the context of service. In the concept evocation, step tokens extracted from both methods are evaluated, and tokens present in both methods are selected to describe the service. In the last step i.e. ontology evolution current ontology is compared with newly extracted descriptors. In this work the description of WS is improved for efficient discovery.

Chakraborty et al. [11] proposed service discovery for pervasive computing. In the pervasive environment usually services are advertised in the broadcast way. However the global broadcasting has limitations i.e. broadcasting of services couldn't be applied for the large-scale network as it works poorly with increasing network size and it uses the more resources and power. In the proposed method solution to overcome the drawbacks of global broadcasting is discussed. It works in two steps. i.e. service caching and group based advertisement of service request. Services are cached at every peer and service requests are forwarded in the group-based approach. Every group of nodes advertises the services provided by the group in abstract way. Hence service request could be easily forwarded to the appropriate group. Group based approach minimizes the efforts to search appropriate node that providing the service demanded by user.

WS description, advertisement, execution and discovery using DARPA agent Markup Language (DAML) is discussed by McIlraith et al. [12]. Descriptive API is used to provide service specification, service capabilities, interfaces and prerequisites for service execution. DMAL Agent based technology is used in this work to discover WS depending on the user preferences and constraints. Zisman et al. [13] proposed the need and solution of runtime service discovery. Service replacement is needed due to various reasons i.e. Unavailability or malfunctioning of service, changes in structure of interface or functionality of service, better service is available to complete associated task. The pull and push model of run time service discovery is used to replace the service that no longer needed. Requirement of Quality of Service (QoS) parameters for WS description and discovery are discussed by Kritikos et al.[14]. QoS parameters are categorized into two types. i.e. domain dependent and domain independent. QoS broker service architecture is proposed in this work. The broker plays the middle layer between user and WS. Analysis of different QoS parameters helps to describe WS semantically with non-functional qualities. Guinard et al. [15] proposed the RESTful service architecture. Proposed

approach is targeted for the IoT environment. IoT devices are resource constraints in nature hence RESTful approach is used for WS. Device profile (DP) is generated for each IoT device that provides services. DP provides services to the users with minimal user interaction. The minimal user interaction is the need of the IoT environment to achieve lightweight service architecture. The context awareness is used as key parameter for service discovery as in future network large number of services will be available. Among such large number of services only appropriate service should be provided to the user hence user preference and context are the parameter for service discovery. In the proposed work these requirements of future network are focused. i.e. RESTful services, Context and user preferences. However access methodology for WS is not addressed in this work. Universal Presence Server (USP) based lightweight RESTful WS architecture is discussed by Chunyan et al.[16]. Proposed architecture includes three entities. i.e. Request Manager (RM), Publication Manager (PM) and Subscription Manager (SM). PM publishes the service description in publication database. SM retrieves the list of services present from the USP database. SM dynamically decides the interface agent to interact with the end user. Dynamic decision of message interface makes this approach lightweight for accessing and interacting with WS.

A vast literature work is done in the area of service architecture to achieve the dynamic, on demand, lightweight and context aware service discovery. Thirteen different approaches of service discovery are analyzed by Debajyoti et al.[17]. i.e. context aware WS discovery, publish subscribe model, keyword clustering, service request expansion method, graph ranking, layer based semantic discovery, WS discovery techniques for heterogeneous networks, WS indexing, structural case based reasoning, agent and QoS based discovery, collaborative tagging, using finite automaton and hybrid approach for WS discovery. When service discovery method is not capable of discovering service based on user's requirement then approximate WS is suggested, for such type of process the behavioral matching of WS is required. The user's requirements are described using behavioral graph and the WS discovery process is converted into graph matching process. From the analysis of different techniques of WS discovery in this work the importance of QoS parameters is focused. As using different semantic and syntactic discovery approach large number of services could be discovered for same type of function. Selecting one WS for user's requirement will be more dependent on the nonfunctional parameters. i.e. QoS parameters. Survey of QoS based WS discovery approaches is done by Phalnikar et al. [18]. The detailed categorization of QoS parameters is discussed in this work. Ontology and syntactic approaches of WS discovery with QoS parameters are compared and the requirements of ontology based WS discovery are proposed in the work i.e. the automatic WS discovery, WS invocation and WS composition. WS description is the base of WS discovery process, efficiency of discovery process increases with semantic description of WS. Bitar et al.[19] reviewed different ways of WS description methods. The need of lightweight semantic description is proposed in this work. WS described using semantic method then that can be efficiently discovered through semantic discovery. In the near future huge number of WS will be present around us hence need of semantic WS discovery is invoked, tremendous research work is going in the direction to discover efficient protocol for WS discovery. Review of different semantic WS discovery approaches is discussed in the [20], [21].

Ibrahim et al. [22] categorized the service matching processes into three types depending on the heterogeneity level in the matching process. i.e. algebraic, deductive and hybrid approach. In an algebraic approach, the degree of similarity between WS descriptions is taken as a parameter to discover appropriate service for user's requirement. Structured graphs are used to find out the degree of similarity between WS descriptions. In a deductive approach, the WS discovery is based on logic i.e. description logic and first-order logic. In this approach instead of semantic different other elements of WS description are considered for service matching process i.e. preconditions and effect matching (PE matching), input and output matching (IO matching), and input, output, precondition and effect matching (IOPE).

IV. COMPARATIVE ANALYSIS

In the above section, different prominent techniques of WS discovery are discussed. In view of realizing IoT application, there is need of dynamic WS architecture hence this literature survey will help to figure out the designing parameters of WS architecture for IoT environment. IoT paradigm requires the major focus on the user's requirement as IoT application will be deployed for the betterment for end user's life. WS will be available in large number as IoT devices providing services are large in number. Hence, appropriate service discovery will play an important role in near future. Thinking ahead, the IoT devices that will provide and access WS are resource constraint in nature hence there is a requirement of lightweight WS architecture. Table 1 summarizes the applicability of WS discovery approaches for IoT environment. Comparative analysis is based on three important requirements of future network. i.e. User preference, context awareness and lightweight framework. In the IoT environment end user may be mobile and may not be aware of services provided at that location. In each location there may be large of services presents among these services end user must be made aware of only few services that are required by end user. Hence the context aware and user preference aware WS framework is required in the IoT environment.

TABLE I. ANALYSIS OF WS DISCOVERY APPROACHES

Approaches	Discovery Technique	UPref	CAW	LW
[7]	Semantic with Latent Semantic Indexing	No	Yes	No
[8]	Semantic with Service Transaction Matrix and Latent Drichlet Allocation	No	Yes	No
[9]	Service profile ontology-based	No	Yes	No

[10]	Term Frequency and Inverse Document Frequency and web context generation	No	Yes	No
[11]	group-based service request forward approach	No	No	Yes
[12]	DARPA agent Markup Language	Yes	Yes	No
[13]	pull and push model	No	Yes	No
[14]	Quality of Service	Yes	Yes	No
[15]	RESTful Approach	Yes	Yes	Yes
[16]	Universal Presence Server	No	No	Yes

UPerf- User Preferences, CAW- Context Awareness and LW- Lightweight

Requirements of WS architecture for IoT environment as follows:

- Semantic description of WS
- Automatic on demand WS discovery
- User-centric approach
- Context awareness approach
- Lightweight registration process for WS
- RESTful approach

V. Conclusions and Future Work

In order to provide WS framework for IoT environment it is important to determine the requirements of WS architecture for IoT network. Hence we have reviewed the literature for service description and service discovery methods. In the literature tremendous work is done for service architecture however this approaches are not appropriate to apply for IoT settings as devices that will provide and access services in IoT paradigm are resource constrained in nature. This survey work will help to determine the designing parameters for WS architecture for IoT network. The user centric approach is the needed in the near future as large number of services will be available, among such huge number of services user must get appropriate service depending on user's requirements. Future plan is to explore a semantic service description method and lightweight, user centric and context aware service discovery methods for IoT network.

***Abstract*—Cloud computing allows the user to outsource their computation and storage overhead to a public cloud, managed by cloud service providers. Data stored in the cloud may reside on remotely servers and this raises security issues. This paper addresses the issue of data storage integrity. The scheme presented in this paper uses the concept of an external Third Party Auditor (TPA). TPA is an external party who is going to perform integrity verification of the user's data on behalf of the user. The proposed scheme assures integrity verification with a dynamic data support, to ensure that changes made to the data are reflected properly. In addition to a simultaneous approach of integrity verification and data dynamics, this scheme enables to determine the performance of the TPA.**

***Index Terms*—Data storage integrity, public auditing, data dynamics, cloud computing, Performance Assessment.**

I. Introduction

Cloud computing is an Internet-based service, which allows the users to access services from a shared pool of configurable network resources[1],while paying only for the portion of the usage. Cloud services have been categorized into three types: (1) SaaS (Software as a Service), (2) IaaS(Infrastructure as a Service), and (3) PaaS (Platform as a Service). Cloud computing enables the users to outsource their tasks of data storage and computation to a public cloud, managed by a cloud service provider. In this paper the major focus is on the cloud storage integrity. When users store their data in the cloud, the user hands over the data to the Cloud Service Provider(CSP). The CSP may have data centers at geographically different places. The benefit of the cloud is that the users can access their data in cloud anytime, and anywhere with a single Internet connection. But the drawback is, that the user has no knowledge or control about where the data is being stored. Data integrity at untrusted servers is an important issue[1]. Data integrity is an act of making sure that the user's data stored in the cloud is correct and consistent. It is an action, which makes sure that data can only be accessed and altered by those who have been authorized to do so. Sometimes to efficiently manage the storage space and to save expenses, the service provider might be a bit negligent to rarely accessed ordinary users data[1]. Hence, it becomes very essential to be able to check the status of the data stored in the cloud. In order to perform data integrity verification, different schemes have been proposed till now[2]. All these prior work considers different parameters in their schemes(e.g. efficiency of the scheme, etc.). Fundamentally, we can distinguish between two categories, public auditing and private auditing. Private auditing schemes are more proficient than public auditing schemes. Public auditing schemes allow for not just the user but anyone to challenge the cloud server for the accuracy of the data. This paper takes the public auditing into consideration. It is not possible for a user to carry out an integrity check on a timely basis. We propose an external Third Party Auditor (TPA),whose task is to verify the user's data stored in the cloud, on behalf of the user. Public auditing is nothing but a verification of the user's data performed by an external TPA, on behalf of the user. For security purposes, the TPA will perform stateless verification, i.e. verification will be performed without retrieving the user's data stored in the cloud. This paper also addresses the issue of dynamic data operations. When the user stores his data in the cloud, the user also makes some modifications to the data,whenever necessary. Data dynamics is an ability to support block level operations, such as block insertion, block deletion, block modification on the data stored. It is necessary to check whether the changes made to the data by the user are replicated properly to the data stored in the cloud. This paper proposes public auditing and dynamic data support for ensuring cloud data storage integrity. Further, we aim to assess the performance of the TPA by enabling to calculate the time required to accomplish each verification request by the TPA.

II. RELATED WORK

Prior to this scheme, a lot of work has been done for remotely stored data integrity verification. Ateniese et. al.[1] are the first to consider public auditing in their scheme 'Provable Data Possession'(PDP) for safeguarding the possession of files stored remotely. In their work they have applied the concept of RSA-based homomorphic tags for auditing remotely stored data. But Ateniese et. al. did not consider dynamic data support. Later in their subsequent work [2], the authors extended the concept of PDP to propose a dynamic form of PDP. This scheme provides efficient and secure provable data possession with less computation overhead. It supports secure and limited dynamic operations on the data. The drawback of this scheme is that it supports only a prefixed number of

verifications. Further, it supports only a limited number of basic block level dynamic operations and does not support block insertion operation. In [3], Wang et.al. considered the dynamic data support in a distributed environment. The authors applied Erasure correcting codes, to support the dynamic operations for the data update, delete and append. This scheme is efficient against Byzantine failure, malicious attacks etc. Though this scheme supports dynamic data operations, it does not support insertion of data blocks in between the data. In [4], Jules and Kaliski, proposed a "Proof of Retrievability" (PoR) scheme. The authors applied the concept of spot checking and error correcting codes, to guarantee both the 'Possession' and the 'Retrievability' of the files stored remotely. The authors used special purpose precomputed encrypted blocks known as 'sentinels', which were included in a file randomly for detection purposes. However, the use of sentinels stops the detection of data dynamics updates. This scheme does not support public auditing properly[11]. In [5], Shacham and Waters proposed an improved PoR Scheme. The authors used the concept of homomorphic authenticators constructed based on BLS-signatures, to aggregate a security proof into a small authenticator value, and to achieve public verifiability. This scheme works only on static files. Erway et.al.[6] were the first to consider 'Dynamic Provable Data Possession '(DPDP), which is an extended version of the PDP scheme. They applied the concept of Authentication Directories with ranking schemes. To provision block insertion, the authors removed the index information in the 'tag' calculation of the existing PDP scheme. This scheme enables efficient proof of the entire file system by providing verification at different levels for different users without downloading the whole data. Though this scheme focuses on both the audit and the dynamic operations of data, its efficiency is unclear. Though various schemes have been proposed for remote data integrity verification, the issue of supporting both public auditing and data dynamics has not been fully addressed. In [7],Wang et.al. have proposed a scheme, which supports both public auditing and data dynamics. They combined the concept of PDP and POR schemes. An external TPA for the verification of the user's data was introduced to the scheme. This scheme is beneficial as it reduces the tasks of the user. The authors have used the concept of homomorphic authenticators and Merkle hash tree, to verify that the values and positions of the data blocks are unmodified. Our scheme uses the same concept of TPA but using zero knowledge proof and CRC-64 techniques rather than Elliptical Curve Cryptographic (ECC) techniques. Our scheme efficiently reduces the time required to perform the verification of the remotely stored data.

III. SYSTEM ARCHITECTURE

The System Architecture is shown in Fig. 1. The following blocks can be defined:

a. User: The user is an entity, who has some data to be stored in the cloud. The user stores his data to the cloud, and depending on the cloud for the computation and the maintenance of the data. The user can be an individual person or an organization. In this paper, we will use terms 'user' and 'client' interchangeably. Whenever the user wishes to perform a verification of his data, he sends a challenge request to the server via the TPA.

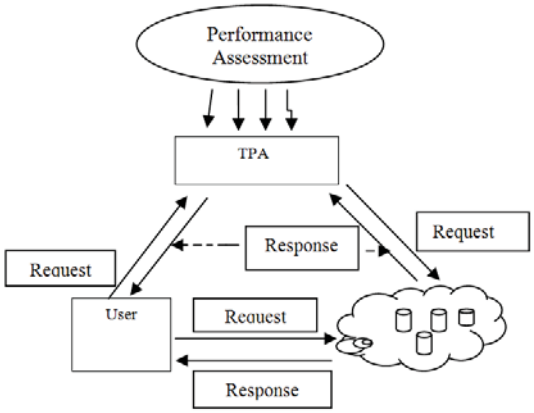

Fig. 1. System Architecture

b. Cloud Storage Server (CSS) or Server: This is an entity who possesses massive amount of storage space and resources needed to manage the user's data. It allows the users to store their data in the cloud storage and to manage the user's data. When the server receives a challenge request from a client, a proof of correctness gets generated and returned to the client.

c. TPA: This is an external entity whose task is to perform the verification of the user's data, on behalf of the user. The TPA performs the verification by challenging the server, to verify that the user's data is unaltered [7]. Though the TPA is going to perform the verification on behalf of the user, it should not retrieve the user's data i.e. the TPA should perform 'blockless verification'. The TPA verifies the user's data without retrieving it[12]. In the cloud model, by keeping larger files to the remote servers, the user can be relaxed from the load of storage and maintenance. As data stored in the cloud can be stored on any geographical distant server, the user does not possess any data locally. Therefore, it is essential for the user to ensure that the data are accurately stored and maintained[9][15]. The user should be able to perform check data accuracy periodically without having any local copies of the data. Practically, it is not possible for the user to take audits on a periodical basis. The user can hand over this task to the TPA[13]. Any TPA with the public key can become a verifier. This scheme assumes that the user can communicate with the cloud server via the CSP, to access, to modify or to retrieve their data. The user or the TPA can challenge the server on a timely basis to check the accuracy of the data. In response to this challenge the server returns proof of correctness.

A. *Proposed Scheme*

This section provides a proposed scheme for the cloud storage integrity. The proposed system supports both data dynamics and public auditing. For public auditing this scheme uses the concept of Zero Knowledge Proof (ZKP) and CRC-64

hashing technique. In general, a ZKP is a way by which the prover (i.e. the server) can demonstrate to the verifier (i.e. the TPA) that a given statement is true, without disclosing any information apart from the fact that the statement is really true. Basically, CRC-64 is an error sensing code, which is mostly used to verify the data transmitted over a network. CRC-64 is used to check that data travelling through the network (cloud) is unaltered. In addition to the efficient provisioning of public auditing with blockless verification, the scheme uses the homomorphic authenticator technique. The homomorphic authenticators are nothing but metadata produced from distinct data blocks, which can be safely combined in such a way to assure a verifier that a linear arrangement of data blocks is properly calculated by verifying only the aggregated authenticator. In the proposed scheme, CRC-64 is used for hashing purposes, where the existing scheme uses merkle hash tree for hashing. Basically, the proposed scheme operation is divided into four steps, as follows:

1. KeyGen(): The KeyGen operation is carried out between the user and the cloud server. By using this step, public and secret keys are generated.

2. SigGen() : The SigGen operation is used to perform the preprocessing of the user's data . In this step, metadata of the user's file is generated and these metadata are signed using a secret key.

3. GenProof(): In the GenProof operation, the TPA gives a challenge message to the cloud server to prove that the data stored in the cloud is accurate and unmodified. The server generates the proof for the respective challenge message.

4. Verify Proof():In verify proof operation, the TPA returns the proof generated by the server to the user. After that, the user verifies his data by using a secret key.

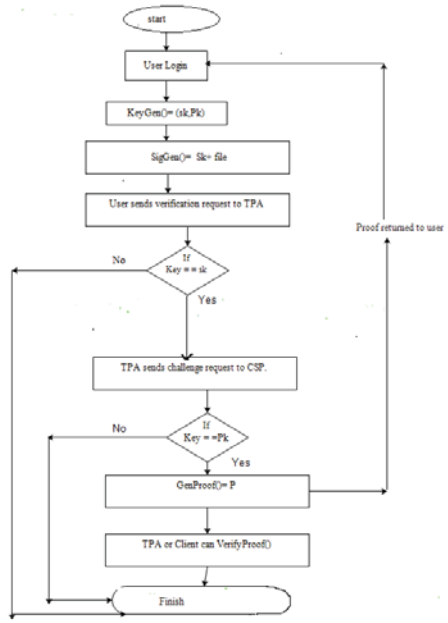

Fig. 2. Flowchart representing public auditing and data dynamics

The Flowchart procedure is shown in Fig. 2. This procedure is used to create security keys, such as a private key and public key. It is achieved by invoking KeyGen(). In the pre-processing, it makes use of the homomorphic authenticators and the metadata. The procedures need two parameters, namely, the file and the key. The contents of the file are divided into several blocks. A hash code is calculated for each block. The hash code of two blocks is then combined. The combined key is further combined with other keys made up of two combined keys. The following steps are carried out for the overall integrity verification and dynamic data operations. For public auditing and data dynamic support this scheme uses the concept of Merkle Hash Tree(MHT). MHT is an authentication structure, which is used to verify the values of data blocks. But in this scheme MHT is used to verify both the values and the positions of the data blocks. MHT is proposed to proficiently and safely prove that a set of elements are untouched and unchanged. MHT is a binary tree, where leaf nodes are hashes of accurate data value. In the top of MHT there is a root value. The authentic root value is acquired from reliable source. Whenever a hash tree is received from any party, the authentic root value acquired from reliable source is compared with the root of hash tree received from other source, to confirm that the set of elements are untouched and unaltered.During the verification phase the following steps are carried out:

1. Let chalmsg be the challenge message. Message chalmsg specifies the blocks to be challenged .The TPA sends a chalmsg message to the server and generate the random set Chalmsg (i,Bi), where i ϵ I.

2. When the server receives the request chalmsg = (i,Bi) the server computes the following:

$\Psi = \sum B_i \; m_i \; \epsilon \; Z_p$ ..... (1)
where ψ is a data set.

3. compute $\Phi = (\Pi i \; \emptyset i)^{Vi}$ ..... (2)
where Φ is a signature set.

Here both the data blocks and the corresponding signature block are combined into a single block. Additionally, the prover will also provide the verifier with a small amount of auxiliary information ω_i. This is the information about the nodes that reside on the path between the root and the requested node i.e. information about neighborhood nodes.

4. The Prover responds to the verifier with a proof

P=(ψ,Φ,H(mi),ω,Sigsk(H(R)))..... (3)

When the client receives the response proof from the server, it verifies the proof by computing the root R using (H(mi),ω) where iϵ I and ω is auxiliary information;then the root would be verified by using sigsk(H(R))else output false if fails. Finally, it verifies the data block mi:

mi,(mi) i.e. (Φ .g) = e(Φ Π H(mi)^{Bi} u$^{\psi}$,V) ..... (4)

To ensure that changes made to the data by user have

been reflected properly, this scheme provides support on data operations such as block insertion, block deletion, block modification, dynamically. To support the dynamic operations on the data, the following steps are carried out.

B. Data modification

1.To modify block mi to mi' generate a new signature for that corresponding block is

Φ'=(H(mi' $u^{mi'}$)$^{\alpha}$.....(5)

2.Upon getting this modification request, the server updates the file F and computes R' and returns

Pupdate = (ω,H(mi)),sigsk(H(R).R') ..... (6)

3.Upon receiving Pupdate, the client computes R usingH(mi),ω).

4. Then it performs the verification Sigsk(H(R)) and the output is 'False' if the verification fails. The following operations Are then performed Compute Rnew using(ω ,H(mi'))Verify update by checking if(Rnew = = (R')sign R' by succeed then finally server update R' signature.

C. Performance Assessment

The existing scheme supports both public auditing and data dynamics .but in the case of failure the TPA becomes the bottleneck to the single point failure. Hence, in the proposed scheme the main focus is on how to assess performance of the TPA. For that purpose this scheme maintains a queue[10][8] . Let λ be the arrival time of customer's request.

Let μ be the service time of customer's requests.

Let Δ be the delay in the queue.

Let the time at which service begins is Sb.

Let the waiting time be Wi.

Let the Total time be T.

Let P be the utilization factor = λ /μ.

The goal is to determine the time taken by the TPA to verify each verification request. Each verification request is placed in the queue before the TPA processes it. Before computing total time we need to consider delay in the queue. We need to compute the time at which service begins is Sb.

Sb = λ + Δ .....(7)

Let the Service time be μ.

Let the Wi be the waiting time and computed as:

Wi = Δ + μ .....(8)

Finally Let T be the total time taken to complete each request can be computed by:

T= λ + Wi .....(9)

Where, T- Total Time

λ - Arrival Time

Wi- Waiting Time

μ - Service time

Sb - time at which service begins. Δ - Delay in the queue.

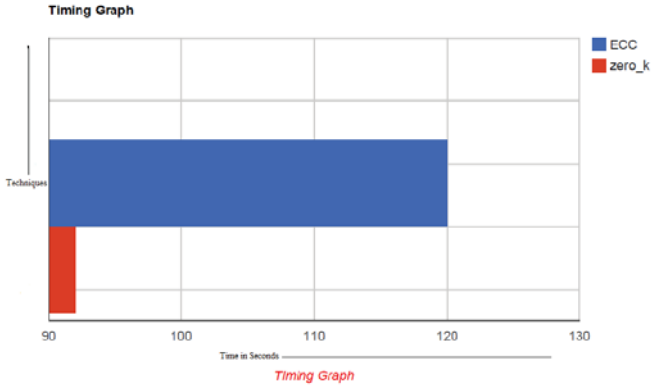

Fig. 3. Graph representing time required to process each user request

Fig. 3 shows the timing graph that represents the time taken by the TPA to perform the verification of each request. Fig. 3 shows the comparison between the time taken by the ZKP technique and the Existing Elliptical Curve Cryptographic (ECC) technique. The ZKP takes less time than the ECC technique.

IV. CONCLUSION

For integrity verification the existing system provides the public auditing scheme using a TPA. The TPA performs the auditing of the client's data on behalf of the client using the challenge response protocol. In addition to the auditing, the existing scheme also supports data dynamics operations, such as block insertion, block deletion, block modification etc. to check whether the changes done by the client are incurred properly to the data stored on cloud. As the TPA is going to perform a number of auditing tasks simultaneously it becomes essential to determine the performance of the TPA, so that it can perform properly in the event of failure. For this purpose the proposed scheme provides a functionality to supervise the performance of TPA for smooth functioning.Our Proposed scheme mainly focuses on Time reduction. As ZKP are probabilistic rather than deterministic, it becomes essential to achieve higher level of security. Though ECC techniques takes much time for verification , they are more secure.Hence to improve the efficiency of algorithm can be considered as a future work.

Abstract— **presently researchers are working on the development of EEG-based human computer interface for enhancing the quality of life in medical as well as non-medical applications. Such technology can be incorporated to psychology, anesthesiology, gaming, security system and for real-time patients monitoring. The Neurosky Mind wave headset devices are generally utilize to detect and measure electrical activity of the user's forehead and transmit the collected data wirelessly, to a computer for further processing. After processing EEG signal, it is categories into various frequency bands for feature extraction. This paper mainly deals in extracting the feature of EEG signal in Openvibe. In this paper, we have proposed an algorithm to extract the features like frequency band, amplitude and power spectral density. Based on the feature extraction, we can characterize the EEG signal and use it for different real-time applications. Furthermore, we have discussed the mental or behavior state of the person (Eye Blink, Meditation, Attention levels) through the NeuroSky Mind wave (MW001) device using Openvibe.**

Keywords— EEG Sensor, BCI, Signal Processing, Openvibe

I. INTRODUCTION

Recently, a new attribute human-centric communication and human-computer interaction is incorporated with digital media has been revolutionized the numerous fields like medical, sports, entertainment, including wellness and quality of life. Most importantly, such technologies are the key interest to the vast potential for various medical applications. Monitoring brain activities with brain-computer interfacing (BCI) has enabled real-time healthcare monitoring applications for much neurological disorder and disabled patients. This field has the potential to shift clinic centric technologies to patient-centric technologies by monitoring brain activities. Generally BCI utilized to performs four distinct tasks. Converting neurological input signals into electrical signals; extracting features; gathering important information, and combine all meaningful information for useful purposes [1].

In BCI system, the user sends the information through the brain signals on the receiver side these signals will be received and apply for target applications. The application then converts these signals into commands that cause movements. The BCI has been used for a widening variety of such applications. The initial applications have been aimed at helping disabled people utilize machines. These days, many researchers consider that wireless BCI systems are a very important step towards getting BCI applications out of laboratories. Recent advances in embedded system, sensor technology, digital signal processing techniques and wireless Communication technology has made real-time brain activity monitoring possible [2]-[3]. The information (brain signal) is transmitted either wired or wirelessly to the computer system using a multiple distributed EEG (electroencephalogram) electrodes or sensors placed over the human head [4]. We have characterized wired and wireless devices based on literature work, recent advances, and their applications. These devices help to improve the quality of life paralyzed or mentally disabled patients in a hospital and home [6].

In this paper, we focus on the different type of EEG systems and their applications. We have also mentioned the state of the art available wireless EEG devices and their features. Initially, researchers proposed wired BCI system to diagnose disease [6] which is very uncomfortable for the patients. Currently, wireless BCI system helps people's life more comfortable. These systems are able to offer improvements in entertainments, games, medical engineering, rehabilitation, and daily life because such systems have obvious advantages. They are simple, convenient, and flexible to use because of wireless.

The NeuroSky MindWave headset is used to collect raw signal from the human brain. The accessed Data from the Neurosky headset are then plotted through the Application Program Interface of Neurosky Inc. using a processing based program. We assign a subject to perform facial gestures and mental activities tasks like smooth and fast opening and closing eye, blink, concentration, and meditation. The real-time raw data was recorded during the subject performed these actions using Openvibe software, Further development of process-based algorithms of concentration and meditation level of recognition for Medical applications.

The rest of paper is as follows Literature Survey on EEG signal and its characteristics are given in section II. Section III provides the proposed work and Section IV provides Results and Discussion on Feature Extraction through Behavior state Monitoring using Neurosky Mindwave Device.

II. LITERATURE SURVEY

EEG is the representation of the electrical signal of the brain activity from the scalp. The first neural activity of the human brain published in Hans Berger (1924) [2] using a simple galvanometer. EEG is generally described in frequency band vary of amplitude and frequency of the wave represent various brain states which depend on internal brain behavior state and external simulation [3]. In recent years, clinical use of EEG 21 electrodes is used to identify 5 fundamental waves.

Generally, brainwaves are classified in five frequency bands i.e., Delta, Theta, Alpha, Beta, and Gamma. Delta signal (0.1-3.5Hz) associates with a deep sleep condition. Theta (4-8Hz) signal consist of with dreams, imaginary, idling, drowsiness. Alpha (8-12Hz) represents relaxed, reflection and pattern appears in wakefulness. Beta (>13 to 30Hz) alert, working active, busy, thinking and concentration and Gamma (30 to 100Hz) is associated with the rhythms for high-level information processing as shown in Table1.

Table 1. Frequency band classification based on Brain Activity

Brainwave Type	**Frequency range**	**Mental states and conditions**
Delta	0 to 4Hz	dreamless sleep, unconscious
Theta	4Hz to 8Hz	recall, fantasy, imaginary, dream, creative
Alpha	8Hz to 13Hz	Relaxed, but not drowsy, tranquil, conscious
Low Beta	13Hz to 15Hz	relaxed yet focused, integrated
Midrange Beta	16Hz to 20Hz	Thinking, aware of self & surroundings
High Beta	20Hz to 30Hz	Alertness, agitation
Gamma	30Hz to 100Hz	Motor Functions

Now a day's great development is happening in wireless EEG devices for patient monitoring, gaming, and other applications. Previously, researchers are using wired EEG devices for patient monitoring but now easily handling through wireless EEG devices [5]. These EEG devices have been developed by Neurosky, OCZ technology, InteraXon, PLX devices and Emotive systems [3]-[4].

III. METHODOLOGY

A. Utilized Resources: Hardware

The main hardware used for this study is NeuroSky MindWave Device, having a single-channel headset and its cost around $100. The device consists of eight main parts - ear clip, ear arm, battery area, power switch, adjustable headband, sensor tip, sensor arm and thinks gear chipset [5]. The main principle of this device is very simple. In this device, two sensors are used to detect the EEG signals and filter out the noise. First sensor tip detects electrical signals from the forehead of the brain, through the electrode positioning (FP1) according 10-20 system of the EEG [2]-[6].

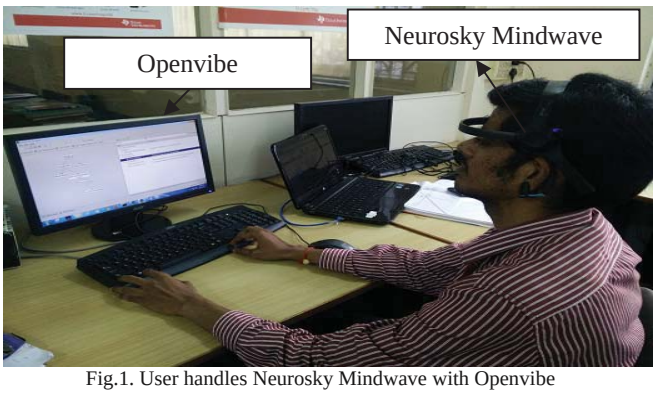

Fig.1. User handles Neurosky Mindwave with Openvibe

The second sensor ear clip is used for ground reference to filter out the electrical noise. Signals from this sensor are receiving via the electrode placed in the left ear lobe, where the data obtained at 512 Hz of sampling rate with each sample there is a 16-bit ADC resolution [7]. User handles Neurosky Device with the computer as shown in Figure 1.

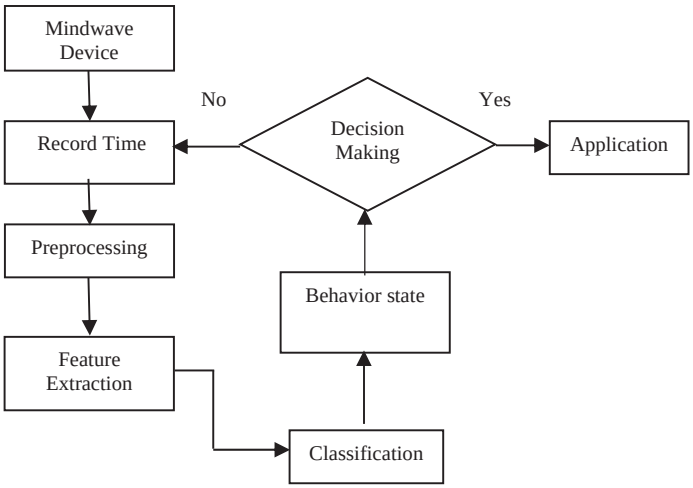

Fig.2. Proposed Algorithm for Behavior state Monitoring

We have proposed an algorithm for behavior state monitoring as shown in Figure 2, with the help of Neurosky Mindwave system. The First step is to setup Mindwave Wireless EEG Device to system/laptop through the wireless communication technology such as Bluetooth through the serial port. Next we have recorded the EEG data for certain time period. Normally these recorded data contains a lot of external noises, so first we have to eliminate this noise using preprocessing techniques. In preprocessing techniques, we are eliminating the artifacts and external noise using filtering techniques. We are setting up the frequency 0 to 40 Hz. After this we normalize the received data and then extract the features from EEG signal such as amplitude, frequency band, power spectral density based on the classification methods

such as Linear discriminant analysis (LDA) and Support Vector Machines (SVM).

B. Utilized Resources: Software

More simplify signal processing techniques and data analysis is possible through the Openvibe software [9]. It is a computing language using software programming designed for data analysis, computation and visualization [8]. Openvibe allows 2D and 3D visualization of data through the topology. In this paper, Openvibe is used to process the EEG signal. Normally EEG machines electrodes are placed on the head of the subject and transmits EEG signal to computer with huge external noise, artifacts and interference but in Openvibe software are easily tackled these issues [11]-[16].

First we setup the Neurosky Mindwave device to the computer over Openvibe platform for acquiring brain signal according to the steps shown in Figure 4. In next step, acquiring server of Openvibe with Neurosky device and device properties will transfer the data after pairing with Bluetooth to the system/laptop. It allows Bluetooth connection which send data in the form of packets. Then, we design our proposed algorithm for behavior state/mental state in Openvibe.

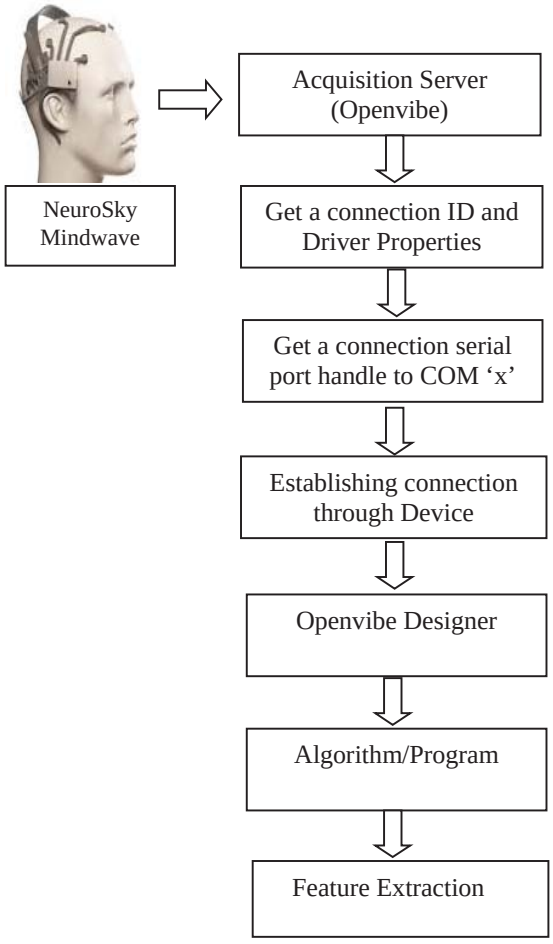

Fig.3. NeuroSky MindWave Communication protocol

IV. RESULT & DISCUSSION

Initially, we setup the Neurosky device setup with Openvibe software which is mathematical and graphical programming language. In Openvibe, it is easy to drag and drop the inserting options. First initiate the acquisition server of Openvibe with Neurosky Mindwave device, sample per count is 32, a connection port is 1024 and sampling frequency of the device is 512Hz. Then open the openvibe designer for programming, we design a simple program for acquisition and signal display as shown in Figure 4. For obtaining raw EEG signal of a user through neurosky mindwave device with a single electrode (Fp1) placed on the forehead. The raw EEG signal is shown in Figure 5.

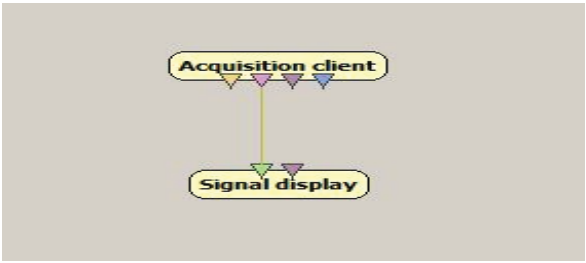

Fig.4. Acquisition of EEG signal in openvibe

The signal shown in Figure 5 is the result of eye blinking of the subject, which is clearly visible.

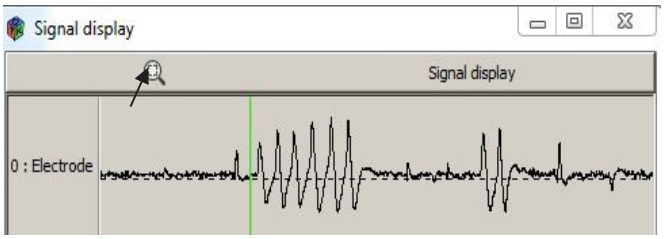

Fig.5. Raw EEG signal

Next we are storing the acquired data into Geographic Data Files (GDF) format shown in Figure 6. Normally stored data is for certain time period. Openvibe is efficient software for storing data into different formats.

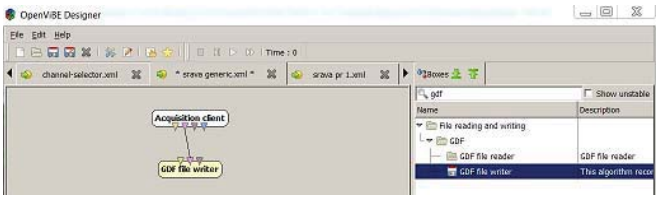

Fig.6. Stored Raw EEG data in GDF format

Brain waves have different types of activity measures in different frequency bands as shown in Table 1. The stored data is classified in different frequency bands as shown in Figure 7. We can observe that only Delta wave and Theta wave are point of concern for further processing.

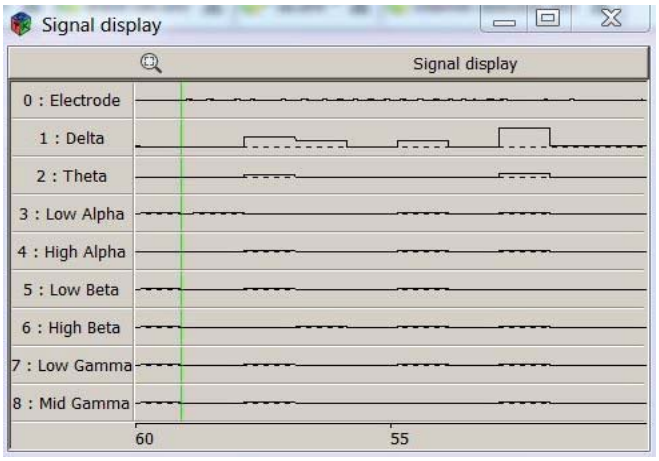

Fig.7. EEG Signal in Frequency Band Spectrum

Next step is to extract features from the stored data with an algorithm shown in Figure 8. The feature for behavior state are amplitude, frequency range and the power contain in these signals. According to the Figure 8, we import the GDF file and place it for reading. Next we are selecting the channel selector for the appropriate frequency band.

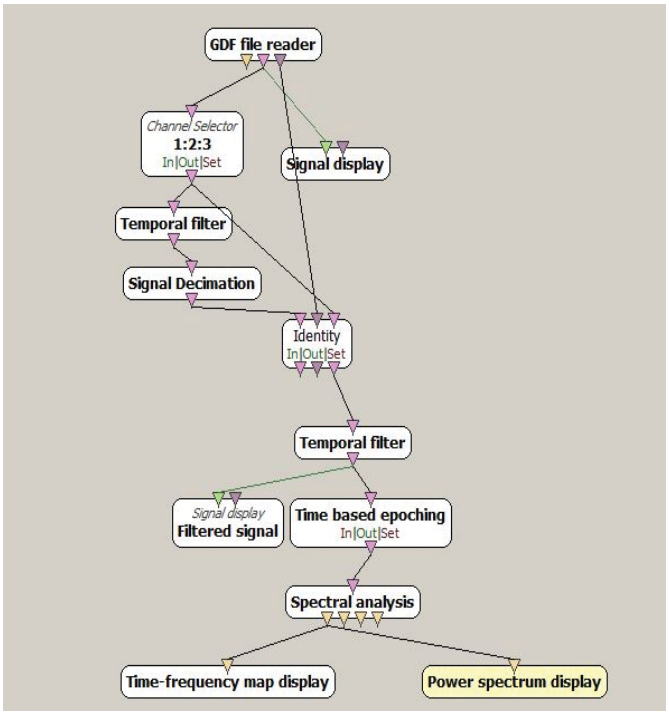

Fig.8. Step used in Feature Extraction from EEG Signal in Openvibe

We are selecting only two frequency bands of the brain signal. One is Delta wave and another Theta wave because Mindwave device has single channel device which is put on the forehead (Fp1) it reads only Frontal lobe of the brain. This device gives sampling frequency 512 Hz and data block size is 32 per samples per second. We are giving the delta and theta wave to identity as input data. EEG signal are non-stationary signal which contains a lot of noise. We remove such noise using a temporal filter. By using Band-pass filter for extracting the required frequency bands. The range for lower cut-off frequency is 0Hz and upper cut-off frequency 40Hz. After filter and eliminate the noise from the signal look like in Figure 9.

Fig. 9. Filtered EEG signal.

Then we are using time-based epoch to divide the signal into time-based epoch that is its gives every second 512 samples and blocks of 32 samples (32/512 = 1/16). Next we are applying time-based epoch signal to spectral analysis. It gives the signal amplitude. Finally, the signal applied to power spectrum display in this we are applying minimum frequency as 0Hz and maximum frequency set to the 40Hz, observing output in Figure 10.

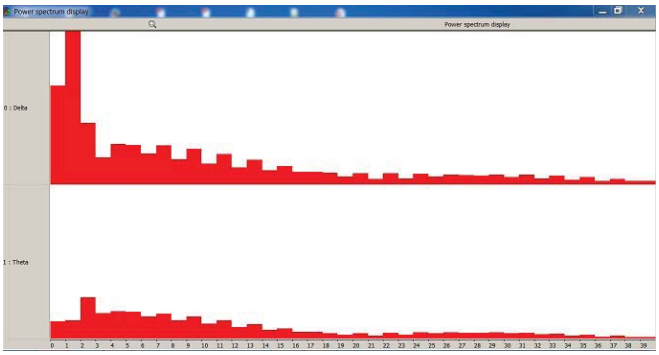

Fig. 10. Power Spectral Density of filtered EEG signal

In this spectrum, we are observing user's recorded data in relaxation state shows user's concentrate or in deep meditation level. Next we have proposed Time-frequency map, it generally measures power spectra of a signals gives over with a time. It displays power spectra of signals over time, making it possible to track changes in amplitudes over a given time span shown in Fig. 11.

From the Figure 11, we can conclude that with our proposed algorithm, we would be able to find the behavior state of the user. Mainly it gives behavior state like attention or meditation levels, Motor skills like hand/Eye Condition and conscious thoughts.

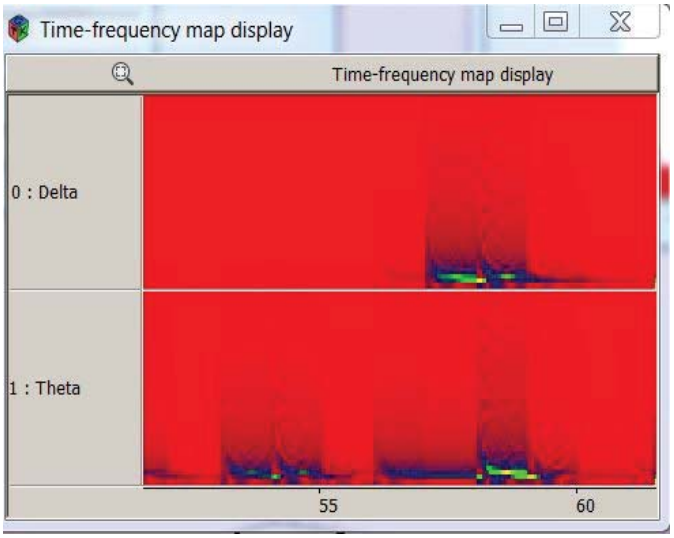

Fig. 11. Time-frequency map display of filtered EEG signal

V. Conclusion

We have proposed an algorithm for the feature extraction from EEG signal in Openvibe environment. First we observe the raw EEG data for a certain time period in Openvibe. Next we have shown how to store the data through a Neurosky Mindwave device in GDF format. We have extracted the feature of EEG signal as amplitude, frequency and power. Behavior state monitor through the single channel device used on the forehead is possible. We would observe the subject attention or meditation levels, motor skills like hand/Eye movement. Generally, health care provider, doctors, and nurses are able to get the status of the patient's health only after the occurrence of the emergency. By analyzing the EEG signal of Subject, we would get the relevant data of patient's disease status before the occurrence of any emergency like heart attack, brain injuries, etc. Literature suggests that proper analysis of brain signal will be very helpful for the improvement of medications and other nonmedical purposes. Our proposal, to somewhat enhance the level of medication given to the patient will be done by the knowledge of what has happened in neuron activity.

***Abstract*—Communicating the Internet of Things (IoT) data relying on Long-Term Evolution (LTE) and WiFi has been been presented in the relevant literature. However, this necessitates devices to have LTE/WiFi capability of their own, that has limitations in the form of power consumption, and radio access congestion. Alternatively, Bluetooth, ZigBee, and Near Field Communication (NFC) are promising technologies for low power personal area network communication, and used for IoT devices. These technologies have not been truly examined for their capacity for IoT as they require a custom gateway to communicate the data to the Internet. In this paper we present a system model wherein the smartphone functions as a gateway for the IoT devices operating on NFC, ZigBee and Bluetooth. The smartphone functioning as a gateway for transferring IoT data. The system modelled in the form of a Markov Chain based on the operational states of the smartphone is presented.**

***Index Terms*—internet of things, LTE, WiFi, gateway**

I. Introduction

The Internet of Things (IoT) and the machine type communication (MTC) devices are expected to bring a paradigm shift in the communication world. A largely accepted notion has been that IoT devices would be operated relying on the Long-Term Evolution (LTE). Similarly use of WiFi has been proposed as an effective means for access and traffic relaying pertaining to IoT. Although utilizing LTE for all IoT devices is challenging considering certain aspects such as that IoT devices have low data rate and can collectively exhibit very bursty behaviour, *i.e.*, many devices reporting the same physical parameter at the same time. They could also be highly variable over a given period of time. Further, the devices are expected to be operated on batteries, and therefore performing the desired utility over extended periods of time is highly desirable.

Enhancements in LTE have been brought in the form of discontinuous reception (DRX/DTX) mechanisms that allow the devices to power on and off as per the requirement [1]. LTE as a gateway for IoT devices to transfer data is presented in [4]. In the paper LTE based data transmission (gateway functionality) is considered in the form of a smartphone, home router, and a road side unit, and the performance analysis of devices served is presented. This paper, however, does not consider the possible utility of WiFi based gateway functionality. Authors in [2] present a mechanism to distribute the devices into clusters such that all devices in a given cluster share similar properties, and access is granted to a cluster through LTE, this however may be hard to implement considering the operational diversity of devices. Authors in [3] present a mechanism for granting access to devices using device to device (D2D) connections between the MTC devices and the smartphone (user equipment (UE)), with the data uploaded using UE along-with the human centric communication data. This is a similar approach to the proposed system in this paper, however, the authors consider that all the MTC devices have the same transmit power with a packet arrival rate represented a Poisson distribution. In the presented system by the authors the operational homogeneity of the IoT devices is not considered. Using WiFi for providing access to the IoT devices has been dealt with in the some of the research works, especially with the advent of the IoT specific communication standard 802. 11ah [5]. Utilizing Bluetooth and its low energy variant Bluetooh low energy (BLE) have been stated as promising technologies for transferring IoT data [6]. Authors in [7] present a Semi Markov Model to represent the traffic flow of IoT data demonstrated through a sensor based event detection application. The paper however does not examine the communication of data through LTE/WiFi or the use of UE as a gateway. Interestingly, to the best of authors knowledge no work has looked onto how ZigBee, Near Field Communication (NFC) and Bluetooth based devices could be brought within the IoT ecosystem utilizing the UE as a gateway device. These technologies are useful considering the fact that they have a low power consumption and offer long term reliable operational capacity. Further, LTE and WiFi have been looked as competing technologies for providing access to the devices and not as complementary technologies that could be utilized collectively to serve the purpose of providing access to the devices. Femtocells and evolved NodeBs to connect WiFi and LTE based devices have been presented in [8] but nowhere is the utility of UE as a gateway discussed. This gains even more prominence considering the fact that current UE's are capable of having parallel connections to WiFi and LTE, in addition to their capacity to communicate with the IoT devices using ZigBee, Bluetooth, and NFC technologies. This is specifically relevant in a home/office environment where the number of devices is expected to be just a handful.

Lately, the immense utility of offloading of human centric

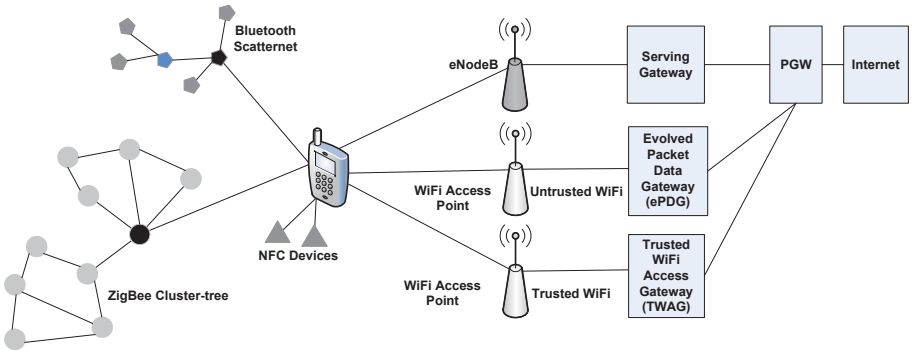

Fig. 1. System model for data transfer using the UE

excess traffic relying on device to device communication has been gaining prominence [9]. Instead of offloading human centric communication data, offloading IoT data has not been considered till date to the best of authors knowledge. This work presents a system model wherein the UE is expected to garner the data from IoT devices relying on the low power technologies and transfer it using WiFi or LTE to the Internet serving as an overall gateway device.

The communication for the devices relying on UE as a gateway should be delay tolerant and it is considered that adherence to the strict delay budget as stated say in [1] regarding guaranteed bit rate and delay budget are not necessary. It is assumed that there is just one UE through which these IoT devices can communicate their data to the Internet. As it is shown through the table the latency in establishing a connection is of the magnitude of maximum few seconds (Table I).

The rest of the paper is organized as follows. Section II presents the proposed system model for collection of data from IoT devices at the UE and transmission to the Internet, and modelling of the various states in the process as a Markov Chain are presented in Section III. Conclusions are presented in Section IV of the paper.

II. System Model

The system for collecting the data from the IoT devices, processed at the UE, and transferred to the Internet using LTE and WiFi is discussed in individual sub-sections. In the system it is considered that the data traffic from the devices is delay tolerant to a certain extent. For a device which requires strict delay budget, this system model would not be appropriate. Such a device should be enabled to transfer its data directly using LTE/WiFi chipset.

A. Bluetooth

As stated earlier Bluetooth, specifically BLE, is regarded as a key technology for IoT. The Bluetooth devices usually operate in a piconet formation wherein one of the device functions as a master and the rest function as slaves, there can be seven slaves for each master device. Additionally, piconets can be merged to work together forming a scatternet [10]. The Bluetooth devices are expected to relay their data traffic to the UE through a master device for the overall scatternet as shown in Fig. 1, master device is shown as a black pentagon, while the blue pentagon shows the device working as slave/master merging the piconets to form the scatternet. The data transferred to the UE is thus the aggregated data from all the devices in the scatternet.

B. ZigBee

ZigBee based PAN comprises of two types of devices, *i.e.*, full functional devices (FFD) and reduced-function devices (RFD). The FFD can operate as an overall coordinator for the PAN, coordinator, or just as a device [11]. ZigBee supports three topologies for operation i.e. cluster-tree, star and mesh. The IoT devices are expected to work as a cluster-tree with the elected PAN coordinator would communicating for all the nodes with the UE [12]. Zigbee is often considered as the communication base for sensor networks, therefore the Zigbee devices could be a sensor network that would communicate relying on the UE [13].

C. Near Field Communications

The NFC communication could take place between a passive tag and the UE. The UE can also communicate with another NFC enabled phone directly. The UE can read and write data on to a passive NFC tag following the NFC Data Exchange Format (NDEF). There are many variations in NDEF format data records, usually a small set of record type definitions are used [14]. The communication between the NFC tags and the UE can only take place if the distance is too short (10 cm), therefore it is assumed that data from the NFC tags would be obtained whenever the UE is in close proximity of the NFC devices.

D. UE - Data Processing

As stated earlier the UE has capabilities to connect with Bluetooth, ZigBee and NFC based devices. In addition, the

TABLE I
IOT DATA COMMUNICATION TECHNOLOGIES

	ZigBee	Bluetooth	Bluetooth Low Energy	NFC	WiFi	LTE
Data rate	250 /40 / 20 kbps	3 Mb/s	1 Mb/s	106/212/424 kbps	54 Mb/s	50 Mb/s
Network join time	30 ms	3 s	3 ms	-	-	-
Number of devices	2^{16}	8	unlimited	-	-	-
Power consumption	30 mW	100 mW	10 mW	-	-	-
Topology	Star/mesh/cluster tree	Piconet/scatternet	Piconet/scatternet	Peer to peer	-	-

UE is capable of concurrently connecting with LTE and WiFi. The data from the Bluetooth, ZigBee or NFC devices comes to the UE as a data stream with the establishment of a connection. The connection time for transferring the data from the devices to the UE is stated in the Table I. It is expected that representing device (master device in ZigBee and Bluetooth) would communicate with UE to transfer the data periodically based on the data generated by the devices that it represents. As all the technologies utilize different packet/frame formats the UE organizes the data in uniform data streams and places them in a buffer. The UE is expected to be capable of establishing connections with the IoT device leader (Bluetooth, ZigBee) or the NFC devices in round-robin manner based on the occurrence of an event/update. The connection establishment times are fairly low for the UE to communicate with the devices following such an order. The UE is expected to only serve one type of IoT devices at a given point of time, if other type of IoT devices try establishing a connection at that instant of time, they would have to reattempt the connection at a later time instant.

E. LTE Transfer

The uplink and downlink transmissions are governed by the eNodeB. The eNodeB provides the resources to each UE as time-frequency domain radio resources referred as resource blocks (RBs) [2]. The RBs span 0.5 ms, *i.e.*, half length of a sub-frame and 180 kHz (12 sub-carriers). The uplink data transmission takes place using the physical uplink shared channel (PUSCH). The possible RBs for PUSCH are provided in the downlink by physical download shared channel (PDSCH). The possible allocations permitted for future states are notified to the UE in preceding downlink channels, the RBs allocated vary for every allocation round [15]. The data if transferred through LTE is send to the eNB that forwards it to the Internet through serving and packet gateway (shown in Fig. 1).

F. WiFi Transfer

The WiFi based access point could be trusted or untrusted and that accordingly whether the connection would be access point and the evolved packet gateway or the trusted gateway. They in turn communicate with the packet gateway which in turn connects with the Internet. The transfer through WiFi would take place under two conditions, primarily, if the UE determines that the RBs needed for data transfer would be more than what is allotted by the eNodeB. This could happen if the allotted RBs would be utilized for transferring human centric traffic (voice and data). Additionally, the data transfer with WiFi is expected to be governed by policies set by the access network discovery and selection function (ANDSF) entity of the LTE core network based on the UE based quality of cellular connection and WiFi. The IP based connection is expected to migrate following mobility with IP address preservation (IPFLOW) or simultaneous IP connectivity to 3GPP and WiFi access networks (MAPCON) [16].

The benefit of relying on the UE for transferring the IoT data would be the difference in resources that would be utilized to transfer through the proposed system and alternatively with each device transmitting its data individually relying on WiFi and LTE. This should be looked into considering the fact that data from few IoT devices if communicating on their own with an end-to-end connectivity on LTE could cause severe radio congestion, involve higher power consumption, and a higher operational cost.

III. MARKOV CHAIN

The data transfer using the UE can be modelled as Markov Chain since the future state is independent of the past system instances. The overall system can be represented as a Markov Chain with four states:

- Idle state
- Processing state
- Transmission state - LTE
- Transmission state - WiFi

1) Idle State: The idle state refers to the state wherein the UE has no incoming data from the IoT device(s). However, the UE could be busy transmitting the human centric communication data. The UE would continue to check periodically for any incoming data in a round-robin manner from the IoT devices.

2) Processing State: The processing state would be the wherein UE is involved in processing the data stream received from IoT device(s). The transition from idle state to processing state would be governed by the probability (p_{ip}) of a data transmission arriving from the IoT device(s). The data to be transmitted is readied by the UE in this state and placed in a transmission buffer.

3) Transmission State - LTE: The transmission of the data from the UE to the Internet would take place preferably through LTE. The probability of transmitting the data using LTE (p_{pl}) would be governed by the conditions stated earlier in Section II-F. Once the transmission is completed the system is expected to transit back to the idle state (p_{li}) or processing state (p_{lp}) depending on the whether the UE has data ready in

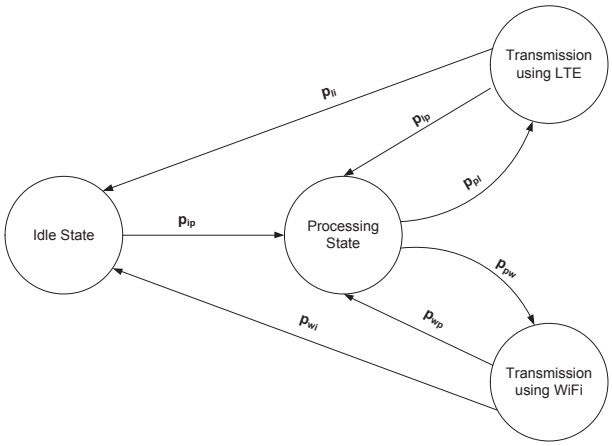

Fig. 2. Markov chain states of the UE for transferring IoT data

the buffer to upload or there will be some data available very soon, alternatively the system transits to the idle state.

4) Transmission State - WiFi: The transmission will take place using WiFi if the data could not be transmitted using LTE governed by the conditions stated earlier. The probability to transfer between the states: processing to transmit with WiFi (p_{pw}) and transmit state to processing (p_{wp}) or transmitting state to idle (p_{wi}) would be in a way similar to those concerning LTE. The actual probability states can be determined by determining the operational characteristics of the IoT devices and based on the human centric data traffic characteristics. Since, the number of IoT devices (Bluetooth, ZigBee, and NFC) in the typical home/office environment would not be many, these characteristics can be approximated fairly well. Subsequent to determining the state transition probabilities the state holding probabilities can be determined. They can be utilized to compare with system operating on end-to-end transmission done through LTE or WiFi.

IV. Conclusions

The presented system model for utilizing UE to transfer IoT data is very promising, especially considering the capacity to avoid the need of placing LTE/WiFi chipset on all devices or designing gateways for individual technologies, viz., NFC, ZigBee, and Bluetooth. The presented UE based gateway system offers additional utility for the UE utilizing functionalities that it is capable of undertaking. Additionally, with the presented system model better utility can be derived for the low power communication technologies that are well positioned for dealing with IoT traffic. Further work would involve comparing the presented system with end-to-end communication of IoT data relying on LTE/WiFi.

Abstract— At present, cyber security has become very significant dilemma. The worldwide security integration gives number of cyber security standards. These standards provide different digital security techniques which are developed to avoid cyber security attacks. These standards propose general outlines and accurate techniques for implementing cyber security. For Architectural integration the cyber security standards play vital role. In this paper, authors are trying to improve security by providing reliable architectural integration. Improvement in security for Advanced Metering Infrastructure (AMI) will make it more reliable and advanced. Smart grid can be defined in one sentence but AMI cannot be defined so. AMI integrates number of technologies to reach its goal. AMI is responsible for collecting all data and information from loads and consumers. Smart architectural integration is very essential for AMI. Infrastructure of AMI consists of basic steps like power generation, substation and distribution. Different attacker attacks on AMI infrastructure. By improving architecture we can make AMI more secure.

Keywords— Architectural integration, AMI, Security, Communication Standard.

I. INTRODUCTION

For Architectural integration cyber security standards play an important role. To protect the cyber infrastructure, National Cyber Security Division (NCSD) has acknowledged two important objectives: To construct and maintain a successful national cyberspace response system and to apply a cyber-risk management program for protection of critical infrastructure [1]. A security strategy should have three goals:

1. To avoid the hacker from getting access to critical data
2. To slow down the hacker enough to be caught
3. To frustrate the hacker enough to cause him or her to quit the hacking attempt

When designing a security policy, care is needed to be taken to identify precisely what you are trying to protect and while we think about the architecture for security above mentioned three security policies should be considered. Table 1 gives brief idea about standards for cyber security which is helpful for architectural integration [1]. These standards give policies for security purpose in architectural integration. Fig. 1 gives the overall idea about cyber security essential for architectural integration. This paper discusses the architectural changes occurring at both the centre and the substation control levels for security purpose [2]. AMI security has become a demanding problem now days because of its integration with the external networks, remote system, and Internet world. Today's metering infrastructure employs computer based monitoring and control operations to enable application of one network to exchange data with other application of different network. Communication protocol, network topologies, and computerization plays vital role to make the metering infrastructure advanced and it is supplementary to make a grid smarter.

Smart Grid has become a necessary requirement of the utilities and its patrons for the reason that digitization of the grid system provides important benefits like wealthy information at minor cost, greener power, greater than before efficiency etc. Metering infrastructure plays significant role in the smart grid and acts as an vital interface between utilities and its consumers. A metering network comprises a large number of different types of energy meters like advanced meters and legacy meters. To achieve the vision of smart grid, similar metering network can be integrated for exchanging the usage data and taking necessary control actions [4]. Cyber-attacks are always linked with the computer networks and communication protocols. It can easily affect the communication of AMI applications [4].Thereby it can degrade the performance. Hence by providing smart architectural integration, cyber-attacks can be removed. This paper further describes different architecture integration techniques, various communication standards for security, parameters for controlled architecture and different algorithms and methodologies.

Fig. 1 illustrates the conceptual structure of cyber security for architectural integration. CIA is nothing but confidentiality, integrity and availability and the main aim of this paper is to provide cyber security by considering improved architectural integration. At present, the transportation of the power system is becoming larger and more complex. At the same time, as the computer networks constitute a core component in the infrastructure, these information and communication components may bring more failures of operations and controls to the power system. By

TABLE1: CYBER SECURITY STANDARDS AND POLICIES PROVIDED BY THE STANDARDS

Cyber Security Standards	Policies/Services provided by the standards
ISO/IEC 27001:2013 International Organization for Standardization (ISO) and the International Electro-technical Commission (IEC).)	It specifies a management system that is intended to bring information security under explicit management control.
Standard of Good Practice	The Information security Forum (ISF) published a comprehensive list of best practices for information security.
North American Reliability Corporation (NERC)	These standards are used to secure bulk electric systems although NERC has created standards within other areas.
National Institute of Standard and Technology (NIST)	It provides computer security policy.
ISO 15408	It allows many different software applications to be integrated and tested in a secure way.
Request for Comments (RFC)	The RFC 2196 provides a general and broad overview of information security including network security.
ISA/IEC-62443 (formerly ISA-99)	It defines procedures for implementing electronically secure Industrial Automation and Control System.
Information Assurance at Small-to-Medium Enterprises (IASME)	It provides criteria and certification for small-to-medium business cyber security readiness.

initiation of malicious cyber-attacks, cascading failures may be triggered from the control system in the substation, thus components in the power system can be de-energized and operation can be irritated. Cyber attacks may hamper the tripping of a breaker or even shut down the generator. The security of the power system is dependent on its ability to resist the cyber attacks targeting the generator and transmission lines [8]. Also cyber security depends upon the architectural integration. Therefore in this paper, authors are trying to provide more reliable and secure AMI by providing different architectural integration.

II. STATE OF THE ART

The architectural solution of the Attack Modelling and Security Evaluation Component is discussed in details here. There is a variety of literature, which considers different approaches for attack modelling and security evaluation taking into account various classes of attacks. We briefly analyse current state-of-the-art with respect to flow of process considered, technology considered for integration, communication standards, parameters for control architecture and different methodologies or algorithms which are shown in Table 2 [5]. Routers, Firewalls and DMZ (demilitarized zone) Hosts provide security to the entire network by configuring policies. Router is a very essential device in networking. The Architectural integration should try to provide security to the router. Areas of router security as shown in fig. 2.

Firewall provides secure connectivity between networks. It is used to implement and insist on a security policy for communication between networks. Fig. 3 depicts various types of firewalls.

Different firewalls help to provide security. Table 2 gives state of the art for cyber security for AMI with architectural integration.

There is lot of literature which has considered different architectural integration for security purpose in power grid. Table 2 gives overall idea about architectural integration, some researchers have considered substation process, and some of them have considered generation and distribution. Still entire smart grid or AMI infrastructure consideration for security purpose is missing**.** Power Generation, Distribution and Harvesting where smart systems convert energy from different sources to electricity, store and distribute it to the users. Energy harvesting usually refers to the process by which energy is derived from external sources, captured and stored for small, autonomous devices at a low scale. Sensor-based systems for control of wind turbines and portable, multipurpose energy harvesting bracelets are just some examples of this increasingly studied field in the today's efforts aimed at lowering the carbon footprint [9].

III. FUTURE SCOPE

From the literature survey it is clear that, at present, there is a big issue of cyber security. In this paper authors are trying to improve security in different processes of smart grid basically for AMI. There are different processes in smart grid like generation, transmission, substation or distribution substation. By considering following benefits researchers should try to improve security:

1. More efficient transmission of electricity.
2. Quicker restoration of electricity after power disturbances.
3. Reduced operations and management costs for utilities.
4. Reduced peak demand, which will also help lower electricity rates.

Fig. 4 gives features of AMI; these features should be taken into account by researchers. The number of researcher have worked on architectural integration for AMI but still no any full proof security in terms of confidentiality, integrity, availability, accountability has come up. Therefore in future the researchers have lot of scope in this field to do research in terms of security.

The researchers should consider risk analysis (identify threats, assess threat's impact and likelihood), risk treatment (compute threat prevention, detection and mitigation actions) and risk monitoring (evaluate risk evolution over time) [10]. For security purpose one of the researchers has considered the principle of false data injection and proposed two distributed detect algorithms. One is DOID (Distributed Observable Island Detection algorithm), which is based on observable islands theory. If a line connected by two nodes is passed through different observable islands, false data injection is detected in this line. The other algorithm is DTAD (Distributed Time Approaching Detection algorithm). For one measuring point, if the state estimation values vary a lot, then attack is detected [11].

Some papers discuss challenges in assuring the trustworthiness (performance, dependability, and security) of the rising smart grid, using example of research started at the DOE and HHS-funded Trustworthy Cyber Infrastructure for the Power Grid (TCIPG) Centre. The objective of TCIPG is to provide trustworthiness in the nation's electric grid cyber infrastructure such that it continues to transport electricity and maintain significant operations even in the presence of cyber attacks. Achieving this objective will involve the extension, integration, design, and development of IT technologies swallowed with key properties of real-time availability and security. This research area provides many opportunities for dependability analysts and engineers to apply and extend their work [12]. Fig. 5 shows breakdown of smart grid benefits.

From the Fig. 5 it is clear that, increased security portion is very small and due to this reason, cyber security becomes essential issue nowadays. Therefore researchers can do lot of work in this field by considering different architectural integration. Some researchers have worked on the dependability issue of control centre networks in Smart Grid. There have been several works in the fields of smart grid security and dependability analysis [13]. Cyber- physical

energy systems is a hot research topic, and this is not likely to change in the near future. Still, there are white spots in this domain, especially in scalability, analytic description, and numeric handling of the used models. This collection of research papers shall serve as a help for researchers on their way in mastering these important but complicated systems [14].

Compliance, Risk Assessment and Security Testing Improvement Profiling CRSTIP as a dissemination tool for RASEN technologies, as it allows identifying maturity levels with respect to key security and compliance areas. Ideally, a concise description for each of the key areas should be available that denote the techniques and tools that can be used to drive the improvement as well as the requirements to other key areas that are the precondition to improve from one level to the next. As future work, our desire is to provide a web-based implementation where users are able to fill in their assessment and obtain information regarding the requirements for moving to the next level in their areas of interest [15].

To achieve cyber situation awareness, the role of human cyber analysts should be considered explicitly important into the design of security tools, algorithm, and techniques, such as attack graph [16]. Therefore, based on existing theories of situation awareness, a cyber situation Awareness (SA) model and an embedded SKRM (Situation Knowledge Reference Model) model are constructed to enhance the coupling of current techniques for situation awareness to enable security analyst's effective analysis of complex cyber-security problems. Current and future work is to demonstrate the potential capabilities of SKRM model for enabling cyber situation awareness.

***Abstract*—Adaptive and intelligent concepts are being employed in the networks to handle increasing dynamic traffic. Incorporation of Cognitive functionality in network nodes is one of the emerging techniques. This paper proposes a cognitive framework for next generation networks to enable flexibility in order to handle the traffic in dynamic manner. The framework is applied to the drop-tail queuing algorithm strategy which is the simplest queuing mechanism for efficient link utilization and congestion avoidance. Additional improvements that transform the networks to be flexible and scalable are presented. The results of the proposed method are compared with drop-tail algorithm in the context of packet loss, queuing time, and queue length. The results promise optimized and flexible operation by reducing up to 60% packet loss and queuing time while solving the problem of buffer-bloat. In addition, the possibilities of extending the proposed framework with target parameters such as energy efficiency, stability, and cost efficiency are discussed.**

***Index Terms*—Cognitive algorithms, queuing strategies, data analytics, next generation networks**

I. INTRODUCTION

THE growth in number of mobile devices is at a rapid pace in the recent years. This growth is assisted by a number of innovative applications that are incorporated in mobile devices. Together with the increase in number of devices and usage scenarios, the mobile internet traffic is ever growing [1]. In the context of increase and variety in mobile traffic, the demands from heterogeneous applications are increasingly stringent. For instance, the rise in services like online gaming and video streaming demands low packet loss. Consequently, providing better quality of service (QoS) to users with effective congestion avoidance mechanisms has been the primary objective for the operators.

Together with the provisioning of QoS and Quality of Experience (QoE) to users, customer differentiation is another important objective for the operators. New business models are evolving on the basis of customer and service differentiation to generate additional revenue for the operators [3]. It is wiser in the operator's point of view to investigate intelligent approaches to gauge traffic dynamics. Time is one of the important parameter to gauge user expectation on a particular service delivery. As all the subscribers are not very active all the time, it is observable to see the separation in peak traffic for different services at different time instances.

Cognitive functionality is one of the emerging approaches in making the radio networks flexible and self-reliant [4]. In the process of developing futuristic network architectures, the concept of cognitive framework was presented in this paper. It is applied to the context of queuing strategies which are designed to handle the congestion in network elements. Congestion is a major problem in next generation networks and is a result of converging services like data, voice, multimedia, etc. [2]. A number of algorithms like Drop-tail, Random Early Detection (RED), RED with In and Out (RIO) were proposed in the past to avoid congestion but very few of them like Drop-tail and weighted RED (WRED) are successful to make their way into the network elements because of their simple yet effective approaches [2], [10]-[12].

The application of proposed framework differentiates itself from all of the existing queuing strategies by reconfiguring the queuing parameters dynamically depending on the operator requirements. In the existing approaches, the queuing parameters are fixed during the initial configuration of the device. Some adaptive algorithms calculate the queuing parameters based on the incoming traffic which incurs additional computational complexity. By using the cognitive cycle, the proposed framework simplifies the process of parameter estimation and further reducing the computational complexity within the network elements.

The paper is distributed as follows: Section II summarizes the background of cognitive framework and related work in the area of queuing algorithms. The framework have been proposed and described in Section III and flexible queuing concept based on proposed framework is presented in Section IV. Simulation and evaluation results are discussed in Section V. Extension of the model is described in Section VI and conclusion is presented in Section VII.

II. BACKGROUND

Cognitive functionality has been addressed in research works for the primary objective of increase in usage efficiency with prior knowledge on the surroundings. The cognitive cycle can be divided in three parts: cognitive learning, decision making, and enforcing action. The cognitive learning phase involves the process of acquiring knowledge by sensing or other methods. The decision making phase includes analysis of the knowledge acquired to draw the decisions. In the last phase, the decisions are implemented in the system with the

corresponding methods. The phases mentioned above are basic building blocks of cognitive cycle since its inception [4].

The utilization of scarce resources like frequency spectrum is in the forefront in employing cognitive functionality. It has been applied to many areas in the communication link namely spectrum sharing, power control, relaying etc [4]. In this paper, cognitive functionality is applied to active queue management (AQM) algorithms. The motives behind queue management algorithms are to reduce the packet loss, queuing time, and improve link utilization. There was a lot of research and proposals in the field of AQM algorithms which is briefed in the following. The algorithms have been divided under two categories:

- *Adaptive parameter tuning:* Many of the first generation AQM schemes were static with fixed thresholds to control the queuing operations. The traditional drop-tail algorithm has evolved by employing fuzzy and adaptive techniques in defining the buffer lengths [2]. Another method, RED is the basis for many of its variants like adaptive random early detection (ARED), weighted random early detection (WRED) and so on. RED is based on dropping the packets before the buffer is full. The packet drop probability is calculated adaptively based on factors like queue length, flow differentiation etc. Algorithms like drop-tail are very simple in operation by dropping all the incoming packets when the buffer space is full [13], [14].

  The above mentioned algorithms are designed to optimize some of the performance parameters. At the same time, the complexity of implementation increases with the optimization of performance parameters. The higher complexity limits the real time implementation as it involves higher computation power and thereby power consumption.

- *Adaptive sizing algorithms:* Some algorithms are focused on changing the buffer size in an adaptive way [5], [9]. They are developed mainly to find the minimum buffer size for parameter optimization. The constraints for the optimization are calculated based on real time measurements. The computational complexity is different for several buffer sizing algorithms but have superior complexity when compared to simple algorithms like drop-tail. They also have the complexity of changing the physical memory segments.

III. PROPOSED FRAMEWORK

As mentioned earlier, the non-uniform dynamic nature of the peak traffic has been the motivation in developing the proposed framework. The proposed cognitive framework can be divided in three parts: cognitive analytics, cognitive engine, and reconfiguration. They can be attributed to the phases of the cognitive cycle: cognitive learning, decision making, and enforcing action respectively.

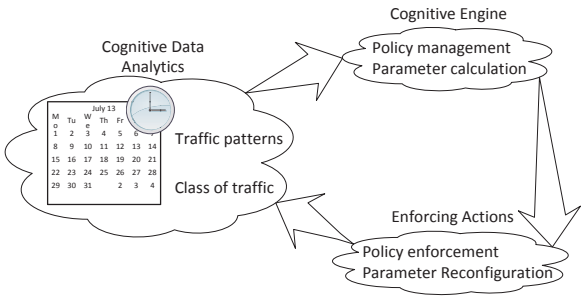

Figure 1. Phases in the proposed cognitive framework

a. *Cognitive data analytics*

In the context of the proposed framework, cognitive analytics is a database which contains the information about user traffic with reference to time axis. The traffic information may include the number of sources based on their priority, type of the traffic, service delivery information, and so on. Cognitive data analytics can provide the data about the time intervals of traffic load for a particular class type. It can be updated at a changeable rate that can be controlled remotely.

b. *Cognitive Engine*

The cognitive engine is a decision making entity which does the calculation of parameters based on the data from cognitive analytics. It analyses the data obtained from the database of cognitive analytics and compute the parameters for the particular node. The computations by cognitive engine are against the required performance parameters that are set by the operator. The cognitive engine is capable of working autonomously in addition to having operator controllability. After computing the required calculations, the cognitive engine sends the data to the corresponding network node.

The location of the cognitive engine is of operator's interest. It can be operated from a centralized hardware or from the cloud. It is also possible to integrate the cognitive engine in individual nodes. In integrated scenario, the cognitive analytics database has to be accessible from the cloud. The number of nodes under single cognitive engine is scalable depending on the computational and connection capabilities of it.

c. *Enforcement of Actions*

The individual network nodes implement the actions defined by the cognitive engine. This kind of enforcement involves, changing the parameters, configuring the buffers, allowing the modules in sleep mode etc. To perform the required actions, the nodes should have the capability of self-configuration. Each of the individual nodes which are implementing the actions may feedback to the cognitive engine and/or cognitive analytics database.

IV. FLEXIBLE QUEUING

In the context of the communication network infrastructure, the cognitive framework is applied to AQM algorithms. A new method of simple queuing strategy, flexible queuing is presented in this section. The flexible queuing strategy works on the principle of cognitive cycle, which was described

earlier. The phases in the framework are mapped to the process of queue management.

a. *Cognitive Learning*

As described in the cognitive data analytics phase of the framework, the learning phase collects the information about the rate of traffic flow with respective to time scale. As mentioned earlier, in real time, not all sources are active at the same time. So, to exploit that separation in the rate of traffic, the traffic is classified in time scale. The cognitive analytics database which was used to validate the framework is shown in the following table.

TABLE I
TRAFFIC LOAD IN DIFFERENT TIME SLOTS

	0-30s (t1)	30-60s (t2)	60-90s (t3)
host1	ON	ON	ON
host2	ON	ON	ON
host3	OFF	OFF	ON
host4	OFF	OFF	ON

The traffic from 4 different sources which have equal priority has been categorized in different time slots, as shown in Table 1. The priority can be different depending on the QoS metrics. For example, real time traffic with latency and packet drop rate constraints may benefit in the presence of non-real time traffic. The case of equal priority has been considered to highlight the benefits of flexible queuing. The time scale in this context is taken as *90s,* which is the simulation time. *Host1* and *host2* are scheduled to send the data in all of the 3 mentioned time slots (*t1, t2,* and *t3*) whereas *host3* and *host4* are scheduled to start sending the data only in the third time slot (*t3*). The duration of the time slots varies as per the need and requirements of the operators. The frequency of cognitive analytics database update is configurable by the cognitive engine. In this context, it updates at the beginning of the simulation as the traffic information is known beforehand. It is also possible to have reservations from the users for particular time slots. The advanced level of differentiation like type of traffic, information on service and customer differentiation can be developed within the cognitive analytics database.

b. *Decision Making*

Being the decision making entity, the cognitive engine implements the algorithms and in this context a flexible queuing method. The corresponding flow chart is presented in Figure 2.

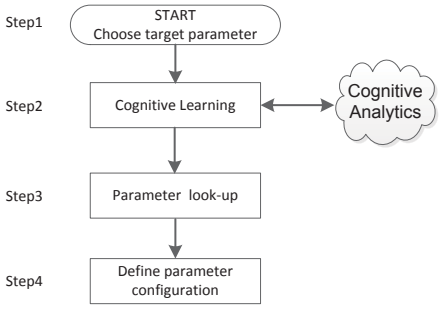

Figure 2. Flowchart of cognitive engine

The target performance parameters for this study are queuing time and packet loss. The queuing time in this context is the time for a packet to pass through the queue in a particular network element. The queuing time is one of the significant contributors to the round trip time. The delays in the network should be minimal to support the interactive multimedia content and other such data services from next generation user devices. The network node drops a packet based on some predefined conditions depending on a particular queuing strategy. In the current context, the packet will be dropped when the available queue length is null. Optimization of packet loss is important to avoid TCP global synchronization problems [6]. Majority of the internet traffic is of transmission control protocol (TCP) type and better handling of such traffic saves the network from serious issues like global synchronization, high packet losses, and high queuing delays [4].

To establish the operation of proposed framework, queuing time is optimized in *t1* and *t2* whereas packet loss is optimized in *t3*. So, the framework optimizes queue length parameter by decreasing or increasing it to improve queuing time or packet loss respectively. With the mentioned parameters, the method operates as follows when a packet arrives.

Step1: queuing time during low traffic from *host1* and *host2*; packet drop for high traffic from *host3* and *host4.*

Step2: cognitive engine acquires the information about data traffic from cognitive analytics. From Table I, it is expected that low traffic from *host1* and *host2* is up to *t2* and host3 and host4 starts sending traffic in *t3* resulting high traffic.

Step3: the cognitive engine read the current queue length parameter (q_{len}) of the node, threshold queue length (q_{thr}) and maximum queue length (q_{max}) which are defined during initial configuration.

Step4: if the threshold queue length (q_{thr}) is smaller than q_{len}, the queue size should be q_{thr} for the duration until *t3*. Otherwise, the q_{len} is maintained as queue size for the same duration. The queue size should be configured as q_{max} from *t3* to reduce the packet loss.

c. *Reconfiguration of parameters*

The new parameters defined by cognitive engine are reconfigured in the nodes either by the nodes or the cognitive engine. In this context of the simulation scenario, the cognitive engine reconfigures the necessary parameters in the nodes. In real time, the nodes should have the capability of self-configuration to enforce the actions themselvesfigures.

V. SIMULATION AND RESULTS

The simulation setup is in OMNET++ environment [7] with 4 hosts and 4 destinations connected through a bottleneck link is shown in Figure 3 and parameters are provided in the following table:

Table II			
Simulation Parameters			
q_{max}	20	*a*	100 Mbps
q_{thr}	10	*b*	1 Mbps
Simtime_tot	90s	*mss*	1000B

The setup generates TCP traffic from the hosts. The hosts employ TCP Reno algorithm in generation of the traffic with no sack support and no delayed ACK support. The simulation time is set as *90s* and the hosts send the traffic as mentioned in Table 1, where the *green* indicates ON state and *red* indicates OFF state. Each of *host1* and *host2* is scheduled to send *1000MB* of data whereas *host3* and *host4* are scheduled to send *500MB* with the maximum segment size as 1000B.

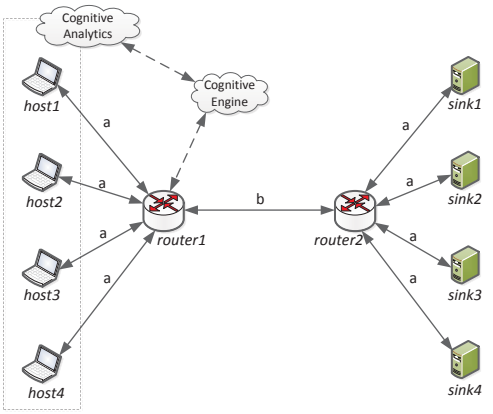

Figure 3. Simulation setup

The hosts send the traffic to corresponding sink nodes like *host1↔sink1, host2↔sink2* and so on. The end nodes are connected by a bottleneck link between *router1* and *router2* as shown in Figure 3. The data rate of *a* links is of 100 Mbps and 1 Mbps for *b* link with 10ms delay.

Drop-tail algorithm is used to collect the results for the cognitive framework setup. Drop-tail is widely considered as simple algorithm with lowest complexity but suffers from high packet drops. By applying cognitive framework in that context, the packet drops can be controlled by selecting appropriate queue size in different time instants.

The cognitive engine configures the *router1* with appropriate queue length based on the simulation time. When $0 \leq simtime_t < 60$, the parameter *pktdroprate* = FALSE and *queuetime* = TRUE. When $simtime_t \geq 60$, the parameter *pktdroprate* = TRUE and *queuetime* = FALSE. The queue parameters are $q_{max} = 20$, $q_{thr} = 10$, and $q_{len} = 20$. To establish the philosophy of flexible queuing, static thresholds are considered for queue lengths. It is up to the Operator to design the strategy with dynamic thresholds which is our future direction of research.

The results for queue length, queuing time, packet drops are compared with the cases of with and without cognition. The plots are downscaled by using exponential moving average with the scaling factor $\alpha = 0.01$ for queuing time comparison, $\alpha = 0.005$ for queue length comparison. By applying the exponential moving average, more weights are given to the recent samples. The moving average is applied to improve the visibility compared to raw plots generated within OMNET++ simulator.

a. Queue Length

The plot in Figure 4 shows the averaged queue length in number of packets corresponding to the simulation time for the drop-tail algorithm with two cases (for the queue size of 10 and 20) and flexible queuing method. In the flexible queuing method, the queue length is configured by the cognitive engine based on the simulation time.

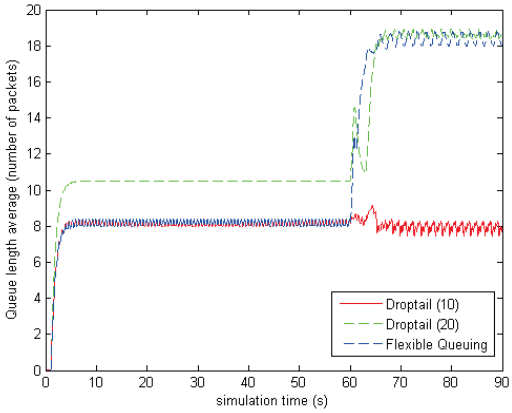

Figure 4. Comparison of queue length variation

In this simulation, the cognitive engine configures the queue size to q_{thr} until *60s* and q_{max} after 60sec to accommodate the traffic from additional hosts. By reducing the q_{len} until *t3 (60s),* it is possible to save some buffer space which can be used for other additional purposes like to store special-type packets and speed-up the system.

b. Packet loss

The packet loss for different methods is presented with a bar chart in Figure 6. As it is mentioned the shorter queue method suffers with high packet loss. With the current schedule of the data transmission, by doubling the queue size, almost 75% of the packet drops can be avoided. By employing flexible queuing, the overall packet loss can be lowered to 40% and at the same time saving the buffer space that can be used for other purposes within the system. So, the proposed method is suitable for avoiding packet loss to reduce retransmissions and TCP synchronization issues with optimal buffer adjustment mechanism.

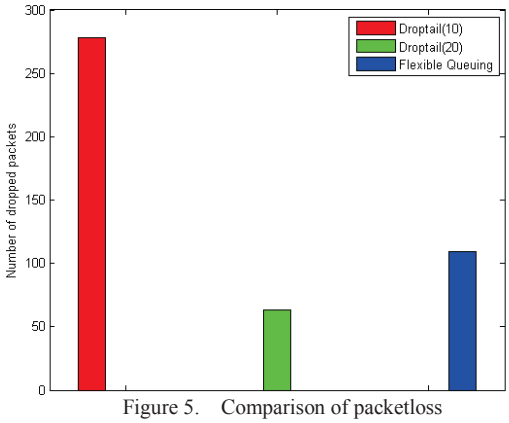

Figure 5. Comparison of packetloss

c. Queuing time

The queuing time is proportional to the queue length. By reducing the buffer length until t3, the queuing time is

optimized. As the *queuetime* parameter is set to *1*, the queue length is set to q_{thr} which reduces the queuing time. It is clear that by employing the flexible queuing method, the *queuetime* is optimized for the required duration as shown in Figure 7. The queuing time for the smaller buffer method is on the lower side of the remaining two methods throughout the simulation time but it suffers higher packet drops.

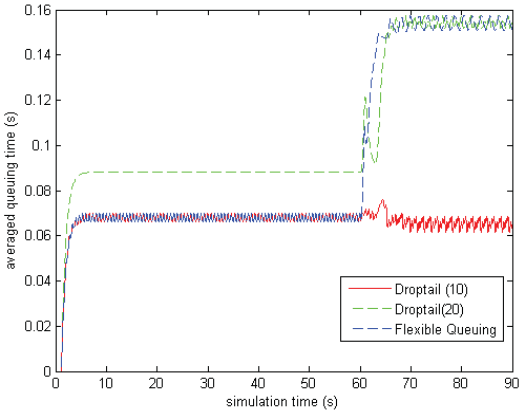

Figure 6. Comparison of queuing time variation

VI. EXTENSION AND FUTURE SCOPE

The cognitive framework is applicable to overall network infrastructure to achieve many objectives like energy efficiency, network stability, cost efficiency and much more. The framework can be extended to improve the energy efficiency of the network element by setting up several components into sleep mode. In that context, the cognitive engine takes up the additional responsibility of controlling sleep periods according to the data traffic. By the same token, network stability and other target parameters can be optimized. In addition to applicability, the location of cognitive engine is an area of research.

Our future work includes investigation of efficient utilization of buffer space in the context of dynamic queue length adjustment. It is much more important when the traffic involves multiple classes of service. The framework is extendable for longer duration of time with advanced functionalities like multiple class of service (CoS), service differentiation, and so on.

VII. CONCLUSION

The cognitive framework is expected to play an important role in automating the networks in the way of realizing flexible, scalable and intelligent networks. The cognitive framework has a number of advantages in terms of costs, operability, service differentiation, and so on. The framework is applied to queuing algorithms for validation. It proves to be a simple framework to deploy with many benefits. The advantages include reduction in packet loss rate, queuing time, throughput, and at the same time promising flexibility to optimize a particular parameter in a particular time. From the observation of the results, the proposed strategy, with intelligent design, benefits real time traffic to a great extent which has constraints on delay and other issues.

The proposed framework plays an important role in the process of instilling self-organization capability in the nodes. To implement the facilities like customer differentiation and service differentiation, traffic engineering on the basis of time scale is the enabling factor. So, the availability of time based traffic dynamics is the key issue for the success of the framework.

ACKNOWLEDGMENT

The authors would like to acknowledge fruitful discussions with Ceragon Networks, Bergen, Norway in defining the system model.

***Abstract*—BiCMOS bandgap reference which having advantage over MOS based BGR in terms of its accuracy at its reference output and very less temperature coefficient. This paper presents bandgap reference circuit with folded cascode operational amplifier(opamp) in order to improve the final Vref output of bandgap reference. The temperature stability of output can be improved by using an extra trimming circuit in voltage mode architecture of bandgap reference still operating with less power consumption. Using only first order temperature compensation technique the proposed circuit gives output voltage of 1.181V with 0 °C to 100 °C temperature variation which corresponds to temperature coefficient of 19ppm/ °C.A single stage folded cascode opamp which is included in the proposed bandgap which improves power supply rejection ratio of BGR and input common mode range, output swing and stability at opamp and BGR output. The simulation results shows that power supply rejection ratio of proposed BGR is -43db from dc to 30KHz frequency, gain of folded opamp is 78db,Phase margin is 70, input offset of opamp is 1.96μV and closed loop gain of opamp in BGR is 118db.The proposed bandgap reference is simulated using MentorGraphics pyxis tool, EldoSpice simulator in 130nm CMOS technology. The proposed BGR output will be used in low dropout regulator circuit which is operating at 3.3 supply and gives regulated output of 1.8V.**

I. Introduction

A stable high performance bandgap reference circuit plays vital role in the high performance circuits like ADC, DAC, LDO, Charge pump circuit. A voltage reference must be highly precise and stable with respect to temperature, supply, process and load variations. High power supply noise rejection ratio (PSRR) of LDOs which merits the noise immunity, since high PSRR of LDOs mostly depends on PSRR of voltage reference [1]. This paper presents design of BiCMOS based voltage reference with good PSRR and low temperature coefficient(TC) which is most important in terms of accuracy of system [3]. A Brokaw CMOS bandgap reference presented by Yongsheng Yin [6], using current mode architecture which gives Vref of 0.5V and better PSRR but drawback of circuit is Vref output is very sensitive with respect to temperature because of sensitivity of resistor at the output and power dissipation in terms of mill volts. This paper presents CMOS bandgap reference with voltage mode architecture with trimming circuit in order to get low temperature coefficient with better PSRR and also start up problem in the conventional bandgap reference (BGR) is avoided using simple startup for proper operation of circuit. The proposed BGR uses PNP bipolar transistor instead of NPN transistor. Since NPN bipolar transistor contributes high current gain, high matching precision, and its difficult to implement the NPN transistor on CMOS process [6]. The proposed circuit produces the reference voltage of 1.181V, to meet the requirements of design under less voltage. By using voltage mode architecture and bipolar transistors, the proposed circuit produces very less TC of Vref with only first order temperature compensation and greatly reduces the circuit complexity as compared to the papers [4] [5]. Compared to conventional BGR which uses two stage operational amplifier(opamp) [8], the proposed circuit uses single stage folded cascode opamp in order to get highly stable output at the output of BGR with low TC since opamp input offset is very low(in terms of 1.96μV) , single stage can give very high gain and PSRR of BGR.

The section II describes conventional BGR principal, section III discusses about proposed BGR principal, section IV includes Simulation results, section V gives conclusion and references.

II. Conventional BGR Principal

The basic principal is V_{BE} (Base to emitter) voltage of bipolar transistor which generates complementary to absolute temperature (CTAT) voltage with negative temperature coefficient and difference between V_{BE} of two bipolar transistor (Thermal voltage V_T) which carrying unequal current densities which exhibits proportional to absolute temperature voltage with positive temperature coefficient (PTAT). The final Vref output is addition both PTAT and CTAT voltage with near zero temperature coefficient is generated [7]. The typical output of BGR is 1.181V, which is close to bandgap voltage of silicon at room temperature.

A. Negative TC Voltage generation

Generally the forward voltage of pn junction diode exhibits negative temperature coefficient (TC), and also the base to emitter voltage of bipolar transistor exhibits the similar characteristics. For bipolar device we can write as

$$I_C = I_S e^{\frac{V_{EB}}{V_T}} \tag{1}$$

Where

$$V_{EB} = V_T ln \frac{I_C}{I_S} \tag{2}$$

where, VT=Thermal voltage =kT/q and Is=The saturation current

$$I_S = bT^{4+m}e^{\frac{E_g}{kT}} \tag{3}$$

b= proportionality factor and m= material constant proportional to electron mobility. Therefore negative TC is given by

$$\frac{\partial V_{EB}}{\partial T} = \frac{V_{EB} - (4+m)V_T - \frac{E_g}{q}}{T} \tag{4}$$

Assuming Ic is constant

$$\frac{\partial V_{EB}}{\partial T} = \frac{V_{EB} - (3+m)V_T - \frac{E_g}{q}}{T} \tag{5}$$

Assuming Ic to be a function of temperature

B. Positive TC voltage generation

If two bipolar transistors operate in unequal current densities then difference between their base to emitter voltage directly proportional to their absolute temperature [7]. While positive TC is given by

$$\Delta V_{EB} = V_{EB1} - V_{EB2} = V_T ln(n) \tag{6}$$

$$\frac{\partial \Delta V_{EB}}{\partial T} = \frac{V_T ln(n)}{T} \tag{7}$$

Now the BGR reference voltage is described as,

$$V_{ref} = V_{EB} + IR_2 = V_{EB} + R_2(\frac{\Delta V_{EB}}{R_1}) \tag{8}$$

The second term in the above equation IR2 has positive temperature coefficient of +0.086mV/$^\circ$C, and first term V_{EB} has negative temperature coefficient of -2mV/$^\circ$C at room temperature. R2/R1 ratio is adjusted such that near zero temperature coefficient of Vref is achieved theoretically [7]. The temperature coefficient of final Vref output is given by

$$\frac{\partial V_{ref}}{\partial T} = \frac{V_{EB} - (3+m)V_T - \frac{E_g}{q}}{T} + \frac{R_2 V_T ln(n)}{R_1 T} \tag{9}$$

After putting

$$\frac{\partial V_{ref}}{\partial T} = 0 \tag{10}$$

in above equation the final BGR output is given by

$$V_{ref} = \frac{E_g}{q} + (3+m)V_T \tag{11}$$

Where Eg is bandgap of silicon at room temperature =1.12eV, V_T=25mV thermal voltage, m is constant factor= -1.5 for silicon. After putting all values Vref=1.25V at room temperature. The conventional BGR uses two stage operational amplifier (opamp) but output of BGR is having high temperature coefficient, which is not a good design [7]. The proposed BGR uses folded cascade opamp , which is highly stable because of single dominant pole which is located near to 3db BW of opamp will explain in next section.

III. PROPOSED BGR PRINCIPAL

The drawback conventional architecture is the opamp output is not stable [8] and hence BGR output, and also start up problem in the circuit. In current mode architecture output is very sensitive with respect to temperature and high power dissipation in the circuit which is in terms of mill volts [1] [6].The proposed voltage mode architecture consists of startup circuit, folded cascode opamp, and core BGR shown in figure 1.

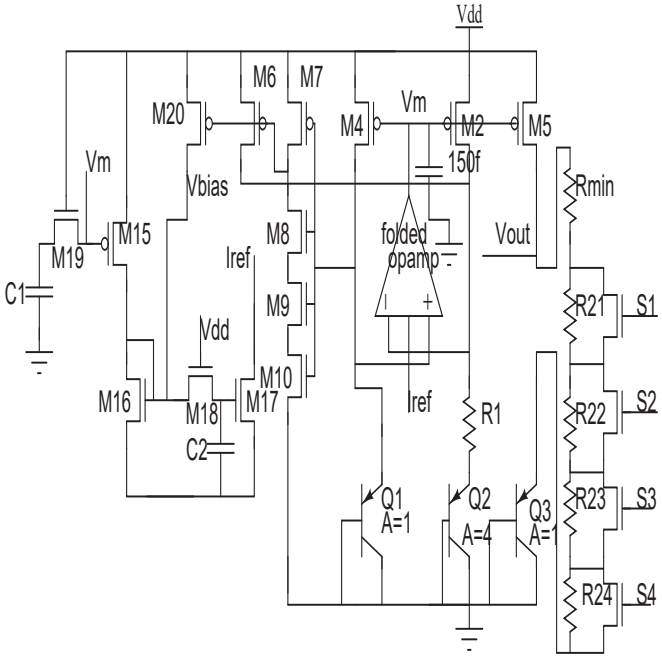

Fig. 1. Proposed voltage mode BGR architecture

For the operation of circuit there are two voltages V_{EB} and ΔV_{EB} are generated with negative and positive TC respectively. A diode connected PNP transistor Q3 at the output generates V_{EB} voltage which having negative TC(CTAT characteristics) and the pnp transistors Q1, Q2 which carries equal currents and having their areas in ratio of 1:4. Since both transistors Q1 and Q2 are unequal sizes which exhibits difference voltage(ΔV_{EB}) across resistor(Difference between node a and b). The voltage across resistor ΔV_{EB} exhibits PTAT characteristics. The R1 resistor decides current flowing in branch-3 and 4(Both carries equal current) and same current is mirrored in the output branch. The voltage across R2 is PTAT voltage and V_{EB} of Q3 exhibits CTAT voltage, the final output is addition of both voltages [7]. The value of R2 is selected such that the Vref output is having very less temperature coefficient.After trimming R2 is sum of R_{MIN}, R21,R22,R23 and R24 are as shown in figure.

A. Trimming circuit

The trimming circuit is added to reduce the temperature coefficient of Vref output at different supply and corners. A 4 bit series trimming circuit is used [10], with resistors

values are selected by calculating fine and coarse variations of resistors at different supply and process corners. The fine resistor value is selected for minute variations and coarse resistor value is selected for large variation of resistor at different supply variations and corners. R_{MIN0}, R_{MIN1} and R_{MIN2} are minimum resistors values obtained at SS, TT and FF corners in order to get required BGR output voltage.Coarse resistors are selected as

$$R_{coarse0} = R_{MIN1} - R_{MIN0} \tag{12}$$

and

$$R_{coarse1} = R_{MIN2} - R_{MIN1} \tag{13}$$

and fine resistors are selected to adjust the resistors at different process corners and supply for minute variations in order to get proper BGR output.From the figure R_{MIN0}=R_{MIN},$R_{coarse0}$=R21,$R_{coarse1}$=R22, R23 and R24 are fine resistors.These values are chosen by NMOS switches in accordingly by their turn on and turn off which is driven by digital circuit [10].

B. Startup circuit

The devices M6,M7 and M8 forms a startup circuit, M7, M8 forms inverter, which is part of startup circuit as shown in figure 1 [1]. Initially when there is no current in core circuit, the top two PMOS M2 and M4 are turned on, which makes input to inverter is one and output is zero. The zero input which turned on the PMOS M6 device, and initiates the current in core circuit. Once the core BGR turned on then startup will turned off and carrying very less current(In terms of pA). The devices M6 in sub threshold region, M7 in triode and M8 in saturation region always for the proper operation of startup [6].

C. I_{REF} generation circuit

The current reference of 1μA for folded cascode opamp is generated from BGR PMOS current mirror as shown in figure 2.The biasing for M15 device is selected from BGR PMOS current mirror by properly adjusting aspect ratio of M15 and same current is mirrored to nmos M16 and connected to I_{REF} of opamp. Now opamp will not work because startup circuit is not included, to aviod this problem an extra PMOS M20 is biased from startup circuit and connected to I_{REF} genaration circuit. So that once startup will initiates the current in Iref circuit, opamp will work properly. The extra RC circuit is included in reference generator to aviod an ac signal coming from opamp cascode structure.A ac signal is coming from opamp output because the circuit is not symmetry at its both cascode branches, so no ac signal cancellation at the output of opamp.There is a loop formed from output of opamp through bias circuit which degrades the phase margin due to additional poles. RC circuit is used to push these poles outside UGB.

D. Operational amplifier

The proposed circuit uses single stage folded cascode operational amplifier(opamp) with high gain and CMRR(Common mode rejection ratio) as shown in figure 2.

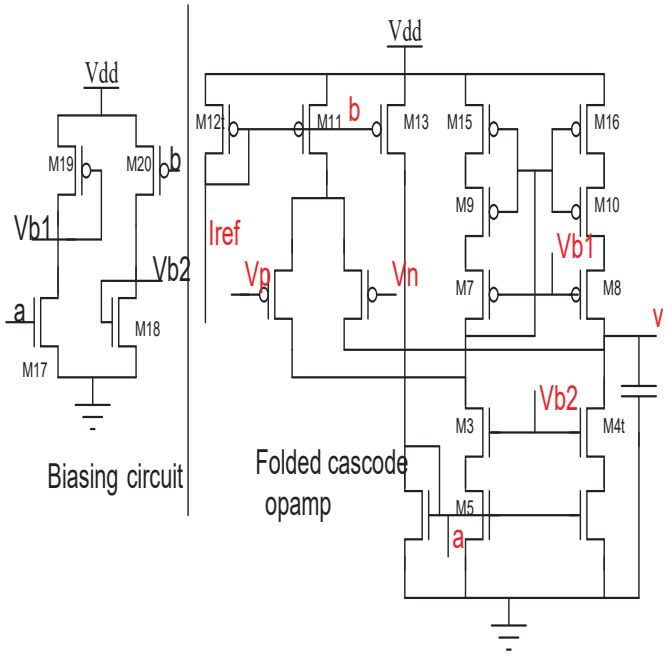

Fig. 2. Folded cascade opamp with biasing circuit

The sufficient high gain improves the PSRR of BGR [1]. The pmos input pair folded cascode opamp is chosen in order to meet the gain, stability[11]. The biasing voltages for opamp cascode stages are generated by using current mirrors as shown in left half of figure 2 [9]. The devices M1 and M2 are input pair of opamp, the inputs to opamp are driven by BGR a and c nodes as shown in figure 1. M11 is the top tail device which carrying 2μA current. Devices M3 to M10 are cascode loads to opamp which carrying 0.5μA current. M5 and M6 are bottom tail devices which carries currents from both input devices and cascode stage. Load capacitance of opamp is taken from adding all capacitance associated with M2 and M3 devices. The overall opamp which carries current of 7μA and operating all devices in saturation [11]. The gain of folded cascode opamp is given by

$$A_V = \frac{gm_2 gm_4 gm_8 R_1}{gds_8 gds_{10} gm_4 R_1 + gds_4 gm_8} \tag{14}$$

The first order gain bandwidth (UGB) is given by

$$\frac{gm_4 gm_8 c_L (gds_8 gds_{10} gm_4 R_1 + gds_4 gm_8)}{gm_2 (gds_8 gds_{10} {gm_4}^2 c_4 R1 + c_2 gds_4 {gm_8}^2 + c_4 gds_4 gm_4 gm_8)} \tag{15}$$

The location of first real pole or domiant pole is given by

$$P_1 = -\frac{gds_8 gds_{10} gm_4 R_1 + gds_4 gm_8}{gm_4 gm_8 c_L R_1} \tag{16}$$

The location of second real pole is given by

$$P_2 = -\frac{gm_4 gm_8}{gm_8 c_2 + gm_4 c_4} \tag{17}$$

The location of third real pole is given by

$$P_3 = -\frac{gm_8c_2 + gm_4c_4}{c_2c_4} \tag{18}$$

The location of high frequency zero is given by

$$Z_1 = -\frac{gm_8}{c_4} \tag{19}$$

IV. SIMULATION RESULTS

Simulations have been carried out using MentorGraphics Pyxis tool with EldoSpice simulator in 130nm CMOS technology with supply of 1.8V with 10 % variations. The operational amplifier used in the proposed BGR is single stage folded cascade opamp, has given gain of 77.6db and phase margin of 72 degree as shown in figure 3.Simulation results shows that after connecting an opamp into BGR, the input offset voltage of opamp is very less voltage around 1.96μV. Figure 4 shows startup behavior of BGR output. The time required for BGR to produce a stable output is 200ns(at typical,27 °C) [1]. The simulation is carried out by performing transient analysis when supply voltage is given as ramp signal varying between 0V to V_{DD} within 10ns, 100ns and corresponding output voltage, which gives the startup behavior of BGR when vdd is ramped up.

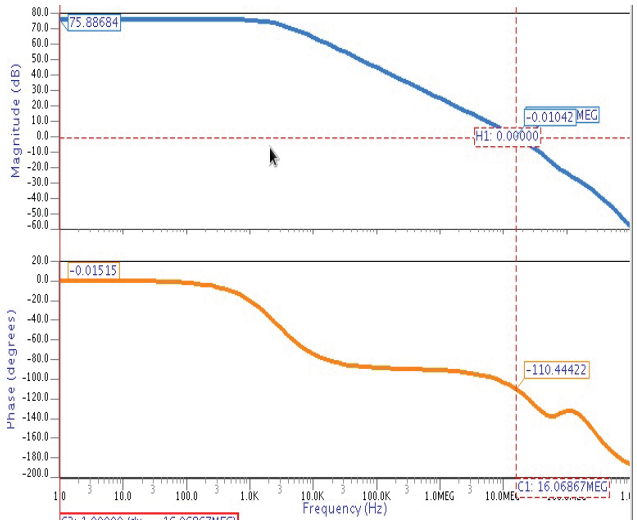

Fig. 3. Gain and Phase plot of folded opamp

The variations of Vref versus temperature at different process corners before trimming, which gives variations of Vref at process corners is 43mV. Figure 5 shows Vref Vs Temp curve at different process corners after trimming ciruit is used, which gives variations at TT, SS and FF are 1.8mV, 4.7mV and 4.5mV leads to TC of 30ppm/ °C, 39.8ppm/ °C and 38ppm/ °C respectively. The overal variation of Vref at different process corners(TT, SS, FF) with supply variations(1.62V ,1.8V, 1.98V) is 4.7mV and TC of 39.9ppm/ °C.

Therefore folded cascode opamp is self compensated and is highly stable without using any compensation techniques [8].

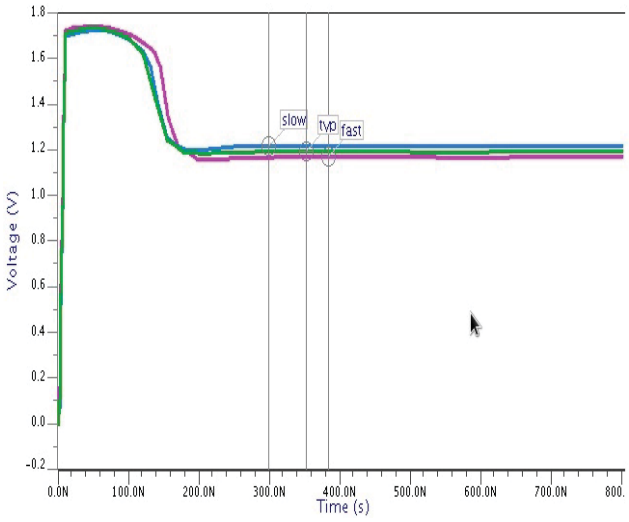

Fig. 4. Start-up behavior of the BGR output voltage with VDD ramp

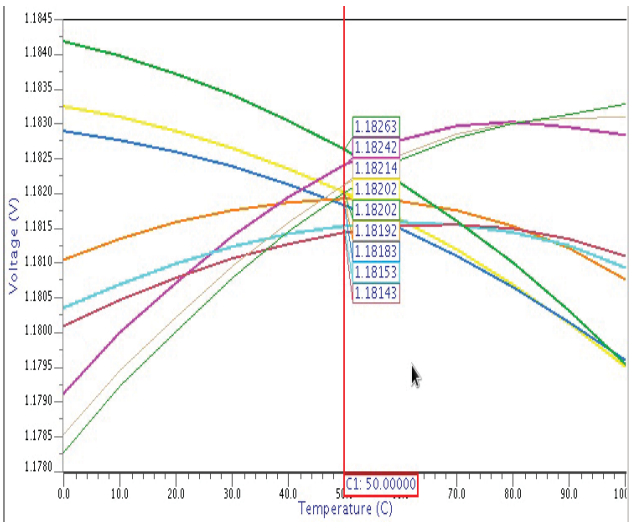

Fig. 5. BGR output after trimming

Table 1 shows the comparision table of Folded cascode opamp performance parameters between theoretical and simulated values. Theoretical values are optained by half circuit smal signall analysis of folded cascode opamp using Maxima tool.As given in equations 14 to 19 which includes approximated gain, UGB and all pole-zero equations.From the table 1 it shows that the percentage of error between theoretical and simulated values is very less and pole1 is domiant pole and it will decides the stability of opamp. The next poles(pole2 and pole3) and zero are located at very high frequency, i.e after UGB, Which all together leads to phase margin of 70 degree. The performance metric of different architectures of bandgap reference are shown in table3 [2] [4]. From the table it can be seen that the proposed circuit got a standard Vref output of 1.181V with bipolar structure which is good reference output as compared to other papers[5] [6]. The

TABLE I
COMPARISION OF PERFORMANCE PARAMETERS BETWEEN THEORETICAL AND SIMULATED VALUES OF OPAMP

Parameters	Theoretical	Simulated
Av(db)	74.8	77.6
UGB(MHz)	15.48	16
pole1(KHz)	−2.74	−2.47
pole2(MHz)	−57	−52
pole3(MHz)	−74.4	−80

variation of Vref curve across temperature is 1.18mV, which is good value as compared to paper [3] and [5].The PSRR of proposed architecture is good value [5] and which is enough for given application (Low dropout regulator).By using voltage mode architecture the proposed circuit achieved temperature coefficient of 19 ppm/°C [5].

The layout of proposed bandgap reference is as shown in figure 6. Which includes opamp, startup circuit, RC filter circuit, trimming and Iref generation circuit. The PNP transistors are used in the ratio of 1:4:1 and layout includes resistors as rnpolyhi and capacitor as mimcap 3x3. The overall area of layout is 80μmX40μm.

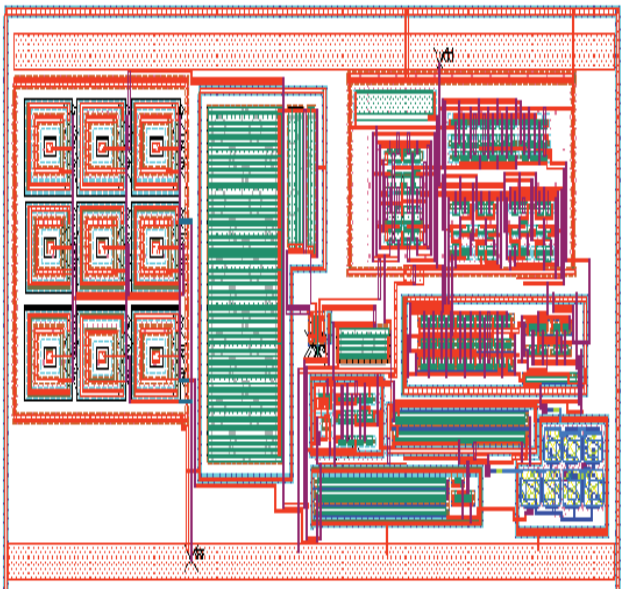

Fig. 6. Layout of BGR

V. CONCLUSION

A BiCMOS voltage mode bandgap reference is designed and simulated with good PSRR and low temperature coefficient. The proposed circuit is simulated with supply of 1.8V with 10% variations, which produced Vref output of standard 1.181V using bipolar version and TC of 19ppm/°C. A single stage folded cascode opamp generates gain of 78db, with very less input offset of 1.96μV because of closed loop gain of opamp in BGR is 118db. The PSRR of overall design is -43db up to frequency range of 30KHz, its good value for given application. The total current drawing from supply is 12.5μA and the overall power consumption in the circuit is 18.4μW. The proposed BGR is well suited for CMOS system on chip applications for its power flexibility, temperature and supply variations stability of reference voltage and its power supply rejection ratio.The proposed BGR output will be use in LDO circuit, which is operating at 3.3V supply and gives regulated output of 1.8V.

***Abstract*—Compressed Sensing or Compressive Sampling (CS) is the process of signal reconstruction using the samples obtained at a rate far below the Nyquist rate from sparse representation on suitable basis. Reconstruction by CS has gained wide spread application in many practical problems that demand satisfactory reconstruction of images from partial sensed data. In literature CS problem is mostly addressed as reconstruction problem done at the place of sensing. But in reality, many applications like Magnetic Resonance Imaging (MRI), Body Area Network (BAN) need data reconstruction at a place far away from the place of sensing. In this work, the effect of additive white Gaussian noise (AWGN) noise and fading channel is shown on the reconstruction process. To overcome the effect of noise and fading, the sensed samples are encoded by low density parity check code (LDPC) before transmission is done. It is observed that longer is the length of the LDPC codes better (lower) is the bit error rate (BER) performance. Here a method to construct larger length but 4 cycle free irregular LDPC codes from IEEE WiMAX standard is also proposed. Extensive simulation results show the efficacy of the use of LDPC codes and the trade-off in code rate and measurements on reconstruction quality.**

I. Introduction

Compressed Sensing (CS) revolves around the idea of reconstructing the original signal from very few measurements [1], [2]. It assumes that the original signal is sparse in some suitable representation space i.e. basis function. It picks up few of these sparse signals from that domain and then reconstructs the original image from these samples. Hence CS overcomes the problem of high speed sampling, reduces transmission delay and saves storage space at the cost of computation for finding a solution to an under-determined system of linear equations. Various methods of reconstruction have been used in CS, namely L_1 optimization [3], Basis Pursuit (BP) [4], algebraic reconstruction technique or stochastic approximation. A standard approach in solving under-determined or ill-conditioned linear systems of equations consists of minimizing an objective function which includes a quadratic (l_2) error term combined with a sparseness-inducing (l_1) regularization term. BP, the Least Absolute Shrinkage and Selection Operator (LASSO) [5], wavelet based de-convolution etc are a few well-known examples of this approach.

The methods stated above are known as parametric reconstruction techniques. Most often a closed form solution is difficult to achieve or they get stuck at local optima. The sparse signals can also be reconstructed by another approach- iterative non-parametric modelling. This method is implemented by the use of spatially denoising adaptive filter based on Robbins-Monro (RM) stochastic approximation algorithm [6]. RM is a family of iterative stochastic optimization algorithms that attempt to find zeros or extrema of functions that cannot be computed directly but can be solved through estimation via noisy observations. In RM-CS reconstruction problem [6], along with the observed space, random noise is inserted on the unobserved portion of the spectrum on each iteration [6]. Adaptive filter is then used to attenuate noise and reveal features i.e. to improve the visual quality of the image. In literature, majority of CS techniques assume that the reconstruction is done at the place of sensing itself. But in reality, reconstruction is often done at a place far away from where the sensing is done, for example, MRI, Computed Tomography (CT) scan, body area network (BAN) etc. All these applications need transmission of sensed data over radio mobile channel with low error rate and possibly in an energy efficient form.

In this work, image reconstruction on CS is done through transmission of measurement using Low Density Parity Check Codes (LDPC) over noisy and fading channel. Here, LDPC is chosen as the error control code as it is capacity achieving, ubiquitous codes i.e. can be applied in any scenario. Irregular LDPC code of length 10 million bit and rate (R) -1/2, has achieved capacity of 0.045 dB from the Shannon limit [7]. First a larger length but 4 cycle free irregular LDPC codes is proposed and is used on CS reconstruction transmission problem. Then a trade off between the number of measurements and code rate on reconstruction quality is studied.

Section II makes a literature review on CS and LDPC. Section III presents the system model the channel mode, the non- parametric CS reconstruction technique used and the proposed extended LDPC codes. Simulation results are shown in Section IV while conclusions are made in Section V.

II. Literature Survey

This work deals with the effect on CS reconstruction quality after transmission of sensed samples through a radio mobile channel using LDPC. So, the literature survey focuses mainly on the works which deal with CS and LDPC codes.

LDPC codes are block codes with parity-check matrices that contain only a very small number of non-zero entries. The parity check matrix is sparse and hence the name low density. LDPC codes are decoded iteratively and may be used for progressive reconstruction of image/video signal. The LDPC

code-words satisfy a set of linear parity-check constraints. One issue in construction of LDPC codes, is that 4 cycles within the parity check matrix or H matrix should be avoided. Presence of 4 - cycle delays the convergence of the decoding procedure. The other important issue is the length of the code. Larger the length of the LDPC code, closer it is to the Shannon limit in error bound.

Of late LDPC codes have been explored on CS. In [8], LDPC codes have been used on CS as a sensing matrix. The H matrix of the LDPC code has been used as the sensing matrix of CS and the sensed samples are reconstructed in situ (at distant place i.e. far away) by Orthogonal Matching Pursuit (OMP). In [9], a relationship between channel coding and CS is established. It shows that parity-check matrices of good channel codes can be used as *good* measurement matrices under BP. In [10], the system design of CS based source encoding system for data compression in wireless sensor applications is described. In [11], a unified CS - EC channel model is given for sparse and almost sparse channels. The decoding of LDPC codes based on CS reconstruction has been attempted in most of the work involving CS and LDPC. To the best of our knowledge this is the first work in which LDPC is considered for channel coding while transmitting CS samples through a radio mobile channel. Furthermore, the present work uses non-parametric method of reconstruction of signal [6] unlike the other existing LDPC-CS unification schemes that use various parametric approaches. The LDPC codes, by providing redundancies, improve the bit error rate (BER) performance. Due to the improved (lower) BER value achieved by adding redundancies, data can be transmitted even at lower SNR. So, energy saving can be achieved. Energy is an important natural resource. In the multi-hop wireless path with battery driven sensors and relays are to be used for image acquisition and end-to-end transmission.

III. System Model

A. RM-CS via recursive spatially adaptive filtering

Energy saving in processing part can be achieved using algorithms that have low computational complexity and hence are less power hungry. Transmission power can be saved by reducing the number of samples to be transmitted i.e. by compressing the signal. This alternative paradigm for CS signal reconstruction replaces the implicit regularization imposed by l_p norms by explicit adaptive filtering. Performance of this approach overcomes the problem of regularization criteria by advanced spatially adaptive (both local and non-local) method [12]. The empirical results presented in [6] show that this approach is able to reconstruct images with improved visual quality from highly incomplete measurements provided that sensing matrix captures low frequency components (high valued sparse coefficients).

Let the original signal x is transformed to y by applying some appropriate transformation basis, assuming that y is sparse in that transformed domain. The work in [6] introduced a binary valued sampling operator S, with values 0 or 1 of the available portion Ω of the spectrum. Thus, the point-wise products $S. * y$ and $(1$ - S$). * y$ produce a decomposition of the spectrum into two complementary parts, $y_1 = S. * y$ and $y_2 = (1$ - S$). * y$. The total signal y can thus be written as,

$$y = y_1 + y_2 = S. * y + (1 - S). * y \tag{1}$$

Here, y_1 and y_2 are the observed (known) and the unobserved (unknown) parts of y, respectively. The goal is to reconstruct θ (or equivalently y_2) from the available data y_1. An estimate of y_2 can be obtained by the following recursive formula after the k^{th} iteration.

$$\begin{aligned} \hat{y}_2^{(0)} = 0,\ (initialization)\ k = 0, \\ \hat{y}_2^k = \hat{y}_2^{k-1} - \gamma_k[\hat{y}_2^{k-1} - (1 - S). * T(\phi(T^{-1} \\ (y_1 + \hat{y}_2^{k-1}))) + (1 - S). * \eta_k], k \geq 1 \end{aligned} \tag{2}$$

From the estimate of y_2, the estimate of the image signal y can be obtained as:

$$\hat{y}^{(k)} = y_1 + \hat{y}_2^{(k)}$$

Taking the inverse transform of the estimate of y gives back the original image.

During the recovery of CS samples transmitted through noisy radio mobile channel, the parametric reconstruction is done not on y_1 but on $Hy_1 + \eta$, where H is the channel fading co-efficient and η the channel noise. For AWGN channel fading parameter $H = 1$.

B. Channel Model

The reconstruction of the original image by RM gives appreciably good results when the reconstruction is done at the same place i.e. reconstruction done at the place where the samples are sensed. If the reconstruction of the original image from the sensed samples is done at a place far away from the place where the samples are sensed, then the samples are corrupted with noise during transmission. During transmission, noise gets added to these sensed samples. In the absence of any error correcting codes (ECC), the samples are decoded by hard decision decoding. So, the reconstruction procedure gets greatly affected due to the noise samples. To improve the reconstructed image quality at the far end, the sensed samples after quantization are encoded with LDPC code for protection from channel errors. The sensed samples can pass through a fading channel instead of the AWGN channel. Image degradation is more severe where transmission through radio mobile channel that creates fading channel. The fading channel degrades the samples more than AWGN noise.

C. LDPC Codes

In IEEE 802.16-2009 standard, LDPC code currently consists of six different code classes spanning four different code rates i.e., 1/2, 2/3, 3/4 and 5/6 [7]. The maximum length of theses codes is 2304. In this work we propose a technique to extend the codes given in the standard. Each entry of the H matrix of the final LDPC code obtained from the IEEE 802.16-2009 standard is expanded by an identity matrix. So, if the original size of the H matrix is m X n and if the size of the identity matrix be p X p, then the size of the extended matrix will be mp X np. The extended parity check matrix H_{ext} can be obtained from the base parity check matrix H by the following formula:

$$H_{ext} = H \otimes B \tag{3}$$

where $\otimes$ stands for Kronecker product and B is the identity matrix of size p X p. H_{ext} can be calculated as follows

$$A \otimes B = \begin{bmatrix} a_{11}B & \dots & a_{1n}B \\ \vdots & \ddots & \vdots \\ a_{m1}B & \dots & a_{mn}B \end{bmatrix}$$

Multiplication of the identity matrix does not introduce 4 - cycle. If the original LDPC code is 4- cycle free then the expanded matrix will not have 4 - cycle. Let the length between two nodes i.e., two entries of the H matrix be L. When each entry of the H matrix is extended by unity matrix, equivalently the nodes are shifted by 1. So, the length L remains constant. But these nodes do not cause any 4- cycle with the existing nodes. Thus by multiplication of the standard H matrix with unit matrix the length of the H matrix is extended without introduction of 4- cycle for H matrices given in the WIMAX standard. As we know that larger the length of the codeword, better is the error protection capability. By the above mentioned method, the length of the H matrix can be increased to get better CS reconstruction i.e. low probability of error. The probability of error of reconstructed data varies with the rate of the error control coding used. Let us define the following notation for a code of rate R:
E_c = SNR per code bit
E_b = SNR per information bit = $\frac{E_c}{R}$.
The probability of error for soft decision decoding for BPSK in AWGN channel is upper bounded as follows:

$$P_e \leq Q(\sqrt{\frac{2E_c}{N_o}\Sigma_{l=1}^{n} c_{j,l}}) \tag{5}$$

where the information vector x_i is mapped to the codeword $c_i = c_{i,1}, c_{i,2}, , c_{i,n}$ [13]. For coded BPSK on Rayleigh fading channel and with Soft decision decoding the probability of error can be given as follows [13]

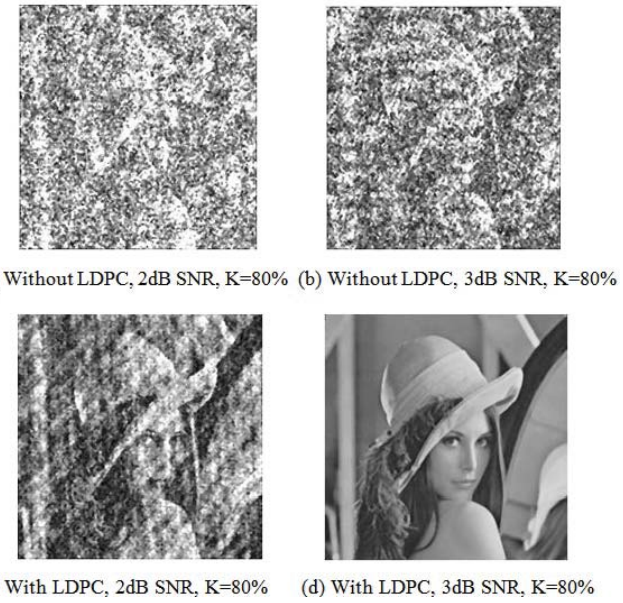
$$P_e \leq Q(\sqrt{2\Sigma_{l=1}^{n} c_{j,l} E_{j,l}}) \tag{6}$$

Deriving the bounds of the probability of error for CS reconstruction with LDPC is an interesting problem.

IV. Results and Discussion

This section presents performance results. The sensed signals are quantized, then BPSK modulated and transmitted through the AWGN channel. Simulation is done over large number of images but due to space limitation few images are shown. In Fig. 1 (a) and (b), the sensed samples (CS measurement space, K = 80% are taken) are transmitted through AWGN channel, SNR is 2 and 3 dB, respectively. The samples received through the noisy channel are used to reconstruct the image. The Structural Similarity Index (SSIM) of the reconstructed images are 0.0877 and 0.1220 and Peak Signal to Noise Ratio (PSNR) are 10.41 dB and 12.25 dB, respectively. Image considered for simulation is (256 X 256), 8 bits/pixel.

The same 80% samples of the image Lena are encoded by LDPC and then transmitted through the same AWGN channel. The images can be reconstructed to visually satisfying values if

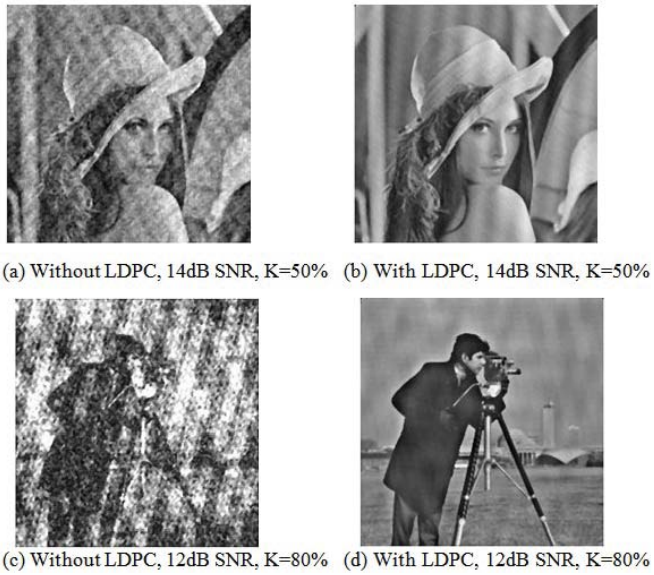


(a) Without LDPC, 2dB SNR, K=80% (b) Without LDPC, 3dB SNR, K=80%

(c) With LDPC, 2dB SNR, K=80% (d) With LDPC, 3dB SNR, K=80%

Fig. 1: Image reconstruction after transmission through AWGN channel

the sensed samples are encoded by LDPC before transmitting, as is evident in Fig. 1 (c) and (d). The SSIM values are 0.2753 and 0.9340 and the PSNR of the reconstructed images are 17.1752dB and 32.0725 dB, respectively.



(a) Without LDPC, 14dB SNR, K=50% (b) With LDPC, 14dB SNR, K=50%

(c) Without LDPC, 12dB SNR, K=80% (d) With LDPC, 12dB SNR, K=80%

Fig. 2: Image reconstruction after transmission through Rayleigh fading channel

The effect of fading on reconstruction without and with LDPC is shown in Fig. 2. As an example to demonstrate the effect of fading, 50% samples of the image Lena is sensed by CS. The samples are transmitted directly through a Rayleigh fading channel at 14dB and also after encoding the samples with LDPC. The SSIM and PSNR of the reconstructed images

without and with LDPC are 0.4959, 0.8418 and 21.5860 dB and 26.9992 dB and are shown in Fig. 2 (a) and Fig. 2(b) respectively. Simulation is also done on the cameraman image by taking 80% samples and the SNR of the channel is set as 12dB. The SSIM and PSNR of the reconstructed images without and with LDPC are 0.3249, 0.7592 and 17.2472 dB and 25.4037 dB and are shown in Fig. 2 (c) and Fig. 2(d), respectively. The effect of noise with the percentage of varying CS samples encoded with LDPC is also studied. The CS samples of the image Lena are picked up from 10% to 50% in steps of 10% and passed through AWGN channel and the SNR of the channel varies from 0 to 4.5 dB in steps of 0.5 dB. The LDPC code chosen is the proposed LDPC code. The basic LDPC code is rate 2/3 taken from the IEEE 802.16 standard. To improve the BER performance, this LDPC code is extended by Kronecker product with an identity matrix of weight 4. Performance comparison with and without LDPC is given in Fig.3.

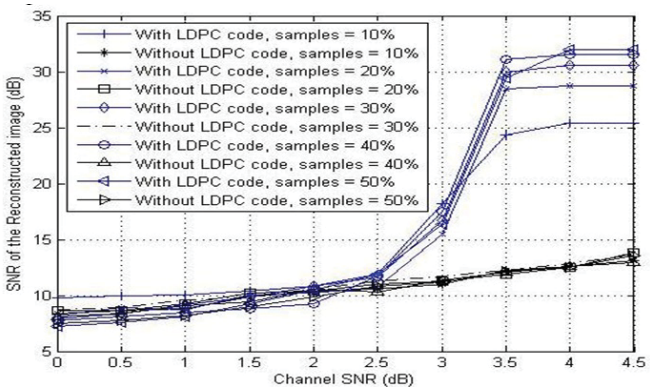


Fig. 3: PSNR of the reconstructed images vs channel SNR

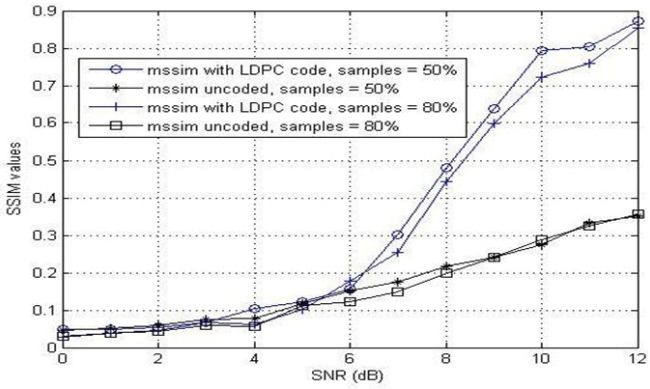

Fig. 4: SSIM of CS reconstructed image vs SNR in Rayleigh fading channel

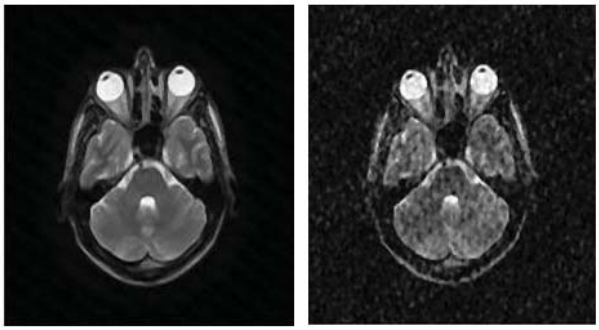
The effect of Rayleigh fading channel on CS reconstruction with the variation in measurements is also studied. The SSIM values of the reconstructed image of the cameraman in comparison with the original image when 50% and 80% samples are sensed and reconstructed are plotted and shown in Fig. 4. The LDPC code used is the proposed extended standard LDPC code. From the simulation results, it is clearly evident that LDPC codes improve the quality of the reconstructed images not only in AWGN channel but also in Rayleigh fading channel.

These days with the advent of Wireless Health Monitoring System, far end reconstruction of medical images has become a necessity. Fig. 5 (a) shows the reconstructed image of MRI head image for CS measurements, K = 50%. The samples are transmitted through Rayleigh fading channel at 16 dB with LDPC coding rate 2/3. Fig. 5 (b) shows the reconstructed image without use of ECC. The SSIM values are 0.9069 and 0.3008 with and without LDPC coding, respectively.



(a) With LDPC, K = 50% (b) without LDPC, K = 50%

Fig. 5: Reconstruction at far end of MRI head image at 16 dB Rayleigh fading channel

The effect of variation in code rates of LDPC was also studied. The SSIM values obtained after encoding the sensed data with different rates of LDPC and transmission through an AWGN channel is shown in Fig. 6. The LDPC codes used were constructed by the proposed LDPC construction technique from IEEE 802.16 standard. From Fig. 6 it is evident that as the code rate increases, the SSIM of the CS reconstructed images increases.

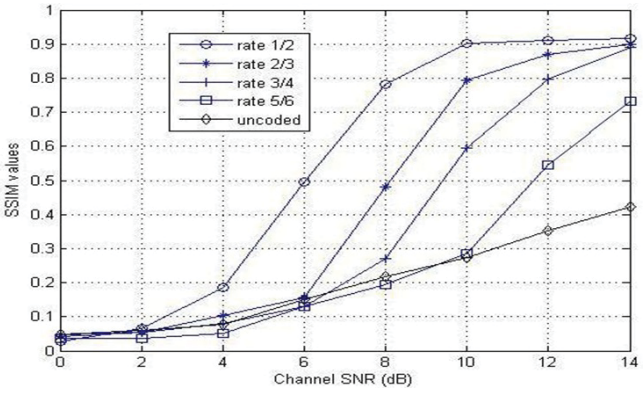


Fig. 6: Varying the rates of LDPC in Rayleigh fading channel

A three dimensional (3D) plot relating SNR vs BER vs SSIM is shown in Fig. 7. Simulations are done over a large number of test images. Numerical values shown are obtained by taking average over 50 images. In Fig. 7, 50% samples of the images are used to study the effect of BER of LDPC

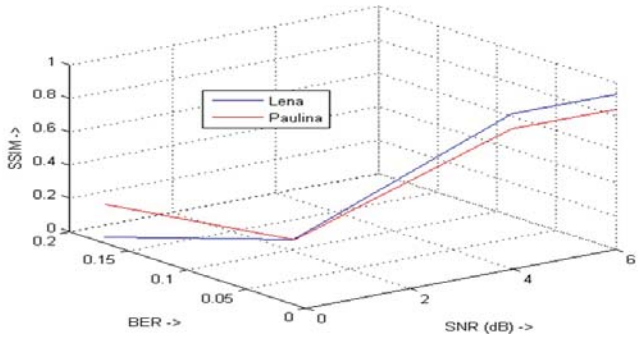

Fig. 7: Effect of channel SNR on SSIM and BER in AWGN channel

on SSIM of CS reconstructed image. As expected, with the channel SNR increases, BER values decrease and hence SSIM values increase.

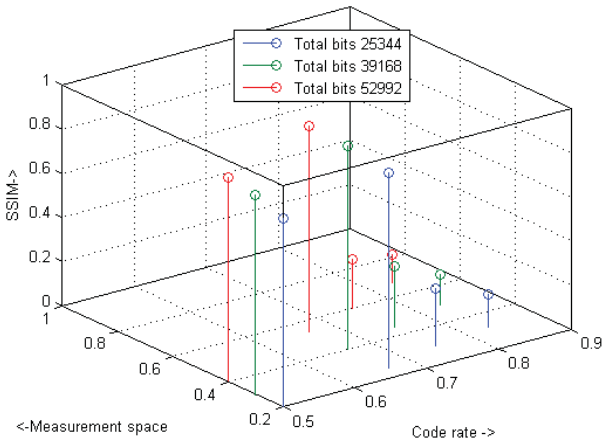

Fig. 8: Variation of SSIM with different LDPC rates and varying sample space keeping total number of bits constant at 4dB SNR

In Fig.8, a plot of SSIM vs the code rates and the number of measurements but keeping the total number of bits constant is shown. The 1st set of data is for rate(R) = 1/2 and measurement space (K) = 0.2; R = 2/3, K = 0.25; R = 3/4, K = 0.3; R = 5/6, K = 0.325. The SSIM obtained are 0.8554, 0.8851, 0.2607 and 0.1474 respectively. The total number of bits = 25344. The 2nd set of data is for R = 1/2 and K = 0.3; R = 2/3, K = 0.4; R = 3/4, K = 0.45; R = 5/6, K = 0. 5. The SSIM values obtained are 0.9023, 0.9232, 0.2774 and 0.1384, respectively. The total number of bits = 39168. The 3rd set of data is for R= 1/2 and K = 0.4; R = 2/3, K = 0.54; R = 3/4, K = 0.6; R = 5/6, K = 0.675. SSIM values obtained are 0.9232, 0.9325, 0.2191 and 0.1239 respectively. The total number of bits = 52992. From the plot it is seen that if the measurement space is increased and a higher rate LDPC code is used then the reconstruction (SSIM) is not good. On the other hand, SSIM of rate 1/2 code is slightly less than that of rate 2/3. Thus simply increase in the sample space or decrease in the code rate does not increase the SSIM. An optimal value of the code rate and sample space/ measurements needs to be obtained.

V. Conclusions

This work studies the effect of a radio mobile channel on CS reconstruction image using RM scheme. It also proposes a method to construct a larger length LDPC code from IEEE 802.16 standard. This work shows that better CS reconstruction is achieved when the CS samples are encoded by LDPC before transmission. LDPC codes lower the BER of the received CS samples. BER of transmitted CS samples, without LDPC coding is sufficiently high. With the increased percentage of CS sample space transmitted through the channel, better reconstruction is obtained. For a fixed CS sample space better reconstruction is obtained when the rate of the LDPC code is increased. Under constant power constraint, simulation results show a trade off relationship between the code rate and the number of measurements on SSIM values. Extensive simulation results show that a moderate CS space encoded by rate 2/3 LDPC code gives significantly improved SSIM values. The proposed work may be extended as a rate and an energy efficient system design.

Spectrum Scarcity at the Extensive and Intensive Edges: From White Space to 5G

Benoît Pierre Freyens
Economics, Faculty of BGL
University of Canberra,
ACT 2601 AUSTRALIA

Abstract[1]— **as with previous generations of networks, future 5G deployments will need to use much larger blocks of spectrum to deliver their services. This additional spectrum can either be found at the extensive edge (e.g. the digital dividend) or at the intensive edge (e.g. spectrum sharing). The successful nature of spectrum sharing in UHF white spaces in the US offers a promising lead to expand the latter, and should be contrasted with far more exclusive spectrum rights in the UHF (and other bands) prevailing in other countries, and which are currently being re-assessed by regulators. This short paper revisits the key mechanisms of the white space model in which spectrum usage rights recognise a primary user, broadcasters, but tolerate opportunistic usage by symbiotic secondary users such as PMSE users, and potentially, much less symbiotic users such as providers of mobile broadband and telecommunications applications. It then draws inference to help define critical spectrum sharing arrangements needed for future 5G deployment and implications for regulatory reforms to highly prescriptive spectrum rights arrangements.**

Keywords **– Spectrum Sharing; White Spaces; 5G; Mobile Broadband; Broadcasting**

I. INTRODUCTION

The massive spectral efficiency gains achieved by the advent of digital transmission technology are slowly dissipating against a backdrop of ever surging demand for spectrum by mobile broadband and other telecommunications industries, which keep exerting pressure on a finite quantum of broadcasting spectrum. In early 2008, the Federal Communications Commission (FCC) auctioned and re-allocated 62 MHz of UHF broadcasting spectrum in the 700 MHz band, known then as the digital dividend 1.0 [1, 2]. Since 2012 the FCC has sought to further recover and re-allocate broadcasting spectrum in the lower 600 MHz band through a 'carrot-and-sticks' package known as the Incentive Auction and Repacking Program [3]. Pursuit of digital dividends 2.0 and 3.0 is also currently underway in Australia and New Zealand [4].

Concurrent to this search for additional spectrum at the *extensive* edge, there has also been successful development at the *intensive* edge. The high economic value of white spaces (unassigned UHF broadcast spectrum) has fuelled competing demands by wireless services with varying capacities to impose- and suffer from interferences. Prominent amongst those services were `symbiotic' devices (land mobile, wireless microphones), `invasive' devices (mobile broadband applications), and carrier services in search of additional UHF spectrum to test for- and prepare future 5G deployments.

The paper takes stock from the regulatory arrangements put in place by the FCC to authorise or, better put, tolerate access of high-quality broadcast spectrum resources by competing services; licensed broadcasting stations (the incumbents), program making and special event (PMSE) users, unlicensed mobile broadband devices, and telecommunications networks. The motivation for the paper is to inform the spectrum scarcity debate that is intensifying in the United States and elsewhere as future requirements for 5G networks are being laid out.

This question is of particular importance because a number of countries such as New Zealand, Australia, and the UK that had legislated or otherwise authorised highly exclusive spectrum rights in 1989, 1992 and 2006 (including property rights regimes) are now pondering the potential negative implications of high exclusivity rights for the spectrum requirements of future network developments. There is increasing understanding that any plan to address spectrum scarcity in the future must necessarily include lowering the extent of these rights to some degree, to allow for instance blanket or conditional permission for secondary users to intervene and exploit even very-short term spectrum opportunities. So, this new development contrasts with the regulatory

[1] Contact details: Ben Freyens, Associate Professor of Economics, Faculty of BGL, University of Canberra, Email: ben.freyens@canberra.edu.au. The views presented in this paper should not be assumed to represent the views of University of Canberra.

orthodoxy prevailing just one or two decades ago in spectrum reforms countries, which emphasised certainty and exclusivity over flexibility and sharing [5]. The white space model is an example of the latter, tolerating secondary usage of assigned but temporary idle spectrum as long as opportunistic users conform to non-interfering etiquette. Although this model has attracted very different types of users and led to no shortage of controversy between regulators and primary users it offers one of the main avenues to reduce spectrum scarcity at the intensive edge for 5G networks.

II. SHARING AT THE INTENSIVE EDGE

The high economic value of white space spectrum and the apparent tolerance of broadcasters for early `symbiotic' white space users soon attracted new generations of innovative wireless technologies, particularly designed for mobile broadband applications (with Microsoft and Google, two major players). Mobile broadband devices generally operate at higher power, use far more sophisticated technology than their predecessors and generate much higher economic value than older, symbiotic devices such as wireless microphones. Concerned about the potential for interference - through critical mass effects - broadcasters have opposed these new `invasive' white space users and, in a high-profile legal action, sued the US regulator (the FCC) for initially authorising their operations [6]. The FCC has since recognised the potential for interference between broadcasters and mobile broadband white space users and has settled the matter by requiring the use of geo-location databases for the operation of low power unlicensed wireless devices (ET Docket 04-186 & ET Docket 10-174) and for unlicensed mobile broadband devices (47 C.F.R. §§ 15.701-.707). The FCC rulings specifically require white space users to identify vacant channels through their devices' geo-location database accessibility capabilities [7]. Similar developments are underway in the UK, with plans for opportunistic use of unused DTT UHF spectrum by the end of 2015 [8].

Market demand for access and use of UHF spectrum holes will only worsen over time. On the one hand, the quality of UHF white space spectrum is such that there is and will be increasing demand for secondary usage of unused UHF spectrum by an ever larger array of wireless services - particularly for `last mile' rural broadband access, machine to machine communications, and for urban broadband architectures. On the other hand, broadcasters and white space users will also soon have to contend with added competition from 4G and 5G networks operators. In the US, Germany and Sweden, the digital dividend (the spectrum made available through higher spectral efficiency of digital technologies) was auctioned to telecommunications carriers. By clawing back UHF spectrum from broadcasters and reallocating the digital dividend to cellular services, regulators now face the arduous task of allocating licences (or unlicensed rights) in ways that maximise the overall economic value generated by three very different types of services on a fixed quantity of very high value spectrum. Broadcasting, mobile broadband and cellular networks vary considerably in the transmission power they use (and implied potential for interference), in their economic nature (public, private or mixed goods) and in the value they generate through company profits and consumption benefits. Consequently, the socially desirable partitioning of this fixed, non-substitutable amount of spectrum (the UHF Band) amongst these three services ranks as one of the most important contemporary policy questions for regulatory agencies such as the FCC, OFCOM and various others.

Regulators have so far threaded cautiously. Except for the FCC's 2008 momentous decision, no other regulatory agency has authorised mobile broadband devices on TV white spaces yet. Except for Australia's 2010 decision to reduce the degree of exclusivity of its property rights regime there are also few indications that regulators would tolerate white space devices in spectrum licensed to cellular network carriers. In their post-digital switchover band planning exercises, regulators have also been careful to assign high power (DTV broadcasters) at the lower end of the UHF band and low-power services (LTE networks) at the higher end, whilst separating the two services with a large guard band. Yet, engineering research suggests that broadcasters 'use of existing cellular infrastructure could release further spectral gains, but would require specific guard space arrangements with carriers, which mobile broadband devices could further exploit (see for instance various contributions to IEEE DySPAN2011).

A. Symbiotic and Invasive Usage of White Spaces

A defining characteristic of white spaces is that they consist of UHF channels *allocated* to broadcasting but not *assigned* to the provision of broadcasting services. Analog TV needs to keep free, unencumbered channels between used channels in any one city in order to warrant sufficient control on interference from signals transmitted by adjacent bands' services. As guard spaces, white spaces are therefore specifically assigned to buffer against interferences from neighbouring broadcasts at the edge of a license area. A device, which opportunistically uses these available channels, is commonly referred to as a white-space device. Historically, there has been two types of devices: (i) symbiotic and (ii) invasive devices, and two approaches

to unlicensed spectrum-sharing: (i) overlay (cognitive radio-based: sensing and occupying idle spectrum, which is vacated upon usage by the primary user) and (ii) underlay (low/spread power but permanent operations under the noise floor of many primary users).

Symbiotic devices have long co-existed with broadcasters on unused UHF guard bands. The best profiled example is wireless microphones used for Program Making and Special Events (PMSE). Wireless microphones are mostly used by stage performers (e.g. for concerts) but also by TV performers (e.g. reality shows), using idle television channels in given locations. Wireless microphones combine a `quasi-overlay' approach - as their operators determine the idle channels that they can safely operate in - with an underlay approach - they are quite low power and operate below the noise floor of many broadcasts transmissions. In the US, the relationship was always based on tolerance rather than legitimacy. Officially part of the American Broadcast Auxiliary Service, wireless microphones are theoretically subject to licensing. However, due to the overlay/underlay nature of the equipment, interferences have been rare, mild and have proved impossible to detect in real time anyway. Consequently, licensing requirements never saw much enforcement by the US regulator (the FCC) and a well-funded corporate media constituency, now politically difficult to disenfranchise, has emerged. To a large extent, this constituency was not perceived as harmful and was quietly tolerated by broadcasters. For many years, the two services have co-existed pacifically on licensed broadcast spectrum. The status-quo was challenged in 2008, when the FCC auctioned the 700 MHz licences clawed back from broadcasters through digital switchover, which required PMSE users to migrate to lower segments of the UHF Band. In Australia as in the UK, the use of wireless microphones for PMSE usage in white space is licensed but subject to refarming after digital switchover. In the UK, for instance, PMSE usage will be migrated out of the 800 MHz band at a significant re-equipment cost to the industry.

Invasive devices followed in the wake of symbiotic devices' lasting success in establishing a niche in white space spectrum. Initially, around 2002, these devices took an `underlay' approach to spectrum sharing, transmitting under the noise floor of primary users. Ultra-wide band devices provide the most obvious examples of underlay signal devices. Ultra-wide band technology operates on very large bandwidths and across a number of bands used by licensed equipment. It is mostly used for personal local area networks, radar, and imaging and surveillance applications. The devices' power density (power per MHz) is so low that they do not cause interference to high power equipment such as broadcasters' transmitters. Although these devices have been allowed in a number of bands in the US, the UK and some Continental European nations, broadcasters remain wary of ultra wide band technology and have successfully obtained regulatory limits to the range of frequencies it can use (in most cases in much higher frequencies than UHF).

However, invasive white space usage re-emerged soon afterwards with the FCC's 2008 decision [6] to open up TV channel white spaces to unlicensed cognitive radio technologies for mobile broadband applications. The degree of technological sophistication, cutting-edge innovation and the high economic value of these applications was the main rationale driving the FCC decisions. For instance, use of TV white spaces by these new technologies has proved highly suited for (i) the deployment of `Wi-Fi on steroids' urban networks (Wi-Fi is low-power and transmits on microwaves, which restricts both range and wall penetration); (ii) the provision of `last mile' broadband in rural services where fibre is too expensive and where, again, long signal propagation properties are needed; and (iii) machine to machine communications, where again white spaces' wall penetration properties could enable automatic utility metering in buildings.

B. Promoting Spectrum Sharing in the White Space Model

Early ideas proposed including GPS receivers and programming each invasive white space device with a database of all TV stations in an area, however this would not have avoided other non-stationary or unlicensed users in the area, or any stations licensed or altered after the device was made. In early 2009, US Broadcasters asked a Federal Court to rescind the 2008 FCC authorization for white space usage by invasive white space devices on the ground that testing of white space sensing devices had been insufficient. Initial tests performed by the FCC in early 2008 showed that portable, unlicensed personal broadband devices operating in the same band as TV broadcasts could indeed cause interference. The FCC subsequently agreed on some device restrictions, including using geo-location technology to allow invasive devices to compare their location against an established database of TV stations. Invasive devices that did not incorporate geo-location capabilities would be considered for authorisation on a case by case basis and have to submit to a rigorous application process for FCC certification. For a while, the deployment of invasive white spaces devices appeared impeded by uncertainties over future reallocation of TV bands, over the certification of technologies intended to identify white spaces, and slow progress on the establishment of a system of geo-

location facilitated database consultations. However, the US Congress then drafted legislation in July 2011 advocating use of incentive auctions[2]as a way to make more UHF spectrum available for mobile broadband devices. Both the FCC and OFCOM have since moved on to a regime allowing non-interfering access through geo-locational capability [7, 8] Finally, Australia has in December 2011 passed legislation amending its Radiocommunications Act 1992 to develop the regulatory discretion to authorise secondary usage of invasive white space devices in spectrum protected by property rights (such as used to license telecommunications networks).

III. SHARING AT THE EXTENSIVE EDGE: SERVICES COEXISTENCE

The deployment of mobile white space technologies on primary and secondary basis is now well underway. In its 2010 National Broadband Plan, which mostly targeted alleviating spectrum scarcity at the *extensive* edge the FCC expressed the need to make 300 MHz of spectrum available for mobile broadband within 5 years, of which 120 MHz should come from TV Bands. Given the fixed physical constraints on the amount of UHF spectrum available such objectives can only be achieved through more efficient use of frequencies allocated to broadcast TV (470-698 MHZ) and auctioned to network services (various blocks between 698 and 806 MHz). Implicitly, improving the economic usage of these blocks of spectrum will require planning for some form of co-existence between the various services involved.

Improved usage efficiency at the extensive edge will also require carefully balancing the economic value created by new services against the interference costs they may generate (or suffer from). These trade-offs will soon emerge in other countries than the United States. A worldwide process of UHF reallocation from broadcasting to telecommunications technologies requiring a high degree of licence certainty (e.g. HSPA, WiMAX and LTE networks) is currently underway in a large number of other OECD countries. There too, the reallocation process will transform the increasingly difficult relationship between broadcasters and white space devices into a triangular, more complex and interactive contest over UHF spectrum rights.

Coexistence will be difficult. In particular, broadcast services (such as DTV) and telecommunications networks (such as 3G) are fundamentally incompatible technologies. Broadcasting uses a small number of sites to transmit at extremely high power over a large area. By contrast, network carriers deploy a much larger number of base stations (usually in cellular-like pattern) and operate at very low power levels. The potential for broadcasters to interfere with networks is large and the general regulatory approach adopted so far in many countries is to separate is to separate the UHF Band in a lower segment (for digital broadcasting) and a higher segment (for telecommunications networks), with a large guard band in between the two services and smaller guard bands between each licensed operator.

An alternative approach is to interleave broadcasting and network services with medium to large guard band separating licensed spectrum blocks from one another. While this approach may appear inefficient due to the larger guard space requirements, the fact that these guard spaces can be used by white space devices to generate important economic benefits suggests the presence of trade-offs so far ignored by regulators. There may also be synergies between broadcasting and network services that have not been explored so far. For instance, Ericsson Research has recently pioneered several experiments in various regions of the US showing the suitability and higher spectral economy of designing alternative transmission architectures for TV broadcasters based on using existing telecommunications networks infrastructure [9]. Whereas the development of new cellular networks for broadcasters would be highly uneconomical, having broadcasters use existing carrier infrastructure would be feasible and more efficient than current broadcasting systems.

These findings spell out a possible future in which TV broadcasters could relinquish a large amount of UHF spectrum for network and broadband applications whilst operating viably and more efficiently using existing cellular infrastructure. Whereas such an arrangement would reduce the power requirements of broadcasters, they would still require regulating large guard bands between TV and telecommunications services. Since mobile broadband devices make a high-value usage of the unused guard bands separating the other two services, there seems to be no economic rationale for regulating against the operations of white space devices in those guard bands. Instead, regulators should be encouraged to find optimal trade-offs between the value generated by mobile broadband applications and the interference cost imposed on the primary users of the UHF Band (especially networks, which are considerably more sensitive to interference).

Of course, entrenched secondary rights for - and widespread use of - invasive white space devices in the UHF band could seriously constrain reallocation of the band from broadcasting to telecommunications if a full-scale migration of broadcasting out of UHF was to proceed later on (a possible digital dividend 2.0 in the

[2] Incentive auctions differ from mainstream auctions in that the FCC manages the auctions, but the seller is a broadcaster acting on a voluntary basis.

medium to long-term). In other words, developments at the intensive edge may thwart or significantly slow down progress at the extensive edge. This would particularly be the case if the regulatory requirements for white space devices are based on the assumption that the UHF band will continue to be used for digital terrestrial television, rather than for a mixed environment also including telecommunications networks. If the former prevails, white space devices may have few incentives to develop a capacity to operate in a telecommunications environment without causing interference. Alternatively, if developers of white space devices invest in the capacity to cooperatively share the UHF band with advanced telecommunications technologies (hypothetically in shared-infrastructure arrangements with broadcasters), the deployment of innovative white space technologies in the UHF band could allow early realisation of the economic potential of the UHF band without compromising higher value use in the medium term.

IV. CONCLUDING REMARKS

The ITU decision at WRC-12 to allow mobile use of 694-790 MHz in Europe, Africa and the Middle East is a clear example of how demand for mobile data is driving regulatory change. Broadcasters initially understood the telecommunications industry to be a competitor for their UHF spectrum resource, but the emergence of mobile broadband devices and standards used e.g. for machine communications present such growth areas for existing networks that we can confidently predict that competition for spectrum (as well as customers) and therefore spectrum scarcity will intensify.

In this context, where then will the new spectrum requirements be met for future network developments, which will have to offer higher throughput, extended device autonomy and much improved latency responses? Without looking too far into the future, how will we release spectrum to run trials on temporary assignments? In this article I have underpinned this question in quantity terms (extensive edge) and quality terms (intensive edge). At the extensive edge, the main challenge is technological (finding new spectrally-efficient technologies) and political (refarming smaller operators). At the intensive edge, the main challenge is no longer technological (the capacity to access spectrum opportunistically in milliseconds is well established) but regulatory: designing licensing arrangements that do not preclude, and ideally encourage spectrum sharing opportunities. Neither an administrative approach nor an exclusive property rights approach to white space assignments would have resulted in the observed successes of this spectrum-sharing model. Any spectrum sharing model in which a primary user keeps the discretion to deny spectrum sharing opportunities to secondary or third users to restrict competition would also be bound to fail.

As the first wave of regulatory arrangements for invasive WSD is finalised and implemented, care must be taken to ensure that regulatory arrangements developed at the intensive edge blend seamlessly with developments at the extensive edge. More specifically, a piecemeal approach consisting of encouraging spectrum sharing by lowering primary users' rights may run into difficulties if these rights remain defined at a much higher degree of exclusivity at the extensive edge.

***Abstract*—This paper presents the measurement of Radiated Emission from GPS based Vehicle Positioning and Localization System and implementation of the mitigation techniques in order to make the system compatible with the EMC requirements as per CISPR EMI/EMC Standard. In current scenario, the GPS based Vehicle Positioning System is essential part in the application areas like Logistics, Public Transports, Naval Ships, Railways etc. Due to its usefulness in daily life, the system has been taken as the test model for this research work. The Radiated Emission test for GPS based Vehicle Positioning System has been conducted at the Centre for Electronics Test Engineering (CETE), Pune, India.**

This model was first tested in the GTEM Cell after which it was found that some of the readings were above the limits specified as per the EMC standard. In this paper, the techniques have been proposed to reduce the level of Radiated Emission. The shielding by Aluminum Enclosure has been implemented. The results of re-testing the GPS based system with Aluminum Enclosure are presented. After re-test it was found that the Radiated Emission level was found to be reduced by 10 to 15 dB making the system compatible with the EMC requirements.

I. INTRODUCTION

Modern electronic equipment operates on high frequency signals. EMI is the major issue as far as the performance of electronic equipments is concerned. Hence, it is essential to overcome the EMI problem and to meet the EMC requirements. The emission from wireless / electronics equipments must be restricted within specified limits as per EMI/EMC standard like CISPR or MIL-461E.

For this research work GPS based Positioning and localization system has been taken as a model. The GPS based system consists of a GPS receiver (Pro Gin SR87), a microcontroller 89S52 to process the positional data and LCD to display the information. This GPS module transmits current position of vehicle with the help of GSM Module (SIM 300) in the form of latitude and longitude via SMS to the registered mobile phone [1]. The accuracy of GPS receiver (10 to 15 meters) can be improved by using Differential GPS (DGPS) up to 3 to 5 meters.

In this research paper Aluminum Enclosure is designed and implemented after comparing the shielding effectiveness of various metals. The block diagram of GPS based Wireless Positioning System is shown in Figure 1.

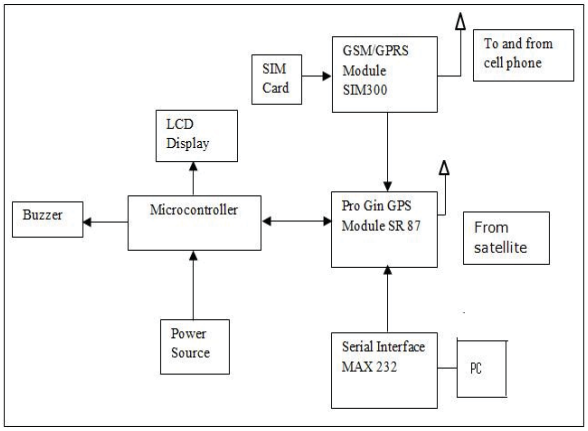

Fig.1: Block diagram of GPS based Wireless Positioning System

II. RADIATED EMISSION TEST IN GTEM CELL

The structure of GTEM (Giga-hertz transverse electromagnetic) cell resembles like a big horn antenna. It can be described as flared coaxial line terminated at one end. The walls form outer shield of the coax, while the inner conductor takes the shape of a septum. While making a connection with an EMI receiver, walls are connected to the shield of the coaxial cable and the septum to the inner conductor.

The septum is terminated at the other end by a resistive termination. The termination is essential to avoid reflection and maintain uniform field. Such terminations can work up to 200MHz. Termination above 200MHz is affected by conical absorbers. It extends the range of GTEM cell up to 40GHz. The termination maintain uniform field and avoid reflections [2].

During the test EUT (Equipment under Test) is placed on a EUT manipulator. The emission from the device is measured and readings from all three axes have been measured. These readings are then fed to the correlation software, from which we get final values. Measurement in a GTEM cell is an alternative to OATS (Open Area Test) [2].

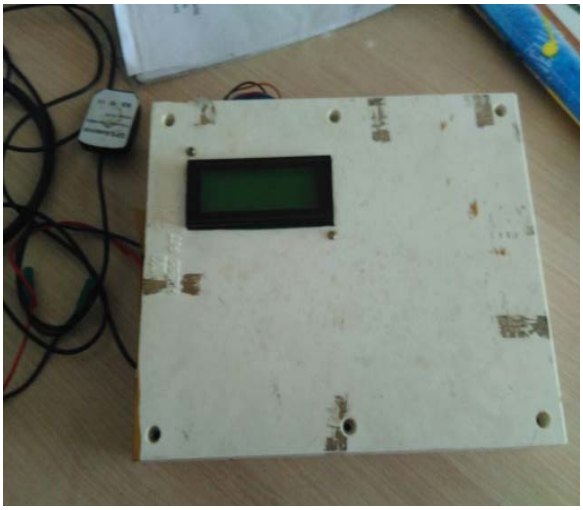

Fig. 2: View of GPS based Wireless Positioning System before shielding

Figure 2 shows GPS based Vehicle Positioning and Localizing system before shielding.

III. Methods to Reduce Radiated Emission

The following methods have been proposed to reduce the radiated emission [3, 4, 5].

A. Shielding with metal enclosures:

Metallic enclosures made from Copper, Aluminum, Mu-metal or magnetic materials could be used to shield entire assembly. The selection of metal depends on the type of wave, amount of attenuation required and the cost of shielding metal.

B. Grounding and Bonding:

Grounding is essential to control EMI. Single point or multipoint grounding techniques can be used depending upon frequency of application. Bonding is processes in which components, equipment, or several systems are electrically connected and further grounded to system earth point.

C. Design of PCB:

Increasing usage of printed circuit board in complex electronics requires unique shielding solutions. Solving EMI problem at PCB level is less expensive compared to further lab testing. When the frequency is greater than 2 GHz, the board-level shielding can be enhanced with the addition of microwave absorbers. From EMI point of view, multilayer PCB is recommended for getting better results [6].

D. Filtering:

RFI Filters can also be added in power supply lines to reduce the radiation. EMI filters can be classified as power line filters and data filters. Power line filters are incorporated into power mains to allow only power frequency while blocking all other frequencies.

IV. Shielding Effectiveness

While exploring the materials for enclosures, various materials like Copper, Aluminum, Mu-metal, Stainless Steel, Mild Steel etc were considered and compared on the basis of various parameters like shielding effectiveness, mechanical strength and immunity to corrosion. Aluminum has less relative conductivity (0.61) than Copper, but it is good option for corrosive environment. Aluminum is a good shielding material specially meant for EMI/EMC conditions. Mild Steel and Stainless Steel having less shielding effectiveness are popular materials used in commercial equipment since they have a good mechanical strength. However, Mild Steel is susceptible to corrosion. Hence Aluminum shielding enclosure has been designed and implemented [7].

The total shielding effectiveness of a shielding material (*SE*) equals the sum of the absorption loss (*A*), the reflection loss (*R*) [3].

$$SE\ (dB) = R\ (dB) + A\ (dB) \quad (1)$$

where,

$$A = 3.34t \sqrt{(f \mu_r \sigma_r)}\ dB \quad (2)$$

$$R = 168 + 10 \log (\sigma_r / \mu_r f)\ dB \quad (3)$$

Thickness of Al enclosure is $t = 0.254$ inch (1mm),

μ_r is relative permeability,

f is the frequency, and

σ_r is relative conductivity

TABLE I: SPECIFICATIONS OF METALS

Material	Relative Conductivity (σ_r)	Relative Permeability (μ_r)
Cu	1	1
Al	0.61	1
Mild Steel	0.178	2000
Mu-metal	0.03	20000

With above mentioned values [3] as indicted in Table I, shielding effectiveness of Al, Mu-metal, Mild-Steel and Copper enclosure is calculated over entire frequency range with the help of MATLAB and plotted as shown in figure 3.

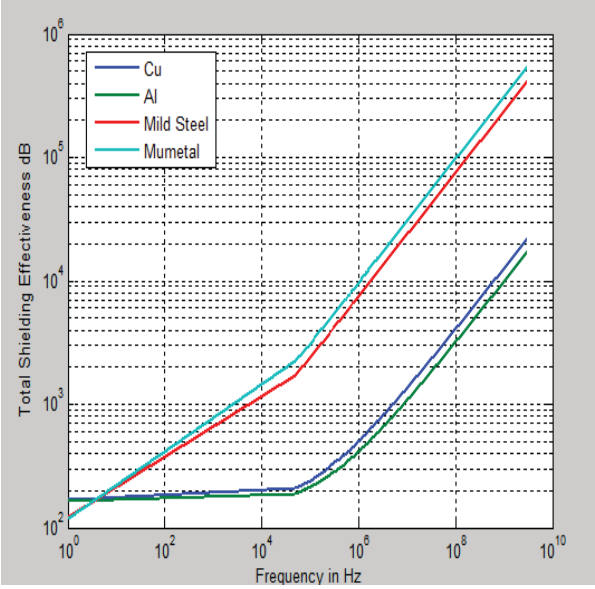

Fig. 3: Graph of Shielding Effectiveness (SE) of Al, Cu and Mu-metal and Mild-steel

.

V. DESIGN OF SHIELDING ENCLOSURE

Aluminum enclosure has been designed with opening for cables and LCD. Dimensions are: (l) =165mm, (b) =115mm, (h) =73mm, thickness (t) = 1mm.

Figure 4 shows Aluminum Enclosure as per the dimensions indicated above, implemented for PCB of GPS based Vehicle Positioning System.

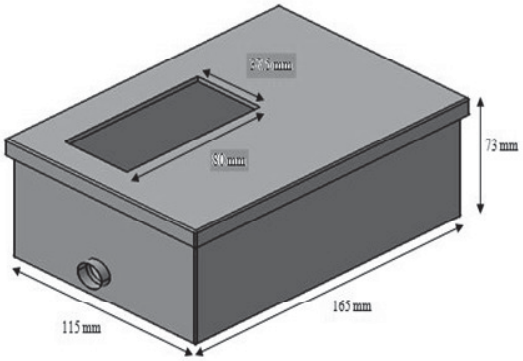

Fig. 4: Aluminum Enclosure for GPS based Wireless Positioning System

The conductive gaskets serve as effective shielding material used in gaps, holes, small openings of enclosures. A gasket may be required if the gaps, slots and holes around the metal plate interface allow excessive radiation of the internally generated electromagnetic waves [3, 4]. Such emissions cause the equipment to radiate more than specified values as per the EMI/EMC standards. The Aluminum EMI Enclosure has been sealed by Silver filled conductive gaskets to avoid any leakage of radiation through holes, gaps and openings. Silver filled Silicon gasket has wider operating temperature range (-55^0 to 165^0C) and good shielding effectiveness (110dB) with lower volume resistivity (0.008 ohm-cm) [8].

Fig. 5: View of GTEM Cell with testing of GPS Model

Figure 5 presents model kept in the GTEM cell for testing of Radiated Emission at CETE, Pune.

TABLE II: RE LEVEL WITHOUT SHIELDING AND WITH AL SHIELDING

Frequency in MHz	E-Field Readings Before Shielding (dBuV/m)	E-Field Readings After Shielding (dBuV/m)
33.12	37.05	26.22
39.76	35.47	32.66
49.76	34.25	20.62
56.80	36.04	21.94
60.88	42.34	25.57
79.28	43.51	37.44
93.52	29.35	25.24
100.72	25.42	17.79
115.20	24.91	14.9
127.20	25.72	20.64
132.74	24.69	21.54
154.80	22.27	20.17
178.80	28.07	27.49
184.32	26.03	21.0
195.32	26.10	22.76
212.00	22.07	20.72

VI. OBSERVATION AND RESULTS FOR VEHICLE POSITIONING AND LOCALIZATION SYSTEM

The model was tested in GTEM cell at Centre for Electronics Test Engineering (CETE), Pune, India. Radiated Emission readings were taken in three orthogonal axes for frequency ranges of 30MHz to 1GHz. In this case, CISPR 11 standard of class A has been taken as a reference. Class A standard is defined for the industrial equipments. Standard level specified is 40dBuV/m for 30-230MHz and 47dBuV/m for the range of 230-1000 MHz frequency.

For initial frequencies up to 300MHz, some of the readings exceed the standard level specified as 40dBuV/m. Shielding Effectiveness is found by MATLAB Simulation. The GPS model has been enclosed with Aluminum shielding cabinet with 1 mm thickness with conductive gaskets and whole assembly was again re-tested. Table II shows RE level before and after shielding.

Radiated Emission from the model was found to be more than specified limits as per the standard for a particular frequency range without Al Enclosure. The radiated Emission was found to be reduced around 10 to 15 dB with Al Enclosure shielding. Table II shows the some of the observations with and without Al shielding. Figure 6 shows the plots of Radiated Emission with and without Al shielding.

It was observed that some readings without Enclosure were above the standard limit hence model was not complying with the EMC standards. Hence, it was essential to implement an appropriate metallic enclosure shielding to the PCB of this model.

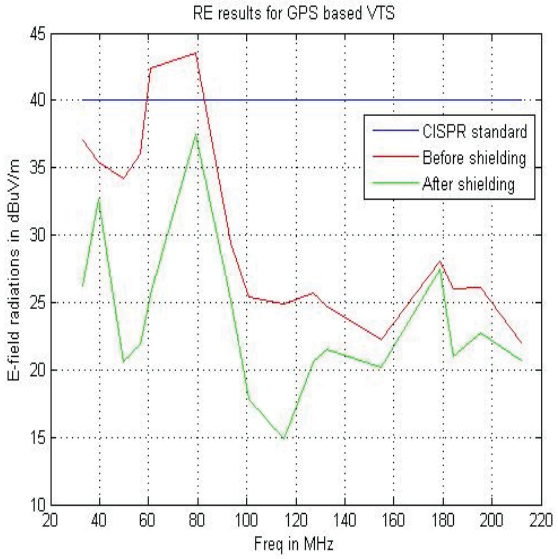

Fig. 6: Graph of observations of E-field Radiated Emission before and after shielding with and without Al Enclosure for GPS Model

The reading without enclosure was exceeding specified level at a frequency of 33MHz. This RE level was due to third harmonic of crystal oscillator (11MHz) of model. The second peak was found at 79MHz frequency. It was also due to harmonic of crystal oscillator. After shielding with Al Enclosure, RE level was found to be reduced below specified level. For further improvement in the results, it is proposed that crystal should be covered with Copper clamps grounded to the system / PCB earth. Figure 7 represents model with Aluminum shielding.

`

Fig. 7: Photograph of GPS based Wireless Positioning System with Al Shielding

VII. Conclusion

The Radiated Emission from the GPS Positioning system model was found to be more than specified limits as per CISPR EMI/EMC standard specifically at frequency band of 60 MHz to 80 MHz. Aluminum Enclosure of 1 mm thickness using conductive gaskets has been designed and implemented for the GPS based Vehicle Positioning System. With the implantation of Al Enclosure, it was found that Radiated Emission level was reduced by 10 to 15 dB. The Model with Enclosure was found to be compatible with CISPR EMI/EMC Standard.

***Abstract*— The main objective of this paper is to measure the Conducted Emission (EMI) and propose mitigation techniques in order to meet the Electromagnetic Compatibility (EMC). For this research work, GPS based vehicle positioning system has been taken as a model. The Conducted Emission test for GPS based system has been performed using SCHAFFNER make Line Impedance Stabilization Network (LISN) and SCHAFFNER SCR 3501 Spectrum Analyzer at the Centre for Electronics Test Engineering (CETE), Pune, India which is Government of India undertaking. This model was first tested without RFI (Radio Frequency Interference) filter. The EMC standard is specified for the frequency range of 150 kHz to 30 MHz for Conducted Emission measurement. The CE level has been reduced by using filtering method. The results obtained were compared with the CISPR standard in order to investigate the effectiveness of the applied EMI mitigation techniques. The analysis and experimental results finally shows that the Conducted Emission has been reduced by 20 dB using the EMI filter.**

***Keywords*— GPS, Conducted Emission, CE, EMI/EMC, RFI, EMC Testing, Vehicular Communication**

I. INTRODUCTION

Electromagnetic Interference (EMI) is an electromagnetic pollution caused by the generation of electromagnetic energy that is unwanted. This energy can interfere with the normal operation of electronic equipment resulting in the degradation of its functionality. EMC stands for Electromagnetic Compatibility and is defined as the ability of equipment to perform satisfactorily in its intended environment without introducing intolerable interference. EMI/EMC is used as a combined term as we try to achieve EMC by limiting EMI. Electromagnetic Emission is defined as the phenomenon by which electromagnetic energy releases from a source. This emission can be in the form of a current via conducting wires known as Conducted Emission (CE) and can also be in the form of radiation through openings like displays, cable entries; ventilation holes etc. and is known as Radiated Emission [1].

Conducted Emission (CE) is the EMI emitted by equipment in the form of a current through any conductor that interfaces the equipment with the outside environment. Conducted Emission measurement is generally carried out over a frequency range from a few kilohertz to tens of megahertz. The term Conducted Emission is actually used by MIL standard 461, while CISPR/IEC based standards use the terms like terminal disturbance voltage or conducted disturbance voltage. The CISPR based test standards specify Conducted Emission (CE) measurement from 150 kHz to 30MHz on the mains cable [1].

II. GPS BASED VEHICLE TRACKING SYSTEM

As numbers of vehicles are increasing day by day, the GPS based positioning system is very useful in order to:

- Track the location of the vehicle,
- Provide protection of vehicle from thieves,
- For security and road assistance,
- For monitoring of delivery time,
- For emergency help.

The areas where GPS based vehicle tracking system is commonly used are: Schools, Public Transports, Railways, Logistics, Rented Taxis etc. The vehicle tracking system is designed using GPS (Global Positioning System) technology. The GPS system works on the principle of "Triangulation". There are 24 satellites available in the space, out of which it is guaranteed that minimum 3 active satellites are available at any time. The GPS based vehicle tracking system consists of a GPS receiver which receives the signals from the satellites. The calculation is based on the time taken by a signal to reach from each satellite. Based on this time calculation, GPS receiver can not only locate the exact location of the vehicle but also it can compute the velocity and time. It also provides details such as longitude, latitude, height from sea level [2]. Figure 1 shows the block diagram for the GPS based vehicle tracking system.

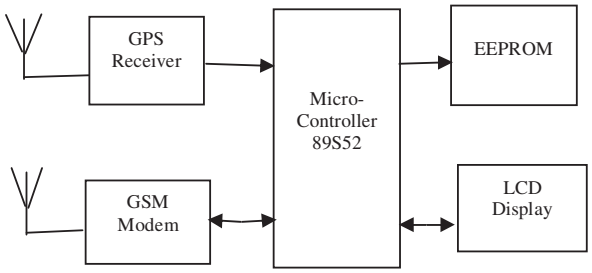

Fig. 1: Block Diagram of GPS Based Vehicle Tracking System

The GPS receiver (ProGin SR87) receives signals from the satellites, and then calculates its current location. This information is then communicated to the microcontroller (89S52) which processes this data using serial interfaces. The GSM module (SIM 300) receives request for sending vehicle location from registered cell phone. The GSM module sends reply SMS to same cell phone giving the vehicle location [2].

III. Test Setup for CE Measurement

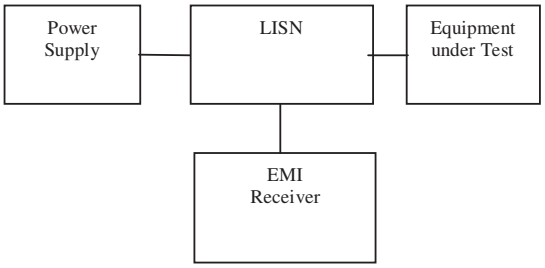

Fig. 2: Block Diagram of Laboratory Test Set Up

A basic test setup for Conducted Emission (CE) measurement is shown in figure 2. The equipment under test is connected to the power supply through a Line Impedance Stabilization Network (LISN). The LISN performs three main functions: First, it acts as a buffer and isolates the EMI receiver from the mains. Second, it functions as a filter and ensures that EUT is fed with a pure mains supply and third, the LISN stabilizes the impedance of mains to 50Ω to match the input impedance of the EMI receiver. For ensuring accurate measurement, the output impedance of the LISN must be constant and equal to the input impedance of the EMI receiver over the entire frequency range of measurement. Any mismatch between these two will result into the measurement error. The output of LISN is fed to the EMI receiver which is a double or triple super-heterodyne radio receiver [1]. The Conducted Emission test for GPS based system has been performed using SCHAFFNER make Line Impedance Stabilization Network (LISN) and SCHAFFNER SCR 3501 Spectrum analyzer at CETE Pune, India.

Conducted Emission Limits:
All EMC standards specifies that the Conducted Emission of an equipment shall be below certain limits. The CISPR standards specifies different limits for industrial use equipment, called as Class 'A' and domestic use equipment, called as Class 'B'. While performing an actual CE measurement, the limits are superimposed on the plotted graphs [1].

TABLE I: CISPR CLASS-A LIMITS (FOR INDUSTRIAL USE)

Frequency (MHz)	Limits dB(uV)	
	Quasi-Peak	*Average*
0.15 to 0.5	79	66
0.5 to 30	73	60

TABLE II: CISPR CLASS - B LIMITS (FOR DOMESTIC USE)

Frequency (MHz)	Limits dB(uV)	
	Quasi-Peak	*Average*
0.15 to 0.5	66 to 56	56 to 46
0.5 to 5	56	46
0.5 to 30	60	50

IV. Results For Conducted Emission Testing Without Filter

Table III gives the readings for GPS based system without filter while tested for Conducted Emission.

TABLE III: FINAL SCAN RESULTS FOR GPS BASED SYSTEM WITHOUT FILTER

Frequency MHz	Avg. Level dBuV	Avg. Limit dBuV	QP Level dBuV	QP Limit dBuV
0.1640	57.49	66.00	60.86	79.00
0.2160	58.65	66.00	60.87	79.00
0.2210	52.50	66.00	55.94	79.00
0.3250	63.90	66.00	65.90	79.00
11.0570	58.87	60.00	61.85	73.00
16.5920	45.98	60.00	49.65	73.00
22.1180	63.83	60.00	65.77	73.00

The Microcontroller 89S52 used in this GPS system consists of a crystal oscillator to provide clock pulses to the microcontroller. The oscillation frequency at which crystal oscillator operates is 11.0592 MHz. After analyzing the test results, it is found that the CE level which exceeded the limit was appearing at the frequency of 22.1180 MHz which is the 2nd harmonic of the crystal oscillation frequency hence

crystal oscillator is the component causing exceeded CE level.

The power supply of the GPS system consists of 1000uF electrolytic capacitor which is the part of the filter, so the other peaks which are occurring below 1MHz frequency range are due to the power supply ripple and its harmonics however these peaks are within limits. Figure 3 shows the graph of Frequency v/s. CE level for GPS system without filter.

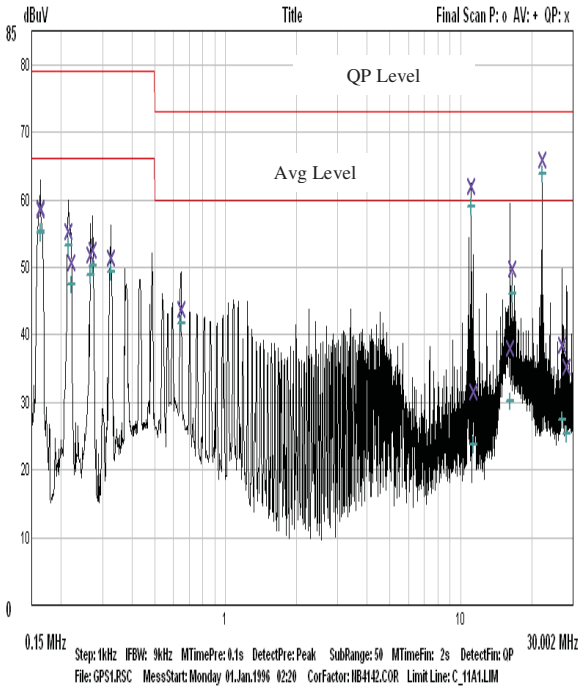

Fig. 3: Graph of Frequency vs. CE for GPS based positioning system without Filter

V. Mitigation Techniques for Conducted Emission

In order for a device to meet the EMC requirements, it must satisfy the requirements set by the American FCC, or European CISPR standards. Following are the techniques which could be helpful to reduce the conducted EMI [3]:

- Grounding technique is a kind of traditional EMI mitigation techniques. It can be applied as either single-point grounding or multi-point grounding; it depends on the noise frequency intended to be reduced. Grounding technique is used to reduce the ground impedance, there by minimizing the potential of ground loop from the circuit consisting of a number of devices/ equipments.

- Shielding is absorbing or reflecting electromagnetic energy via all kinds of shielded material, to prevent external interference or restricting devices emitting electromagnetic energy, preventing interference with other devices. Shielding is commonly a barrier, a thin piece of metal, placed between circuit boards or electronic equipment.

- Filtering is the most effective and common measure to suppress conducted EMI. Design and Implementation of Radio Frequency Filter (RFI) with X and Y capacitors and choke are used in power supply circuits to reduce the CE level within limits.

- The wiring connection to and from the power supply should be reliable and as short as possible to minimize wiring loops.

- Implementation of shielded cables with shield grounded at one end of the equipment.

VI. Results For Conducted Emission Testing With Filter

To reduce the Conducted Emission level, design and implementation of RFI filter has been proposed and implemented. A line filter is made up of capacitors and inductors which form the basic elements. The inductive part is designed to act as a low frequency pass device and as high frequency blocking device whereas the capacitors are used to shunt the unwanted high frequency noise. The basic property of EMI filter is the Insertion Loss characteristics which is basically frequency dependent. It refers to the attenuation offered by the EMI filter. Higher Insertion Loss means increased level of attenuation. Insertion Loss (IL) is the ratio of the signal level, testing without filter (v1) to the signal level with filter (v2) [4, 5].

$$IL\ (dB) = 20 \log_{10} [v1/v2] \quad (1)$$

The required attenuation can be calculated by substracting the limit from the value obtained while tested without filter.

$$(A_{req,\,CM}) = (A_{CM})_{dB} - (A_{Limit})_{dB} \quad (2)$$

$$(A_{req,\,DM}) = (A_{DM})_{dB} - (A_{Limit})_{dB} \quad (3)$$

From attenuation, the value of corner frequency can be calculated by drawing a 40db/dec slope which is tangent to the required attenuation for DM and CM. Ideally a second order filter provides 12dB per octave of attenuation after the cutoff frequency f_0.

$$f_0 = 1/[(2*3.14)\sqrt{(LC)}] \quad (4)$$

Where f_0 is corner frequency, L is the choke value and C is the capacitance value. Its transfer function is given as:

$$f(s) = 1/[1+LS/R_{load} + LCS^2] \quad (5)$$

Now in terms of radians:

$$F(w) = 1/[1+jwL/Rload + j2w2LC] \quad (6)$$

$$\text{Since cutoff frequency } f0 = 1/ [(2*3.14) \sqrt{(LC)}] \quad (7)$$

$$\text{Hence in radian } w_0 = 1/ [\sqrt{(LC)}] \quad (8)$$

and

$$\text{Damping factor} = 1/ 2R [\sqrt{(LC)}] \quad (9)$$

The damping factor describes gain at the corner frequency. As it becomes smaller, the gain at corner frequency becomes larger. From design point of view, minimum damping factor is 0.707, which provides 3dB attenuation at corner frequency. Component values can be calculated as:

CM components: C_y is limited to 3300pF because of safety reasons and the corner frequency $f_{R,CM}$ can be calculated as mentioned in above steps so we get the common mode inductor

$$L_{CM} = [1/2*3.14* f_{R,CM}]^2 * [1/2 C_y][6] \quad (10)$$

DM components: The corner frequency $f_{R,DM}$ has been found in previous steps thus the DM capacitors are

$$C_{X1} = C_{X2} = [1/2*3.14* f_{R,DM}]^2 * [1/L_{leakage}][6] \quad (11)$$

By putting the values of X and Y capacitors alongwith the corner frequency, choke value can be estimated.

Filter Specification: As far as GPS based system is concerned, following are the values for:

Rated Current: 1A
Leakage Current: 2 x 0.3 mA
(X = 0.1uF, Y= 3000pF, L= 30mH, T= 1mH)

Here P.S. = Power Supply, Eqp. = Equipment

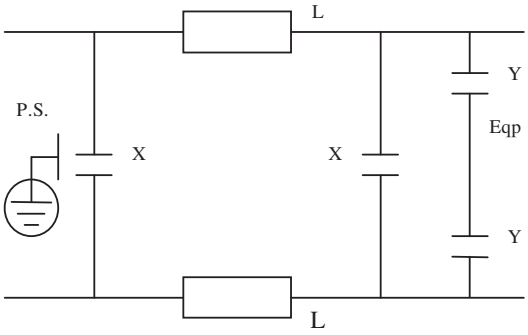

Fig. 4: Schematic of RFI Filter

Figure 4 is the schematic of RFI filter, whereas figure 5 is showing the testing of GPS system with filter [7].

Fig. 5: GPS based positioning system with Filter

TABLE IV: FINAL SCAN RESULTS FOR GPS BASED SYSTEM WITH FILTER

Frequency MHz	Avg. Level dBuV	Avg. Limit dBuV	QP Level dBuV	QP Limit dBuV
0.1640	55.00	66.00	58.82	79.00
0.2150	53.20	66.00	55.29	79.00
0.2210	47.51	66.00	50.59	79.00
0.3250	49.28	66.00	51.45	79.00
11.0570	23.67	60.00	31.63	73.00
16.5920	30.21	60.00	38.10	73.00
22.1180	49.64	60.00	51.28	73.00

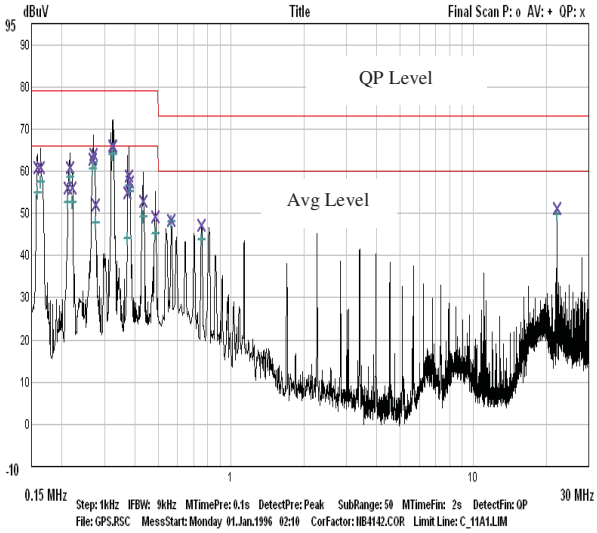

Fig. 6: Graph of Frequency vs. Conducted Emission for GPS based positioning system with Filter

The proposed EMI filter for the mitigation of conducted EMI for the GPS based Vehicle Tracking System has been designed and implemented. After re-testing the system with this filter, the Conducted Emission was found to be within safer limits making the system compatible with the EMC requirements. The average levels with filter, for the frequencies 22.1180 MHz, 0.3250 MHz and 11.0570 MHz have been observed as 49.64 dBuV, 49.28 dBuV and 23.67 dBuV respectively. From the graph shown in the figure 6 and readings as per Table IV, it is clear that peaks are reduced to the safer limits as per CISPR EMI/EMC Standard.

VII. Conclusion

The analysis of Conducted Emission from the GPS based vehicle positioning system has been performed. It was found that the CE level was exceeding the limits, specifically at the frequency of 22.1180 MHz and some of the peaks were at the boundary level of specified limits of the standard. The RFI Filter has been designed and implemented to meet specific requirements of GPS based positioning system. With incorporation of RFI Filter in power supply section, reduction in Conducted Emission level was found to be about 20dB. Results of experimentation indicate the effectiveness of the proposed EMI filter making the GPS based positioning system meeting compatibility requirements as per CISPR EMI/EMC Standard.

***Abstract*—In this paper we present design of a low voltage bandgap reference (LVBGR) for supply voltage of 1.2V which can generate an output reference voltage of 0.363V. Traditional BJT based bandgap reference circuits give very precise output reference but power consumed and area consumed by these BJT devices is larger so for low supply bandgap reference we chose MOSFETs operating in subthreshold region based reference circuits. LVBGR circuits with less sensitivity to supply voltage and temperature are used in both analog and digital circuits like high precise comparators used in data converter, phase-locked loop, ring oscillator, memory systems, implantable biomedical product etc. In the proposed circuit subthreshold MOSFETs temperature characteristics are used to achieve temperature compensation of output voltage reference and it can work under very low supply voltage. A PMOS structure 2stage opamp which will be operating in subthreshold region is designed for the proposed LVBGR circuit whose gain is 89.6dB and phase margin is 74°. Hence a LVBGR is designed which generates output voltage reference of 0.364V given with supply voltage of 1.2 V with 10 % variation and temperature coefficient of 240ppm/°C is obtained for output reference voltage variation with respect to temperature over a range of 0 to 100°C .The output reference voltage exhibits a variations of 230μ with supply range of 1.08V to 1.32V at typical process corner.The proposed LVBGR circuit for 1.2V supply is designed in Mentor Graphics Pyxis tool using 130nm technology with EldoSpice simulator. Overall current consumed by the circuit is 900nA and also the power consumed by the entire LVBGR circuit is 0.9 μW and the PSRR of the LVBGR circuit is -70dB.**

***Index Terms*—Bandgap reference circuit, PTAT, CTAT, temperature coefficient**

I. INTRODUCTION

Bandgap reference (BGR) is a circuit which provides a stable output voltage reference which is temperature and supply insensitive. A precise and stable reference voltage is used in analog to digital (A/D) and digital to analog (D/A) converters, voltage regulators, DRAM etc. As the demands for smaller area, low power consumption and low sensitivity to the supply voltage and temperature are increasing it becomes very essential that we design low voltage bandgap reference circuit.Traditional bandgap reference which use bipolar transistors (BJT) temperature characteristic produce output voltage of 1.2 V which is very precise but the drawback of this BGR is power conumed is very larger so for low supply and current we prefere CMOS transistors which will be made to operate in subthreshold region so that its characters are comparable to that of BJT because MOSFETs operating in subthreshold will operate at very low power supply levels[1].In BGR circuits output reference which is less sensitive can be obtained by adding (PTAT) proportional to absolute temperature voltage and complementary to absolute temperature (CTAT) voltage where PTAT voltage has positive temperature coefficient and CTAT voltage has negative temperature coefficient .In traditional BGR circuits PTAT voltage can be derived from the difference between the base to emitter voltages of the two BJT devices and CTAT voltage can be derived from base to emitter voltage of single diode connected BJT device.The traditional BGR circuits performance was very good because there power supply was large i.e 3V to 5V but this BGR will not be suitable for low supply voltage in proposed circuit i.e 1.2V so in order to obtain a stable refernce voltage at low supply and current we use MOSFETs which are operate in subthreshold region because these transistors operate near threshold voltage Vth so MOSFETs operating in subthreshold minimize power supply voltage.In the proposed circuit PTAT voltage is obtained by taking the difference between the gate to source voltage of two MOSFETs which will be operating subthreshold and CTAT voltage is taken from gate to source voltage of single MOSFET which is also operating subthreshold region and finally by adding the two voltage we get output reference of 0.364V.

The section II describes the traditional bandgap reference circuit, section III describes the proposed bandgap reference circuit, section IV operating principle of proposed bandgap reference circuit, section V includes analysis of simulation results of proposed BGR circuit and section VI concludes the designed bandgap reference circuit.

II. TRADITIONAL LVBGR CIRCUIT

Current-mode bandgap architecture was proposed so that it can works for low supply voltage as shown in Figure. 1.In this architecture addition of currents is done so that it operates for low supply voltages and advantage of this architecture is that it is can provide good PSRR. But the drawback of this current mode architecture is that its output voltage is only temperature compensated current of output resistor so this output voltage can be more sensitive to power supply noise and resistor mistatches as compared to traditional BGR. There are some more disadvantages in this current mode architecture i.e these PNP transistors are process dependent. So in order to over come these disadvantages we chose voltage mode architecture for low voltage bandgap reference circuit.

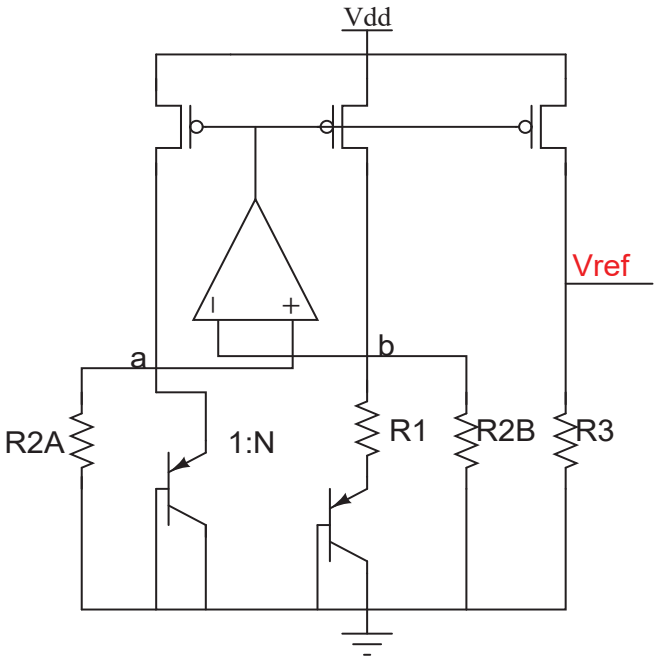

Fig. 1. Traditional Current Mode Bandgap reference circuit

III. PROPOSED LOW VOLTAGE BANDGAP REFERENCE CIRCUIT

The proposed low voltage bandgap reference (LVBGR) circuit uses voltage mode architecture with subthreshold CMOS devices for low power. The LVBGR circuit has 2 main blocks:

A. Startup circuit

Startup circuit is used to ensure that all the device start working correctly in known states during power up. The devices M7, M8 and M9 form a startup circuit and devices M8,M10,M11,M12 and M13 are used to weaken the M8 device. M7 and M8 form an inverter which is a part of startup circuit as shown in figure 3. Initially when supply is off there is no current in core circuit which makes top PMOS M4 and M5 turn on and input to inverter M7 and M8 is logic one and inverter output is zero. The zero output of inverter which turns on the PMOS M9 device whose output initiates the current in core circuit. Once the core LVBGR turns ON startup will turn off and carrying very less current (12pA). The devices M9 will be in subthreshold region, M7 in triode and M8 in saturation region for the proper operation of startup. Also M14 is used to avoid startup problem for Iref generation in opamp.

B. Ireference Generation Circuit

Current Reference for 2stage opamp is obtained from LVBGR P-MOS current M5 and by properly varing the aspect ratio of M15,M16 and M17 device we can obtain the required reference current i.e 50nA for 2stage opamp as shown in figure2 and Vbias for this current reference circuit is taken from Startup circuit in order to over come startup problems.

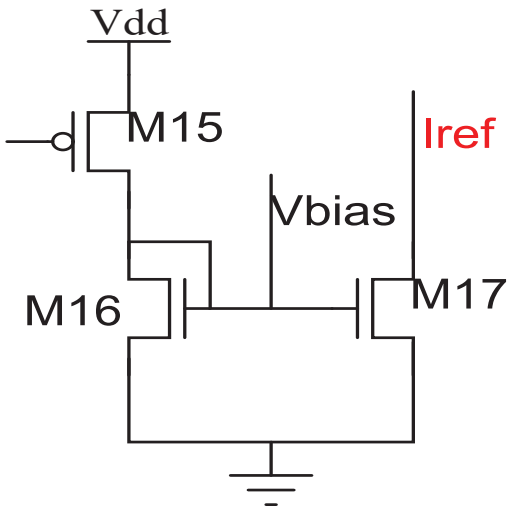

Fig. 2. Ireference generation circuit

IV. OPERATIONAL AMPLIFIER

A two stage Op-amp operating in subthreshold region is chosen to meet the low supply voltage and gain requirement is as shown in figure 2 and Miller-compensation capacitor is used to get good Phase Margin[2]. First stage of 2stage opamp has PMOS differential pair with NMOS current mirrors and second stage has common-source amplifier. The PMOS input pair of 2stage opamp operating in subthreshold is chosen in order to meet the low supply voltage requirement and input common mode range. The devices M4 and M5 are input pair of 2 stage opamp, the inputs of opamp is driven by LVBGR circuit a and b nodes as shown in figure 4. MOSFETS M2 to M6 and M1 and M8 are operate in subthreshold region and are implemented as first and second amplifier stages. TheMiller compensation capacitor Cc provides frequency compensation required to achieve closed-loop stability of the 2stage opamp. Thus entire 2stage opamp is designed to operate in subthreshold region i.e. Vgs $<$ Vth, where reference current carries current of 0.05μA which is generated from LVBGR circuit as explained above and the entire opamp consumes current of 0.45 μA. Load capacitance of opamp is taken from adding all capacitance associated with M4 and M5 devices of LVBGR circuit figure3. The approximated gain, poles and zero of 2stage opamp are given as

$$A_v = A_{v1}.A_{v2} = g_1R_1.g_2R_2 \quad (1)$$

where g1=gm5, g2=gm8, R1=r4,5 || r6,7 and R2=r1 || r8

$$P_1 = \frac{1}{cc.gm2.r1.r2} \quad (2)$$

$$P_2 = \frac{cc.gm2}{c1.c2 + c2.cc + 2(cc)^2} \quad (3)$$

$$Z_1 = \frac{gm2}{cc} \quad (4)$$

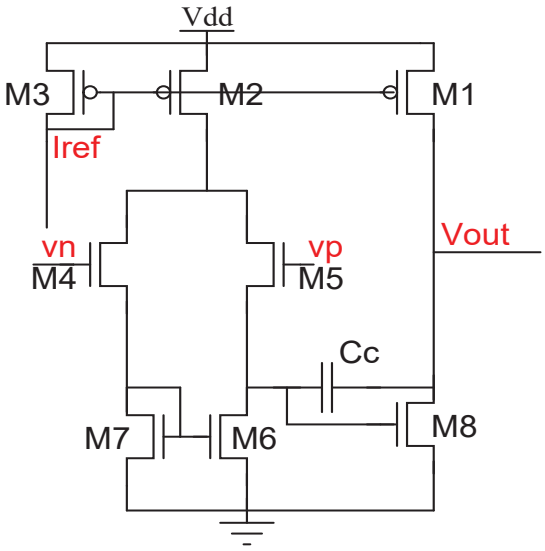

Fig. 3. 2stage opamp operating in subthreshold region

A. OPERATING PRINCIPLE

The CTAT voltage is obtained from gate to source voltage of MOSFET which is operating in subthreshold region which is given as [3]

$$V_{gs} = V_{vth} + \eta V_T[lnC - ln\frac{W}{l} + (\gamma - 2)lnT] \quad (5)$$

Where and n represents MOS constants which are related to the process and C represents Subthreshold MOSFET current. The first-order derivative of equation (1) is a negative value [4] i.e. gate to source voltage of MOSFET which is operating in subthreshold region has negative temperature coefficient. PTAT voltage is obtained by taking the difference between the gate to source voltage of two MOSFETs which will be operating subthreshold with same current flowing through them but with different ascept ratios

$$\Delta V_{gs} = V_{gs1} - V_{gs2} = \eta\frac{V_T}{R_1} + ln\frac{\frac{W_2}{L_2}}{\frac{W_1}{L_1}} \quad (6)$$

if (W/L)2>(W/L)1, then ΔV_{gs} has positive temperature coefficient so with device sizes M2 four times of M1 we get PTAT voltage and from M3 device Vgs3 we get CTAT voltage. Devices M4 and M5 will have the same size to make sure that M1 and M2 will have the same Id drain current flowing through them.Since the input impendence of 2stage opamp in subthreshold is very large so current flowing through M2 is same as current flowing through R1 which is ΔV_{gs} divided by R1.

$$I_2 = \frac{\Delta V_{gs}}{R_1} = \eta\frac{V_T}{R_1}ln\frac{\frac{W_2}{L_2}}{\frac{W_1}{L_1}} \quad (7)$$

M6 mirrors I2.The output voltage reference of LVBGR can written as:

$$V_{out} = V_{gs3} + I_3R_2 = V_{gs3} + \eta\frac{V_T}{R_1}ln\frac{\frac{W_2}{L_2}}{\frac{W_1}{L_1}}.R_2 \quad (8)$$

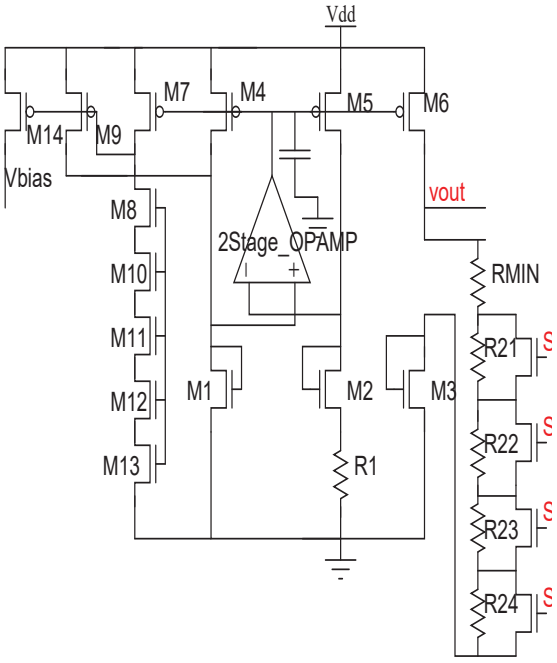

Fig. 4. Proposed low voltage Bandgap reference circuit

Hence the output voltage of LVBGR circuit is obtained by adding the gate to source voltage of M3 device which has negative temperature coefficient and the voltage drop across R2 i.e. the trimming resistors which gives positive temperature coefficient and the effects of positive temperature coefficient and negative coefficient cancells by adding in order to get stable output voltage reference which is less sensitive to supply and temperature. Since the output voltage is taken across both resistor and MOSFET it is less prone to resistor mismatches. R2 is obtained from trimming circuit such that the Vref output is having very less temperature coefficient.

B. Trimming circuit

The trimming circuit is used to reduce the temperature coefficient of output reference voltage of LBGR circuitfor different supply and process corners. A 4 bit series trimming circuit has resistors [10], whose values are chossen by calculating fine and coarse variations of resistors at different supply and process corners. The fine resistor value will be used for minute variations and coarse resistor value will be selected for large variation of resistors for different supply variations and process corners.

R_{MIN0}, R_{MIN1} and R_{MIN2} are minimum resistor values obtained at SS, TT and FF corners in order to get required LVBGR output voltage.Coarse resistors are selected by using the following equations

$$R_{coarse0} = R_{MIN1} - R_{MIN0} \quad (9)$$

and

$$R_{coarse1} = R_{MIN2} - R_{MIN1} \quad (10)$$

and fine resistors are used to make minute variations of resistance value which is require at different process corners and supply in order to get proper LVBGR output.From the figure R_{MIN0}=R_{MIN},$R_{coarse0}$=R21,$R_{coarse1}$=R22, R23 and R24 are fine resistors.These resistors are chosen by NMOS switches by their turn on and turn off which is driven by digital circuit [10].

V. SIMULATION AND RESULTS

Simulations have been carried out using MentorGraphics Pyxis tool with EldoSpice simulator in 130nm CMOS technology with supply of 1.2V with 10 % variations. The operational amplifier used in the proposed LVBGR is 2 stage opamp operating in subthreshold, which gives gain of 89.6db and phase margin of 74 ° as shown in figure 5.

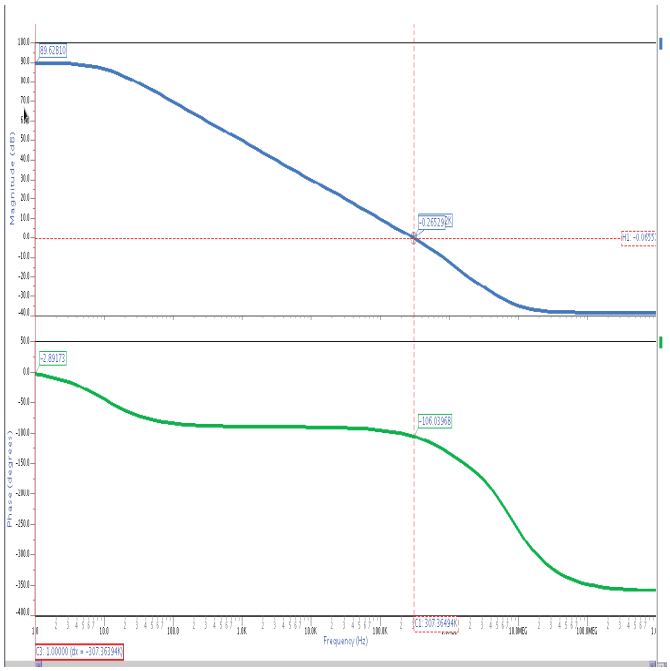

Fig. 5. Gain and Phase plot of 2stage opamp in subthreshold region

Figure6 Shows startup behavior of LVBGR output with supply variation. The time required for LVBGR to produce a stable output is 50μ (27C) and settles at 0.385V. The simulation is carried out using transient analysis.

Figure 7 shows the Vref variation with respect to temperature without trimming circuit and figure 8 shows the Vref variation with respect to temperature with trimming circuit for all the process and supply variation. The output of LVBGR with trimming circuit for supply voltage of 1.2V for TT,SS and FF process corners has variation of output voltage of 230μ with trimming circuit and without trimming circuit it was 132mV. With trimming circuit in LVBGR the temperature coefficient(TC) for all the process corner and supply variation

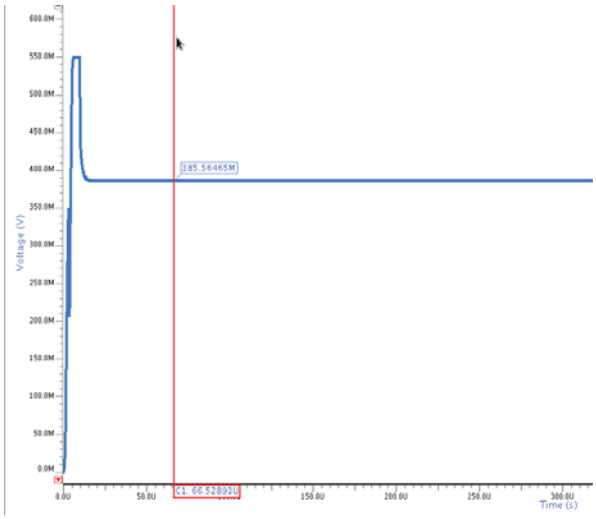

Fig. 6. Start-up behavior of the BGR output voltage with VDD ramp

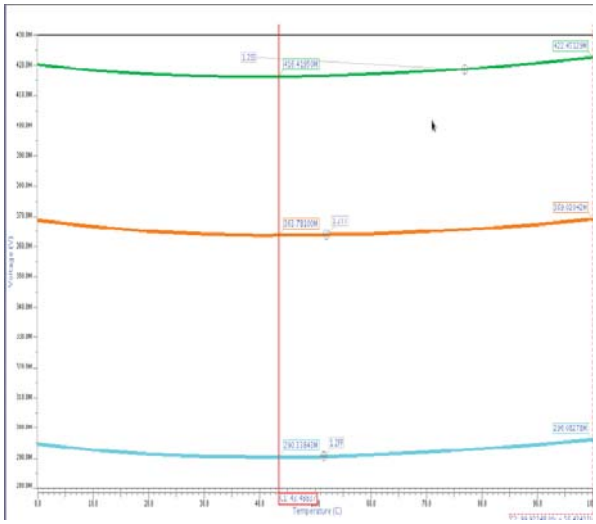

Fig. 7. Vref Vs Temperature for different process corners in LVBGR without trimming cicrcuit

TABLE I
SIMULATION RESULTS OF 2 STAGE SUBTRESHOLD OPAMP

Supply	Process corners	DC gain(dB)	UGB(KHz)	PM(degree)
1.08	TT	89.5	303	74
1.08	SS	90.1	282	75
1.08	FF	87.73	307	74
1.2	TT	89.6	307.36	73.9
1.2	SS	90.16	286.2	74.96
1.2	FF	87.76	316.76	73.7
1.32	TT	89.6	306.6	75
1.32	SS	90.2	294	75.2
1.32	FF	87.79	311	75

is 827ppm/ °C. Hence the output voltage variation of LVBGR is reduced with the help of trimming circuit.

The performance metric of different architectures of low

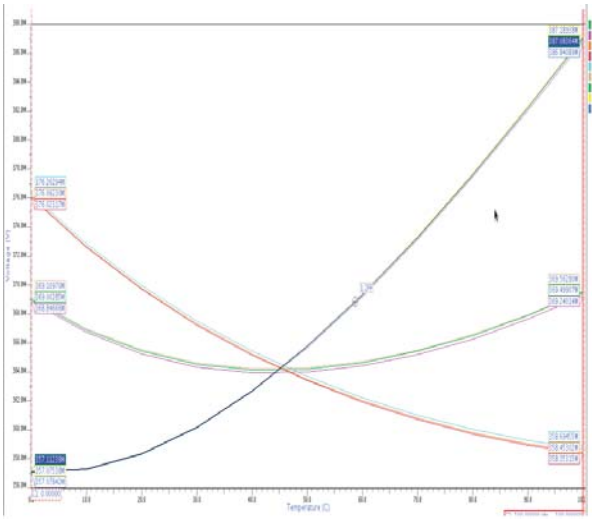

Fig. 8. Vref Vs Temperature for different process corners in LVBGR trimming cicrcuit for all the process and supply variation

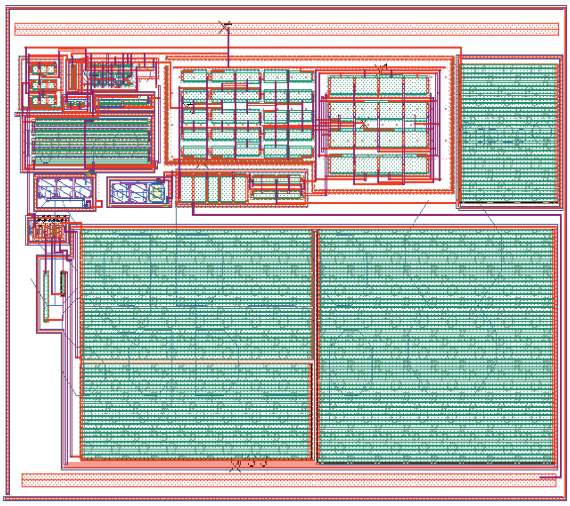

Fig. 9. Layout of proposed LVBGR circuit

TABLE II
PERFORMANCE COMPARISON OF LOW POWER BANDGAP REFERENCE CIRCUITS

Parameters	[5]	[6]	[7]	[8]	[9]	Proposed Design
CMOS Tech.	0.35	0.18	0.18	0.45	0.13	0.13
Vdd (V)	0.87	1	0.9 to 2.5	0.8	0.6	1.2
Vref(V)	0.611	0.630	0.22	0.310	0.429	0.34
Temp. range °C	-10 to 70	-20 to 70	-20 to 120	0 to100	20 to 80	0 to 100
TC ppm/ °C	20	93.33	-	14.62	25.6	240
Power μW	45	86.19	3.3	13.73	-	0.9

voltage bandgap reference are shown in table1. From the table it can be seen that the proposed LVBGR circuit has got a VREF output of 0.364V with subthreshold MOSFETS. By using voltage mode architecture the proposed circuit achieved temperature coefficient of 240ppm/ °C. Layout of proposed LVBGR circuit is as shown in figure9 which occupyies an area of 100μmx80μm.

VI. Conclusion

A bandgap reference with low supply voltage is presented by using the characteristics of subthreshold MOSFET. It can work under supply voltage of 1.2V with 10percentage variation which gives temperature coefficient of 240ppm/ °C. Compared with traditional current-mode BGR for low voltage application, the proposed LVBGR circuit is less sensitive to resistor mismatchs. Output variation is reduced from 132mV to 230μV with the help of trimming circuit.Simulations are done using MentorGraphics Pyxis tool with EldoSpice simulator in 130nm CMOS technology and the entire circuit of LVBGR consumes 9nA of current and total power consumption of 0.9W and this LVBGR circuit is used for low dropout reference(LDO) application which will be having a supply of 3.3V and must produce an output voltage of 1.8V.

VII. Acknowledgment

The authors would like to thank the SmartPlay Technology for their support in designing the low voltage bandgap reference circuit.

***Abstract**: Clustering is a group of patterns, classes or concepts .The main goal of clustering is to represent large datasets by a fewer number of clusters or prototypes. The ease of modeling data plays a central role in the process of knowledge discovery of data (KDD). We propose a PSO based relevance feedback & GA approach for data clustering to improve the accuracy of the results. First to implement the concept of relevance feedback for clustering based on parameters like mean, standard deviation, minimum value, maximum value, rank & accuracy. RFB uses the number of nearest neighbors from different classes of dataset for a particular query point using various similarity metrics like camberra distance, chebyshev distance etc. Second by implementing particle swarm optimization, this is a computational method for finding the best global optimum solution. Genetic Algorithms, being global search technique, have been widely applied for discovery of clusters. It aims to enhance the accuracy by incorporating PSO in the results presented to the user for analysis. Combining RFB with PSO & GA with PSO is the third method. Finally it can be ascertained that combined approach i.e., GAPSO gives better accuracy compare to RFBPSO algorithm.*

Keywords: RFB, GA, PSO, accuracy, similarity metrics, RFBPSO & GAPSO.

I.INTRODUCTION

Data mining is a detection process that allows users to comprehend the substance and relationships amid the data. Data clustering is the technique of consorting of data objects into dissimilar groups or clusters, which is the main task in data mining. Objects have utmost similarity, within the cluster. Outside the cluster, other objects are divergent to each other. Based on the attribute values the objects similarities and dissimilarities are assessed. Data clustering is a method in which we make cluster of objects that are somehow similar in distinctiveness [6, 7].

Relevance feedback is a feature of some information retrieval systems. The connotation of feedback is to obtain the user vector values and use the information to analyze whether the results are relevant to a new query.

Darwin's theory inspired Genetic algorithms development. GA is evolved to resolve solution to this problem [2, 3, 4, and 5]. Algorithm starts with a set of solutions (chromosomes) known as population. Outcomes from a population are taken and used to structure a new population. This is aggravated by optimism, and the new population will better the old. Chosen solutions are used to form new solutions (offspring) which are selected according to their fitness values- the more apposite will lead to more chances of reproduction.

Particle Swarm Optimization (PSO) is a population based algorithm [1]. Even though the search process is not random it searches for optimum solution. RFB is a type of correlation analysis and to perceive attributes which do not bestow to the clustering attribute subset assortment can be used. Genetic algorithm, were in each 'individual' of the generation represents a feasible solution to the problem, coding distinct algorithms/parameters should be evaluated by a fitness function.GA operators cause mutation (change of random position of the chromosome) and crossover (change of slices of chromosome between parents).

Relevance feedback supports for the general quadratic distance metrics. Similarity measure is defined such that relevance degrees between objects are respected when they are ranked according to their pair wise similarity [8, 9, 10, and 11]. A novel particle swarm optimization with genetic algorithm is an optimization task which runs after the genetic algorithm, later terminates in order to improve the value of fitness function. Final point from the genetic algorithm is taken as initial point in this function. Particle Swarm Optimization (PSO) is a swarm intelligence method for global optimization. Each unique object of the population adjusts its path to its own prior finest pattern, and towards the preceding finest position attained by any member of its topological vicinity in classical PSO. To trace the exact place of the cluster centers, a cluster center movement RF & GA is combined with PSO.

II.RELEVANCE FEEDBACK ALGORITHM

One among the adopted solutions was to directly take benefit of the human proficiency in the retrieval process, known as Relevance Feedback (RF). For a certain retrieval objects, user has to offer feedback by spotting the results as relevant or non- relevant data objects. With this information, the system then repeatedly computes an enhanced depiction of

the information desired and also retrieval is further refined. Relevance feedback (RFB) is a technique that helps searchers improve the accuracy of their query statements and has been shown to be effective in non-interactive experimental environments. RFB ppseudo-code can be represented as:

[1]In the clustering phase, *k* is a user-defined constant, and an unlabeled vector (a query or test point) is classified by calculating the distance between the cluster seed point and all the points in the dataset.

[2]The loop repeats until all the points in the dataset are completed.

[3]The obtained distances are then sorted and according to the k value, those neighbors are plotted on the graph.

[4]The user preferences are then taken into consideration.

[5]Distances are calculated between the cluster seed point and points in the user vector.

[6] These distances are also sorted and according to the k value, those neighbors are marked or plotted on the graph in addition to the already retrieved neighbors.

[7]If the neighbor lies in a particular class, then it is considered as true positive otherwise it is taken as true negative.

[8]Accuracy is calculated based on the true positive and true negative value the.

A. Similarity Metrics

In most algorithms, the dataset to be classified is represented as a set of objects X={x1, x2, …., xn}, where the object *xi* corresponds to a single object and predicts to which class label it belongs[1]. Over the years, two prominent ways have been proposed to compute the similarity between objects m_p and m_j

B. Camberra Distance

The Camberra distance *d* between objects **x** and **y** in an *m*-dimensional object space is given by:

$$D(x,y)=\sum_{i=1}^{m}\left|\frac{(x_i-y_i)}{(x_i-y_i)}\right|$$

Where $x=(x_1,x_2,...,x_m)$ and $y=(y_1,y_2,...,y_m)$ are two points in Camberra *m*-dimensional space[5].

C. Chebyshev Distance

The two dimensional manhattan distance also has circles in the form of squares, with sides of length $\sqrt{2}r$, oriented at an angle of $\pi/4$ (45°) to the coordinate axes, the planar Chebyshev distance can be viewed as equivalent by rotation and scaling to the planar manhattan distance. The Chebyshev distance between two objects x and y, with standard coordinates xi and yi, respectively in m-dimensional object space, is specified by:

$$D(x,y)=\max_{i=1}^{m}\left|(x_i-y_i)\right|$$

where $x=(x_1,x_2,...,x_m)$ and $y=(y_1,y_2,...,y_m)$ are two points in Chebyshev *m*-dimension space.

D. Chi-square Distance

The Chi-square distance *d* between objects **x** and **y** in an *m*-dimensional object space is given by:

$$D(x,y)=\sum_{i=1}^{m}\left(\frac{1}{sum_i}\right)*\left[\left(\frac{x_i}{size_x}\right)-\left(\frac{y_i}{size_y}\right)\right]^2$$

sum_i is the sum of all values for attribute *i* taking place in the training dataset, and $size_x$ is the sum of all values in the object ***x***.

E. Cityblock Distance

City block distance is also called as manhattan distance

$$D(x,y)=\sum_{i=1}^{m}|xi-yi|$$

City block distance is a exceptional case of the minkowski metric where p=1.

F. Kendall Rank Correlation

The Kendall Rank Correlation distance *d* between objects **x** and **y** in an *m*-dimensional object space is given by:

$$D(x,y)=1-\left(\frac{2}{n(n-1)}\right)*\sum_{i=1}^{m}\{\sum_{j=1}^{i-1}[(x_i-x_j)*(y_i-y_j)]\}$$

Where $x=(x_1,x_2,...,x_m)$ and $y=(y_1,y_2,...,y_m)$ are two points in object *m*-space and n is the number of observations in the given dimension space.

G. Kulczynski distance

The Kulczynski distance *d* between vectors **x** and **y** in an *m*-dimensional real vector space is given by:

$$D(x,y)=\sqrt{\frac{\left(\sum_{i=1}^{m}|x_i-y_i|\right)}{\min(x_i,y_i)}}$$

where $x=(x_1,x_2,...,x_m)$ and $y=(y_1,y_2,...,y_m)$ are two points in vector *m*-space.

H.Sorensen distance

The Sorensen distance *d* between vectors **x** and **y** in an *m*-dimensional real vector space is given by:

$$D(x,y)=\sqrt{\frac{\left(\sum_{i=1}^{m}|x_i-y_i|\right)}{\sqrt{\left(\sum_{i=1}^{m}|x_i-y_i|\right)}}}$$

where $x=(x_1,x_2,...,x_m)$ and $y=(y_1,y_2,...,y_m)$ are two points in vector *m*-dimensional space.

III.GENETIC ALGORITHM

Conceptual representations of realistic solutions are represented by GA work with a population of individuals. Performance of the solution it represents is measured by individuals assigned fitness function. Fitness function of each individual is measured in each generation. To form a new population individuals are stochastically elected from a current population (based on their fitness), and customized by means of operators mutation and crossover.

Genetic Algorithms Operators

The fundamental genetic algorithm operators are crossover and mutation. These two operators are work together to explore and exploit the search space by creating latest variants in the chromosomes. Many experimental studies have been carried out on the similarities between crossover and mutation. It is confirmed that mutation operator play the similar important role as that of the crossover.

A. Crossover

Fundamental role of the genetic algorithms is that crossover (recombination) plays best design and implementation of vigorous evolutionary systems. Through GA, individual are epitomized by fixed-length strings and crossover operates on pairs of individuals (parents) to construct new strings(offspring)by exchanging segments from the parent strings. Traditionally, the number of crossover points (which determines how many segments are exchanged) has been stable at a very low constant value of 1 or 2.

B. Mutation

Mutation is a common operator which is used to evaluate and preserve diversity in the population by finding new points in the search space. A random change is made to the values of some locations in the chromosome, when a chromosome is chosen for mutation. Single point mutation is the commonly used method. This type of special mutation is used for various kinds of problems and encoding methods.

IV. PSO ALGORITHM

PSO is an evolutionary based computation method that performs robust and efficient optimization. It's a population-based optimization procedure, where in a population is termed as a swarm. The fundamental thought depicts, each particle represents a prospective resolution which it updates according to its own experience and that of its neighbors. The PSO technique searches in analogous via group of individuals. Individuals in as swarms, surface to optimum solution through the current velocity, prior experience and the experience of its neighbors. PSO will search the problem domain when trajectories of moving points are adjusted in multi-dimensional space. For optimal solution, the activity of individual particles is governed through the interactions. The connectivity among individual particles is established by the position, velocity, best performance of individuals and their neighbors.

Notations for PSO

1.The position of the i^{th} particle of a swarm of size n, is projected by the D-dimensional object space, xi= (xi1, xi2, ..., xiD).

2.The best previous position (i.e., the position giving the best function value pBest) of the i^{th} particle is recorded and represented by pi= (pi1, pi2, ..., piD).

3.The position change (velocity) of the i^{th} particle is Vi=(Vi1, Vi2, ..., ViD) .

4.The position of the best particle of the swarm (i.e., the particle with the smallest function value) is denoted by index gBest.The particles are then manipulated according to the following equations.

$$V_{id}(t+1) = V_{id}(t) + C_1*rand*(pBest(t) - x_{id}(t)) + C_2*rand*(gBest(t) - x_{id}(t)); \quad (1)$$

$$x_{id}(t+1)=x_{id}(t)+V_{id}(t+1) \quad (2)$$

where d=1,2,…..D and i=1,2,…..n.

V: Velocity

C1, C2: positive constant parameters =1.49

rand: random numbers between (0,1)

V.RELEVANCE FEEDBACK WITH PARTICLE SWARM OPTIMIZATION (RFBPSO)

Relevance feedback success depends on positive assumptions. Initially, the user must have ample knowledge to make first seed point, proximity to the object they covet. Anyhow greatly needed for victorious information retrieval in the essential case, but it is vital to observe the kinds of problems that relevance feedback cannot work alone Relevance feedback can also have realistic problems. The seed point that is generated by straightforward application of relevance feedback techniques is inefficient for a typical IR system. Good performance will incur for this fallout and also result in potentially long response times for the user.

Pseudo-code of RFB when combined with PSO:

- Using RFB alone gives less accuracy and the performance is low.
- It overcomes the drawbacks of RFB Algorithm.
- The output obtained by Relevance Feedback technique is given as input to the PSO. Thus the best algorithm can be found which can do efficient retrieval. Thereby, efficient results are obtained.

VI. GENETIC ALGORITHM WITH PSO

Information sharing is notably dissimilar when compared with genetic algorithms in PSO. In GAs, sharing of information among chromosomes takes place which triggers a complete population movement resembling single group movement to best possible solution space. With PSO, information can be passed to other objects by gbest (or lbest) solution. In local version of most cases, all the particles tend to converge to the best solution rapidly when compared with GA. Degrade in regulation of its speed and direction indicates PSO algorithm suffering from the partial optimism.

Procedure for PSO with GA

1. Apply GA on the datasets for clustering.
2. The results are passed to the PSO for execution.
3. PSO is applied on the output obtained from GA.
4. Repeating step 2 and 3 until the convergence is achieved

VII.RESULTS & DISCUSSION

The experiments results have been carried out to authenticate the accuracy of the proposed model. The properties of the dataset are described as:

A. Data sets

Examining the conduct of the respective clustering methods, Iris data sets are used.

Iris plant data set: Which is comprised of 150 data points, include 50 instances of all the three types of iris plant.

B. RFB Algorithm Results

An assortment of similarity metrics like are camberra distance, chebyshev distance, chi-square distance, cityblock distance , kendall rank correlation, kulczynski distance & sorensen distance are analyzed for the number of nearest neighbour from different classes of dataset for a particular seed point.

C.Figures and tables

Attributes	Min	Max	Mean	StdDev
Sepal Length	4.3	7.9	5.848	0.829
Sepal Width	2	4.4	3.054	0.436
Petal Length	1	6.9	3.774	1.761
Petal Width	0.1	2.5	1.206	0.76
Sepal Length	4.3	7.9	5.848	0.829

Table-1: Comparison of min, max, mean and standard deviation of each attribute for iris dataset.

For each attribute of iris dataset four different measures min, max, mean, standard deviation are specified.

Table-2: Selection of attributes for iris dataset based on rank priority

ATTRIBUTES	RANK
Sepal Length(1)	0.43
Sepal Width(2)	0.73
Petal Length(3)	1.351
Petal Width(4)	1.427

Above table-2 states that the rank value is better for third and fourth attributes i.e., petal length and petal width compare to other attributes.

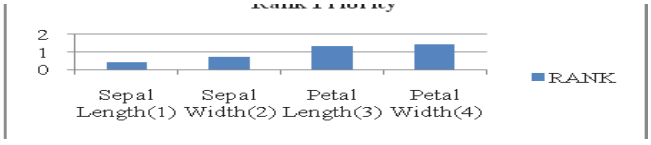

Figure-1: Selection of attributes for iris dataset based on rank priority

The figure-1 depicts that the rank value is better for third and fourth attributes with utmost values (1.351, 1.427) compare to other dimensions.

Table-3: Accuracies of iris dataset for different metrics in RFB.

Metric	Accuracy
Camberra	66.666
Chebyshev	33.333
Chi-square	33.333
Cityblock	66.666
Kendall	33.333
Kulczynski	66.666
Sorensen	66.666

The table-3 states that the accuracy is better for Camberra, Cityblock, Kulczynski and Sorensen distances on iris dataset when compared to other similarity measures.

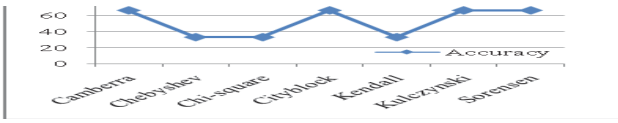

Figure-2 Comparison between the accuracies of Iris dataset for different metrics for RFB.

D.PSO

Comparison of PSO is done between the OFV and CPU time with the clusters. By taking various cluster values the comparison is done between cluster and time and also between cluster and OFV for PSO algorithm.

Table-4: Analysis of PSO Algorithm based on OFV and Time for iris datasets

DATASETS	OFV	TIME
Iris	-107.0286	33.1000 sec

Time exhausted on relevance analysis along with the time spent on learning from the resulting reduced dimensions (or feature) subset, must be lesser than the time that would have been spent on learning from the original set of attributes. Hence, these results are able to better clustering accuracy and scalability.

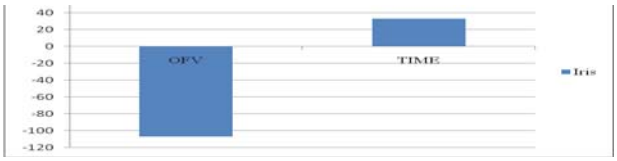

Figure-3: Comparison between the OFV and Time for iris datasets with PSO

E.RFB with PSO:

Relevance feedback lets the user guide the system.Various similarity metrics like Camberra distance, Chebyshev distance etc are being used for analysis. The output matrix obtained after applying RFB on the datasets is given as input to the PSO algorithm and thus we get RFBPSO algorithm.

Table-5: Comparison of distance metrics for Iris dataset for fitness and time

Algorithm	OFV	Time
Camberra	-82.6139	11.912
Chebyshev	-14.4605	12.357

Chisquare	-82.6139	12.193
Cityblock	-14.4655	12.359
Kendall	-154.3372	11.983
Kulczynski	-82.6139	12.691
Sorensen	-82.6139	11.961
Euclidean	-14.4605	12.595810

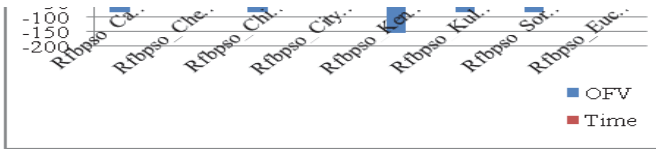

Figure-4: Comparison of distance metrics for Iris dataset for fitness and time

The table-5 & figure-4 depicts that Kendall distance is better for iris dataset compared to other similarity measures since it has the low OFV value and low CPU time.

F. Genetic Algorithm Results

In order to show the results there has been a comparison done between the OFV and time with the clusters. By taking various cluster values the comparison is done between cluster and time and also between cluster and OFV for PSO algorithm for all the datasets.

Table-6: Analysis of PSO_GA algorithm on four datasets based on OFV & time.

Datasets	PSO	GA_PSO
PSO_GA based on OFV		
IRIS	-107.8089	-147.2694
PSO_GA based on time in seconds		
IRIS	32.928	34.084

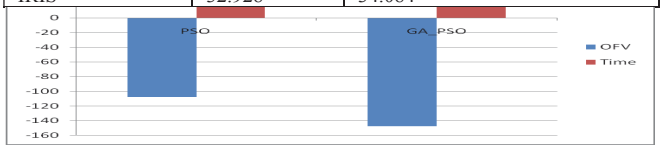

Figure-5: Analysis of PSO & GA_PSO algorithm on iris datasets based on OFV & time.

From table-6 and figure-5 it can be stated that GA_PSO is better algorithm in terms of OFV and it takes slightly more time than PSO but the difference in OFV compensates the time factor. Faster convergence rate because when stagnation of PSO occurs, even though the solution is worse GA diversifies the particle position which makes PSO_GA extra flexible and robust. Distinct to standard PSO, PSO_GA is extra consistent in giving better fitness solution with reasonable computational time. Experimental results are examined with benchmarks functions and outcomes specify proposed PSO_GA model betters the standard PSO.

VIII.CONCLUSION

PSO with combination of techniques for its relevance feedback & GA convey gleaming clustering results. Using RFB approach difficulties may arise if the data set is very large and incorrect assumption of seed point results in a more overheads for retrieval and potentially long response times for the user. Relevance feedback success depends on certain assumptions. The user must have generous knowledge to make an initial seed point which must have close proximity to the data objects they aspire. For exultant information retrieval in the fundamental case these are desired, also vital to observe various problems that relevance feedback cannot solve alone. RFB is used to compensate the semantic gap between low level attributes, high level attributes and also accuracy improvement. Solving optimization problems on the natural selection is the best method to defeat this GA. GA endeavours best point in population which later reaches to optimal solution with rapid convergence rate. The end results are the fusion of PSO_GA whose performance is notably enhanced when compared to former algorithms for these data sets.

***Abstract*— Since its dawn in mid-1980's, till the present time, the Mobile Cellular Communication (MCC) has been following a common silhouette of the network architecture. In every generation of the mobile cellular technology, the final radiating elements or antennas are exclusively mapped to their respective Base Stations (BS). Moreover, in earlier generations of MCC, antennas were deemed collocated with their respective BSs. Later, the concepts like Distributed Antenna Systems (DAS) and Cloud RAN (C-RAN) made it possible to place these antennas distant from their respective BSs. However, being mapped with their respective base stations, spectrum pooling and management at antenna end is not efficient. The situation worsens in Heterogeneous and Dense-net conditions in an Area of Interest (AoI). In this paper, we propose a DAS based intelligent architecture referred to as Self Configurable Intelligent Distributed Antenna System (SCIDAS) that can simultaneously accommodate multilayer communication environment over a common BS.**

Keywords—Distributed Antenna Systems; Cloud RAN; Intelligent Networks;

I. INTRODUCTION

This section describes those challenges and limitations that are in present Mobile Cellular Networks (MCNs) and have motivated the idea discussed in this paper.

A. Background

The upswing in MCC evolved in steps of technological advancements that we call as "generations" of mobile communications [1]. With every new generation, the service providers demand better spectrum utilization and approachability with more control over the Capital and Operational Expenses (CAPEX and OPEX). However, when viewed in the background of the present overwhelming growth rate of potential subscribers and data based services [2], this demand is still bewailing for parity. The transfiguration of the mobile user equipment from a mere communication device to a personalized access and media center was the primary reason for the booming rise in capacity demand per subscriber. Ergo, technologies and architectures have been transmogrified over the time to satisfy these ever overwhelming demands, especially, the subscribers' capacity demand. This growth expectancy is lucidly mentioned in "The Mobile Economy 2014" report [3], which nicely shows the collaborative and individual transitional growth of the various technologies.

Like any other transient evolution, the existing technologies are bound to overlap with upcoming technology/ies in the same length of time and form a composite network environment. And, as newer technologies involve a more recent style of network planning, it is taking considerable time for the service providers to upgrade the network. As an example, by the time some service providers upgraded their network from 2G/2.5G to 3G (LTE), the newer technology LTE –Advanced (4G) knocked the door. Therefore, the technological overlap is a long lasting event before a technology becomes the solo MCC platform. Till then, it is required to have a multi-layered network that has backward compatibility with the previous generations. Therefore, the newer technologies like 5G [4] will be bound to maintain this hierarchical polymorphic network approach. Hence, the *coexistence* of the various generations in same time span is one of the major challenges in present and future wireless networks.

Another "hard to swallow" problem in the present and future times of the MCN is the approachability (coverage). As in previous generations, the lower capacity demand enabled higher spectrum reuse, certain carrier bands such as 900 MHz (mostly used for GSM technology) proved to be sufficient in the covering PAN areas by traditional discrete base station subsystems (BSSs). However, in the aeon of high capacity demanding subscribers, it is imminent to disseminate the carriers in every corner of the service area. Following these demands, the network architecture of 4G LTE is significantly trimmed as compared to its previous generations(such as removing the Base Station Controller from the conventional architecture) to fit into the Area of Interest (AoI) or service area [5]. However, such architecture is not ample enough to beat the whooping network requirements. Hence, an advanced architecture that is easy to deploy and manage the scarce spectrum resource efficiently is required. Next we discuss the limitations of LTE that raises the motivation to look for more.

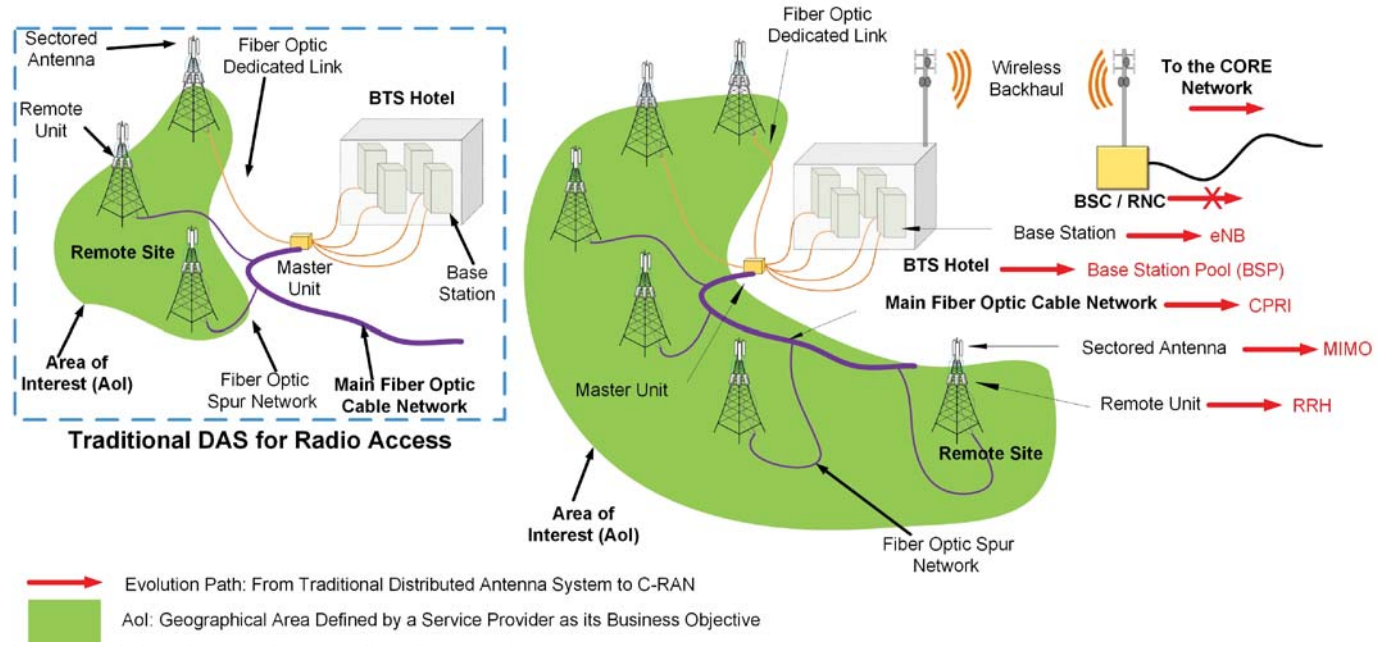

Figure 1: Evolution of C-RAN from a Traditional DAS Architecture

B. Motivation: Evolution and Limitations of LTE

Figure 1 shows the evolution of LTE architecture, where the Base Station (BS) is evolved as a clever amalgamation of the Radio Network Controller (RNC) and the Base Stations (BS) of the previous generation architectures. Therefore, an LTE BS, known as evolution-NodeB (e-NodeB or eNB) is directly connected to the core network and is simpler to deploy as compared to the previous mobile generations. The radio access part of LTE technology is known as Evolved UMTS Terrestrial Radio Access Network (E-UTRAN) [6][7]. One of the unique features of the EUTRAN that has revolutionized the deployment efficiency is the distributed BSs. This feature uses the conventional Distributed Antenna System (DAS) concept, as also shown in Figure 1, to separate the serving base stations from the radiating elements.

The distributed BS architecture of LTE allows antennas to reside near the vicinity of the strategic positions whereas; the corresponding BS may reside distant apart which saves the cost of BS equipment (as in discrete architecture) and infrastructure. Like a usual DAS, in LTE, the conversion of optical bits to RF is handled by the Remote Radio Head (RRH). The RRH receives the optical signal, converts it to digital and then to analog sinusoidal waves and feeds it to the serving antenna. The eNB-RRH concept is extrapolated to the larger context and evolved to what we know as the Cloud Radio Access Network (C-RAN) [8][9]. As discussed in [9] and [10], that, in a C-RAN the eNBs collocate at a central location that we call here as Base Station Pool or BSP (also known as Master Base Station, Centralized Base Band Unit, etc., see, figure 1) and the remote antennas are connected with RRHs for further feeding to antenna/s.

In spite of a very efficient architecture, the C-RAN is still a BS centric solution; just like any conventional architecture. This is because even though a service provider may enjoy better spectrum management using C-RAN due to better spatial carrier distribution, however, this flexibility is limited to the BS to which the RRHs belong. Thus, a subscriber in C-RAN network is still tied to a particular BS, although, the roaming space is considerably increased. Consequently, it can be observed that every antenna in the C-RAN (as in traditional DAS network) has a strong belongingness towards the feeding eNBs (also known as Baseband Unit or BU) at BSP. This leads many limitations, and the following are relevant to the present paper:

1) Just like traditional DAS network, all RRHs are exposed to all carriers of BSs at BSP. As the received signal at the user end is the superimposition of the signal levels from all the surrounding nodes, in an ultra dense network (Dense-net), this may lead to high interference situations.

2) Infrastructures convolve around respective technologies and are not considered as an independent concept. Therefore, much of the investment in an infrastructure is worthless once a newer technology takes over.

3) It is practically unviable to lay a high capacity fiber network at every possible place in AoI. Therefore, C-RAN architecture has limited scope.

4) Although, being placed on the user ends, RRHs along with their antennas do not have any idea about subscriber behavior at the particular location in AoI.

5) Also, remote units do not participate in the holistic physical restructuring of the network for the betterment of the network environment and subscriber needs in the AoI.

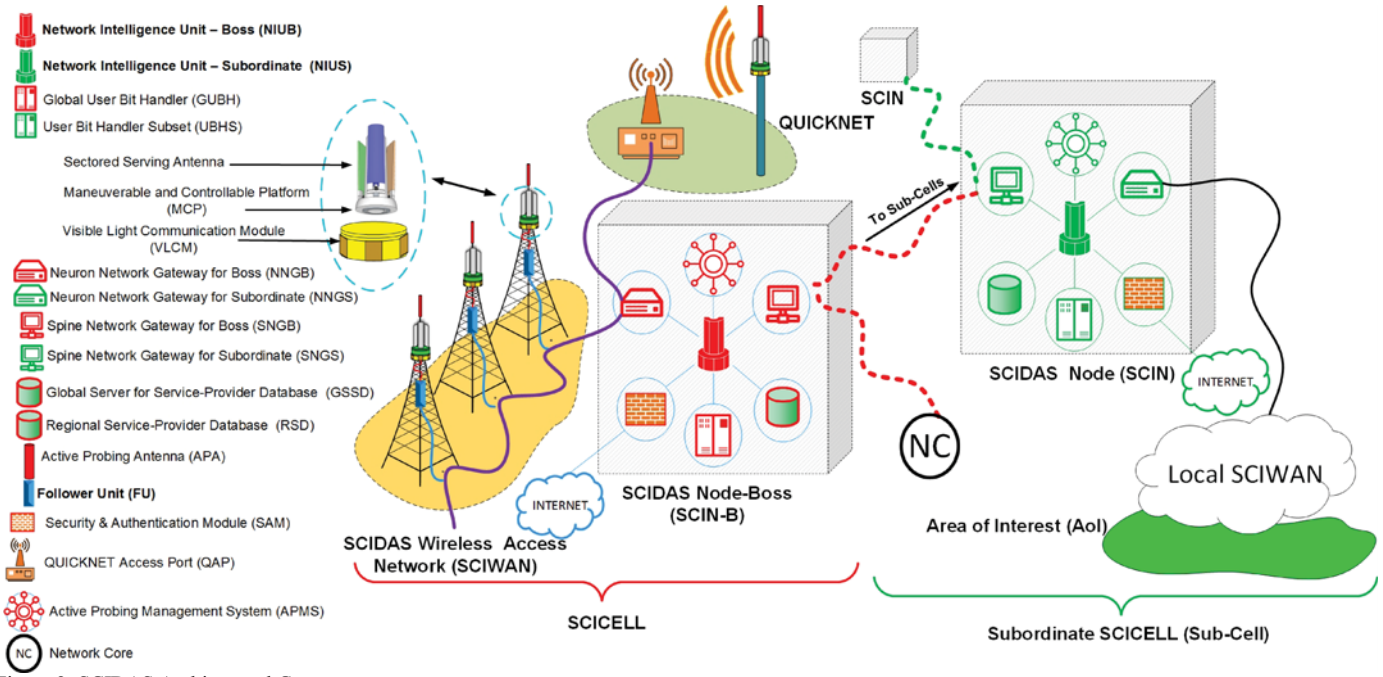

Figure 2: SCIDAS Architectural Components

6) RAN sharing (multiple service providers on common RAN infrastructure) will only distribute the additional resources over the existing infrastructure and not over the actual areas in need.

7) The existing networks respond to on-demand basis and are not proactive to the dynamic network environment.

8) Newer technologies will require overhauling of entire network elements and infrastructure as well.

9) Coexistence of new and old layers is a challenge in the present environment. Sharing RAN and CORE is only limited to basic infrastructural elements such as tower, shelter, rooms, power line, etc.

Our previous work [11] identified the challenges that wobble up when subscribers density vary significantly from place to place in AoI. [11] focuses on the significant variation in the network behavior even though the subscribers' count is constant in AoI, which means that the capacity requirement is dependent not only on the subscribers' count but also their movement and position. This phenomenon was termed as *Place Time Capacity* [11].

II. SCIDAS CONCEPT

Figure 2 shows the basic components of the *Self-Configurable Intelligent Distributed Antenna System (SCIDAS)*. The SCIDAS has an intelligence layer over the DAS-based C-RAN network for intuitive, proactive and efficient spectrum utilization. By intelligence, we mean the *ability to respond to dynamic network conditions at each and every remote unit distinctively, exclusively and simultaneously*. This is possible only when there is a common intelligent unit that generates location-specific instructions, and there are intelligent followers at each remote unit to receive and respond to these instructions. Also, please see legends of Figure 2 to refer the abbreviations used this point onwards. The major components of SCIDAS (see Figure 2), are the following (other components will be explained as they appear during discussion):

1) SCIDAS adopts a hierarchy in its architectural elements that we distinguish in two categories, the Boss and Subordinate/s (or *Sub/s*) (see figure 2). At the Boss level, processes like gathering, planning, deciding and configuring the global and respective local network functions will be carried out for the SCIDAS Network level, whereas, Sub functions are strictly local.

2) BTS Hotel or BSP equivalent in SCIDAS is the SCIDAS Node (*SCIN*). The type of SCIN, which will encapsulate the Boss elements, is the *SCIN-B*.

3) The *Network Intelligence Unit (NIU)* is a component residing in the SCIN. This entity adds technology independent intelligence functionality layer on the top of the present DAS paradigm. We distinguish between two types of NIUs, Boss (*NIUB*) and Sub (*NIUS*), based on the roles they perform (discussed later in this paper).

4) The *Follower Unit (FU)* is the equivalent of RRH in C-RAN; it differs from the RRH by its wide multi-technological support. As RRHs are responsible for feeding the antennas with carriers, in SCIDAS, we propose the radio part to reside only in FU (rather than BS, as in conventional architectures). This will enable NIU to select the individual carriers/subcarriers and to feed individual antenna differently. FU performs according to instructions from NIU rather than the Base Band Unit (*BBU*) thereby making SCIDAS more

5) suitable for the multi-technology and dense-net environment.

6) Unlike the usual DAS/C-RAN, SCIDAS has two layers of the distribution network. First one, the *Neuron Network (NuN)*, will fan out from respective NNGB/S to connect the FUs (*SCIWAN*). This will be done through fiber optic network/s or the wireless access port/s, QAP. The QAP is an easy deployment option for inaccessible areas (in terms of laying optical fiber) and/or sporadic network scenarios as a sub-network system (branched expansion) that we call as *QUICKNET*. We call a SCIN with its respective SCIWAN as a *SCICELL*. This SCICELL is building-block that will repeat in entire AoI.

7) The second network layer, the *Spine Network (SpiN)*, will connect the SCICELLs with each other through a high capacity network (Fiber or wireless) via respective SNGB/S.

8) The *Maneuverable and Controllable Platform (MCP)* is the docking station for the antennas and resides at the FU. MCP, as shown in figure 2, handles the physical conditioning of the network by orienting and tilting the antenna of every sector of the remote unit. MCP is controlled by the NIU via the FU by sending instructions to the FU.

9) *The Global User Bit Handler (GUBH)* is a type of BS/eNB with its RF and modulation techniques separated out from the module. Thus, a GUBH will process the user/subscriber bits in terms of handling the user packets (such as addressing, sending and receiving, etc.) and security/parity coding.

III. SCIDAS IMPLEMENTATION

The concept has been conceived to address the following grass root challenges that are considered obvious in architectural design of a network technology:

i) How will the network accommodate the "*Place Time Capacity"* challenge?

ii) Why do the antennas need to be dedicatedly associated to a BTS/eNB or BTS/eNB pool and cannot dynamically choose the portion of resources? Currently, RRHs may choose the carriers among the available resources. However, the total available resource is measured by available eNBs to which RRHs are connected

iii) When the end RF feeders are RRH (or similar), why BBUs should bother about the radio access technology at all? The answer to this question will allow multiple technologies at air interface end to be accommodated on the same platform.

iv) How can a single C-RAN architecture be smeared across AoI? This will benefit in terms of easy to deploy and manage.

A. Spectrum Mangement and Utilisation

The service providers' database of the allocated bands in each technology will be updated in the Global Server for Service-Provider Database module (GSSD). Based on the GSSD, the GUBH is configured to set out the traffic in the network. Once the network is deployed and FUs are distributed in the AoI, the APMS module, with the help of Active Probing Antennas (APA), will gather the information about the network environment and the subscriber concentration at each and every site location iteratively. By site, we mean the infrastructure that holds necessary equipment at a distant location that needs to be served. The NIU-B will segregate the information received from APMS in the following categories:

i) The capacity that is predominantly static to the respective location. Such traffic is generated from the slow or static subscribers.

ii) Capacity generated due to individual subscriber motions.

iii) Capacity due to excessive subscriber gathering

iv) SINR at each site location

Depending upon the user concentrations at each site locations, the NIUB will allocate the carriers for each FU and the carrier table is propagated to every FU via the NNGB. In this way, the same carries can be reused after a suitable distance as the baseband is not directly associated with radiated carriers. Also, based on the SINR, the serving channels and sub-channels can be individually selected by the NIU for every FU. Hence, the user bits can ride over any subcarrier and NIUB will map the subcarrier with the respective user data stream. Therefore, the processes such as carrier aggregation, carrier selections, etc., will be performed at the utmost basic level without affecting the user connectivity at all.

B. Subscriber Mobility in Multi-technology Environment

When FUs are considerably far from the respective NIUB, commutation of bits between the NIU and the FU will observe a significant delay. To overcome this situation, we have proposed the concept of Subordinate SCICELL or Sub-cell. Once the user/s will move significantly away from the NIU-B in the SCICELL, it will copy the user profile from GUBH to the User Bit Handler Subset (UBHS), which is similar to the GUBH with limited resources to manage.The UBHS will start performing as if the BS itself has moved from the initial to the final location. Also, the NIUB will instruct NIUS to imitate the portion of itself (NIUB) while the user/s roam in its (NIUS) vicinity. The user data packets will now be mapped onto the SUBH, and Sub-cell FUs will serve the user/s. In this way, a subscriber can roam in the AoI from one SCICELL to another and one Sub-cell to another without realizing the background management. In the case of an optimized network, the user/s may be served by a certain definite group of carriers thereby reducing the spectrum need. For the intra-SCIDAS calls, the GUBH and the UBHS can manage the calls by directing the user packets within or in between the

SCICELLS. However, for the calls that are made out of a SCIDAS network, the Network Core (NC) will be in use.

For the user packets to freely float across this kind of solutions, they must have a universal address for it to be transmitted securely and collected reliably. This we term as the *Universal Packet Addressing Scheme* (UPAS) that may embed the packet headers with the source and destination subscribers' user device address/information. UPAS will allow the multi-technology to ride on the same platform. Whereas the old technologies like 2G can be accommodated with SCIDAS performing as a usual DAS, the future technologies like Visible Light Communication (VLC) may need only a VLC module to be installed at the remote end for the user packets to float over it.

C. Handling the Place Time Capacity (PTC)

When a huge subscriber group moves from one place to another, they generate huge capacity burst that wobbles from place to place. The usual BSs are planned and deployed for normal subscriber density, and these bursts generate capacities that crave for the capacity beyond the serving capacity of the BS. Hence, such cases are undoubtedly a severe situation for all service providers as they often lead to network congestion and poor SINR (due to high uplink/downlink communication). The proposed SCIDAS will handle the PTC in more efficient way. Firstly, the accumulated users will be layered depending on the technologies they use by illuminating the area in congestion with multi-technology. This will spread the traffic in various layers. Then, for each layer, each FU, that handles the area, will be allocated individually with a maximum number of carriers to consume the generated traffic. As GUBH and UBHS will have the only responsibility to handle the user bits and not the technology of operation, the frequency reuse at the remote end can be done rigorously and dynamically without affecting the user bit flow.

As the total number of subscribers in a given AoI is predominantly constant, the neighboring FUs can be downgraded in their carrier allocation to avoid interference without losing subscriber connectivity. The APMS continuously monitors the entire spectrum related activity without imposing any burden on the user layer by using unused carriers for active probing. Finally, as the group moves in a pattern, the APMS follows and predicts the next affected zone; the FUs in that area will prepare themselves by loading the same carrier configuration as what it would be in the previous set of FUs. When the subscribers move to the next area, the FUs of the previous area will downgrade their carriers to avoid interference in the next area. In this way, the PTC burst is dissolved by SCIDAS.

IV. Conclusions and Future Work

This paper addressed the need for a novel type of architecture to handle the ever increasing number of mobile subscribers and their service demands. The paper builds on the concept of Place Time Capacity as the "motion with accumulation" and is the main challenge for the service providers. We have investigated how C-RAN are accommodated to handle some of those challenges but are not close enough. To overcome these challenges, we proposed SCIDAS, as an architecture that overlays intelligence over the conventional DAS architecture. We discussed the ease of deployment of SCIDAS where the FUs can be connected by a regular fiber optic network or by QUICKNET, which is a wireless port to connect FUs where fiber cannot reach. We also discussed MCP, another unique feature of SCIDAS that allows remote antennas to alter their physical parameters according to the dynamic network conditions. We have also discussed that why baseband unit should not bother about modulation techniques. We have promoted the role of an antenna from a passive radiator to a more active participant in carrier segregation. We have introduced a unique Active Probing Concept that will allow a network to have a panoramic view of the network and predict the future subscriber behavior. Lastly, we have discussed how the PTC is handled in SCIDAS with lesser interference and congestion.

The proposed SCIDAS concept contemplates about the need for a holistic paradigm shift in communication architecture. Separating the user data from the Radio Access technology will allow us to investigate radio part and data part as separate entities and to accommodate multi-technology on the same user bits. The proposed work also allows us to work on non-conventional communication techniques like VLC to be adopted into the mainstream communication.

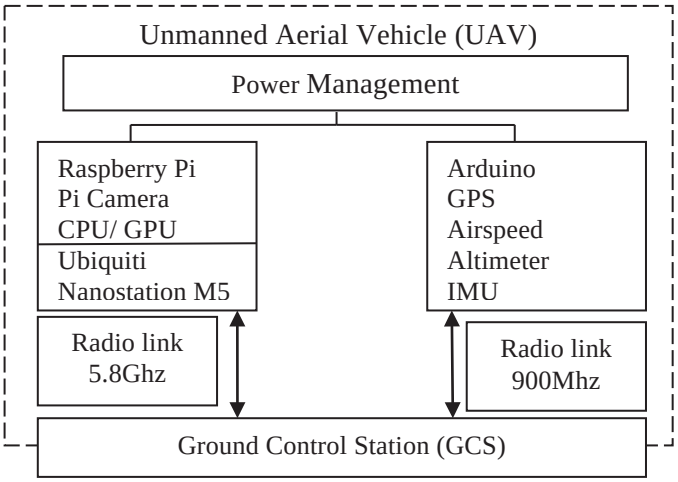
***Abstract*— Drone technology has advanced to aid applications in field of defense, emergency, disaster relief and digital imaging. Inheriting all such applications for Unmanned Aerial Vehicle (UAV) in low cost scale to make system for ubiquitous for all domains is the motive for our system. Hence, embedding high quality video feed and controlling flight data characteristics to execute several applications. Our system has been devised specifically for air navigation and hence, seamless performance of all the components placed on-board is maintained with high compactness in form factor. First Person View (FPV) is provided for pilots for to achieve long distance mission execution along with image processing for accurate data analysis of flight characteristics. Along with this, the telemetry data procured from Arduino integrated with sensors viz., GPS, Altimeter, IMU assists the pilot for maintaining steady flight characteristics. Our system has been rigorously tested and has also been presented for Society of Automotive Engineers (SAE) Aero Design competition to accomplish humanitarian relief operation. The low-cost general processing boards like Raspberry Pi and Arduino facilitates versatility in embedding various sensors based on requirements of the pilot. Along with the on-board the telemetry system, the Ground Control System (GCS) provides first person visual aid on base station. The JavaFx interface is platform independent with features like FPV video streaming in real-time, representation of UAV's altitude, orientation and position at every instance of time. Moreover, the trans-receiver communication allows controlling flight characteristics from the interface, increasing the scope of applications with UAV.**

Keywards— Arduino, Rasp pi, pi camera, Image Processing, FPV, Ground Control Station (GCS), Java FX, Video Processing

I. INTRODUCTION

Aerospace has advanced with the advent of drone technology, to add the inclusion of Unmanned Aerial Vehicle (UAV) in artillery , the air borne application have increased multi folds. Citing these applications, we devised a system which could help supplement such applications using low cost components with capability of video processing and data telemetry with platform independence in hardware requirements. Our system was successfully tested in the Society of Automotive Engineers' (SAE) [1]. Collegiate Aero Design Competition in March 2015, which had humanitarian rescue mission application, in which we burgeoned with premier accolade for the Design and the system of the UAV. The use of on-board processors, camera and telemetry system yields robust performance for long ranges navigated with the help of Ground Control Station(GCS). The GCS is a javaFX application which can run on any standard web browser, serves as a platform independent interface for planning missions from the base station. And also, recording of the real-time data telemetry of sensors and video feed of the on-board camera is embedded in the GCS interface. On-board image processing algorithms intelligently enables the pilots to derive accurate data analysis of flight data in real-time. These features provide plethora of air surveillance applications like search and rescue, aerial farming and product delivery.

II. BLOCK DIAGRAM



While implementing Video processing and Data Acquisition from the sensors we used a combination of Arduino and Raspberry Pi[2]. The advantage this combination is exploiting all functionalities from these two components which facilitates real-time data transmission with web Controlled Connectivity from multiple sensor data and also video streaming on variable operating systems with highly functional GUI. The Data Acquisition system consists of a sensor mesh which acquires data and sends it through a radio link to the ground station. We make use of a pair of X-bee Pro 900 HP radio.

In order to deploy successfully we need to have sizeable data at the ground station. Thus we have the GPS which gives us accurate location of our drone, the Inertial Measurement Unit (IMU) which gives the orientation of the drone, altimeter which helps get height above ground level and the air speed sensor which gives us the speed of the drone. The data acquired from this system is then processed at real time on the ground station which in-turn will direct the secondary pilot for deployment. [3]

III. VIDEO PROCESSING

First-person view (FPV) is an aid used by pilots to facilitate control of the remote-controlled vehicle from its view point. Most commonly it is used to pilot an unmanned aerial vehicle (UAV). In our system, Raspberry pi [5]along with Pi camera is used for HD live stream at maximum resolution of 1080x720 in real-time latency. This system gives a bird eye view for the UAV which is controlled remotely using the GCS interface. Thus, FPV enables UAV pilots to fly beyond the Line of Sight range and can execute missions with the aid of on-board processed video. To help enhance features of video feed, image processing at maximum rate of 12 Frame per Seconds was implemented using MATLAB[4] and FFMPEG. Algorithms like Feature Extraction, Shape detection, Object detection were implemented on raspberry pi using MATLAB raspberry pi support library. The video stream quality is maintained for long ranges due to the use of 5.8Ghz transmission frequency, as 5.8Ghz allows minimum interference and high bandwidth channel. Transmission of the video is achieved through Ubiquiti Nanostation M5, which serves as an Access point for the router ie. Ubiquiti Rocket M5 on the base station.

IV. HARDWARE

A. Raspberry Pi

A Single Computer processor with compact and light form factor, large processing power and with up to 24 GFLOPS becomes ideal for on-board image processing and flight characteristic sensor integration. Raspberry pi along with the Pi camera serves as the FPV system for the UAV. Image processing algorithms are implemented using python language and its simpler integration with the Pi Camera CSI interface provides better processing than USB camera.

Fig. 1 Raspberry Pi

B. Pi Camera

To achieve high quality FPV streaming with light weight components with digital streaming The Raspberry Pi camera module is used to take high-definition video; it has a 5 megapixel fixed-focus camera that supports 1080p30, 720p60 and VGA90 video modes. The Raspberry Pi camera board transfers data through an extremely fast camera serial interface (CSI-2) bus directly to the system-on-chip (SoC) processor. It does this through a 15-pin ribbon cable, also known as flexible flat cable (FFC), and connects to the surface mount ZIF 15 socket in the Raspberry Pi board. Owing to its low weight, small dimensions and high resolution, the Pi camera was found to be suitable for use in the UAV as compared to USB camera.

C. Arduino Uno microcontroller

The features of Arduino microcontroller are as follows:

Microcontroller	ATmega328
Operating Voltage	5V
Clock Speed	16 MHz
Digital I/O Pins	14 (of which 6 provide PWM output)
Weight	28 grams

The Arduino[6] is an inexpensive, easy-to-use microcontroller board. Its flexible programming environment provides the user the freedom to program either in Java, C++ or C language. With various libraries available online, the Arduino is one of the most sought after microcontroller boards available in the market.

Fig. 3 Arduino Uno Microcontroller

D. U-blox LEA-6H GPS Module

The GPS module has been incorporated into the system to obtain the real-time location co-ordinates of the UAV with respect to a set reference point. The on-field GPS coordinates of the target helps in determining the course of UAV to the drop point. The module has been selected for the following features:

- 5Hz update rate
- High precision-2.5m accuracy
- Super Sense® Indoor GPS: -160 dBm Tracking Sensitivity
- Dimensions: 37x37x9mm
- UART, USB and DDC (I2C compliant) interfaces

Fig.4 GPS module consisting of U-Blox LEA 6-H

The GPS module can also be used in weak signal environments. The antennae should be exposed to the sky to get proper locking of the GPS module.[7]

E. Inertial Measurement Unit- MPU6050

The InvenSense MPU-6050 sensor incorporates an MEMS accelerometer and a MEMS gyro on a single chip. It is very accurate, as it contains 16-bits analog to digital conversion hardware for each channel. Therefore it captures the x, y, and z channel at the same time. The sensor gives 6 Degree of Freedom (DOF), 3 DOF for the accelerometer and 3 DOF for the gyroscope. The sensor uses the I2C-bus to interface with the Arduino.

Fig. 5 IMU MPU-6050

The MPU 6050 was selected as a part of DAS because of its precise reading and updating process. It gives the Yaw Pitch and Roll of the UAV with respect to a predefined point. This helps us in understanding the flight in a 3-dimensional manner.

F. Altimeter – Parallax MS-5607 Altimeter Module

The DAS design objective states the use of a Data Acquisition System (DAS) to record the altitude (in feet) with a precision of at least 1 feet. The altitude must also be recorded at the time of release of the expellable cargo. The following requirement was implemented using the Parallax altimeter module MS5607[8]. The MS5607 module includes a pressure sensor and a temperature output and can be used for implementing an altimeter. [8]

The features of the module are given as:

- High resolution : 20cm Pressure range : 10 to 1200 mbar
- Supports I2C and SPI communications
- Power requirements : 3.3 to 6.5 VDC
- Dimensions : 0.85 in x 0.80 in
- Weight : 5 grams Fig. 2: Parallax MS-5607

Fig. 6. Parallax MS-5607 Altimeter Module

Altimeter Module Owing to its low weight, small dimensions and high resolution, the particular module was found to be suitable for use in the UAV.

G. Radio Communication

To channelize for the optimum bandwidth usage for transmission of large video feeds, we decided to choose 5.8 GHz frequency band. It is very advantageous to use machines that are functional at a 5.8 GHz frequency because it provides a wider coverage than that of with the 2.4 GHz frequency. Compared to the 5.8 GHz devices, 2.4 GHz 802.11g hold only about three channels, which are not overlapping. Since a number of routers may be present on ground station, using 5.8 GHz will prevent any overlapping with other channels while transmitting video streams. For video streaming we employed Ubiquity M5 rocket and Ubiquity M5[8] nanostation.

Establishing point to point connection via the Ubiquiti rocket M5 and nanostation M5 routers, ensured long range proximity for FPV streaming. Transmission of telemetry data is controlled by Arduino. We used Zigbee Transmitters for this purpose. Telemetry data like Altitude, latitude, longitude, airspeed etc are obtained by microcontroller using two digital pins, programmed as software serial ports. Programs are written to process the data from all the sensors in standard Arduino language. After processing this data, data is parsed, cleansed and then sent to Zigbee at the receiving end. We use 900 MHz for transmission of these data. 900MHz can go a lot farther with a high gain antenna (up to 15miles for the Pro modules and a high gain antenna). Also the lower the frequency the greater penetration the signal has. Also, trying to squeeze in these various components in compact weight and size forms was essential considering the aerodynamic features for any UAV. All the sensors and routers at the UAV end are of pocket size hence reducing the overall size and weight of the hardware components on UAV.

H. X-bee Pro 900-HP

The rulebook states that the telemetry system should not use 2.4GHz frequency. For this reason, we have chosen X-Bee Pro 900 HP.[9]

- Frequency band: 902 to 928 MHz
- Data Rate: 10 Kbps or 200 Kbps
- Data Interface: UART (3V), SPI

The processed data obtained from the Arduino is transmitted to the base station via the XBee modules. The X-Bee usually sends data to the computer terminal. But when the package is to be deployed i.e., the "Fire" button is pressed on the GUI, the X-Bee module works in full duplex mode.

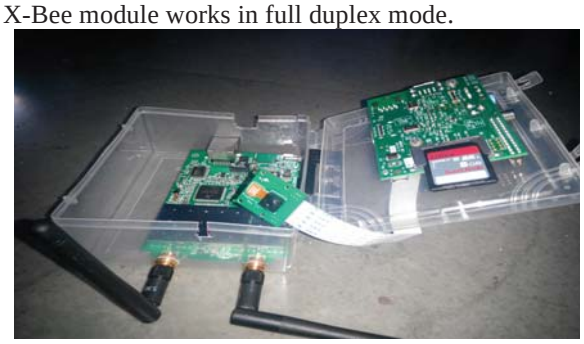


Fig. 7 Raspi+ Pi camera+ Ubiquiti NanoStation m5 with Linear Antenna

V. POWER MANAGEMENT

The most crucial part of any electronic mobile device is its battery life, in our case flight time of our system. We have used the Raspberry pi and Arduino for accurate and optimum results. In order to achieve optimum results a flight time of 45 min to 1 hour is a must. Hence battery selection at this stage is paramount, we have to select a battery which is conducive to the Arduino, Raspberry pi and the Ubiquiti router. The Raspberry pi works on 5V DC, Arduino Uno works on 9V DC supply and the Ubiquiti router works on 14.8 V. To tackle this problem we have made the use DC-DC buck converter.
The concept of DC-DC buck converter is; input power = output power, unlike the normal voltage regulator the excess power doesn't get dissipated but instead gets utilised. We have used a 14.8 V 2.5A Lithium Polymer batter (LiPo) and two DC-DC buck converters. One pertaining to the Raspberry pi of the rating and the other to the Arduino with the rating.
The below table and pie chart depicts the power distribution in our system.

Sr.No	Voltage	Current	Power
1. Ubiquiti	14.8V	1A	14.8W
2.Rasp. pi	5V	.8A	4W
3.Arduino	9V	1.3A	11.7W

From our LiPo battery of rating 14.8V 2.8 A battey we get 37 W/hour and the actual power required is 30.5 W. This wouldn't have been the case if we had used anything but DC-DC convert. With the obvious approach of voltage regulator the system wouldn't have lasted half the time as that with DC-DC converter.

Sr.No	Power consumed with DC-DC converter	Power Consumed with Voltage Regulator
1.Ubiquiti	14.8	14.8W
2.Rasp pi	4W	11.84W
3.Arduino	11.7W	19.42W

As we can evidently see that with the use of voltage regulatorwe would have consume 45.52 W instead of 30.5 W.

A. DC-DC converts

We make use of two LM2596 DC-DC buck converters.
The DC-DC converter is used in order to enhance the efficieny of the system. The DC-DC converter is an essentail tool for optimising battery usage. Specifications:

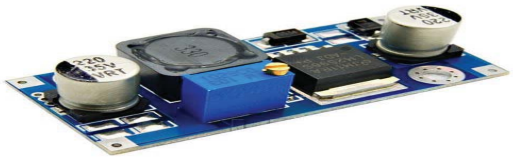

Fig.8. DC-DC Converter.

- LM2596 DC-DC Buck Converter Step Down Module
- Output: DC 1.5V to 35V voltage continuously adjustable, high-efficiency maximum output current of 3A.

VI. GRAPHICAL USER INTERFACE (GUI)

In order to present all the telemetry data and real time video streaming at the base station, platform independent single window GUI is made. GUI is made using cross-platform JavaFX API. In order to incorporate visual navigation and to

help UAV drop the package at perfect instant, various features have been added to GUI.[10]Live http streaming is achieved by establishing point-point bridge connection over the Ubiquiti rocket M5 router mounted on UAV and the Ubiquiti nano-station router at the base station. A full-fledged FPV with textual overlays using JASON(JavaScript object notation)is then embedded in GUI. This is achieved using JXBrowser API which allows chromium based browsers to be integrated into Java AWT/Swing/FX applications. With JXBrowser you can embed a lightweight Swing/JavaFX component into our Java application to display web pages, supporting the latest web standards such as HTML5, CSS3, and JavaScript etc.GPS coordinates obtained from Arduino are parsed and displayed on the GUI. But coordinates in it are not sufficient for navigation; hence UAV co-ordinates are represented on a map embedded in a GUI using Leaflet API. This JavaScript mapping library allows us to asynchronously plot the co-ordinates on the map without the need of refreshing it. Readings from MPU 6050 i.e., yaw, pitch and roll are used for getting the real time orientation of the UAV. Using these readings, aerial time simulation of a UAV is modelled using a processing sketch which is embedded in JavaFX GUI. The processing language itself builds on Java hence can be easily integrated in our GUI. Equipped with the data such as UAV's GPS co-ordinates and yaw, pitch and roll of UAV obtained from MPU 6050, precise package dropping at a specified target can be achieved. Using projectile motion equations , instantaneous package drop location is calculated at each instant of time ,having known the yaw and pitch of the UAV at that instant. Package is dropped at the instant when package drop location calculated at that instant coincides with the target location. Fire button on the GUI is pressed so that the package can be released. This is achieved using Java RXTX library which allows us to read and write data on a COM port. Xbee trans-receiver connected to the COM port then sends command to release package to the Xbee trans-receiver mounted on UAV. When the fire button is pressed; latitude, longitude and altitude at that instant are also shown on the text fields in the GUI. For representation of Altimeter and Airspeed data, Gauges are made using library of gauges.

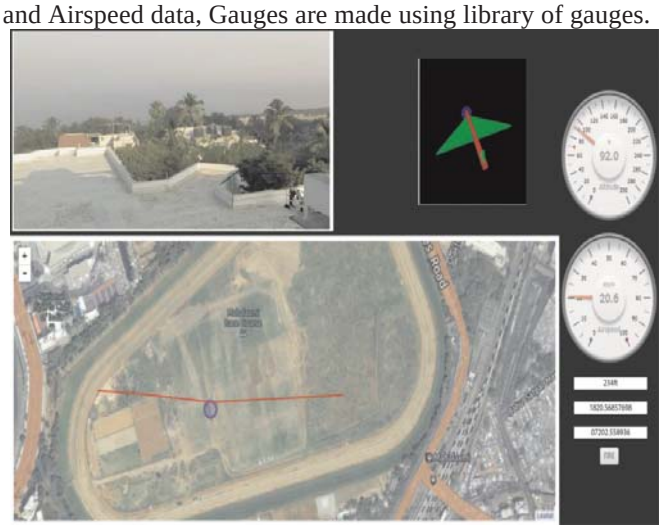

Fig.9 Graphical User Interface (GUI) application in JavaFX.

VII. FUTURE SCOPE AND CONCLUSION

Our system consists of two general purpose processing boards, Arduino Uno and Raspberry Pi as we intended to maintain redundancy in the case of failsafe situations. However, similar system can be also embedded on Raspberry Pi alone with video processing through Pi Camera and telemetry data interfaced through GPIO ports. Such system could be processor optimized and compact, but may be unreliable in the event of failure.Also, similar hardware components could be executed in Software In The Loop mechanism to achieve autonomous capabilities. To implement autonomous UAV flight PID controller can be programmed using the IMU sensor.The system designed is highly reliable in natural disaster environments because in the event of signals getting lost from one bandwidth we can still receive signals from another bandwidth which makes it possible to have atleast basic information about the area. The system can be used in Nuclear Disaster area and can be embedded with radiation sensors and one can have live video surveillance of the fatal prone area. The stability of the Drone is high in which this system is used which makes it to be used in harsh environments. One can attach robotic arms to collect samples of area where human intervention is nearly impossible.

Abstract

This paper deals with the electricity theft control system and an initiative to save power. The growing electricity theft in the form of overloading in the houses has motivated us to design such a system for household electricity supply which will work to solve the problem of overloading and voltage fluctuations. We have developed the prototype system based on wireless sensor network (WSN) of sensor motes installed with the prototype circuit of household electricity circuit. The WSN is formed among the houses having sensor motes attached with their electricity meter. The household load and power are measured and controlled with these sensor motes. Moreover, the gateway which is the sync node in the network is placed in the power house control room attached with the computer. In this work real time measurement and controlling of current, voltage and power of the prototype circuit is done through Crossbow wireless sensor motes using Moteworks 2.0 environment and displayed on Mote View software. The relay in the sensor mote is used to control the sensed parameters. The network health is also indicated using health packets containing received signal strength indication and retransmissions displayed via Mote View.

Keywords: WSN, Electricity

1. Introduction

This Electricity theft is becoming a growth theft. Electricity theft drags down not just the power sector but the entire nation. This work is the initiative to control this growing problem of electricity theft. We have developed such a prototype system which will work to stop electricity theft by controlling the household overloading issue. We have implemented the wireless sensor nodes for automatically controlling the load at the houses. These sensor nodes are forming the Wireless sensor networks. This technology in recent years is acquiring importance as a promising technology, as using WSN real time monitoring and controlling of the sensed parameters can be done.

The gradual improvement in Micro-Electro-Mechanical Systems (MEMS) technology has alleviated the development of smart sensors. The research in wireless sensor networks (WSNs) is gradually increasing in recent years as these sensors are small with limited processing, computing resources, and cheap compared to traditional sensors. These sensor nodes can sense, measure, and gather information from the environment and based on some local decision process, nodes can transmit the sensed data to the user [1,2].

The concept of wireless sensor networks is based on a simple equation: Sensing + CPU + Radio = Thousands of potential applications

Smart sensor nodes consist of sensors, a processor, memory, a power supply, a radio, and an actuator. Sensor nodes may be attached to a variety of mechanical, thermal, biological, chemical, optical, and magnetic sensors to measure properties of the environment. The radio part is very crucial and it is implemented for wireless communication to transfer the data to a base station (e.g., a laptop, a personal handheld device, or an access point to a fixed infrastructure), as the sensor nodes have limited memory and are typically deployed in difficult-to-access locations. In a sensor node, battery is the main power source[2,3].

2. Electricity Theft: Motivation behind the Work:

In several countries electricity theft has some kind of endemic character. Here are the following ways in which electricity theft can be done:

a. Bypassing the feeder.
b. Another way of theft of electricity is to invert the meter (pull the meter out of the socket and plug the meter back in upside down).
c. A popular way to slow down a meter is the use of strong permanent magnets like rare earth neodymium.

3. Software

The sensor nodes in WSN are described as little computers capable of doing different tasks of sensing, tracking and data acquisition. Therefore these nodes need an operating system to measure and send data to base station. An important step towards attaining the vision behind wireless sensor networks is the design of a software architecture that links the hardware capabilities and a complete system. There are numerous restraints placed on the software of WSN. It must be effective in terms of processor, memory and power so it meets firm application requirements. It must also permit multiple applications to concurrently use system resources such as communication, computation and memory. The operating system designed particularly for networked sensors is TinyOS. Figure 2 shows the architectural layout of WSN where operating

systems exist in between the actual sensor hardware and application. The wireless sensor nodes utilize less complex operating systems and event driven programming models because of its design restriction and limited resources [4].

In WSN an operating system hides the low level facts of the sensor node by giving virtual access to the device.

The key characteristics an operating system must provide in WSN are power management, memory management and bandwidth [5].

The software platform used for this work was Mote Works 2.0F, provided by Crossbow Technology Inc. and Microsoft Visual C++ Studio 2008. Mote Works 2.0F includes:

- **TinyOS and Mote WorksTool**: An event-driven OS for wireless sensor network and tools for debugging
- **nesC compiler**: An extension of C-language designed for TinyOS.
- **Programmer's notepad**: IDE for code compilation and debugging
- **MoteConfig**: GUI environment for Mote Programming and OTAP
- **MoteView** : An interface ("client tier") between a user and a deployed network of wireless sensors.

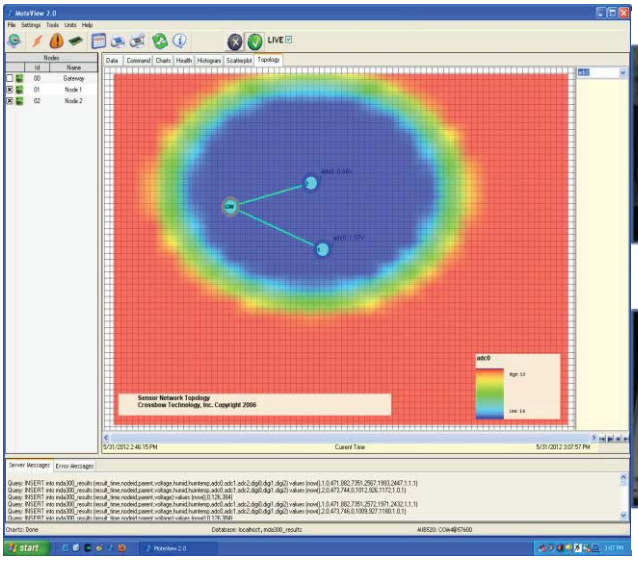

Figure 1: Showing Topology of node 1, node 2 & gateway in terms of ADC "0" voltage.

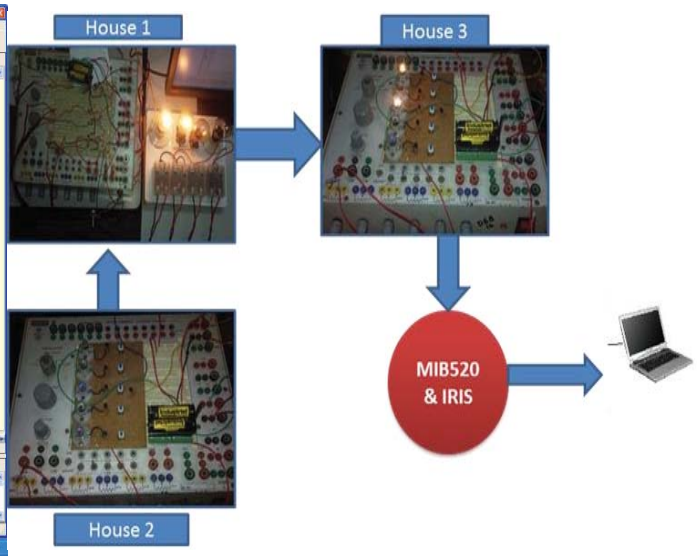

Figure: 2 Prototype System

4. Automatic Household Power Measurement & Control System

I. Experimental Setup.

To control electricity theft we have developed a prototype system based on wireless sensor networks to measure and control household power. Hence our system will perform following functions:

- Monitors and measures the household power
- Cuts power supply to houses if exceeds threshold load
- Gives back power if load is reduced
- E-mail the user of the house about the disconnection
- E-mail the user total Electricity bills

These are operations which our system will perform in order to control the problem of electricity theft in India. The prototype system is shown in the figure 2.

Figure 1 shows the nodes are attached to the electricity circuit developed and it senses the voltage as the current changes in the circuit through the ADC "0" line of the sensor board. Hence the nodes are communicating in multi hop fashion and transmitting their information to the gateway then to PC as shown in figure 2 in the moteview software. This forms the wireless Sensor Network of the motes kept in houses which will work together to control overloading problem in that area.

The prototype system developed will disconnect the supply of house 1 if ADC"0" >=1.8V and of house 2 if ADC"0" is 0.65V and connects the supply back of the load of the house or prototype circuit is reduced.

II. Circuit Design

There are two circuit designs in our system:-

- The Prototype circuit of household electricity network
- The circuit developed to generate pulse for billing application

III. Prototype: Household Electricity Network

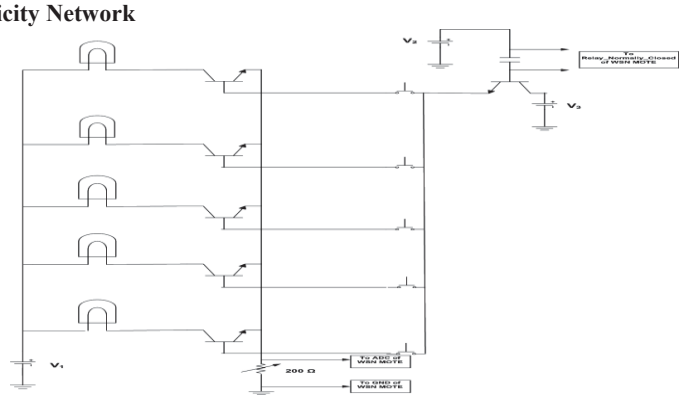

Figure 3: Prototype circuit diagram of household electricity.

Prototype circuit diagram of household electricity circuit is shown in figure 3. The specifications of the circuit are written below:

- V1 = 5volts
- V2= V3 = 7.5 volts
- Bulbs of 3.6 volts
- Transistors BC147
- Variable Resistance, R1 = 200 ohms
- Resistance, R2 = 100 ohms
  R1 || R2, hence
  R nearly 50ohms
- Current by V1 = IR
- I=2. 5/50=50mA

IV. Counter Circuit

A counter circuit is shown in figure 4 and counter pulse is shown in figure 5. A high quality Multivibrators can be generated using 555 timer IC adding external resistors and capacitors.

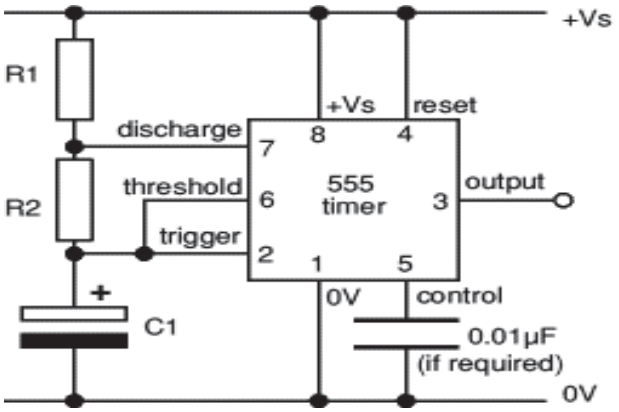

Figure 4

This circuit is used here to generate square pulse to operate Counter terminal in MDA300 sensor mote. As the counter is rising edge triggered, we need to implement the timer for rising edge. For pulse of (>50% duty cycle).

- By 555 Timer IC
- Supply voltage = 6V
- RA = 10K, RB = 10k (POT)
- C1 = 5 micro F
- C2= 0.1 micro F
- Time period= 0.1sec

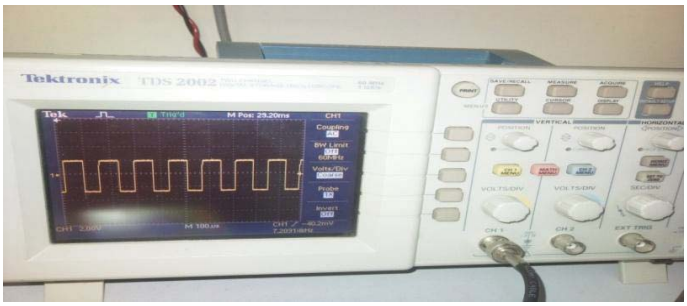

Figure 5: Square pulse for counter

5. Working

I. To Control Power Overloading

The prototype developed is common emitter based configuration with emitter Resistance. As we give load the current across R changes and hence voltage across R changes which goes to ADC line of sensor mote. When the load increases above the threshold the relay normally closed is opened which disconnects the electricity supply. When the load is reduced below the threshold the electricity supply is connected back. In our program we have set our threshold ADC0 line value = 1.8Volts so as we turn on the switches to increase the load in the circuit simultaneously the voltage across resistance (R) changes and hence ADC line input increases then when the value of voltage passes 1.8V the power cuts and ADC line displays zero volts this power cut can be reverted back if load is reduced in the circuit hence power will come back and ADC voltage will vary from 0 volts.

II. Readings:

The readings using the prototype are tabled below in table no. 1 which shows the ADC Voltage against the load connected. As shown in figure 6 the ADC Voltage when one bulb is connected is 0.34 and so on. When the load is greater than threshold load then there occur power cuts as shown in figure 6 and figure 7.

Table 1

LOAD (bulbs)	ADC_0 voltage
0	0V
1	0.34
2	1.15
3	1.2
4	1.56
5	2.19 (Power Cuts)
NO bulb ON	0V
4 (after reducing load)	1.7V (Power back)

Therefore the user has to turn off the load to bring back the electricity. The prototype circuit developed:

- It is based on common emitter based configuration with emitter Resistance.
- As we give load the current across R changes and hence voltage across R changes which goes to ADC line of sensor mote.
- When the load increases above the threshold the relay normally closed is opened which disconnects the electricity supply.
- When the load is reduced below the threshold the electricity supply is connected back.
- The amount of electricity used is also monitored and stored in a variable such that billing is done automatically using that variable.

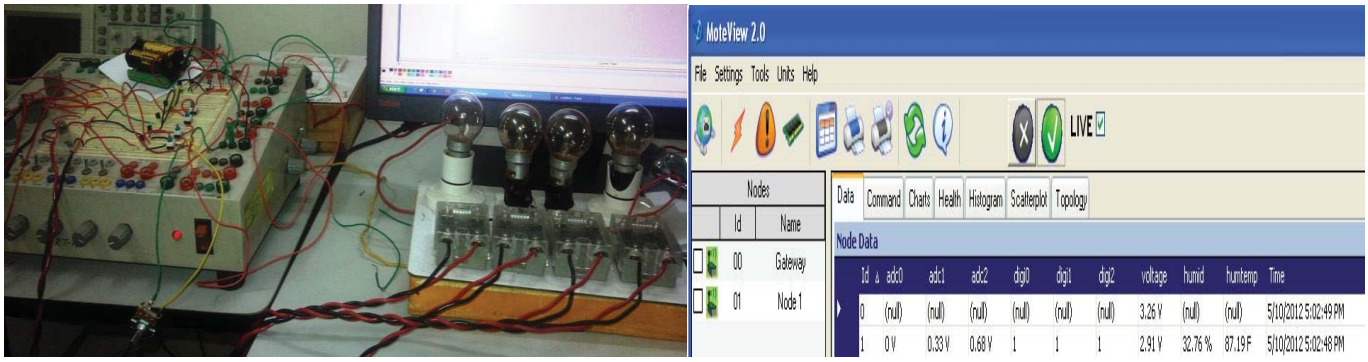

Figure 6: When NO bulb is ON and corresponding ADC voltage.

Figure 7: When "1" bulb is ON and corresponding ADC voltage.

Generate Bill

Then billing is a very significant part it is done with the help of counter port in the sensor board. To use the counter port the square pulse of 0.1sec is given to the ports counter is a rising edge triggered. The pulse was generated with the help of 555 timer circuit as shown in Fig 5. The pulse is of >50% duty cycle. The counter used is positive edge triggered and it counts 10 times in every second. The counter will count only when the ADC0 line voltage in mote view is not zero that is the when the supply is given to the circuit which means the house is not overloading. Hence when there is no overloading condition the counter counts 10 times per sec and calculates power at every instant according to the variable voltage value in adc line.

$$E = \sum_{v=1}^{N} P_v$$

Where, E is the energy used in N sec.

$$P_v = \frac{V^2}{R}$$

Where V is variable ADC0 line voltage at different counting instants , R is 50 ohm. E is the total Energy in watts sec. Pv is the instantaneous power at ADC "0" as voltage changes at different count instants. N is the total number of counts (10 per second).

Hence, E=E/10

Total Bill= E*(rate in rupees for per watt sec)

Future Work

Hence the bill will be emailed to the user's email address through MIB600 Ethernet interface board which is connected to the hub/switch/router and also the message of electricity disconnect will be emailed to the user as the power cuts due to overloading.

But unfortunately due to the lack of technical support from the developers of the sensor motes, Crossbow Technology and MEMSIC the billing of the electricity does not shape up into reality. Moreover, we have developed the logic and made the suitable changes in the program to do the billing of the electricity used in each houses but due to the programmed Mote view display, the value of the counter was not displayed in the Moteview. Hence the calculation for evaluating bill is incomplete. The email from the Mote View was also not sent due to the server issues in our working environment.

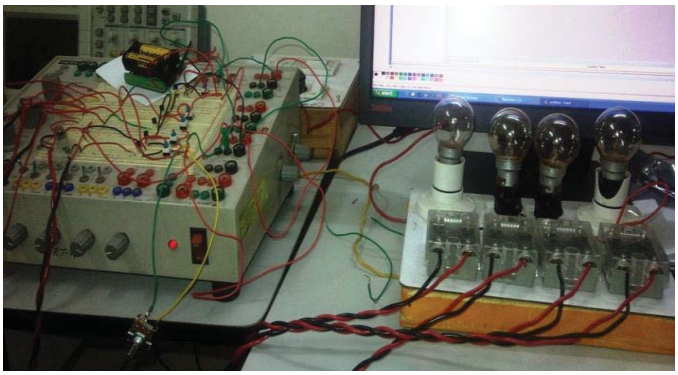

Figure 8: ADC "0" voltage is >1.8V condition of overloading, hence Electricity is disconnected.

6. CONCLUSION

This work is the first step towards the future for saving power by preventing power overloading and hence preventing voltage fluctuation, this has also reduced cables and configuration issues. The measurement of the voltage drawn from the prototype circuit (of houses) is done through Crossbow wireless sensor motes using Mote Works environment through ADC"0" line and displayed on Mote View. The charts & topology plots of ADC "0" line of both nodes have been displayed. Wireless Sensor Network health is also indicated using health packets containing path cost, RSSI and retransmissions displayed via Mote View. Variation of received signal strength and retransmissions with different antenna orientations and inter mote distances have been demonstrated. The current state of the work is the platform on which design enhancements can be made and real time power management & controlling can be done. The system developed has constant sampling rate of 10 samples per second, low latency and high reliability because of XMesh. Network Route Update Interval is 36 seconds. The route update interval can be increased to lower power consumption and increase the lifetime of node. Electricity billing is automatic and is received at the user end through e-mails and payment can be done online and hence no paper work is required.

***Abstract*—Service oriented architectures (SOA) provide functional and configuration flexibility in closed communication environments, where security and service-related orchestration issues are controlled within the local network. For automation systems, these SOA-based networks can have core services, such as Service Registry, Orchestration, Authorization, and so on. A set of such core services are defined, implemented and made available through the Arrowhead framework. Since the Core Services are distributed resources available for all systems that wish to consume them, these networked services can be considered a cloud. As one cloud cannot serve for all, there is a need for such automation system clouds to interact with each other: use the services of one from another. This paper presents a solution for providing inter-cloud servicing capabilities in the Arrowhead framework by introducing a gatekeeper concept. The main idea is to extend the service discovery functionality outside the boundaries of a single cloud, and solve the security and orchestration issues in a way that fits into the general Arrowhead concept. This paper also introduces the methodology of creating secure connections between service consumers and producers situated in different clouds.**

I. Introduction

The purpose of this work is to introduce a gateway, or rather, a Gatekeeper as a new optional Core System for handling interactions between Arrowhead Local Clouds. Arrowhead is a joint collaboration project within the EU, with the grand challenge of enabling interoperability between systems that are natively based on different technologies. This enabler includes design and development methodologies, implemented Core Systems and Services, and a documentation structure to support the common understanding of the experts from various fields. It targets five business domains: production (processing and manufacturing), smart buildings and infrastructures, electro mobility, energy production and the virtual markets of energy.

The integration of the projected, very large collaborative automation systems requires that the participating systems can dynamically exchange information during run-time. This raises issues – among others – of service discovery, orchestration and security. For the use case scenarios of very large system-of-systems – i.e. whole cities – the present solutions do not scale favorable. Thus SOA (Service Oriented Architecture) approaches have been investigated to address large scale automation systems [1], [2], [3], [4].

These Arrowhead Framework compliant system-of-systems will be called Arrowhead Local Clouds. By definition, one Arrowhead Local Cloud consists of various Systems and their Services and are governed through the use of mandatory (and optional) Core Services provided by the locally involved Core Systems – the manner of the realization of the Framework is depicted in Fig. 1.

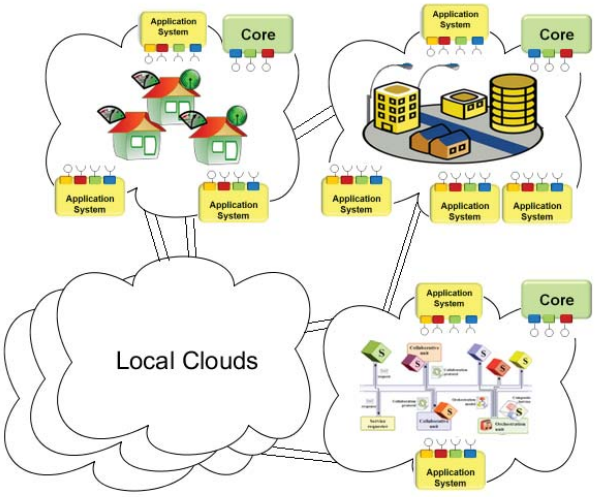

Fig. 1. Interconnected local collaborative clouds

II. The Arrowhead Framework and Related Work

The objective of the Arrowhead Framework is to efficiently support the development, deployment and operation of interconnected, cooperative systems based on the SOA approach. The building elements of the Framework are *Systems* that provide and consume *Services*, and cooperate as a larger *Systems of Systems* (SoS) called *Local Clouds*. There are three mandatory Core Services that are required to create a minimal working SOA Local Cloud based on the Arrowhead Framework. These Services are namely the Service Discovery (from the group of Information Assurance services), Authorization (Infrastructure services) and Orchestration (System Management services). Other (optional) Core Services have been also created to further enhance the capabilities of Local Clouds, such as System Configuration and Service Metadata Stores or Event Handler Services. These Core Systems are the central entities of the Local Clouds and can provide their capabilities IT cloud-based, as well.

1) Services: A Service within the Arrowhead Framework is the exchange of information between a provider System and a consumer System, as seen in Figure 2. In a service, capabilities are grouped together if they share the same context [5]. As an example, a service in a REST [6] architecture can be constituted by all interfaces which are related to the same REST resource (meaning an information source). In the context of Arrowhead, a resource might be a temperature sensor or a power consumption reading from a power meter. The same approach also applies to the other technologies being used in Arrowhead, such as COAP [7], XMPP [8] or OPC-UA [9].

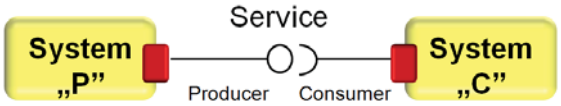

Fig. 2. Services produced and consumed by Systems

The Arrowhead Framework also implies the usage of a number of service orientation principles derived from high level objectives and properties. By definition, a Service can be realized by an arbitrary number of producers and consumers, therefore insuring its *reusability*. An Arrowhead Service might also support different kinds of *non-functional requirements* such as security, real-time constrains or different levels of reliability. Systems should also be capable of sequentially providing and consuming different types of Services with the help of the Orchestration in order to fulfil a more complex task – *composability of Services*.

Finally, in relation to Service development and maintenance, a Service has its own group of appointed stakeholders with an interest in the Service by being responsible for its governance (definition, development, deployment and maintenance). However, Services are not limited to a specific type (or instance) of a System and might not even share the same stakeholders with any System.

2) Systems: A System is what is providing and/or consuming Services (see Fig. 2). A System can be the Service Provider of one or more Services and - at the same time - the Service Consumer of one or more other Services. It normally includes software executing on (often constrained) hardware. It might support different protocol implementations of Services associated with it. A System can be a user interface display, a complete HVAC sytem within a house, but it can also be a small temperature sensor that complies with the Framework.

3) System-of-systems: When Arrowhead compliant systems collaborate, they become a System-of-Systems (SoS), see Figure 3. There are five main characteristics that differentiates these SoS realizations from other very large and complex, but monolithic systems [10], [11], namely (i) the operational and (ii) management independence of its Systems, (iii) evolutionary development, (iv) emergent behaviour, and (v) geographic distribution. Since these System-of-Systems should also collaborate, the Arrowhead framework becomes a natural enabler of further, complex solutions.

As an example, Systems A1, A2 and A3 are grouped together to create *System-of-Systems "A"*. This SoS then can be bundled together with other Systems (such as B1, C1 and D1, also depicted in Fig. 3), since they are Arrowhead

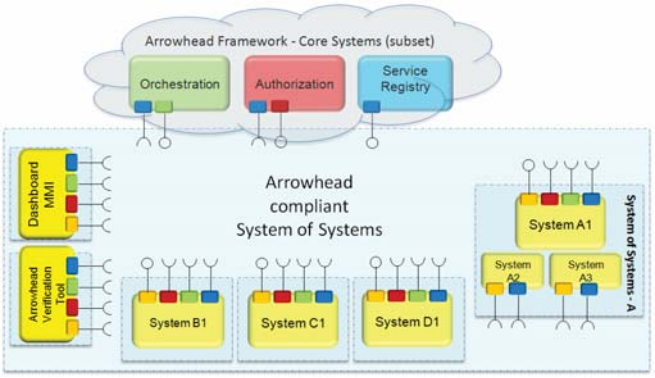

Fig. 3. Arrowhead core components support the system-of-systems - an example

compliant as well. The Arrowhead Framework provides Core Systems, such as *Orchestration*, *Authorization* and *Service Registry*, which help on establishing the most adequate and secure connections between the players. All these Application Systems are consumers of the Services of these Core Systems, which then forms this Arrowhead Local Cloud. The *Dashboard MMI* (Man-Machine Interface) allows interaction with this SoS; whereas the *Arrowhead Verification Tool* provides means for testing Arrowhead compliancy.

A. Requirement against gateways in various domains

Gateways serve various purposes in the different communication domains. They stand at the border of a subnetwork, a service area, or an operator. Their purpose is to provide means of connection and data exchange between the internal and external worlds. There could be very specific requirements against gateway functionalities, but in general, the following challenges can be dedicated to gateways:

- protocol and data format conversion or translation,
- addressing translation,
- security and AAA features,
- access control with content filtering,
- in- and outbound link control and their resource management.

These are not always solved by the gateways themselves; some methods of inter-domain communications handle these issues through specialized protocols, or have designated nodes to handle some of the above mentioned functionalities. A brief summary of gateway requirement and solution approaches within various domains are is given in Fig. 4. General interoperability issues and their handling are covered in [12], where the authors raise the performance and QoS issues regarding gateways as well. There are further, less general requirements and solutions listed for IPv6-based Internet of Things solutions in [13], for ad hoc vehicular military systems in [14], and for IT services in [15] and [16]. In the following Sections, we will heavily depend on these requirements when designing the enriched gateway concept as a Gatekeeper System, and describe its functionality. (Gatekeepers are special gateways, equipped with some decision-making functionalities – not merely on the network layer.)

	Protocol and data conversion	Address translation, Addressing issues	Access control, content filtering	Security & AAA	Link & Resource management
Managed Internet Services	-	Network Address Translation (NAT)	firewall, proxy	separate AAA servers; secure VPNs	queue management, QoS solutions (IntServ, Diffserv); Content Delivery Networks (CDN)
VoIP service	signaling conversion, dialing tone regeneration, media codec conversion	ISDN GT <-> SIP, H323 addresses	central access control, or Private Branch Exchange (PBX)	separate AAA servers	separate management for outgoing lines to PSTN, PLMN
Cellular mobile networks	-	multihoming of network nodes (transparent redundancy); roaming addresses for endpoints	Access control by Home Location Register	Ciphered communication; Separate nodes for AAA: Authentication Center, Equipment Identity Register; Charging server	handled through network layer protocols
IT Cloud solutions	cloud technology drivers (e.g. Azure - amazon conversion)	public address and NAT management (exposure issues); injecting routing info to partner cloud	Cloud Networking Gateway	secure VPNs between clouds	Virtualization; Grid resource management

Fig. 4. Requirements for various gateways and their solution approaches within different domains

III. Gatekeeper Services for Inter-Cloud Collaboration

In this Section, we introduce the Gatekeeper as a new Core System concept – as shown in Fig. 5 – for providing inter-cloud servicing capabilities in the Arrowhead framework. All inter-cloud preparations are to be handled by these Gatekeepers until the System (that requested the Service) enters the new, "Partnering Cloud", in order to create the desired producer-consumer connection. However, these modules are not involved in the data path as they operate on the control plane, see in Section III-E. In the followings we will discuss the processes and the issues involved and need to be addressed in this architecture.

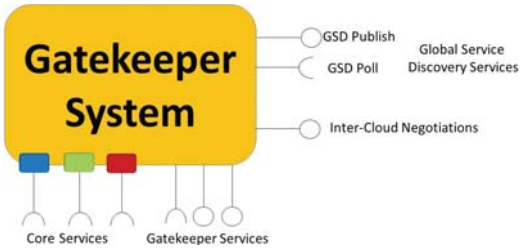

Fig. 5. The proposed gateway service module.

A. General requirements

There is a valid need for inter-cloud servicing, as one single Arrowhead cloud cannot serve for all demands. Here are some examples (use cases) when inter-cloud relations are necessary or simply better than handling requests at a local level:

- Servicing is not possible: no service provider locally.
- Service provider is not available: is in out-of-order status or registered, but not found at the time.
- Servicing is currently not possible: no free resources or the QoS expectations cannot be met locally.
- Servicing within the home cloud is not optimal (e.g. geographically a different cloud is closer or better).

One of the major philosophical questions here is about data ownership, whether the command over servicing belongs to the System (e.g. it can choose its partners) or to the managing central entities of the Local Clouds (and these Core Systems pair up Systems for servicing). As various intelligent decision-making processes (e.g. resource management) are implied here, in our primary scenario we assume that

- data ownership belongs to the Local Clouds (but this is not a necessity of the Gatekeeper Services concept),
- one identity of an Arrowhead SoS Cloud is requesting a service that cannot be fulfilled in the local cloud and therefore
- it might be viable to look for clients in other Arrowhead clouds.

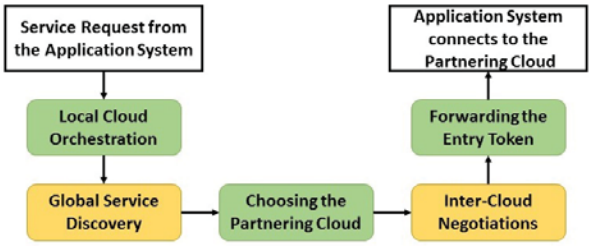

Fig. 6. Creating inter-cloud consumer-producer relationship methodology.

This Core System will provide the following functionality (see Figure 6):

1) *Global Service Discovery*: Finding other Arrowhead Local Clouds with suitable providers for the requested purposes.
2) *Inter-Cloud Negotitations*: authentication, identity verification of the chosen Partnering Cloud, authorizing transactions and establishing secure connections by managing the dialogs ("negotations") between the Clouds for establishing the inter-cloud producer-consumer relationship.

B. Security Issues

Interactions in a closed Arrowhead Local Cloud are secured by the central entities (Core Systems). As one Local Cloud might be a whole cyberphysical system (e.g. smart cars), we face serious security concerns when Service procurement goes outside the boundaries of the Cloud. One Cloud has to be

absolutely certain that it can completely trust its Partnering Cloud when redirecting its System there. For this reason, AAA will play a key role. Since a central *Authentication Service* (e.g. Certificate Agency) might not be available in an ad hoc and volatile inter-cloud environment, these issues might require new approaches like decentralized certificate management [17] or trust management [18]: as trust can also be built on previous experience or the partner simply being a trustworthy contact of my contacts. In this concept, *authorization* and *accounting* (the remaining A-s in AAA) can still be handled on the Local Cloud level with the proper Core Systems, see Section III-E.

C. Global Service Discovery

In this section, we provide approaches that would extend the Service Discovery functionality between Arrowhead Clouds. In our proposition, the Gatekeeper Systems have the ability to look for resources outside the boundaries of their Clouds. They are capable of searching for specific types of Services that are available somewhere else (in different Arrowhead Clouds) and provide the Local Cloud with options for redirection. There is *no* authentication or identity checking at this phase, but tracking the trustworthyness of the "advertisers" might be viable in some cases.

There are several approaches to this tracking of available service locations. These approaches are suitable for different environments and requirements depending on the regularity of inter-cloud interactions, the volatility of service availability in the different Clouds and the flexibility required from the collaborating Arrowhead System-of-Systems.

1) Strict rules on possible gatekeeper connections: The most basic approach is hardwiring – and manually configuring – information about a certain set of other Gatekeepers into each Gatekeeper where they can turn to, see Fig. 8. This can be based on the Service type, time of day, geographical requirements (choosing a physically close partner), etc. This concept brings several advantages and limitations as well. In this scenario, Cloud operators have strict oversight of their Arrowhead Clouds and can easily log the interactivity, set up billing and access control between operators (fits business purposes). It is also highly secure: no need for authentication, identity control or trust management in any phase. However, there is the need for manual edition of configuration and hence there is absolutely no option for scaling automatically.

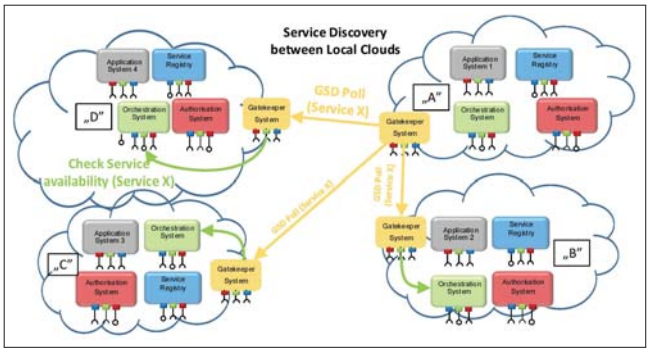

Fig. 7. Service Discovery in a hardwired inter-cloud scenario.

2) Ad hoc neighborhoods: The second approach is still based on per-transaction polling of neighbors, but letting the Gatekeepers automatically detect and poll their neighborhood. The ad hoc peer-to-peer detection of neighbors can provide adaptivity for volatile environments (e.g. moving cars looking for charging stations along the road). However, it will also pose a high administrative overhead (for Gatekeeper components) and cause scaling issues. This methodology will also present a limited list of available resources to the Local Cloud (just from the current contacts). There are several problems to solve here, such as the tracking, trust management and authentication of a rapidly changing neighborhood.

3) Cloud-of-Clouds: The third approach is pointing towards the creation of a dedicated inter-cloud system, where the "demand and supply" of inter-cloud requests can meet. The main purpose of this is to take off the computational overhead from the Arrowhead Cloud Gatekeepers and local Core Systems in a stock-market like environment (see Fig. 8). This centralized entity could provide global matchmaking for the participants of the Cloud-of-Clouds and could also centralize resource allocation and trust management. This can be achieved by tracking the reliabilitiy of the parties and providing the requester Clouds with only the globally optimal Partnering Cloud.

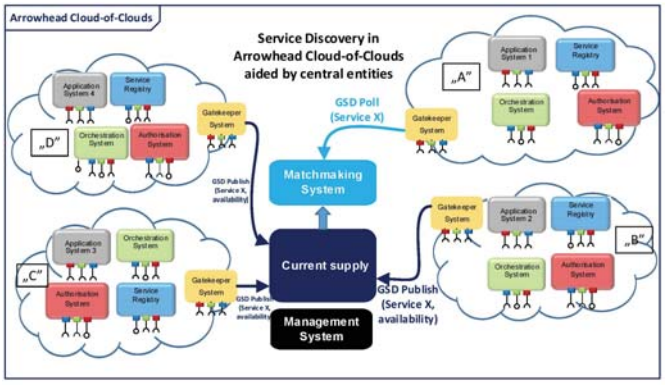

Fig. 8. The Cloud-of-Clouds concept.

D. Inter-Cloud Negotiations

After the requesting Cloud decides for a Partnering Cloud, the Gatekeepers of these Clouds will have to perform negotiations to settle the different aspects of the transaction. At the end of this phase, the requesting System gets a token that will authenticate and navigate it in the Partnering Cloud (using the local Service Discovery data). During this process, the following issues are to be handled:

1) protocol negotiations (Arrowhead Framework version and protocol matching),
2) mutual authentication and identity checking of the parties,
3) actual admission control (authorization and resource allocation for the transaction in the Clouds),
4) establishing a secure connection between the Gatekeepers, therefore the Arrowhead Clouds (creating the data path),

5) sharing the local Service Discovery data of the Partnering Cloud (addressing the Partnering Cloud from the outside),
6) injecting temporary authorization information into the Authorization System in the Partnering Cloud (access control of the ”foreigner” System),
7) the Partnering Cloud Gatekeeper issues a token for the requester with temporary entry and shares it with the requesting Gatekeeper,
8) the requesting Local Cloud forwards this token to the requesting System,
9) the System connects to the producer using the Partnering Cloud’s Core Systems.

E. Requirements for local Core Systems and Services

The proposed inter-cloud servicing methodology will require new functionalities from the Core Systems of the Arrowhead Framework. These new functionalities must include the followings.

- *Authorization:* inter-cloud transactional rights management (access rights from and towards external Clouds)
- *Authentication:* identity verification of other Local Clouds and their Systems
- *Orchestration:* intelligent resource management and Service matchmaking capabilities based on the current local and inter-cloud situation in a scalable but robust manner
- *Additional services* for supporting the inter-cloud activity (e.g. logging, status reporting) the hosting cloud Orchestrator could instruct the foreigner System to contact the Core Services from both Clouds for these purposes. This way everyone will be notified properly of the happenings.
- *QoS Management:* the Global Service Discovery response can also take into account the requested QoS parameters
- *Security System:* the creation of the data path between the Clouds require specialized Systems that handle all the network configurations required for the transaction

IV. A CASE STUDY

In an average situation the sequence depicted in Fig. 9 would lead to System 1 (from Arrowhead Cloud A) connecting to Arrowhead Cloud B for getting Service X from a System in that SoS. This sequence consists of the following logical steps:

1) Normal service orchestration procedure begins (with the help of Cloud A’s Core Service components).
2) In case the request cannot be fulfilled locally, the Orchestrator A will turn to the Gatekeeper A and initiate a Global Service Discovery (see III-C).
3) Gatekeeper A provides a list to the local Orchestrator on Arrowhead Clouds where Service X is currently available.

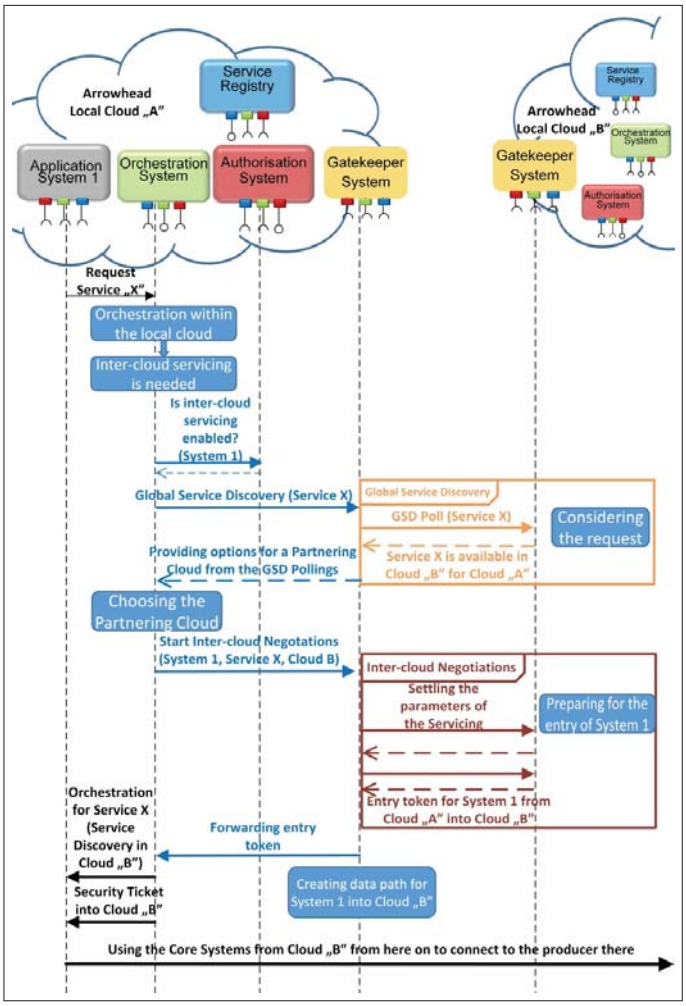

Fig. 9. An example inter-cloud servicing sequence diagram.

4) Cloud A will decide where it will redirect System 1 for Service X (in this case: Cloud B).
5) If there is a suitable Arrowhead Cloud, where Service X is optimally available, Cloud A will check for the requesting s (System 1s) AAA status and rights (e.g. if it has right to use outside resources).
6) Gateway A will start negotiating with Gateway B for access to Cloud B (Inter-cloud Negotiations) as in Fig. 10. Cloud B will also prepare for System 1’s entry.
7) When access to Cloud B has been granted for System 1 (from Cloud A), Gateway B will share the Cloud B access data (e.g. Service Discovery address) and send the transaction token via Gatekeeper A. This token will enable System 1 to access Cloud B.
8) The local cloud of System 1 (Cloud A) will orchestrate these information back to System 1 and redirect it to discover the Services in Cloud B.
9) With the help of the token, System 1 will enter Cloud B to perform Service X using the normal orchestration process of Cloud B.

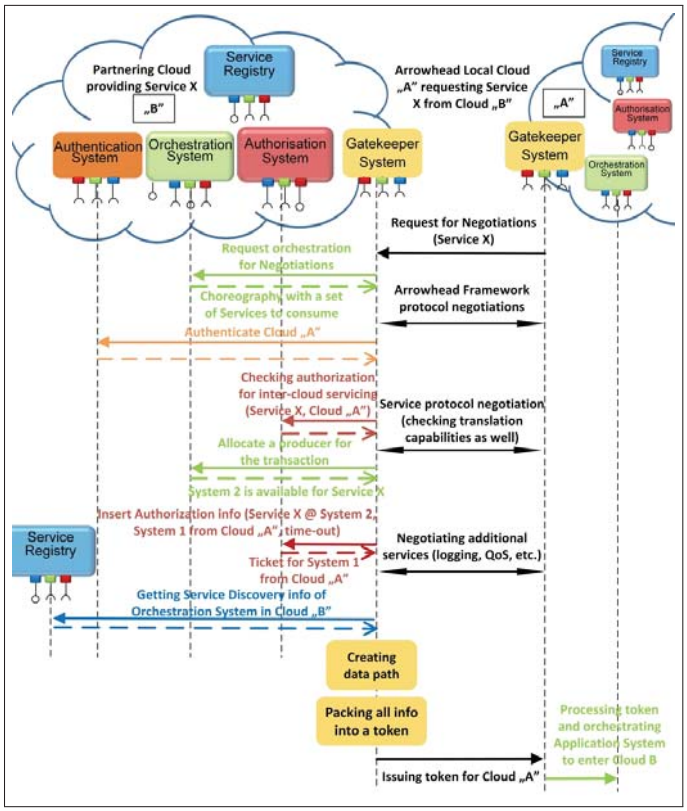

Fig. 10. An example Inter-Cloud Negotations process.

V. Further Work

The intention of the authors with this paper is to ignite discussions about (not just high-level) SOA and inter-cloud architecture designs and methodologies. We have proposed several possible ways and listed the major prospects and issues of those paths. This field requires serious further work on all design level but might be rewarding in the long term as the applications for a robust and intelligent collaboration between automation systems are endless.

VI. Summary

While the current Arrowhead Framework provides means for Systems to collaborate in a service oriented way, the Core Services can merely solve issues within the borders of a given Local Cloud– so far. These System-of-Systems form servicing realms with the help of their instance of Core Systems – and there is demand appearing for inter-cloud collaboration. The concept of Gatekeeper as a new Core System introduced in this paper can solve many of the arising issues, including security, service discovery, orchestration, and other requirements set by the Local Clouds. We described methods for the interworking with the help of such Gatekeepers, and presented a case study of a service consumer System connecting to a service consumer from a different Arrowhead Cloud.

Acknowledgment

***Abstract*—: In orthogonal frequency division multiplexing (OFDM) systems, the implementation of full frequency reuse (FFR) scheme to attain capacity upper bound of cellular system is limited due to inter-cell interference (ICI). To combat ICI, long term evolution system-advanced (LTE-A) employs the coordinated multi-point (CoMP) transmission where exchange of instantaneous channel state within the cluster is essential for joint processing. The major challenge in practical implementation of CoMP is huge backhaul overhead and latency due to congestion. This paper proposes a novel technique for downlink in ICI dominating region where the need of exchange of information through backhaul has been eliminated. In this technique, the number of antennas used in each enhanced nodeB (eNB) per user equipment (UE) is same as the number of signals received by the UE above the interfering threshold level. To pre-cancel the interference, the proposed technique generates an interference aware precoding vector at each eNB based on the instantaneous channel associated with the same eNB.**

***Keywords*-: LTE, OFDM, Inter-cell interference, CoMP cluster, Joint Processing, Backhaul Information.**

I. INTRODUCTION

To optimize the spectral efficiency, the next generation networks employ full frequency reuse (FFR) scheme, where each cell uses the total available bandwidth. Though with this scheme the capacity upper bound of cellular system is attained, a significant degradation in the performance of orthogonal frequency division multiplexing (OFDM) systems is being registered due to inter-cell interference (ICI). The cell-edge user equipments (UEs) experience a poor signal power to interference plus noise power ratio (SINR) compared to the UEs closer to the servicing enhanced node B (eNB) as the powers of interference signals at the cell-edge are comparable with the power of signal from the servicing eNB. This issue has been addressed by Third Generation Partnership Project (3GPP) with coordinated multi-point (CoMP) transmission which has been included in the features of long-term evolution – advanced (LTE-A) standard. Here, coordination is being established among more than one geographically separated eNBs connected through reliable backhaul forming a CoMP cluster [1-6]. This concept was initially discussed in release 10 and further developed with subsequent releases, release 11 and release 12 [7-8]. The CoMP with joint processing (CoMP-JP) promises a significant performance gain where the received signal quality and throughput of the cell-edge UEs is improved by jointly transmitting the intended data of a particular UE from multiple eNBs. In the information theory paradigm, the capacity upper bound is achieved as the different locations of transmitters provide uncorrelated independent paths.

Though theoretically, a significant performance improvement and capacity enhancement for cell-edge UEs is achieved with COMP-JP, its practical implementation faces major challenge with heavy backhaul traffic due to information exchange between eNBs within the CoMP cluster and the latency involved with it [9-10]. The backhaul architecture of LTE can be realized as a tree where multiple eNBs are connected with advanced gateway (aGW) having two logical interfaces; the user data moves from the aGW to each eNB through S1 interface and the mutual information exchange between the cells is made through X2 interface. In CoMP-JP, the preprocessing for interference cancellation has to be carried out at a centralized processing unit (CPU) which is either located at independent location or co-located with any one of the eNBs in the cluster which requires the information data intended for all UEs as well as instantaneous channel state information (CSI) of all paths within the CoMP cluster [11-12]. Hence the performance is limited with significantly high backhaul traffic. The delay in the exchange of instantaneous CSI due to the latency in backhaul causes a sever degradation in system performance [13]. The precise synchronization within the participating eNBs is also a critical issue [14-15].

This paper proposes a novel downlink technique for the UE present in ICI dominating region that completely eliminates the need of any information exchange through backhaul. This technique exploits the recent development in large scale MIMO where the number of antenna present in eNB is much larger than number of UEs is being served in one channel [16]. To pre-cancel the interference, the proposed technique generates an interference aware precoding vector at each eNB based on the instantaneous channel associated with the same eNB. The simulation results show the proposed technique works as good as the CoMP-JP. The organization of the paper is as following: downlink techniques for cell-edge UEs in LTE system are presented in section II, the proposed downlink technique with no backhaul information exchange is presented in section III, performances of different systems with

estimated channel are analyzed in section IV, the simulation result with discussion is provided in section V and section VI concludes the paper. [*Notations*: The bold faced letter $\mathbf{A}$ and bold faced letter with curly bracket $\{\mathbf{A}\}$ represents vector and matrix respectively, $\mathrm{E}\{.\}$ represents the time expectation operation].

II. DOWNLINK FOR CELL-EDGE UEs

Consider an interference region where the UE receives signal from N_T different eNBs with strength above the threshold. The air interface technique in the downlink of LTE system is considered as OFDM due to its robustness against the frequency selectivity of the multipath wireless channel; each OFDM symbol is spreaded over N sub-carriers. The number UE to be served per time-frequency resource per cell site is considered as one. The superscript k is the index of the sub-carrier. The power control in each eNB is assumed to be perfect to normalize the large-scale fading coefficients. In this section the following cases are being considered:

A. Interference system with no CoMP

Here there is no coordination among the eNBs and each eNB transmits its own precoded signal. The signal received at *l-th* UE is given by

$$\begin{aligned} Y_l^k &= \sum_{i=1}^{N_T} H_{i,l}^k \widetilde{X}_i^k + N_l^k \\ &= H_{l,l}^k \widetilde{X}_l^k\big|_{i=l} + \sum_{i=1,i\neq l}^{N_T} H_{i,l}^k \widetilde{X}_i^k + N_l^k \end{aligned} . \quad (1)$$

where $\widetilde{X}_i^k$ is the signal transmitted by *i-th* eNB, $H_{i,l}^k$ is the frequency domain channel gain between *i-th* eNB and *l-th* UE and N_l^k is the frequency domain noise at *l-th* UE, $\mathrm{E}\{|N_l^k|^2\} = \sigma^2$.

B. Ideal case with no interference

This is the ideal case introduced for reference; the interference is considered to be null. Hence the equation (1) reduces to

$$Y_l^k = \sum_{i=1}^{N_T} H_{i,l}^k \widetilde{X}_i^k + N_l^k = H_{l,l}^k \widetilde{X}_l^k\big|_{i=l} + N_l^k . \quad (2)$$

The spectral efficiency per cell site is given by

$$\eta_{\mathbf{no_int}}(\sigma) = \mathrm{E}\left\{ \frac{1}{N} \sum_{k=1}^{N} \log_2\left(1 + \frac{1}{\sigma^2}\left|H_{l,l}^k \widetilde{X}_l^k\right|^2\right)\right\}. \quad (3)$$

C. CoMP-Joint Processing:

In the downlink of CoMP-JP, a virtual spatial multiplexing environment is created where the information symbol for each cell-edge UE is transmitted from all eNBs in the cluster. With all eNBs are equipped with single transmitting antenna, the number of UE in same time-frequency resource per cell site is one. As the transmitters are geographically separated, the preprocessing for interference cancellation has to be carried out at CPU which needs the information symbol of all servicing UEs as well as instantaneous channel information associated with each path through X2 interface. The signal received at *l-th* UE is given by

$$\begin{aligned} Y_l^k &= \sum_{i=1}^{N_T} H_{i,l}^k . \widetilde{X}_i^k + N_l^k = \sum_{i=1}^{N_T} H_{i,l}^k \sum_{q=1}^{N_T} B_{i,q}^k . X_q^k + N_l^k \\ &= \underbrace{\sum_{i=1}^{N_T} H_{i,l}^k B_{i,l}^k X_l^k\big|_{q=l}}_{\text{Signal}} + \underbrace{\sum_{i=1}^{N_T} H_{i,l}^k \sum_{q=1,q\neq l}^{N_T} B_{i,q}^k . X_q^k}_{\text{Interference}} + \underbrace{N_l^k}_{\text{Noise}} \end{aligned} . \quad (4)$$

where X_q^k is the intended signal for *q-th* receiver and $B_{i,q}^k$ is the $(i;q)$ entry of precoding matrix $\{\mathbf{B}^k\}$ generated at CPU. The terms in the r.h.s. are associated with signal, interference and noise respectively. The condition for zero interference is obtained by setting the precoding matrix as

$$\{\mathbf{B}^k\} = \{\mathbf{H}^k\}^{-1} . \quad (5)$$

Here $\{\mathbf{H}^k\}$ is the frequency domain channel matrix with its $(i;l)$-*th* entry is $H_{i,l}^k$. Hence the knowledge of the channels corresponds to all paths in the cluster are essential at CPU which propels instantaneous CSI exchange in the cluster through X2 interface. The high backhaul load and the latency involved in this process limit the performance of CoMP-JP in its practical deployment. With perfect knowledge of channel state, the interference at all UE reduces to zero and the SINR is

$$\left(SINR_l^k\right)_{\mathbf{JP_Ideal}} = \frac{1}{\sigma^2}\left|\sum_{i=1}^{N_T} H_{i,l}^k B_{i,l}^k X_l^k\right|^2 . \quad (6)$$

The spectral efficiency per cell site for CoMP-JP technique is given by

$$\eta_{\mathbf{JP_Ideal}}(\sigma) = \mathrm{E}\left\{ \frac{1}{N} \sum_{k=1}^{N} \log_2\left(1 + \frac{1}{\sigma^2}\left|\sum_{i=1}^{N_T} H_{i,l}^k B_{i,l}^k X_l^k\right|^2\right)\right\}. \quad (7)$$

III. PROPOSED DOWNLINK TECHNIQUE WITH NO BACKHAUL INFORMATION EXCHANGE

Unlike CoMP-JP, the proposed technique eliminates the need of information exchange between eNBs through backhaul and the cell-edge UE gets its information only from the servicing eNB. Consider an interference region

where the UE receives signals above the interference threshold is N_T and hence same number of UEs being served in one channel. With this technique, the number of antenna used in each eNB per UE in each cell site is also N_T. Each eNB receives complex information symbol for its own UE through S1 interface and generates an (N_TX1) interference aware precoding vector; for *i-th* eNB it is $\mathbf{P}_i^k$. Hence the signal transmitted from its *j-th* antenna is given by $\widetilde{X}_{(i,j)}^k = P_{(i,j)}^k X_i^k$ where $P_{(i,j)}^k$ is the *j-th* element of $\mathbf{P}_i^k$. The signal received by *l-th* UE is given

$$\begin{aligned} Y_l[k] &= \sum_{i=1}^{N_T}\sum_{j=1}^{N_T} H_{(i,j),l}^k.\left(X_i^k.P_{(i,j)}^k\right)+N_l^k \\ &= \underbrace{\sum_{j=1}^{N_T} H_{(l,j),l}^k.\left(X_l^k.P_{(l,j)}^k\right)\Big|_{i=l}}_{\text{Signal}} + \underbrace{\sum_{i=1,i\neq l}^{N_T}\sum_{j=1}^{N_T} H_{(i,j),l}^k.\left(X_i^k.P_{(i,j)}^k\right)}_{\text{Interference}} + \underbrace{N_l^k}_{\text{Noise}}. \end{aligned} \quad (8)$$

The terms in the r.h.s. are associated with signal, interference and noise respectively. The condition for zero interference is

$$\sum_{j=1}^{N_T} H_{(i,j),l}^k.P_{(i,j)}^k = \begin{cases} 1 & for\ i=l \\ 0 & for\ i\neq l, \end{cases} \quad \forall i,j \le N_T. \quad (9)$$

In vector notation,

$$\{\mathbf{H}_l^k\}\mathbf{P}_l^k = \mathbf{0}_l, \quad (10)$$

where $\{\mathbf{H}_l^k\}$ is the (N_T X N_T) channel matrix for *l-th* eNB and $\mathbf{0}_l$ is a (N_T X 1) column vector whose *m-th* element is given by

$$\mathbf{0}_l(m) = \begin{cases} 1 & for\ \ m=l \\ 0 & for\ \ m\neq l. \end{cases} \quad (11)$$

The equation (20) makes *l-th* participating eNBs in the cluster aware of the interference caused by others and generates interference aware precoding vector. The precoding vector for *l-th* eNB is

$$\mathbf{P}_l^k = \{\mathbf{H}_l^k\}^{-1}.\mathbf{0}_l. \quad (12)$$

The precoding vector used at *l-th* eNB is identical with the *l-th* column of the inverse of the channel matrix associate with same eNB. Hence no knowledge of CSI associated with other interfering eNB is required resulting no need for exchange of information between eNBs through backhaul. The expression for SINR with precoding vector calculated from exact channel knowledge is given by

$$\left(SINR_l^k\right)_{\text{Prop_Ideal}} = \frac{1}{\sigma^2}\left|\sum_{j=1}^{N_T} H_{(l,j),l}^k.\left(X_l^k.P_{(l,j)}^k\right)\right|^2. \quad (13)$$

The spectral efficiency per cell site for the proposed technique is given by

$$\eta_{\text{Prop_Ideal}}(\sigma) = \mathrm{E}\left\{\frac{1}{N}\sum_{k=1}^{N}\log_2\left(1+\frac{1}{\sigma^2}\left|\sum_{j=1}^{N_T} H_{(l,j),l}^k.\left(X_l^k.P_{(l,j)}^k\right)\right|^2\right)\right\} \quad (14)$$

IV. SYSTEMS WITH ESTIMATED CHANNEL

In practical scenario, the CSI of all involved path has to be estimated. The LTE supports TDD system where the channel reciprocity is exploited; the downlink CSI is estimated via uplink training and the process is called channel sounding [17]. In the training phase, each UE of the cluster broadcasts their respective pilot sequence; to combat transmit diversity problem at the estimation end, the sequences have to maintain orthogonality among each other. The estimation process generates the estimate of channel gain H^k as $\hat{H}^k$ with estimation error given as

$$\delta^k = \hat{H}^k - H^k, \quad (15)$$

The error in the estimation process is assumed to be bounded in a spherical uncertainty region defined as [18]

$$\Re = \{\delta^k : \|\delta^k\| \le \varepsilon\}, \quad (16)$$

where ε is the radius of uncertainty sphere. Hence the SINR at the *l-th* receiver for CoMP-JP and the proposed technique are respectively given as

$$\left(SINR_l^k\right)_{\text{JP_Est}} = \frac{\left|\sum_{i=1}^{N_T}\hat{H}_{i,l}^k B_{i,l}^k X_l^k\right|^2}{\sigma^2 + \left|\sum_{i=1}^{N_T}\delta_{i,l}^k \sum_{q=1,q\neq l}^{N_T} B_{i,q}^k.X_q^k\right|^2} \quad (17)$$

$$\left(SINR_l^k\right)_{\text{Prop_Est}} = \frac{\left|\sum_{j=1}^{N_T}\hat{H}_{(l,j),l}^k.\left(X_l^k.P_{(l,j)}^k\right)\right|^2}{\sigma^2 + \left|\sum_{i=1,i\neq l}^{N_T}\sum_{j=1}^{N_T}\delta_{(i,j),l}^k.\left(X_l^k.P_{(i,j)}^k\right)\right|^2}. \quad (18)$$

And the corresponding spectral efficiencies per cell site are

$$\eta_{JP_Est}(\sigma)=\mathrm{E}\left\{\frac{1}{N}\sum_{k=1}^{N}\log_2\left(1+\frac{\left|\sum_{i=1}^{N_T}\hat{H}_{i,l}^{k}B_{i,l}^{k}X_{l}^{k}\right|^2}{\sigma^2+\left|\sum_{i=1}^{N_T}\delta_{i,l}^{k}\sum_{q=1,q\neq l}^{N_T}B_{i,q}^{k}.X_{q}^{k}\right|^2}\right)\right\} \quad (19)$$

$$\eta_{Prop_Est}(\sigma)=\mathrm{E}\left\{\frac{1}{N}\sum_{k=1}^{N}\log_2\left(1+\frac{\left|\sum_{j=1}^{N_T}\hat{H}_{(l,j),l}^{k}.\left(X_{l}^{k}.P_{(l,j)}^{k}\right)\right|^2}{\sigma^2+\left|\sum_{i=1,i\neq l}^{N_T}\sum_{j=1}^{N_T}\delta_{(i,j),l}^{k}.\left(X_{l}^{k}.P_{(i,j)}^{k}\right)\right|^2}\right)\right\} \quad (20)$$

V. SIMULATION RESULTS AND DISCUSSION

In this section, the downlink for cell-edge UE has been simulated. Hexagonal cellular structure is considered as shown in Fig 1, where the number of eNBs from which a UE receives signal with significant strength is three.

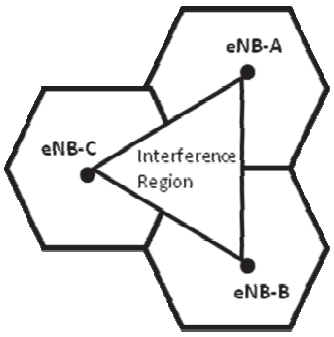

Fig.1. Region of interference in hexagonal cellular structure

A perfect power control in each eNB is assumed so that the received powers of all signals in the cluster are same. The following systems are simulated and performances are compared. (1) A system having no CoMP; the UE receives signal from its servicing eNB as well as from the other two interfering eNBs. (2) An ideal scenario with no interference; the UE receives signal only from its servicing eNB. (3) A CoMP-JP system with UE being served in same time- frequency resource equals to the cluster size. A perfect backhaul with zero latency is assumed. (4) The proposed system where the numbers of antennas present in each eNBs is equal to the number of signals received by the UE above the threshold level. The simulation includes an ideal system where perfect CSI of all paths assumed to be present at transmitting end along with the estimated system where each eNB estimates the channels associated with them using channel sounding technique. For estimated system, type-1 frame structure for LTE is considered where each sub-frame is of duration 1ms, consists of 14 symbols where in every seventh symbol dedicated estimation slot is present [19]. Details of simulation specifications are given in table-1.

Table-1 Simulation Specification

Parameters	
System Specification	
Signals received by the UE above interfering threshold level	03
No of UE/channel in interfering region	03
Transmission Specification	
Air interference	OFDM
FFT size	512
Length of cyclic prefix	16
Types of modulation	QPSK
Channel Specification	
Type of channel	6 tap, COST 207 Typical Urban
Maximum Doppler shift	5Hz

Cumulative distribution function (CDF) of spectral efficiency per cell site (Bit/sec/Hz/cell site) at SNR=10dB is shown in Fig. 2 and the spectral efficiency per cell site (bits/sec/Hz/cell site) vs SNR performance is plotted in Fig. 3.

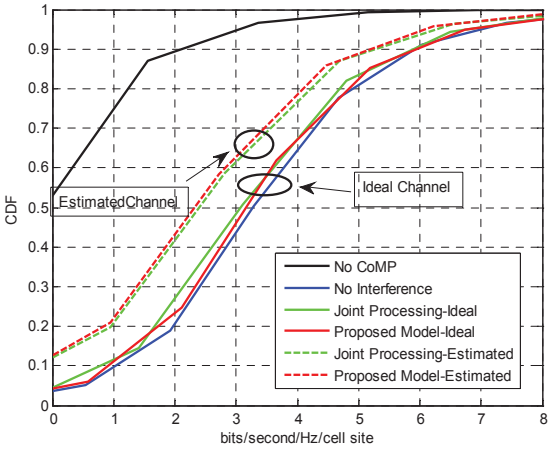

Fig. 2 Cumulative distribution function (CDF) of spectral efficiency per cell site (Bit/sec/Hz/cell site) at SNR=10dB for UE receiving signal with same power from all the immediate neighboring eNBs

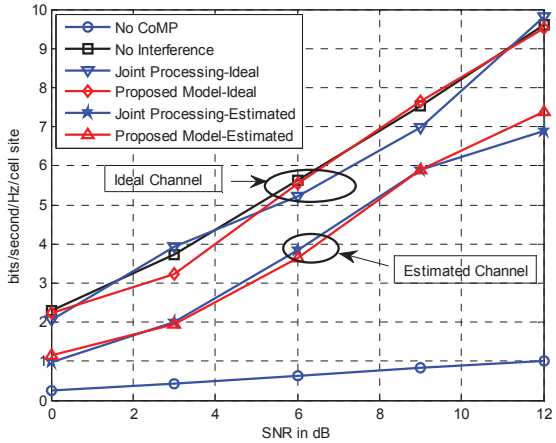

Fig. 3 Spectral efficiency per cell site (Bit/sec/Hz/cell) site performance for UE receiving signal with same power from all the immediate neighboring eNBs

Fig. 4 provides the uncoded BER vs SNR performance for UE receiving signal with same power from all the immediate neighboring eNB with different CoMP systems.

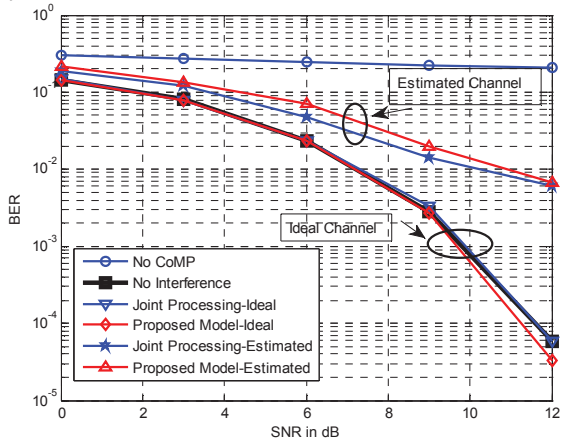

Fig. 4 Uncoded BER performance for UE receiving signal with same power from all the immediate neighboring eNBs

The performance of the system with no CoMP is too poor to be used as the signals from other two eNBs are considered as noise. It is observed that the proposed technique performs equally well as the CoMP-JP for both ideal and estimated CSI cases; for the former case with true knowledge of channel state, complete interference cancellation takes place and its performance approaches that of the system with the no interference. As the proposed technique matches with the performance of CoMP-JP, its implementation for interference cancellation at cell-edge UE has a significantly upper hand. In the proposed technique, no real-time information exchange between eNBs of the cluster is essential. Unlike the CoMP-JP, all the participating eNBs in the CoMP cluster are aware of the interference and generate their respective precoding vector by using only the channel matrix associated with the same eNB.

VI. CONCLUSION

This paper proposes a novel downlink technique for cell-edge UEs to combat ICI with no information exchange through backhaul. The proposed technique shows almost identical performance, in both ideal and estimated cases, with CoMP-JP technique which has huge backhaul overload. Using this technique, the challenge of practical implementation of FFR scheme in OFDM system, to achieve upper bound of capacity, has been reduced significantly.

Abstract – This paper investigates efficient filtering techniques for chronic wound (CW) image pre-processing under Tele-wound network. In CW healing progress knowing the status of the wound is important as the status of the wound is the indicator of amount of healing. Hence, it is required for the doctors to check the status of CW periodically to track the healing process. But this becomes difficult for the patient who has to visit the doctors again and again. The objective of this research work is to accurately access the healing status of CW with improved image processing techniques with help of proper filtering. Efficient filtering techniques help to reduce the noise for CW images. The experimental results are presented by comparing different parameters. Performance parameters are peak signal to noise ratio (PSNR), mean square error (MSE), signal to noise ratio (SNR) and mean absolute error (MAE). Results shows Median filtering provides better performances with respect to high PSNR and reduced MSE between original and filtered image.

Keywords – Median filtering; Chronic wound; Wound images; Image processing

I. INTRODUCTION

An accurate and systematic CW assessment is the important task of wound care. Wound healing takes longer duration and regular check-up with certain interval is one of the big obstruct in wound caring [1]. Efficient screening of CW images is important for prognostic and therapeutic intervention. Visual assessment by medical people is time-consuming; subjective; and inconsistent whereas computerized analysis of wound images will be rapid and efficient approach; which requires appropriate image processing techniques and experts' domain knowledge for improved screening. A CW not only affects the individual but entire family gets suffered due to the enormous cost of wound care. Furthermore, it should be noted that without intensive medical care and treatment, a CW will most likely never heal. The effects of wounds are mainly delayed to repair or suspended skin re-growth, slow older cell proliferation rate, social isolation, depression, and a decrease in productivity, long-term and costly treatment. Five types of open wounds are abrasion (topmost layer of the skin is removed; painful), incision (smooth edges), laceration (irregular edges), puncture (deep; narrow wound) and avulsion (bleed heavily) respectively. The acquired CW images have been processed over wireless medium. The color changes of CW's gives important implication of the wound healing status to the patients, so proper filtering is required to remove the random or impulse noise. The image noise is the variation of color information randomly in images produced by image sensor with smartphone's and digital camera. The morphological filtering is used to preserve edge information of an image and eliminating the noise [3]. Wild et al. [4] developed digital wound measurement system where quality of the pictures has been maintained by filter of the device.

Tele-wound network (TWN) is defined as the delivery of medical health care services and sharing of clinical information over a distance using telecommunication platform [1, 2]. The aim is to provide better healthcare service to any place wherever and whenever required. TWN system offers reliable and efficient diagnostic aids to patients at affordable cost. TWN allows new technologies in sensing, medical imaging and wireless data communications with much lower cost, enabling the development of new widespread remote medicine initiatives. An optical imaging system is used for the TWN system for capturing skin wound images of a patient. Skin's abnormal conditions are common in the developing countries where symptoms of skin diseases are observed.

Christos et al. [5] has been taken 77 color wound photographs through Nikon digital SLR camera and used polarized filters to reduce the light reflection from CW surface. Lie et al. [6] captured wound images by the smartphones camera and used Gaussian smoothing filter to minimize the noise. Barone et al. [7] used SCIELab spatial filters for original CW image. Ederson et al. [8] applied anisotropic diffusion filtering to avoid the undesirable effects on segmentation for dermatological ulcers. Marina et al. [9] used difference of Gaussians (DoG) filter for wound segmentation. In the help of DoG filtering, local intensity variations has been equalized. Dorra et al. [10] used Gabor filtering technique for multispectral imaging. In this paper, the objective is to investigate best filter amongst all used filters on the basis of image quality assessment. The camera images

mostly suffer from independent impulse noise that can be introduced on a CW image may be salt and pepper or random-valued impulse noise. The best filtering technique is required to remove the noises for better quality of image.

The organization of paper is as follows: Section II describes the system architecture of tele-wound system. In section III comparative measures are defined. Section IV provides the experimental results for filtering and their effect on performance evaluation parameters. Finally section V describes conclusions.

II. System Architecture

TWN system is used to processing and monitoring the wound images. TWN has been proposed for this case could be efficiently used in remote location where specialists' services are not readily available. TWN system is used for characterizing wound tissue accurately and deals with large number of wound affected patients. TWN would reduce the problem of repeated and timely visits to doctors by remote monitoring and controlling. TWN minimizes the burden of health care unit and decreases the patient concerns. This TWN system consists of three modules namely image acquisition, tele-medical hub (TMH) and doctor's feedback. The portable, handheld device like smartphones can be used to capture high-quality red-green-blue (RGB) wound images and acquire patient's demographic information and send it to the TMH [11] [12] through wireless medium viz. 2G to 2.5G (iDEN 64 kbps, GPRS 171 kbps, EDGE 384 kbps), 3G (WCDMA, CDMA2000, TD-CDMA), SATELLITE, WLAN and 4G systems where the provision of faster physiological data transfer rate remotely. Wound healing process is totally depended on time i.e. may be required lengthy and several appointments with a clinician. The wound image quality can be enhanced at pre-processing stage by filtering techniques. Fig. 1 represents the TWN system for wound status monitoring. The processed CW image goes to image processing in TMH for pre-processing purpose. The wound image filtering technique is required to remove the noise. The CW image is smoothed by a median filtering for noise reduction by providing well-defined and continuous edge information. Wireless communication supported TWN system reduces the need to transport patents for physical consultation from the doctor, avoiding physical and mental stress, time and expense. This framework is effective for both rural as well as urban people; it gives good performance in terms of CW data monitoring and advanced diagnostic. Fig. 2 depicts the schematic diagram for wound image processing.

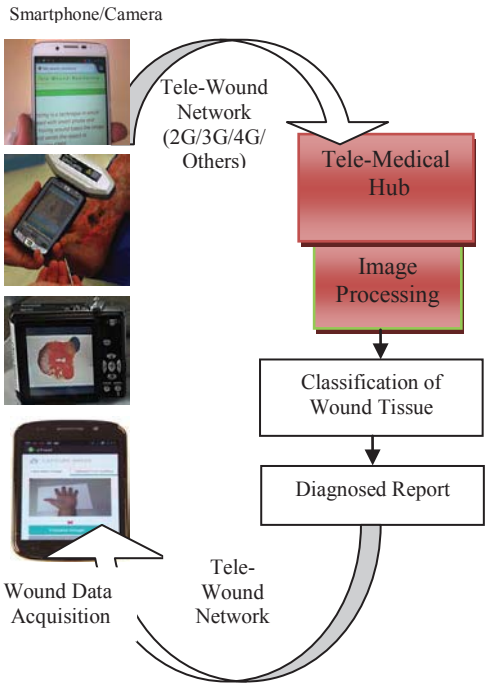

Fig. 1. Tele-wound network system

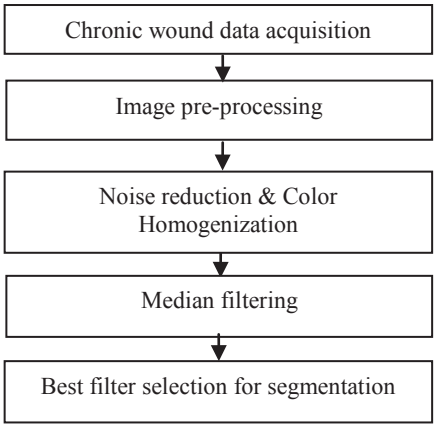

Fig. 2. Schematic diagram for wound image processing

III. Denoising Filters for Wound Imaging

The image denoising is a significant medical imaging task that is able to remove noise while preserving edges. In this paper, ten different filters have been considered and a comparative study is presented below.

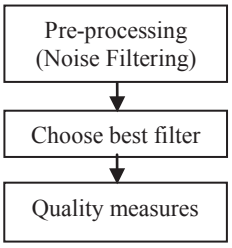

Fig. 3. Steps for quality measures

These important filters are as follows: Mean filter, Average filter, Min filter, M3 filter, Max filter, Log filter, Laplacian filter, Midpoint filter, Gaussian filter, and Median

filter respectively. The quality measure step is shown in Fig. 3. The $f(x,y)$ is represented as filtered image and $g(s,t)$ is the original corrupted image.

Mean filter – This filter is belongs to linear filtering scheme. This filtering is used to smoothing the images, mainly reducing the intensity variation between pixels. It is useful for removing Gaussian noise but preserving criteria is poor. The statistical model of the noise is swown in below.

$$p(x) = \frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{(x-\mu)^2}{2\sigma^2}} \quad (1)$$

$$\textit{Mean filter } (x_1 \ldots . x_N) = \frac{1}{N}\sum_{i=1}^{N} x_i \quad (2)$$

Where, $x_1 \ldots . x_N$ is the pixel range of image.

Average filter – It is non-linear smoothing filter. This filter is used to avoids the edge blurring by searching the homogenity of current pixel neighbourhood and sharpend resulting image.

Min filter – This filter is used to fine darkest point in an image and also reduces the salt noise.

$$\textit{Min filter } \hat{f}(x,y) = \min_{(s,t)\in S_{x,y}} \left[g(s,t) \right] \quad (3)$$

M3 filter – This is the smoothing and hybrid of mean and median filter and used to remove the noise.

$$\textit{M3 filter } f(x,y) = \max\left[\underset{(s,t)\in S_{xy}}{mean}\{g(s,t)\}, \underset{(s,t)\in S_{xy}}{median}\{g(s,t)\} \right] \quad (4)$$

Max filter – This filter is used to findout the brightest point in an image and reduces the pepper noise.

$$\textit{Max filter } \hat{f}(x,y) = \max_{(s,t)\in S_{x,y}} \{g(s,t)\} \quad (5)$$

Log filter – This filter is smoothing the imageand are very sensitie to noise.

Laplacian filter – It is used to sharpening and calculates the second derivatives of an image and also measures the rate of change the first derivatives.

$$\textit{Laplacian filter } g(x,y) = f(x,y) + c\left[\nabla^2 f(x,y) \right] \quad (6)$$

Midpoint filter – This filter is very much useful or gaussian and uniform oise. It is the average of highest pixel and the lowest pixel with respect to intensity within the window size.
Midpoint filter

$$\hat{f}(x,y) = \tfrac{1}{2}\left[\max_{(s,t)\in S_{x,y}} \{g(s,t)\} + \min_{(s,t)\in S_{x,y}} \{g(s,t)\} \right] \quad (7)$$

Gaussian filter – This filter is responsible for corrects the spectral coefficient and aplitude spectrum officients within filter window.

Median filter -

The Median filter is used in pre-processing stage for providing the image color identification. The bright white spot arises on the wound image due to reflection. Median filter [13] with 5×5 window size is employed to eliminate the salt and pepper noise in wound images. The median filter can smooth noisy regions, enhance the low-contrast wound region and better preserve the structure of the edges. It considers each image pixel and looks at its close by neighbors to choose whether or not it is representative of its environs. Median filter replaces the value of central pixel with the median of all the surrounding neighborhood pixel values. The median is intended by first categorization the entire pixel values from the neighboring neighborhood into numerical categorize and then restoring the pixel being measured with the middle pixel value. The average of two middle pixel values is taken when the neighborhood under consideration contains an even number of pixels. The Median filter is represented as:

$$\textit{Median filter } (x_{1} \ldots x_N) = \textit{Median } [||x_1||^2 \ldots\ldots ||x_N||^2] \quad (8)$$

The two major advantages of median filter [14] over mean filter are: (a) the median is more robust averages than mean and as such, a single very unrepresentative pixel in a neighborhood will not significantly affect the median value and (b) as the median value is actually the value of one of the pixels in the neighborhood, it does not generate new improbable pixel values when the filter straddles an edge. Hence, the median filter is much superior at preserving sharp edges than mean filter.

A. Color homogenization

CWs are having complex mixture of colored tissues with varied intensity. Anisotropic diffusion filtering [15] is used for homogenization of color along with preservation of edges, only smoothing between edges. The objective of this method is to reduce image noise without eliminating significant portion of the image. The color homogenization is used in this work using combined Gray world assumption and Retinex theory [16].

IV. Simulation Results

The outcomes of the different filters are presented in this section. Total ten filters were implemented and output images are represented in Fig. 3. Most of them use mathematical morphology operations. 5×5 square structuring elements were used. These filters were applied on set of fifty five randomly selected wound images from our developed wound database as well as an online wound image database. The number was significantly reduced to the best five to have an automatic filter selection. In order to access the quality of image, four

different quantitative performance measures are defined as MSE; PSNR; SNR; MAE respectively.

(a) MSE – It is the most important image quality measuring method. It is basically squared error between enhanced image and original CW image. Mathematically, defined as:

$$MSE = \frac{1}{M \times N} \sum_{x=0}^{M-1} \sum_{y=0}^{N-1} \left[F(x,y) - F_{fltr}(x,y) \right]^2 \quad (9)$$

where, $F(x,y)$ and $F_{fltr}(x,y)$ are the input and filtered output images.

(a) PSNR – It is used to calculate the ratio between maximum possible intensity value of the CW image and MSE. PSNR is defined as:

$$PSNR = 10 \log_{10} \left[\frac{R^2}{\frac{1}{M \times N} \sum_{x=0}^{M-1} \sum_{y=0}^{N-1} \left[F(x,y) - F_{fltr}(x,y) \right]^2} \right] \quad (10)$$

Here, R is the maximum possible peak intensity value of the image.

(b) SNR – It is the ratio between signal i.e. enhanced image and noise in the spatial domain. In this case, noise is the difference between input image and filtered image.

$$SNR = \left[\frac{\sum_{x=0}^{M-1} \sum_{y=0}^{N-1} \left[F_{fltr}(x,y) \right]^2}{\sum_{x=0}^{M-1} \sum_{y=0}^{N-1} \left[F(x,y) - F_{fltr}(x,y) \right]^2} \right] \quad (11)$$

(c) MAE – This method is used to measure how close predictions are to the eventual outcomes. The MAE is given by

$$MAE = \frac{1}{n} \sum_{i=1}^{n} |f_i - y_i| = \frac{1}{n} \sum_{i=1}^{n} |e_i| \quad (12)$$

where, MAE is an average of the absolute errors, $e_i = |f_i - y_i|$, f_i is the prediction and y_i is the true value, n is the number of observations.

The four important parameters have been analyzed for the quality of images. Lower value of MSE indicates that there is very small change between original and filtered image. On the other hands, higher value of PSNR, SNR reports that there is very small change. From Fig. 5-8, we observe that median filter is the best choice for visualization because it provides good PSNR (67.28), SNR (54.56), MAE (0.22) and MSE (3.29). This filtering technique improves the segmentation performance with the maintaining proper homogeneity of the image. The median filtering technique provides better visualization after observing the all filtered image results.

V. Conclusion

In this paper, we have discussed about the different filtering techniques for chronic wound analysis under tele-wound network. The acquired CW image undergoes filtering scheme to remove the noise from the CW image. It is observed that median filter performs well for noise removal out of others filters with respect to different performance parameter like PSNR, MAE, SNR and MSE. We have done a comparative studied with all the filters and taking best filter selection based on average values of set of images. Results shows Median filtering provides better performances with respect to high PSNR and reduced MSE between original and filtered image. The outcome obtained manifests a system has greater scope of utilization in the field of evaluation through tele-wound network.

Performance Analysis Of Interference Cancellation In MIMO-FBMC

V.Padmapriya [1] and N.Venkateswaran[2]
Department of Electronics and Communication Engineering
SSN College of Engineering
Chennai,India

***Abstract*— FBMC has been researched as an heir to OFDM with the aim of enhancing bandwidth of the physical layer in conventional wireless communication techniques. Its application in new age systems like cognitive radio and MIMO has been a topic of great interest in recent times. MIMO systems built on FBMC modulation promise very high data rates in terrestrial wireless communication. Data streams from multiple antennas can cause serious interference at the receiver. De-correlating these streams is necessary to ensure accurate detection of the transmitted symbols. In this paper we analyse the performance of three interference cancellation techniques in FBMC based MIMO systems, namely-FBMC-ZF, FBMC-MMSE and FBMC-SVD based signal de-correlation. Simulation results show that FBMC SVD signal de-correlation is superior to the other two de-correlation techniques.**

I. Introduction

OFDM has been widely accepted as a successful modulation format for nearly two decades [1].However it does have its share of limitations. It requires the transmission of cyclic prefix and it uses a rectangular window to shape the signals, which inturn degrades the stopband attenuation. These limitations cost heavily interms of the required spectrum . In [1] OQAM based FBMC system,which uses well contained waveforms to shape the signals, is suggested as an alternative to OFDM. Also [1] asserts that FBMC systems are a superior choice for many applications like cognitive radio, DSL and uplink of multi user multicarriersystems. This techniqe is the brainchild of Saltzberg [2].

In recent times the demand for high data rates has increased significantly.Both the number of users and the kind of data that is being transmitted on the wireless channel has placed heavy demands on the available spectrum. MIMO has emerged as a promising solution to requisite.In [3],[4] the performance of FBMC-MIMO system is analysed .In [4][5] [6] it is show that FBMC's performance is as good as that of OFDM. Though it has been argued that FBMC is more demanding in terms of complexity it is suggested in [3] that this can be overlooked when compared to the complex signal processing required for synchronization in the case of uplink OFDM-MIMO systems.

The MIMO scheme can characterised by $y = Hx + n$ Where y and x are the received and transmitted vectors respectively. H is the MIMO channel matrix. In the single user scenario the transmit vector x consists of several parallely encoded data streams. The multiple subcarriers transmitted by each antenna are of the same frequency. These parallel data streams superimpose at the receiver antenna array. The interference presented by the neighbouring data streams may cloud the decisions at the receiver. It is necessary to separate these signals to achieve an acceptable BER performance. This paper considers three techniques which can be deployed to mitigate multi-antenna interference in FBMC-MIMO systems. Their performance has been compared under the assumption of a flat-rayleigh fading channel.

The paper is organized as follows: The basic FBMC-MIMO system is presented is section-II. The zero forcing based inter antenna interference cancellation technique is discussed in section-III.A. This is followed by a description of MMSE based interference cancellation in section III.B. The application of SVD for signal decorrelation is discussed in section II.C. The simulation results have been provided in section IV. Conclusions drawn based on these results have been presented in section V.

II. FBMC OQAM-MIMO System Model

The overall architecture for FBMC based MIMO transceiver is shown in Fig.1.The input bits are first subject to OQAM pre-processing. These symbols are then mapped to multiple carriers by the synthesis filter bank. The independent data streams from each antenna is passed through the MIMO channel. The inference caused by the data streams from the neighbouring antennas is then cancelled using any of the interference mitigation techniques discussed in section III. The independent data streams are filtered using analysis filter bank. The output is finally recovered by subjecting the received stream to OQAM post-processing.

This paper focuses on a multiantenna configuration consisting of N_T transmit antennas and N_R receiving antennas. The signal at the output of n^{th} transmit antenna is given by

$$S_n(k) = \sum_{i=-\infty}^{\infty} \sum_{m=0}^{M-1} V_{nm}(i) f_m(k - \frac{iM}{2}) \quad (1)$$

where,

$$f_m(k) = p(k) e^{j(\frac{2\pi m}{M}(k - \frac{L_p - 1}{2}))} \quad (2)$$

$$m = 0, 1, 2, ...M - 1, k = 0, 1, 2, ...L_p - 1$$

Here $Lp = Mg - 1$ denotes the length of the filter.The parameter g denotes the overlapping factor which gives the number frequency co-effecients introduced in between the FFT filter co-effecients[8],[9]. f_m is used to construct the analysis and synthesis filter bank. M denotes the number

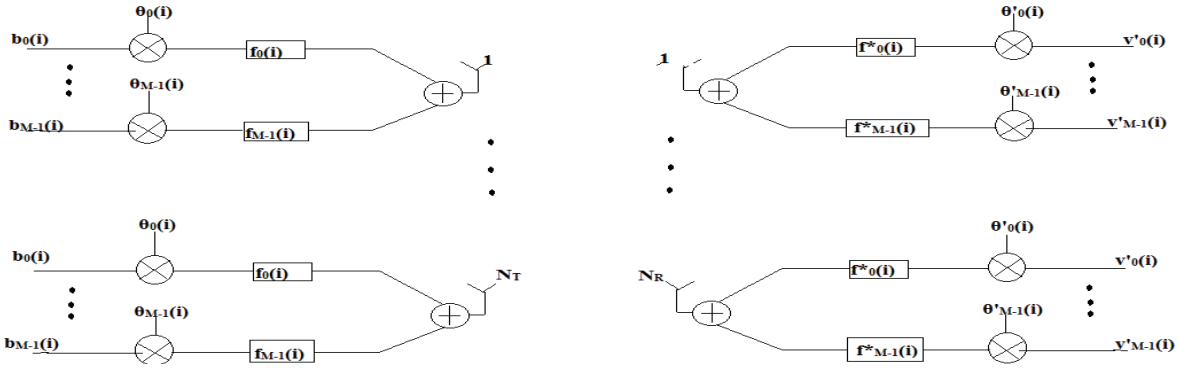

Fig. 1: Overall architecture of a MIMO-FBMC system

Table 1. COMPARISON OF PHASE CHANGE BETWEEN ADJACENT SYMBOLS IN QAM AND OQAM

Period	QAM			OQAM		
	Inphase Component	Quadrature Component	Resultant Phase	Inphase Component	Quadrature Component	Resultant Phase
T/2	1	1	180	1	0(assumed)	270
T	1	1	180	1	1	180
3T/2	0	0	0	0	1	90
2T	0	0	0	0	0	0
5T/2	-	-	-	0(assumed)	0	0

of carriers and V denotes the OQAM symbols.A detailed description of each of the various sub-bolcks is as follows.

A. OQAM Preprocessing

Offsetting the in phase and quadrature phase carriers alleviates the problem of phase noise. This is because the maximum change in phase between two consecutive symbols is restricted to be 90^0.This can be comprehended from Table.1 which compare the phase of the transmitted signal for the QAM and OQAM.The bit stream considered in the tabulation is 1100.

The transmitted OQAM symbols can be expressed as the product of the real valued PAM symbols $b_m(i)$ and the phase term $\theta_m(i)$ .The transmitted OQAM symbols can be expressed as

$$v_m(i) = b_m(i)\theta_m \tag{3}$$

Where,

$$\theta_m(i) = \begin{cases} 1, \ if \ m+i \ is \ even \\ j, \ if \ m+i \ is \ odd \end{cases} \tag{4}$$

B. The Analysis And Synthesis Filter Banks

The filter bank used is based on the complex modulated - overlapped filters designed in [7].It uses FIR filters which are designed to have superior stopband attenuation. The impulse response of the prototype filter is give by

$$p(k) = \begin{cases} \frac{1}{N}\left(C_o + 2\sum_{l=0}^{g-1} C_l cos(\frac{2\pi lk}{N}), & 0 < k < N-1 \\ 0, otherwise \end{cases} \tag{5}$$

Where $N = gM$ .The fourier transform of $p(k)$ consists of the fourier transform several overlapping rectangular windows which are shifted in frequency by $\frac{2\pi}{M}$.The proper choice of filter co-efficients C_l can be used to achieve filters with excellent stop band attenuation. It ensures that the spectrum of each subcarrier is well contained within the specified bandwidth. In this paper uses a filter with an overlapping factor of four is considered. The values of C_l used in this paper are obtained from [7] tabulated in Table.2.The complex modulated filter bank can be obtained by localizing the prototype LPF over different frequencies. The filter bank can be obtained using the expression (2). The frequency response of the first five analysis fillters is shown in Fig.2. The Analysis filter bank is matched to the synthesis filter bank and is thus denoted as $f_m^*(k)$. A FFT based implementation of these filter banks is followed as depicted in Fig.1.

C. The MIMO System

The MIMO configuration transmits N_T parallel filtered data streams. It is necessary to render these streams to be independent of one another as they propagate through the

TABLE 2. FILTER COEFFICIENTS

Coefficients	Corresponding Value For g=4
C_o	1
C_1	-0.97195983
C_2	0.70710678
C_3	-0.23514695

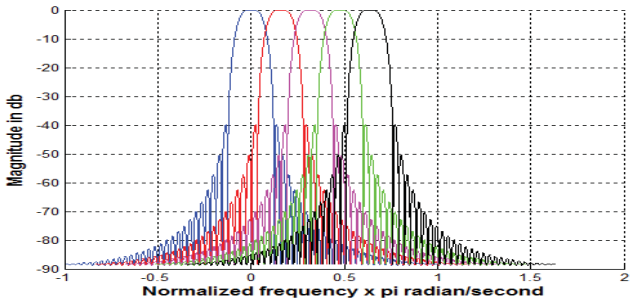

Fig. 2: Frequency response of first five subcarrier analysis filters

MIMO channel. Assigning a different set of carrier frequencies to each antenna might be an easy way out. However this becomes impractical when the number of transmit antennas grows to be large. Same set of carrier frequencies is assigned to each of these antennas to override this difficulty. The composite signal is passed through the MIMO channel. The signal at the input of the q^{th} receiving antenna is given by

$$r_q(k) = \sum_{n=1}^{N_T} S_n(k) h_{nq}(k) + w_q(k) \tag{6}$$

Where, h_{nq} represent the elements of the MIMO channel matrix H. The received signals are the de-correlated using any of the techniques discussed in section III. The independent streams are filtered using the analysis filter bank.

D. OQAM Post Processing

The filtered outputs from the analysis filter bank are subject to OQAM post-processing. The filtered output is first processed to compensate for the phase term θ_m given by (3).The output of OQAM post-processing is given by

$$v'_m(i) = b'_m(i)\theta^*_m \tag{7}$$

where b'_m represents the interference subsided, filtered stream on the m^{th} subcarrier. The antenna index is dropped for simplicity. The input bit stream is recovered by subjecting the real part of v'_m to PAM demodulation.

III. INTERFERENCE MITIGATION TECHNIQUES

In the following section we present three techniques that are employed for signal de-correlation in the multi-antenna scenario.

A. Zero Forcing Decorrelator

The zero forcing decorrelation is implemented by multiplying the received data streams by the following weighing matrix

$$W_{ZF} = (H^H H)^{-1} H^H \tag{8}$$

It functions by inverting the effects of the channel.

$$r_{ZF} = r_q W_{ZF} \tag{9}$$

$$r_{ZF} = r'_q + (H^H H)^{-1} H^H \tag{10}$$

$$r_{ZF} = r'_q + noise_{ZF} \tag{11}$$

The resultant signal r'_q is independent of inter antenna interference. Zero forcing however suffers from the problem of noise enhancement[10].This can be overcome by the MMSE based technique discussed in the following section.

B. MMSE Decorrelator

In this case square of difference between the transmitted symbols and the detected outputs is take as the performance metric. This technique looks to strike a balance between interference cancellation and noise enhancement. The MMSE weighing matrix is given by

$$W_{ZMMSE} = [H^H H + (\frac{1}{varience(noise)})]^{-1} H^H \tag{12}$$

From (12) it can be observed that at high values of SNR the MMSE based technique is equivalent to the ZF decorrelator.

C. SVD Decorrelator

Singular value decomposition is another technique to decorrelate signals from multiple antennas. The task of interference cancellation is jointly performed both at the transmitter as well as receiver. The SVD of the channel matrix H is given by

$$H = U \Sigma V^H \tag{13}$$

Where U and V are unitary matrices. They contain the eigen vectors of HH^H and $H^H H$ respectively. Σ is a diagonal matrix containing the singular values of H. The transmitted data stream is precoded by multiplication with the matrix V. The post processing is carried out by multiplication of the received streams with U^H. Fig.3 provides a pictorial overview of the signal processing at the transmitter as well as the receiver. As a result received stream is thus transformed into independent parallel data streams.

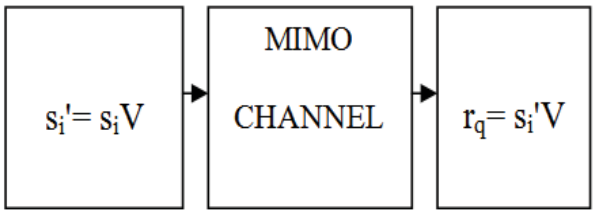

Fig. 3: SVD based precoding and receive antenna shaping

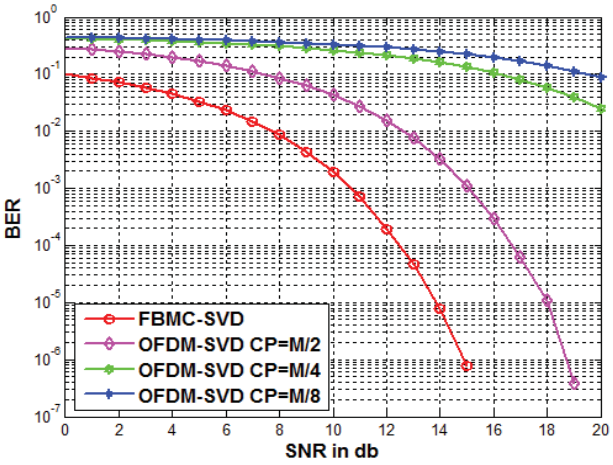

Fig. 4: Comparison of the BER performance of FBMC-SVD and OFDM-SVD signal decorrelators

IV. SIMULATION RESULTS

A 2X2 MIMO FBMC system was considered. The architecture shown in Fig.1 was simulated assuming a MIMO Rayleigh flat fading channel.The filter co-efficients used are those suggestes in [7].Due to the sharp sidelobe fall off rate an overlapping factor of 4 is chosen . Perfect CSI is assumed at the transmitter as well as the receiver.Fig.4 compares the performance of FBMC-SVD and OFDM-SVD signal decorrelators.Since FBMC uses filter banks which produce a sharp fall of rate, there is no need to transmit redundant bits as cyclic prefix.In the case of OFDM the number of bits allocated to serve as cyclic prefix is assumed to be a fraction of the number of carriers.The number of carriers is taken to be 128.Fig.4 confirms that the performance of OFDM-SVD signal decorrelator improves when the number of cyclic prefix bits increases.However it is also observed the FBMC-SVD performs better when compared to OFDM-SVD.

Fig.5 provides a comparison of the three interference cancellation techniques presented in this paper,namely,FBMC-SVD,FBMC-ZF and FBMZ-MMSE.It also provides a comparison of the corresponding OFDM counterpart.The number of cyclic prefix bits considered in this case is $M/8$. It is observed that at low values of SNR MMSE based decorrelator performs better than Zero-forcing based detecter. This is because the channel inversion is accompanied by noise enhancement in the case of zero forcing based interference

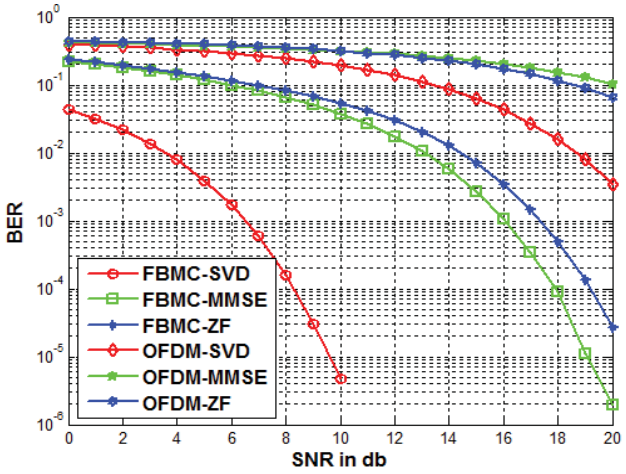

Fig. 5: Comparison of the BER performance of multi-antenna interference mitigation techniques

cancellation.The superior performance of SVD based interference cancellation can be credited to the fact that both U and V are unitary matrices. Hence the channel noise remains unaffected when the signal is subjected to receiver based signal shaping.Despite the fact that FBMC does not require the transmission of cyclic prefix, its performance is superior when compared to OFDM.This is clearly refflected in Fig.5.

V. CONCLUSION

In this paper we presented three techniques for multiantenna interference rejection in FBMC-MIMO systems.From the simulation results obtained it can be concluded that SVD based precoding and receive shaping outperforms ZF and MMSE based interference cancellation in a multi antenna scenario.The simulation results also confirm the superiority of FBMC over OFDM based MIMO systems.FBMC based MIMO systems promise high data rates while making efficient use of the available spectrum.

End-to-End Delay Analysis of IEEE 802.15.6 Standard for WBAN Medical Paradigm

Vivek Kumar, *Member, IEEE*, and Bharat Gupta, *Senior Member, IEEE*

***Abstract*— In recent years, a very rigorous researches are focused towards the development of Wireless Body Area Networks (WBAN) for health monitoring. WBAN impels to make use of wearable and implanted sensor devices for monitoring various physiological sign. The standard specification is projected to achieve a vast scope for implementation possibilities for WBAN in order to gain high performance, ultra-low power consumption and high quality of service with variable data rates from few kbps to mbps. In this paper, we present a brief discussion on IEEE 802.15.6 UWB PHY specification. Moreover, we have calculated the end-to-end delay (D_{E2E}) performance of IEEE 802.15.6 Carrier Sense Multiple Access with Collision Avoidance (CSMA/CA) mechanism. The simulated results shows that the maximum end-to-end delay is less than WBAN medical healthcare application requirement of 250 ms.**

***Index Terms*— WBAN, IEEE 802.15.6, CSMA/CA, UWB PHY, Delay**

I. INTRODUCTION

Advances in wireless technology with supporting infrastructure provide unprecedented opportunity for ubiquitous real-time healthcare and wellness monitoring. WBAN based remote and ubiquitous healthcare monitoring services have proved to be a great success in this context. WBAN emerge as a subcategory of wireless sensor network (WSN) [1, 2]. They provide novel and unlimited possibilities for medical and non-medical application. [3, 4]. A WBAN comprises of miniaturized and lightweight sensor nodes mainly employed to monitor numerous body functions. Such type body-centric communication system are enamoring considerable attention from research and industrial communities. Medical application make use of tiny sensor nodes in, on, or around human body for various vital sign monitoring. These devices provides a scalable, robust, long term and real-time health monitoring of individual personal without encumbering daily life activities. Non-medical applications includes personal assistance, ambient intelligence, gaming, entertainments, social networking, environments monitoring, military, sports and consumer electronics [5-9].

Small size, flexibility, and seamless connectivity are the important issues of WBAN for providing real-time healthcare monitoring. However, the energy efficiency is the prime constraint of this field. In fact, WBAN's nodes have limited power source (battery driven) and replacing or recharging of battery is undesirable due to implanted node. Thus, an efficient power management to reduce energy consumption is the key towards prolonging WBAN life-time in order to provide long time healthcare monitoring. Moreover, for real-time healthcare monitoring, most of collected information are sensitive to the latency, and end-to-end delay must be restricted to 250 ms, since the large traffic load may give rise to unendurable latency. Thus, it very important to categories the information based on priority level and traffic pattern, so that significant information can always communicated prior to others. Hence, an energy-efficient context-aware and traffic-aware MAC protocol is essential requirement for such lifesaving application.

Therefore, in this paper, we have investigated and evaluated the end-to-end delay performance analysis of IEEE 802.15.6 CSMA/CA protocol for medical healthcare application of WBAN. We have developed a discrete-time Markov chain (DTMC) to analyze the performance of mentioned standard. We model DTMC for CSMA/CA technique under non-saturation state. We present a simple and accurate simulation model in order to evaluate end-to-end delay of proposed protocol for different data rates. A few similar Markov chain based analytical works have been proposed earlier [10, 14]. The rest of the paper is organized as follows. Section II provides brief discussion about IEEE 802.15.6 standard. Section III present IEEE 802.15.6 CSMA/CA MAC protocol end-to end delay analysis. Section IV present simulated results and related discussion. Finally, section V concludes our work and future scope.

II. ANALYSIS OF IEEE 802.15.6 STANDARD

The IEEE 802.15.6 is a standard optimized for ultra-low power miniature devices that are deployed in, on, or around human body to serve numerous medical as well as non-medical application [15]. The IEEE 802.15 Task Group 6 (TG 6) launched standard back in 2007 but final version of standard came later in February 2012 [16]. The IEEE 802.15.6 standard defines PHY layer into three frequency bands namely Narrowband, Ultra-Wideband (UWB) and Human Body Communication (HBC) in order to address variable data rate imposed by medical and consumer applications. Fig. 1 shows the available frequency spectrum for WBAN [17]. IEEE 802.15.6 standard supports two types of access mechanism at the MAC sub layer. These two techniques are contention access and contention free access. In contention access phase the standard incorporate either CSMA/CA or slotted ALOHA based medium access techniques. While in contention free

phase, the standard utilize polling based access mechanism as well as scheduled based access mechanism.

There is only one coordinator node (CN) in WBAN which manages the medium access and power management of respective node. The number of nodes in a WBAN is varied between 0 to *mMaxBANSize*. The medium access is scheduled in time, where the time axis is divided into beacon period (superframe boundary) of equal length.

The PLCP construct the PHY layer Protocol Data Unit (PPDU) by concatenating PHY layer Header (PHR), Synchronization Header (SHR), and the PHY layer Service Data Unit (PSDU). The UWB PHY offer 11 channels (each channel having 499.2 MHz bandwidth) with central frequencies starting from 3494.4 MHz for channel number 0 to 9984 MHz for channel number 10. These channels are categorized into two bands: Low band (from channel number 0 - 2) and High band

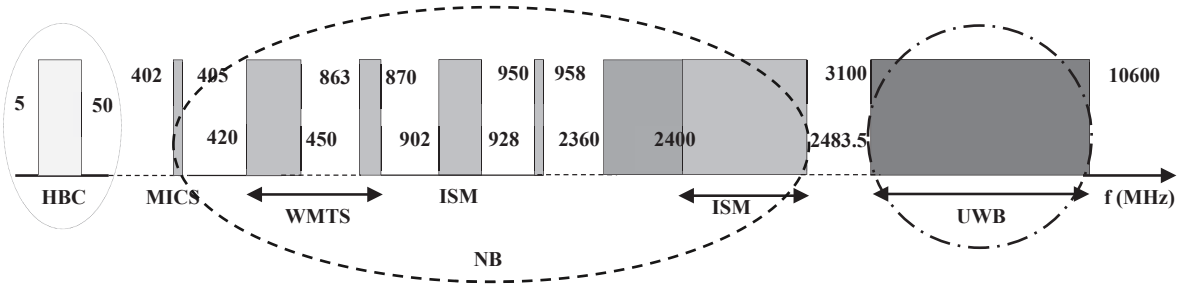

Figure 1. IEEE 802.15.6 frequency bands allocation

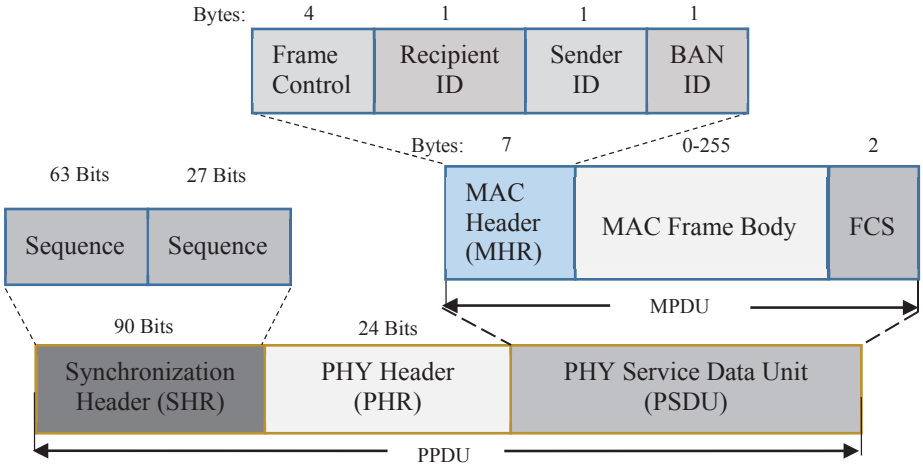

Figure 2. IEEE 802.15.6 Standard PPDU Frame Format for UWB PHY

Each superframe constitute of allocation slots of equal length and numbered from 0 to *s*, where $s \leq 255$. The coordinator broadcast beacons to specify the superframe boundaries and slots allocation. The coordinator transmit beacon in every superframe except those that are inactive. In this paper, we focus on the end-to-end delay analysis for UWB PHY with CSMA/CA based MAC access mechanism.

A. IEEE 802.15.6 UWB PHY Specifications:

The UWB PHY specification is projected to achieve a vast scope for implementation possibilities for WBAN in order to gain high performance, low complexity, and ultra-low power consumption. Furthermore, the UWB's signal power level is similar to MICS band signal power limit. Thus, providing the safe power levels for human body exposure and limiting the interference from other devices. The data interface provided by UWB PHY, which is governs by Physical Layer Convergence Protocol (PLCP).

(from channel number 3 - 10). The standard provides 2 UWB technologies namely, Impulse Radio (IR-UWB) and Frequency Modulation (FM-UWB). In WBAN, a coordinator shall implement either IR-UWB or FM-UWB but a device can implement either IR-UWB or FM-UWB or both. UWB PHY support two modes of operation: Default mode and High Quality of Service (H-QoS) mode. The default mode is utilized for both medical and non-medical application while the H-QoS mode support only high priority medical application. The minimum coded data rate offered by standard for on-off signaling is 397.8 Kbps, 202.5 Kbps by FM-UWB, and 243 Kbps by IR-UWB having DBPSK/DQPSK modulation scheme.

B. IEEE 802.15.6 UWB PHY Frame Structure:

UWB PPDU structure or UWB PHY frame format is formed by adding SHR, PHR, and PSDU as shown in Fig. 2. PSDU contains the MAC Protocol Data Unit (MPDU). The MPDU

includes MAC Header (MHR), a variable MAC frame body, and Frame Check Sequence (FCS). Moreover an additional BCH parity bits are available in H-QoS mode. The data bits of MPDU are first scrambled in order to eliminate possible long string of 1s and 0s. Than a BCH Encoder followed by Pad bits, and a Bit interleaved to generate PSDU for transmission.

The channel code BCH (n = 63, k = 51) and BCH (126, 63) are used for default mode and H-QoS mode. The number of code words in a frame is given as:

$$N_{CW} = \left\lceil \frac{N'_{PSDU}}{k} \right\rceil \quad (1)$$

Where N'_{PSDU} is the number bits in PSDU that comprised of MHR, MAC frame body, and the FCS.

$$N'_{PSDU} = 8(N_{MACHeader} + N_{MACFrameBody} + N_{FCS}) \quad (2)$$

The BCH (126, 63) encoder can be utilized according to Hybrid Automatic Repeat Request (HARQ). In UWB PHY, during default mode of operation, the maximum number of retransmissions (NR) is set to four as compared to seven in case of IEEE 802.15.4 standard. HARQ stores packets when an error packets are arrived at transmitter or receiver and authenticate the certain packets repetition. Thus, it require the interaction between UWB PHY and MAC during retransmission which is given as H_0 and H_1 in PHR.

Moreover, a systematic bits (*D*) at MHR and MAC frame body to perform error detection encoding at UWB MAC and error correction encoding at UWB PHY. When erroneous packets arrived it stored at receiver and no ACK is sent at the transmitter. A parity bits *P* of same size and *D* is added to FCS in order to construct the transmitted PSDU. Thus repetition of Both *P* and *D* bits are utilize to reconstruct the original packets using BCH coding. This repetition continues until *D* bits received successfully or a maximum number of retransmission is reached. Finally interleaving is applied prior to modulation in order to provide robustness against error propagation.

Fig. 3 shows the IEEE 802.15.6 superframe structure. In beacon mode with superframe boundaries, the coordinator is broadcast a beacon frame during each beacon period except inactive superframe. The superframe formed by concatenating nine phases namely as: beacon, exclusive access phase 1 and 2 (EAP1 and EAP 2), random access phase 1and 2 (RAP1 and RAP2), managed access phase 1 and 2 (MAP1 and MAP 2), and the contention access phase (CAP).

The beacon frame transmitted by CN to provide network management. It sent in first slot of each superframe. Beacon provide the device synchronization, medium access, and power management to the nodes in WBAN. The CN provide a specific time in a beacon period of each superframe to transfer the traffic of the highest user priority (UP). time in a beacon period of each superframe to transfer the traffic of the highest user priority (UP). This time span is termed as EAP1 and EAP2. These time slot carry the life sensitive information such as, emergency and medical implant event data. RAP1, RAP2, and CAP are provided to transfer traffic with low UP such as normal or routine traffic. The managed access phase dedicated for managing the uplink, downlink, and bi-link allocation interval. Whereas the 2nd beacon which precede CAP is utilized for grouping the ACK, beginning and the end of CAP, and information related to other device existence.

The coordinator generally employ a slotted ALOHA or CSMA/CA techniques for each access phase except managed access phase. The network CN divide time into superframe which initialize by a beacon frame. For data traffic with highest UP (UP_7), only EAP1 and EAP2 periods are utilized.

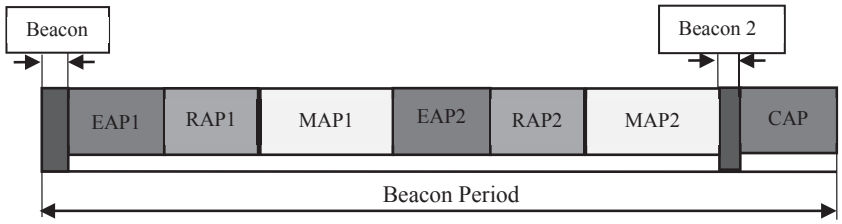

Figure 3. IEEE 802.15.6 Superframe structure

Table 1. IEEE 802.15.6 PHY PARAMETERS

UP	CW_{min}	CW_{max}	Traffic
0	16	64	Background
1	16	32	Best Effort
2	8	32	Excellent
3	8	16	Video
4	4	16	Voice
5	4	8	Medical data
6	2	8	High priority medical data
7	1	4	Emergency report

While in case of slotted ALOHA mechanism, the whole random access phase 1 and 2 are replaced by another exclusive access phases. Table 1 provides the information of Ups depending upon the CW bounds used for CSMA/CA. The detail discussion of MAC access mechanisms are as follow:

i. *CSMA/CA:* In order to obtain a new contended allocation, the nodes initialize its backoff counter to a random integer number distributed uniformly over interval [1, CW]. The CW values belong to (CWmin, CWmax). The values of CWmin and CWmax can be chosen in accordance to UPs. Whenever node sense an idle CSMA slot having length equal to *pCSMASlotLentgh*, it decrement its backoff counter by one. The data frame is transmitted when the counter values reaches to zero. The node freezes its backoff counter when it

sense the channel is busy and the CW is doubled for each failure until it reaches CWmax.

ii. *Slotted ALOHA:* In order to obtain contended allocation, a node uses predefined UPs based on contention probability threshold. These CPs values remain freeze for every consecutively odd number of failures and node halved its CPs for every consecutively even number of failures.

III. End-to-End Delay Analysis

In this analysis, we have calculated the maximum permissible D_{E2E} of IEEE 802.15.6 beacon mode with superframe boundaries for healthcare application under real-time constraints. The calculation is done for UWB PHY over frequency band of 3.1 – 10.6 GHz. Fig. 4 shows the basic data transfer models for normal and emergency or on demand traffics. Depending upon user priority CN allocates an available channel to WBAN nodes. The D_{E2E} for CSMA/CA algorithm can be defined as

$$D_{E2E} = macMaxFrameRtx \times (T_{DIFS} + T_{CW} + T_{Frane} + T_{TA} + T_{ACK} + T_{IFS}) \quad (3)$$

T_{DIFS} , is the longest wait time for medium access. If node sense medium idle for at least DIFS (Distributed Coordination Function Inter Frame Space) period, it can access the medium at once. T_{DIFS} is expressed as follow:

$$T_{DIFS} = T_{pSIFS} + 2 * T_{pCSMASlotLength} \quad (4)$$

$$T_{pCSMASlotLength} = T_{pCCATime} + pCSMAMacPHYTime \quad (5)$$

The expression for T_{CW} can be given as:

$$T_{CW} = CW_{\min} * T_{pCSMASlotLength} \quad (6)$$

Transmission time of one frame T_{Frame} , for maximum payload length is given as:

$$T_{Frame} = T_{Preamble} + T_{PLCPHeader} + T_{PSDU} \quad (7)$$

Where $T_{Preamble} = \frac{N_{SHR}}{Datarate}$, $T_{PLCPHeader} = \frac{N_{Header} \times S_{Header}}{Datarate}$ and

$$T_{PSDU} = \frac{N_T \times S_{PSDU}}{Datarate} = \frac{[N_{PSDU} + (n-k) \times N_{CW} + N_{Pad}]2}{Datarate} \quad (8)$$

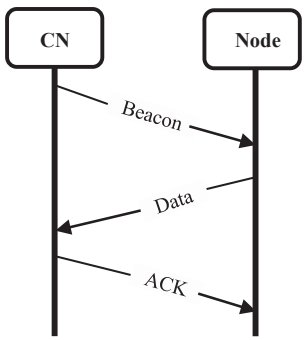

Figure 4. Data transfer model for normal traffic

The UWB PHY offer the least coded data rate of value 0.3978 Mbps for on-off modulation. The turnaround time can be given as:

$$T_{TA} = T_{pSIFS} + T_{pExtraIFS} \quad (8)$$

The expression for T_{ACK} is given as

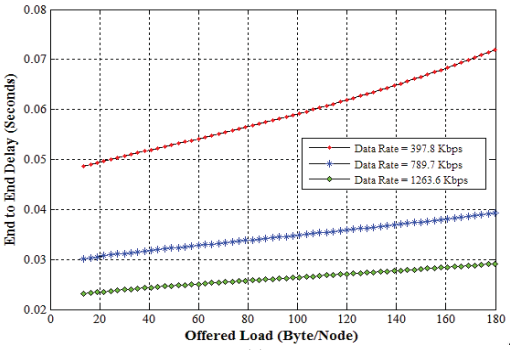
$$T_{ACK} = \frac{(MHR + FCS) \times 8 + PHR}{Bitrate} \quad (9)$$

Thus, we can calculate the end-to-end delay for maximum payload of 255 bytes having data rate of 397.8 Kbps with *macMaxFrameRetries* = 3.

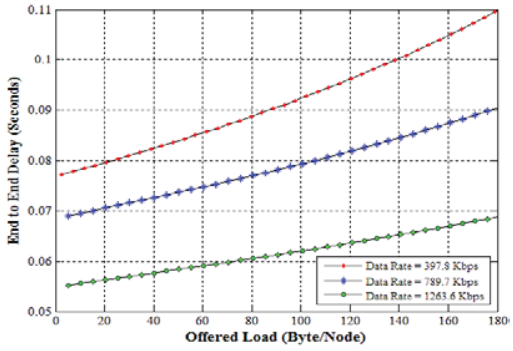
IV. Simulation Results and Discussions

In this section we have simulated end-to-end delay of IEEE 802.15.6 CSMA/CA mechanism. In section III, we evaluated the expression for end-to-end delay under ideal channel condition. But, in actual channel condition is non-ideal. Thus, to analyze the significant performance, we have calculated probability of collision and packet discarded probability based on our DTMC model under non-ideal channel condition. The packet has been either discarded due to clear channel access (CCA) failure or maximum retry limit reach.

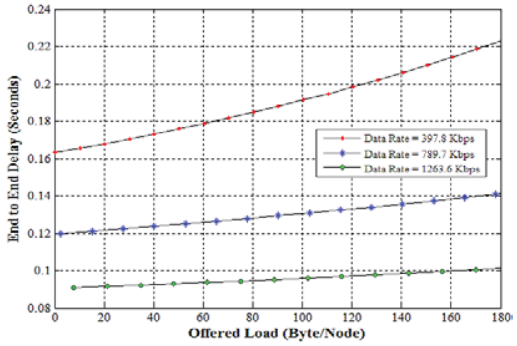
The UWB PHY layer support minimum coded bit rate of 397.8 Kbps. In order to calculate end-to-end delay, we have taken three data rates having values 397.8, 789.7, and 1263.6 Kbps. Also, we have analytically modelled the average wait time possessed by a node to receive acknowledgement after packet transmission. Depending upon the equations as discussed in section III, we calculate end-to-end delay of IEEE 802.15.6 CSAM/CA MAC mechanism for 5 nodes.



(a)



(b)



(c)

Figure 5. End to end delay evaluation for different frame length a) 2 bytes b) 75 bytes and c) 255 bytes with number of nodes = 5

We have simulated end-to-end delay for three variable payload of size 2 bytes, 75 bytes, and maximum payload of 255 bytes offered by standard as shown in Fig. 5. We have simulated maximum delay of 220 ms for minimum coded rate of 397.8 kbps for maximum payload of 255 bytes as shown in Fig. 5(c). While much low end-to-end delay of 140 ms and 100 ms have been examined for higher data rate of 789.7 kbps and 1263.6 kbps for maximum payload. In conclusion we can summarize that the end-to-end delay is proportional to traffic load and the number of nodes operated in a WBAN. Depending upon application type and proper traffic management, we can limit end-to-end delay as per requirement.

Fig. 6 shows the end-to-end delay performance of standard with number of node variation of 5, 10, 15 nodes. We have simulated for minimum payload size of 2 with data rate of 397.8 Kbps. Similarly, we can plot number of nodes variation against different data rate at different payload size.

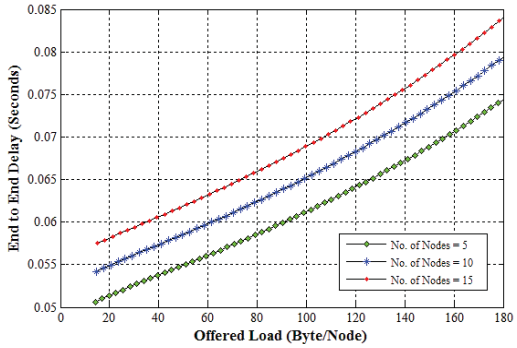


Figure 6. End to end delay evaluation of frame payload of 2 bytes with data rate of 397.8 kbps with number of nodes variation of 5, 10, 15

CONCLUSION

WBAN are the premature promising technology that has the ability to revolutionized next-generation healthcare monitoring system. WBAN enables the precise remote healthcare monitoring for a longer time period along with real-time feedback to the medical personnel. Though the WBAN technology emerges as an outstanding future e-health solution but diversified uses assign the limitation. The multiple collocated WBAN within a close proximity still hinder the full potential deployment of WBAN.

A brief discussion about IEEE 802.15.6 standard has been overviewed and we have evaluated the end-to-end delay performance of IEEE 802.15.6 CSMA/CA mechanism. We have calculated end-to-end delays of 100, 140, and 220 ms with data rates of 1263.6, 789.7, and 397.8 kbps with 5 nodes. We have concisely discussed the medium access approaches and the frame structure of IEEE 802.15.6 MAC protocols. The calculated result shows that IEEE 802.15.6 MAC is highly suitable for WBAN medical healthcare application. The least delay is the most desirable for such real-time healthcare monitoring system which is very sensitive to latency (250 ms).

***Abstract*— The objective of this work was to reveal the tuberculosis condition of human patients by means of the voice recording and processing, in order to evidence deviations, if any, with respect to the voice parameters of healthy people. Comprehensive voice signal recording was obtained with low-cost apparatuses, and voice signal processing was realized using very low-computational effort parameters. A total of 312 patients were engaged, 284 tuberculosis diagnosed and 28 in healthy status as an age- and sex-matched control group.**

We demonstrated that the voice can be used as a discriminating source of information between healthy subjects and tuberculosis patients, since evidence of alterations founded in some of the voice features.

Keywords*— *human voice; voice analysis; voice signal processing; tuberculosis

I. INTRODUCTION

Historically, sounds from the body have been clinically evaluated for diagnostic purposes. We can refer to the act of auscultation (in general using a stethoscope) for examining the heart, the breath and the gastrointestinal sounds. Aside from sounds revealed from traditional auscultation, in the latest years the sound of the voice has been considered [1], in particular for determining voice pathology [2-4] or voice disorder [5-7]. Since the voice is the result of sounds, produced by modulation of pushing out air flow, related basically (but not exclusively) to glottis, larynx and lungs, the voice signal processing has been useful to reveal diseases [8-10], disorders [11] or pathology [12] of larynx, inflammation of the lungs [13], and obstructive airway disease [14] or sleep apnea [15].

Within this frame, we considered the possibility that the voice analysis could lead to more intriguing possibilities in diagnosing [16], so that we performed the current study with the aim to determine the relevance of voice signal processing, if any, in diagnosing the laryngeal/lungs tuberculosis.

Recently, the World Health Organization referred of epidemiological burden of tuberculosis (TB) of about 7 million people every year [17], especially focused in developing countries. This really huge number has to be reduced as low as possible and, in such a view, the diagnosis plays a fundamental rule. Currently, the diagnosing tests leave millions undiagnosed and untreated [18], being the high-tech high-cost ones confined to industrialized countries and not still implemented in high-burden developing countries to any significant degree. This is why any technology or tool, useful for diagnosis purposes, which can result affordable, convenient, robust and reliable is welcome. In such a frame, the voice signal processing can potentially furnish an answer, being low-cost, easy manageable, safety and non-invasively recorded.

In general, the voice signal processing have been performed in the *time domain* [15, 19], in the *frequency domain* [6, 11], and in the *quefrency domain* (by means of cepstrum analysis, related to the inverse Fourier transform of the logarithmic amplitude Fourier spectrum) too [11, 20]. Different domain analysis can be convenient to evidence different aspects and parameters related to the voice sounds. In addition, a class discrimination of the speech waveform can be performed [19], and this has been done by means of classification algorithms such as Hidden Markov Models [2], Neural Networks [8], Prototype Distribution Map [8], Self-Organizing Map [8], Support Vector Machine [3, 4, 10, 12, 20], Gaussian Mixture Model [20], Linear Discriminant Analysis [4, 15], and Random Forest [12].

Regardless the so many different possibility to explore, we established to work in time and frequency domain, but limiting our attention to the most common, known and used statistical tools, in order to avoid to work with sophisticated algorithms which can be effective but can result as a step ahead towards complexity. This is to make results easily intelligible for the most part of people potentially involved in clinical treatments.

As far as we know, this is the first work addressing the relevance of the signal processing of the human voice in diagnosing tuberculosis on the basis of hundreds of evaluated subjects, with a unique prior work that considered the change in the quality of the voice of only one subject, a 28-year-old female with laryngeal and pulmonary tuberculosis [21].

II. 2. SUBJECTS, MATERIALS AND METHODS

A. Subjects

Voice data present noteworthy age-related [22], gender-related [23, 24] and ethnics-related differences. Therefore, it was fundamental to compare patients within a no meaningful difference in age, of the same gender, and members of the same ethnicity. It is reasonable to believe that also weight, height, smoking, alcohol consumption, social surrounding and culture can have some impacts on the production of voice,

nevertheless we did not considered these variables, so leading to a certain degree of uncertainty, but at this stage empirically esteemed to have a second order influence in diagnosing tuberculosis.

We had 312 male subjects who undertook this study, 28 of them were healthy and 284 of them was lung tuberculosis diagnosed. The 284 subjects diagnosed for tuberculosis claimed no other diseases differently related. The common symptoms like cough, fever, weight loss and loss of appetite were observed. The mean age of the subjects was 39.67 year, within 25-58, all subjects coming from Mumbai (India).

The voice recordings were performed at Tata Memorial Hospital (ACTREC, Sector 22, Kharghar, Navi Mumbai - 410208, India.), D.Y.Patil Hospital (Sector 5, Nerul Navi Mumbai, Maharashtra 400614), Sharma Hospital (Sector 11, Kharghar Navi Mumbai 410210 India), Navjeevan Hospital (Sector 17, Kharghar Navi Mumbai, Maharashtra 410210) and Sanjeevani Hospital (Sector 2 CBD Belapur Navi Mumbai, Maharashtra 400614). The local ethical guidelines were followed for each institution, and a written consensus was obtained for all the subjects.

Every patient was asked to phonate a predefined text in local language. In particular, we considered the Marathi and English alphabets for constructing the words of speech text. Each type of pronunciation [25-28] were related with different letter, words and phrases of spoken language. Consequently, the recruited subjects phonated: "Aai Aai Ye Ekade, Aapn Doghe Milun Jaun Tikade, Sundar Maze Gaon, Sunder Maze Ghar. Salgale Miluni Aankhi Banavu Aapn Tayala Aankhi Sunder. Swatch Asel Aapule Gaon Aani Ghar Thr Aaajar Aapnhun Jail dur. Tar Mag Maja Mothi Karu, Mayene Mazya, Msatine Mulayam Karu. Aapli Maja Aanel Rangat, Sagele Houn Jau Aandi Aani Kamat Dang". (The not fundamental translation is: "Mother, Mother come here, we together will go there, Beautiful home, will make beautiful village, We all together can make it more beautiful, If our village is clean, disease will automatically run away. Then we will enjoy a lot, our fun will bring joy, we all can focus on work.").

This text was considered to have phonetics useful to the extraction of the "voice signature" for tuberculosis. For example, the words having maximum phonetic similarity with English alphabet "U" were chosen to extract the information of lungs and chest area. In addition, the text was designed to give the sensation of a poem about cleanliness and healthy, to generate the interest of the patients.

B. Materials

In order to record the voice, we used a unidirectional microphone (8-28000Hz,-59dBV/µBar,-39 dBV/Pa+/-4dB, by Logitech, Lausanne, Switzerland) hold 6-8cm from the patient's mouth (2cm of possible oscillation). The frequency range considered was limited to an audible range, in particular 200-18000Hz.

The time recording was 30sec, so that all the voice parameters could be exhaustively expressed. Every patient was asked to avoid any high-volume talk to prevent electrical saturation of the microphone.

The output signal from the microphone was fed to a pc running our home-made software termed "Audalysis", capable to record and process the voice parameters. Audalysis is a modular, user-friendly and graphics-driven software (a block diagram reported in Figure 1) useful to avoid any special training to use it. The software allows selecting the sample rate (6000Hz, 8000Hz, 11025Hz, 22050Hz, or 44100Hz), the number of the audio channels (1 or 2) and the resolution in bits (8 or 16). For the current work we selected 44100Hz, 2 channels and 16bits. Audalysis stores the subject's voice in a .wav-format file and can compute up to 12 voice parameters. Anyway, for further simplification purposes, we limited our attention to the 6 parameters we empirically believed as fundamentals: the peak frequency, the peak amplitude, the signal to noise distortion (SINAD), the inter modulation distortion (IMD), the signal-to-noise ratio (SNR), and total harmonic distortion (THD), all in their absolute values.

Collected data were analyzed by means of suitable statistical analysis techniques and results were stored both in excel and in notepad files.

C. Methods

Body Conditions:

Body parts play important roles in production of the voice, so that it is fundamental to avoid unnatural body postures and constrains. Particular body conditions, such as abdominal cramping, bowel disorder, musculoskeletal problems, etc. may have an impact on the voice production. In addition, the diaphragm and abdomen conditions are important in supporting the voice that is stronger when the body is in the upright position. Even the psychological conditions are important in the confidence one has in the voice, as can be seen by the fluttering of the voice when a person is nervous or anxious.

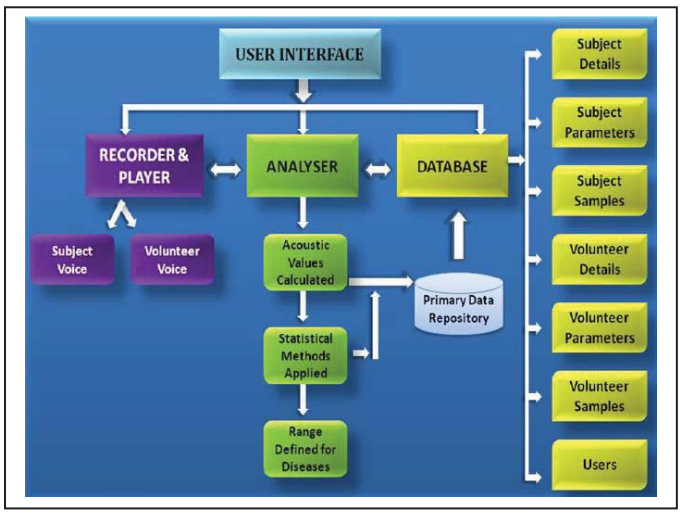

Fig. 1. Audalysis is the home-made software used to record, store and process the signal voice parameters. Its modular architecture consists of three main blocks: the recorder/player, the analyzer and the database ones.

Therefore, we paid particular attention to the mentioned conditions, so to make the voice's recording as strong as

possible to express all the detectable characteristics. Each patient was relaxed, seated on a comfortable chair, the elbows forming a 90° angle, the arm placed on a front table, and the microphone 6-8cm apart from the mouth.

Statistics:

Determination of a statistically significant difference in voice variable values between the control group and the patient group was achieved using one-way analysis of variance (1-way ANOVA). If a statistically significant difference in a voice variable was detected, a threshold value was assigned as the upper limit of the 95% confidence interval (mean +1.96 standard deviation) of the control group value. It was then used to assess the statistical significance of the distribution of the data.

ANOVA was used as a statistical method for comparing acoustic measurements because of its useful characteristics. In particular, ANOVA was most appropriate as our sample size (312 subjects), removes random variability (so significant differences can be easily found), allows to evidence interactions between factors. In order to adopt the 1-way ANOVA we assumed that (1) the observations were dependent on the parameters (acoustic measurements) involved; (2) the sampling distribution was normally distributed; (3) the samples, and their populations, had equal variance.

III. Results and Discussion

There was significant difference in the acoustic parameters between the two states (healthy and unhealthy) in all subjects. For instance, the voice peak frequency for TB conditions showed a mean value of 158.922Hz with a 95% confidence interval in mean with upper bound of 166.869Hz and lower bound of 150.977Hz, rather different from that of healthy conditions, within the 472.714-427.693Hz range. The IMD values significantly change in diseased ranging from 80.815 to 89.322 with respect to the "healthy" interval found to be 511.971 to 565.861. We revealed these as the most significant deviations in percentage for patients suffering from tuberculosis. The overall frame of the obtained results is summarized in Table 1.

TABLE I. Comparison of 6 different parameters between control healthy people and patients suffering from TB. The most relevant variations regards the peak frequency and the inter modulation distortion (IMD).

	Peak Freq. [Hz]	**Peak Amp. [dB]**	**SINAD**	**IMD**	**SNR**	**THD**
Healthy	427.693 to 472.714	65.751 to 70.041	1.9093 to 1.9285	511.971 to 565.861	3.1991 to 3.5361	122.081 to 134.932
TB	150.977 to 166.869	52.020 to 65.917	1.7503 to 1.9346	80.815 to 89.322	3.1391 to 3.4694	124.527 to 137.635

Functioning of all systems and subsystem of human body are dependent on oxygen supply it receives during the breathing process and way they adapts to the changing input of the oxygen. Organ having direct role in oxygen supply and breathing pattern are lungs and heart. We are aware of the trivial fact that, breathing and heart rhythm changes if there is change in need of oxygen by various system of human body. It means lungs and heart functions as per the need of other system of human body. The detail biological explanation is beyond the scope of this paper, but we can conclude that heart and lungs can alters their functioning to suite the various conditions e.g. diseased, health, ideal etc. It means there is an association between functioning heart and lungs to normal and diseased conditions. (This does not require any proof as it is well accepted fact by Modern Medicine, Ayurveda: "Nadi Pariksha" and all branches of diagnosis & treatment.) Now, the sound production process here means converting the steady pressure of lungs into nonlinear acceleration of air flow. The capacity of lungs to exert the pressure on vocal track to produce the voice will change as per the phase and "magnitude of activity level" of various organs and systems of human body. Claims made by authors that, "changes in biochemical parameters of measuring health status can be mapped to corresponding changes in magnitude of voice parameters". This is evident in case of lungs tuberculosis, as stated in Table 1. The reason for variation in peak frequency, peak amplitude and IMD in case of tuberculosis is probably due to a resonance of vocal tract that directly affects the peaks in the output signal.

IV. Conclusions

We evaluated the possibility that the human voice could furnish a cost-effective reliable tool in view of non-invasive safety diagnosis of human tuberculosis. Our intent was to develop a system for voice signal acquisition and processing which could be easily usable and intelligible for the most part of people potentially involved in clinical treatments.

In such a frame, we proved how the tuberculosis affects voice production to significant extents. The most significant parameters, among the six we examined, were found to be the Peak Frequency and Inter Modulation Distortion, which showed a major deviation in control group with respect to subjects suffering from tuberculosis.

The proposed technology can be made as a portable battery-operated voice sample analytics system for diagnosis purposes, which can be used in remote areas where access to robust diagnostic health care facilities is not available, and which can be adopted in high-burden developing countries.

Further investigations will be focused on revealing at what stage the tuberculosis can be usefully revealed, so to understand if the "early" stage can be revealed to help for better cure and infection control, by making subject aware about the disease.

Acknowledgment

The authors like to acknowledge the contribution of project students Ms. Priyanka Chauhan, Ms. Rashmi Chakraborti, Ms. Priya Garg, physicians of various hospitals who allowed us to collect the voice samples; Dr. S B Muley for his support for statistical analysis of data; Ms. Monali Bobade for her guidelines for designing the text to extract the information; Mr. Virupaksha Bastikar and Dr. L. H. Kamble for their help in understanding the biochemistry behind voice production.

***Abstract*—Logistic and maintenance operations play a prominent role in several enterprise asset management systems. Thanks to the progress in technology, these tasks can be executed in an easier and more efficient way, by mean of solutions that combine system integration with new service models. Real scenarios present several challenges such as the unavailability of Internet connection in the maintenance area, the harsh conditions in which some apparatuses are installed or difficulties in identifying the apparatus on which they operate. The paper details the identified architecture, technologies and best practice derived as part of activities in the frame of the LogICoS project, opening the way to additional definition and implementation activities as future works.**

Keywords*—Maintenance Operations, Logistics, Augmented Reality, Ambient Intelligence, Peer-to-peer.

I. Introduction

Asset maintenance is the most complex sub process of asset management [1]. Indeed the overall maintenance process involves specialized personnel and complex procedures and the cost associated to such operations during the entire life-cycle of a device can easily exceeds the mere cost of the asset itself. Unfortunately there is not a "silver bullet", as the maintainability heavily depends on an underlying wide set of different factors such as the equipment type, vendor, state of deployment and configuration; hence the correct set of operations to cope with everyday real problems dramatically varies case by case. For this reason, industrial and the academic communities [2] studied and developed different systems and tools to efficiently cope with such complexity [3], [4], automating whenever possible some procedures, and, whenever this is not possible, providing the maintainer with the right set of tool to limit the possibility of making errors while, on the other hand, to minimize the duration of the maintenance operation and the required skills.

Among the various ICT technologies that are changing the world of asset maintenance, the diffusion of mobile devices such as tablets, smartphones, etc. arouse a strong interest since they represents a great opportunity providing advanced interfaces and with a small cost thanks to the wide market. However several challenges must be addressed to cope with real needs of operation procedures: in many cases the personnel shall perform operations in complete lack of connectivity (e.g., underground data centers, isolated environments due to security constraints, etc.), or partial connectivity to the Internet (e.g., remote areas, high EM interference ICT rooms, etc.) and thus to the main logistics and maintenance system.

A fundamental problem today is that asset management systems collect a lot of information through continuous monitoring several different parameter of systems that are more and more complex. This information must be made available during the operations of scheduled/unscheduled maintenance in an efficient way, so that the *relevant* information of a given failure must be given to the maintainer, possibly in a as simple as possible form. The overall management framework has been studied by researchers from industry and academy in the framework of the Logistics Innovative Coordination Suite project (LogICoS) [3]. In this context, starting from the expertise of the industrial partnership, we selected as use case the maintenance operation on an airport data network comprising several different devices (routers, switch, etc.) spatially distributed in a relatively wide area. The data network is a base asset that enables the proper functioning and monitoring of other systems.

This paper described the study and development of an architecture and a mobile oriented solution to support logistics activities by ambient intelligence technologies also designed for partially connected environments. The proposed solution, the proper architecture and technological details will be described in the paper. Our goal is to introduce an efficient workflow that minimizes the intervention time, the possibility of mistakes, while introducing logistics automation and a centrally controlled connection-less operation environment. The main feature of the proposed solution are outlined herein and detailed in the rest of the paper: i) self-sustained solution for mobile-to-device interaction; ii) tag based augmented reality (AR); iii) visual content description with standard web technologies; iv) peer to peer local communications, and visual procedures display.

Practical use-cases will be described, with the detailed architecture proposed and screenshots from a demo Android App developed on purpose. Specifically, two intervention will be detailed: the first one addresses the troubleshooting of a network printer, and the second one covers the maintenance and issue-solving of network router/switch within a rack including many network devices.

II. Related Work

A. Advanced IT for maintenance

The commercial systems for managing the logistics and maintenance of company assets such as SAP EAM, IBM Maximo AM or Oracle EAM are increasingly based on the technologies of the ICT world. In past years several experiments have been conducted introducing new IT technologies in order to enhance the usability of these systems.

In this field, one of the main challenges, it is to integrate with previous enterprise data management solutions that in turn usually store a large amount of information. Various IT technologies have been considered to contextual data that can be searched or filtered out by using RF or visual tags as in [5] or in [6]. Another challenge is the presentation of that information to the operator while she/he is on the maintenance site. Accessing to manuals and other documentation using the smartphone/tablet can present severe usability issues and other presentation forms have to been investigated. For example [7] uses context aware and augmented reality technologies to enhance the data presentation to the operator on mobile devices.

Similar technological assets have been successfully applied also in the constructions and building management, [8] where is fundamental to deliver information directly on-site. These applications however present specific problems of data visualization that are usually solved using GIS technology [9]. Finally, the training of the operators using AR technologies has growing in importance day by day. Recent studies [10] demonstrate how the learning experience can have a dramatic impact on the operation efficiency itself.

B. Augmented reality for smartphone

Currently the use of AR on mobile terminals exhibits specific problems not yet fully addressed. Although today there are several open and commercial solutions [12], there is not a clear reference model as severe user experience and applicability problems come out when these solutions are used the real field [11]. These impairments can be related to the characteristics of the smartphones that are clearly designed with a different goal in mind. A game changer in this field can be represented by the introduction of smart glasses that allows hands-free operations [15].

For what concern the adopted technologies, web technology have been widely used to describe the augmented reality. That description with HTML5 and JS is implemented in large framework e.g. Wikitude [12] or tool open as jartoolkit [13]. Moreover specific markup languages have been defined such as ARML [14] that is derived from the popular KML.

III. SCENARIO

As the introduction already stated, the variability and configuration of maintenance and logistic operations may be very diverse and with an high degree of complexity. Furthermore, such operations shall be carried out under different connectivity conditions and even within critical infrastructures. Within this context, IP connectivity that may be already available on the remote site (e.g., WiFi, LAN, 3G), can not be assumed available as well to the maintenance personnel for different reason, among which: remote location or room shielding, use of existing network for internal and secure communications, firewalling and IT restrictions, network access control and authentication.

A reference scenario shall be been identified, so that it can allow to tailor the system definition, the architecture, the technological aspects (e.g., communication protocols, standards, existing APIs and libraries, etc.) and the implications to a realistic use case. Out of the may applicable scenarios, we decided to focus (also considering project needs) on airport facilities and their associated ICT equipment.

We assume then as reference scenario, within the distributed critical infrastructure represented by many airports managed by the same service-maintenance company, an underground data center where air traffic control data is received. The focus then is to define the application criticality and propose a solution (architecture and software for a demonstration activity) for an effective support to the personnel.

In this specific case, the facility to maintain include at least (among several other equipment) network-specific device (i.e., router) workstations and general purpose network device (i.e., network printer). This Data Center is assumed within a local LAN without external connectivity.

This reference scenario is represented in figure 1.

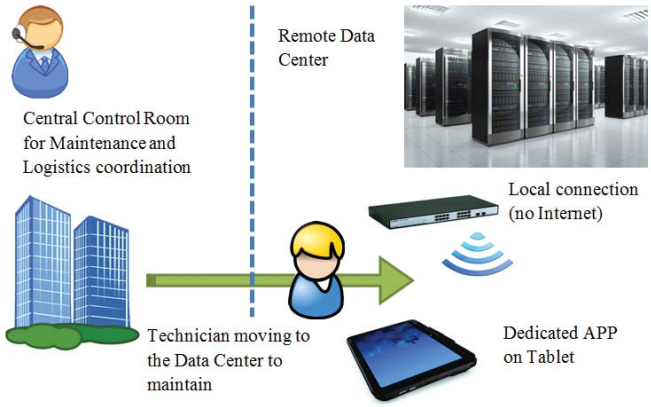

Fig. 1. Reference Scenario

It is proposed as solution, through interactions with the players involved in this scenario, an integrated and autonomous platform making use of commercial tablets and local interconnections with ad-hoc hardware. Through an augmented reality interface, the operator should identify the target object among many others present of similar aspect, and perform mobile-assisted operations to identify its status and perform the correct recovery operations. The augmented reality interface shall be provided locally by a dedicated server, to avoid the need of receiving live data by the control room. The interface is updated with tracking mechanism and part of data pre-loaded on the define according to the planned maintenance operation foreseen.

A relevant use case to drive the system requirements, the system definition and outline main technical issues is described. It consists in the recovery of a generic network device. It can be further split in the following operations: i) Ticket download at the control room through the app on the tablet of the maintenance personnel. This include all required offline data to re-establish the functioning of the required devices; ii) The personnel travels to the remote premise, at the underground data center (where connectivity to the internet and the Central control room is not guaranteed) with guidance of the App; iii) Identify through tagging and with support of the tablet pre-installed App the ICT devices to assess; iv) Establish peer-to-peer communication with the device identified; thanks to the ticket downloaded in advance and realtime data, the

troubleshooting of the device shall be straightforward and easily traceable; v) The tablet may upload new permanent data to the device after intervention; When back to the main control room, the operations performed and state update shall be pushed to the system.

The main challenges and user requirements can be inferred starting from the previously defined use-case, and different technologies shall be integrated to propose an effective solution. A preliminary analysis outlined the following principal technical and architectural aspects to solve for.

Initially, the definition of permanent data and content to be available within the mobile tablet the support in the logistics and planning activities (i.e. which tickets have higher priority? in which order to perform operations? on which devices? which aspects shall be monitored and where the malfunction may be identified?). Secondly, a key aspect, the device tagging (i.e., use of visual tagging or e.g., RFID) to allow a direct relation without interacting live with the Control Room,to relate the alert and the intervention on the target device. Then, the establishment of local peer to peer communication by means of a dedicated mediation device (called DIM and described in the following part) in between the mobile tablet and the target hardware. Finally, the implementation of effective supporting Augmented Reality views, paired with straightforward troubleshooting ambient intelligence interfaces.

These key aspects will be addressed in the following section, before discussing the test performed on two specific use cases on real and emulated devices.

IV. Proposed architecture and technology

A. Architecture

With reference to figure 2, the proposed architecture is composed essentially by two main components:

1 - an **Ambient Intelligence Application (AIA)** running on the maintainer mobile device (tablet/AR glasses/smartphone). More technically the application can i) scan QR code; ii) automatically connect to a given network; iii) fetch an HTML page and display them through a fullscreen webview displayed on top of the camera input. The page presents a transparent background to show the augmented information on top of the ”reality” displayed by the camera

2 - a software module called **Device Interconnection Module (DIM)** that runs on an embedded device called Interconnection Device. This device is capable to on one side to interact with the tablet using a suitable and supported wireless technology (e.g. bluetooth, wifi, wifi direct) and on the other side to interface with the maintained hardware through its specific communication protocol (e.g. serial cable, infrared etc). The role of this device is to decouple the application interface from the specific operating protocol of the object to be maintained or repaired. Moreover this device contains all the interface and logic to inspect and operate on the hardware. This information is stored as HTML pages and served by a web server installed on the Interconnection Device. Specific server side programs give the access for interacting with the device through web API for instance to turn on/off the device or visualize data.

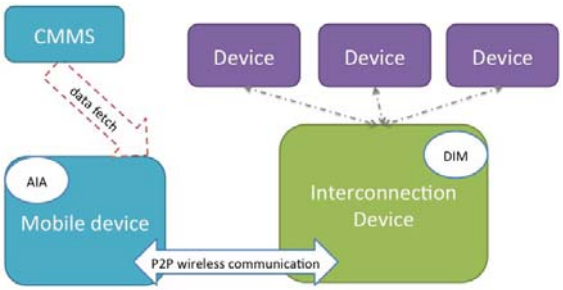

Fig. 2. Architectural representation of the proposed solution

B. Rescaled web interface

The heart of this solution is the rescaled web interface. All the augmented information displayed on top of the reality is represented through web graphic objects where standard web technologies (HTML5, css style and javascript dynamic behaviour) can be applied. Through an interaction between the tablet operating system and the web page, the size of the page is adjusted to cope with different resolutions of screen and camera. Then, parts of the page can be rendered with a “fixed” position (e.g. a side bar), while other parts can be bounded to a specific point (e.g. an arrow on a physical button of the maintained device). Differently to other literature approaches, these second part (technically html div container marked with a class), are dynamically *rescaled* real time to maintain proportions between augmented object and the reality. The information needed for this rescaling is obtained by the QR code whose dimensions must have a fixed size ($3cm \times 3cm$ in our case). A continuous QR scanning operation permit to move, rotate and rescale the bound object according to the new position of the maintained object so that the augmented data will be always bound to a specific place. This is a key point of the proposed solution as it allows on one side to pinpoint some specific part of the device (e.g. an arrow that point to a device button), and on the other side this solution does not rely on object recognition, allowing the maintenance of several (almost) identical devices such as a specific router inside a rack with other routers.

The content of this webpage as well as the possible interactions with the maintained device are defined inside the pages contained in the DIM so that, by browsing different pages, the maintainer can have different views of the status of the maintained device. With this architecture, the same AIA can operate on different devices. In turn, different maintained devices must have different web pages and different server side script to make these pages dynamical, feeding them with device information or providing API to handle common operation on the device to be maintained (e.g. turn on and off the device). In this way we re-use all the existing web technologies. The interface between the web and the device is performed by the DIM module that converts a web request in some operations on the maintained device and bring back the results in standard web format.

C. Example of operations

The proposed solution allow these typical usage model. Everything started with the retrieval of a ticket from the a Computerized maintenance management system (CMMS) by a maintainer though its ambient intelligence application (AIA). When she/he goes on the physical place, the maintainer identifies the right object to maintain by scanning a QR code displaced on the object itself. Querying a local yet asynchronously synchronized database, the AIA retrieves the information needed to automatically connect her/his terminal to the interconnection device (e.g. WiFi parameters such SSID, Channel, WPA password etc) as well as the entry point of the web page to visualize (i.e. the URL of the index page such "/"). Then the AIA visualizes the html page located at the entry point on a full screen webview. Since this moment, the operator can interact with the device, visualize contextual information, perform the most frequently used commands.

This flow is represented in figure 3.

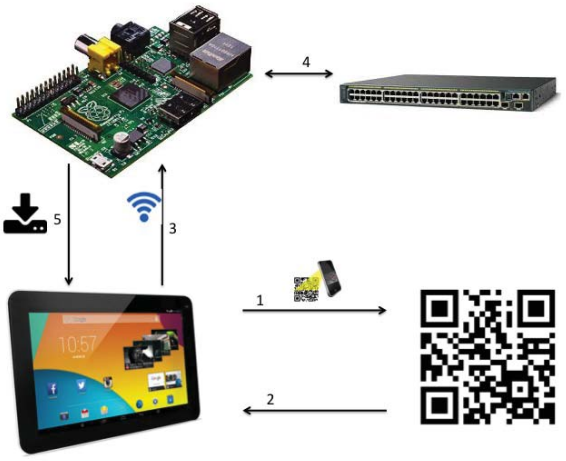

Fig. 3. Example of work flow: the mobile device scans the QR code (1. and 2.), then connects to the Interconnection Device (3. 5.) that in turn communicates with the maintained device (4.)

D. Addressed challenges

The proposed solution address several challenges presented by the proposed scenario such:

offline communication: relying on peer-to-peer wireless communication, no internet access is needed during the maintenance procedure. All the guides, manuals can be stored inside the DIM module and retrieved by the application using the peer to peer wireless connection. This is particularly important when the device to be maintained is located in the basement or in a shielded or rural area where 3G network is unavailable. Moreover this ease the deployment of the Interconnection Devices.

distinguish between similar items: object recognition algorithms can easily fail when there are several identical objects in the nearby, for instance in a rack there are several routers/switches of the same type. Hence, the detection of the right object must be performed in a different way. We choose the visual tag (QR-code) that is on one side very economical choice, and on the other give us a reference measure for applying the augmented interface with a known proportion (see next point).

pointing object parts: The presented solution allow to identify a part of the object for instance by placing an arrow on buttons, plugs, cables. This is done by re-scaling the web page according to the size information read on the visual tag as explained in sec IV-C.

interoperability with propriety solutions: air conditioning system, routers, SCADA devices typically use proprietary protocol and/or require specific hardware to communicate with. The Interconnection Device can be equipped with the required hardware to perform such communication while the DIM module can transform the interaction on the web page in proprietary commands for the maintained device.

usability and context information: Maintaining a complex object typically require to perform complex operations (e.g. router configuration) that an augmented interface is not designed to perform. However, by visually analyzing the most important parameters with a simple interface where only contextual information are shown, brings the benefit of quickly having a picture of the status that can improve efficiency in troubleshooting.

V. Description of the test cases

The practical operations of maintenance with regard to a server PC and a printer are illustrated herein. App screenshots and the sequence of operations are described in details. Both devices maintenance operational data are downloaded to the App at the control room. Details on their location and the position to the CED are uploaded as well. Other maintenance tickets may be uploaded as well by the system, in case multiple intervention are foreseen. When reaching the designated area, the App starts its AR interfaces, after that a manual scan of the QR-code tag have been done by the operator.

A. Printer

A first test case for the proposed solution is the maintenance of a printer.

Fig. 4. Printer maintenance interface: the augmented reality shows relevant information about the networking status, the toner level and provides an easy access to the documentation

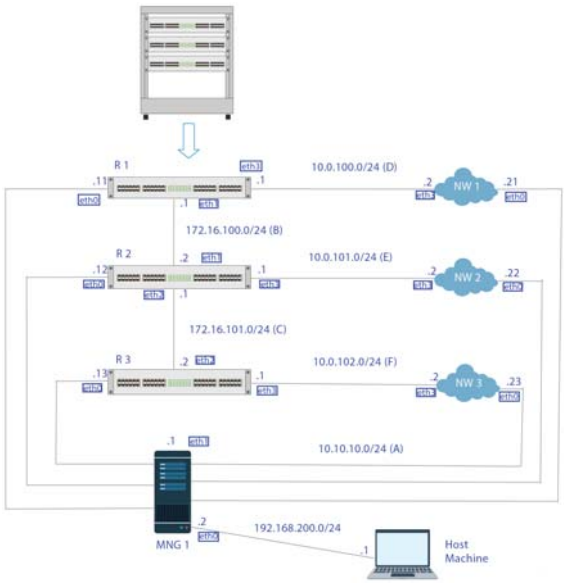

Fig. 5. Representation of the simulated topology. R1 is the router upon which we want to perform maintenance.

Fig. 6. Augmented reality interface to maintain and control the status of a switch. The interface is composed by a fixed part (side and bottom bar) and a mobile part that tracks the port of the router/switch.

These devices indeed require physical operation to be performed in order to replace the toner, or feed the paper tray as well as information monitoring for the status of the toner, out of paper messages or paper jam in the tray. A sidebar and a bottom bar are fixed as shown in figure 4 while contextual information on how to open the paper feed are displayed when needed by arrows that point to the unlocking button for opening the tray.

B. Router

A second test case has be done for router/switch maintenance in a rack. As the previous case, this one requires both physical operation (e.g. connect a cable to a Ethernet plug) as well as the observation of important parameters such as the traffic incoming/outgoing to/from a specific port. To better simulate the real characteristic of the environment, the Interconnection Device is connected to a network emulator (netkit: www.netkit.org) to emulate the topology represented in figure 5 and to simulate hardware and software malfunctioning. The augmented interface represented in figure 6 displays a side and bottom fixed bar, the status of CPU and RAM, information about the hardware and access to specific guides and documentation. The four small squares displayed on the switch ports display the status of the port. When the user click on them, the in/out bandwidth graphs related to the specific port are shown. The Interconnection Device can get those information for instance by connecting the the console port of the switch.

VI. Conclusion and future works

The architecture proposed, paired with a simple App exploiting peer to peer communications and ticket store-and-forward, allowed to illustrate the benefits to maintenance and logistics for ICT equipments. At present the implementation is at a prototypal stage, with the aim to preliminarily validate the solution and technologies identified. As continuation of this activity and future works, the App visual interface will be enhanced, with the possibility of building at the control room simplified wizard-like procedures for maintenance, with better usability and user interface. At the same time, additional development efforts are required trying to define an high level API to be used within future systems based on this concept. Finally, the platform will be migrated from tablets to Google Glass, in order to exploit at best the advantages of Augmented Reality for ambient intelligence and maintenance/logistic operations.

***Abstract*—Cognitive radio is the emerging standard for spectrum efficient wireless systems. Heart of cognitive radio is spectrum sensing, which requires the detection of the primary user in worst environmental condition and make the way for the secondary user to use the unused spectrum efficiently. More recently time-frequency based spectrum sensing techniques are examined for simultaneous detection of unused spectrum in time and frequency domain. Time-frequency distribution of received signal is obtained using time-frequency tool to enhance the information preserved in the noisy signal. This paper investigates the cooperative spectrum sensing using modified Wigner-Ville detection, called S-method time-frequency distribution. The paper uses the S-method detector as local spectrum sensing unit and hard-combining at fusion center to make the global decision. Performance of the time-frequency based cooperative sensing is quantified using ROC curve.**

Keywords- Cognitive radio, Time-Frequency Representation (TFR), S-method, Cooperative spectrum sensing

I. INTRODUCTION

Main function of CR is to efficiently detect the primary licensed users and make use of unused spectrum by allocating secondary users leading to high throughput. Spectrum sensing is considered to be the most prominent function,that has been well researched in the last decade[1]. Because of highly time-varying nature of wireless medium, primary user detection becomes very challenging task in the CR. Due to fading and shadowing, primary signal would be attenuated to very low value and causing the low Signal-to-Noise Ratio (SNR) scenario. So this demands need for powerful spectrum sensing techniques. In cognitive radio scenario, primary users (PU) parameters and noise environment parameters are unknown. It makes the need for spectrum sensing techniques, that are robust to low SNR and ability to detect the PU blindly. Energy Detection (ED) is one of the most researched, simple, blind spectrum sensing technique that is used for coarse sensing. But it suffers from low SNR limit[1]. So semi blind techniques like cyclostionary and feature based detections have been re investigated for spectrum sensing. These method work robustly at low SNR, but they need information about type of modulation used and are complex in implementation[1]. Statistical covariance based methods are proposed that are blind in nature. But these are suitable for correlated signals only and hardware implementability is also complex [1][2].

Some recent work on Time-Frequency based spectrum sensing have been explored [3][4], that take advantage of time and frequency dimension to separate the signal form weak noise. Time-frequency distribution are widely used for detection and estimation weak signals in non-stationary scenario [5]. So Wavelet transform (WVT), Wigner-ville distribution (WVD), Gabor transform and Short Time Fourier Transform (STFT) based spectrum sensing techniques have been seen to performing well compared to previously mentioned semi-blind and blind techniques [3, 4, 6, 7]. Guibene *et.al* used the WVD distribution and arithmetic detection for spectrum sensing and shown that, it works well at low SNR around -35 dB [7]. Biagi *et.al* converts the noisy signal into two-dimensional image using WVD and use the pattern recognition method for finding the vacant spectrum [3]. Similarly in Tian *et.al* Wavelet transform based edge detection for wide band spectrum sensing. Most of time-frequency method employ the WVD because of its good time-frequency resolution and highly concentrated energy density of signal, but it suffers from cross-wigner energy density terms that may be mistakenly depicted as signal, though it may not be signal. So in our recent work, we proposed the modified WVD based SS called S-method time-frequency spectrum sensing [8]. S-method previously used in radar detection [9], when employed for spectrum detection found to be performing better than energy detection.This method combines the advantage of STFT and WVD , extending same for hardware implementation is also seen to be simple [9].

Last decade research on spectrum sensing shows that single CR receiver have a certain limitation on sensing due to shadowing and fading. Hidden node problem, that occur due to shadowing causes large interference to the primary user [10, 11]. So Cooperative sensing or distributed sensing that are previously used in radar and acoustic signal processing are investigated for spectrum sensing. Because of space diversity, it overcomes the ill effects of single user receiver due to shadowing and fading. Cooperative sensing are well explored using basic detection techniques which are mentioned previously [11].This paper proposes the cooperative spectrum sensing based on S-method based time-frequency distribution. Paper considers all three dimensions time, frequency and space to explore the vacant spectrum. In this paper hard decision based cooperative spectrum sensing is analyzed using the time-frequency based spectrum sensing. It is first of this kind, where spatial, time and frequency dimensions have been used for spectrum detection. The paper uses the Monte Carlo simulation approach to show the detection performance. Spectrum sensing performance is justified by using Receiver Operation Char-

acteristics (ROC) curve for of cooperative decision methods. Sensing performance is analyzed by varying the number of antennas. Results are tested for both Additive White Gaussian Noise (AWGN) and Rayleigh fading channels.

Following this introduction, the remaining part of the paper is organized as under. Section II describes the importance of time-frequency distribution and S-method based Time-frequency detector. In Section III Cooperative spectrum sensing and system model are discussed. Simulation results and analysis are presented in section IV. Conclusion is given in section V.

II. Time-frequency distribution and local spectrum detection using S-method TFR

Time-Frequency tools are mainly used in analysis, processing, detection and parameter estimation of non stationary signals. First of this STFT, is derived from traditional Fourier analysis also called windowed Fourier transform. Other important important TF tool is Wigner distribution derived from quantum mechanics [5][9]. Though STFT suffers from poor time-frequency resolution, but it is free from cross terms. Whereas, Wigner distribution produces concentrated energy distribution at the cost of cross-terms. S-method TF representation combines the good properties of STFT and Wigner distribution. STFT as previously said windowed Fourier transform, that is obtained by applying Fourier transform to localized signal $x(t)$ using the sliding window function $w(t)$ [9]. STFT is defined in continuous domain as [9]

$$X(t,\omega) = \int^{\infty} x(t+\tau)w(\tau)e^{-j\omega\tau}d\tau. \quad (1)$$

In discrete domain it is defined at an instant n and frequency k as

$$X_N(n,k) = \sum_{m=-\frac{N}{2}}^{\frac{N}{2}-1} x(n+m)w(m)e^{-j\frac{2\pi}{N}mk}. \quad (2)$$

In the above case it is assumed that the number of discrete frequency points is equal to window length. In (2) wide window covers the large signal samples over wide time interval, that increases the frequency resolution at cost of time resolution [9]. Reverse phenomena can be found in the case of narrow window.
To improve the TF concentration of non stationary signals quadratic distribution are introduced. Most basic quadratic distribution is Wigner distribution, that was well defined in quantum mechanics and was reintroduced to signals by Ville, so it is called Wigner-Ville distribution (WVD). Modified Discrete pseudo Winger distribution (WD) is defined as

$$WV(n,k) = \sum_{m=-\frac{N}{2}}^{\frac{N}{2}-1} w(m)w(-m)x(n+m)x^{\star}(n+m)e^{-j\frac{4\pi}{N}mk}. \quad (3)$$

in which *w(m)* is time window. WD due to quadratic product it exhibits the cross-terms and that limits its application to multi-component signals [9]. So to overcome the cross-terms in WD, variant quadratic distribution with limitation on signal concentration are introduced [5][9]. Concentration of auto terms and appearances of cross-terms are contradicted to each other. Stankovic *et.al* [9] discussed the novel method called S-Method (SM), that preserves the concentrated auto-terms as in WD and reduces significant cross terms as in STFT. SM derived using relationship between the STFT and pseudo WD, which is given as

$$WV(n,k) = \sum_{i=-\frac{N}{2}}^{\frac{N}{2}-1} STFT(n,k+i)STFT^{\star}(n,k+i). \quad (4)$$

Using (3) SM time-frequency distribution is defined[9]

$$SM(n,k) = \sum_{i=-L_d}^{L_d} P(i)STFT(n,k+i)STFT^{\star}(n,k+i)$$
$$= |STFT(n,k))|^2 +$$
$$2Re\left[\sum_{i=1}^{L_d} P(i)STFT(n,k+i)STFT^{\star}(n,k+i)\right]. \quad (5)$$

Where $P(i)$ is a finite window, $P(i) = 0$ for $|i| > L_d$, with L_d being its width. By setting $P(i) = \delta(i)$ spectrogram is obtained and $P(i) = 1$, pseudo WD is obtained. It can produce the TF representation of a multi component signal such that the distribution of each component is its pseudo WD, avoiding cross-terms, if the STFTs of each component do not overlap in frequency plane [9].

A. Time-frequency based spectrum sensing

In case of single user detection, decision regarding availability spectrum is tested based on two hypothesis.

$$H_0 : \mathbf{y}[n] = \mathbf{w}[n], n = 1, ..., N \quad (6)$$
$$H_1 : \mathbf{y}[n] = \mathbf{x}[n] + \mathbf{w}[n], n = 1, ..., N$$

where $x[n]$ represents a primary signal, $w[n]$ is noise and n represents time, where $y[n]$ is received signal. If there is presence of primary user in received noisy signal than it is referred as hypothesis H_1 and absence of PU considered as hypothesis H_1.

First step in TFR based sensing is to find time-frequency based energy density using S-method. Here (5) used to find TF representation of $\mathbf{y}[n]$. Next is to calculate the test statistic for spectrum sensing using the energy density obtained in previous step. Last step is to compare the test statistic using predefined threshold to carry out likelihood ratio test to know the presence and absence of PUs. Difficult task is to find the test statistic and predefined threshold based on fixed probability of false alarm. In this work, test statistic is obtained using procedure given in the [9]. Path of maximum energy density is found by scanning along time and frequency plane and maximum of that path is used as test statistic for decision making. Test statistic is found by following steps as mentioned in [9].

1) $SM(n,k)$ is time-frequency representation of $\mathbf{y}[n]$,where $k = 0, 1, ..., M-1$ and $n = 0, 1, ..., N-1$.

2) Considering that instantaneous frequency of a primary signal s(n) is continuous, define a path in time-frequency plane as an array of N frequency indices *w(n)*, with $0 \leq w(n) \leq M$ for every n.
3) Obtain ensemble of W_D of such paths of having the property $|w(n) - w(n-1)| \leq D$, for some specified value of D for all n. Where D is maximum allowed frequency step for two consecutive time instants.
4) $w_m(n)$ is one observed path belonging to W_D and sum the T-F representation along this path, that results as

$$J_m = \sum_{n=0}^{N-1} SM(n, w_m(n)). \tag{7}$$

5) Same calculation done for all ensemble paths of W_D and maximum of them represented by J_{max}, which is used as test criteria for hypothesis testing. J_{max} is defined as

$$J_{max} = \max_{w(m) \in W_D} J_m = \sum_{n=0}^{N-1} SM(n, w_{max}(n)). \tag{8}$$

Primary signal is detected if

$$J_{max} > \gamma_{TF}$$

where γ_{TF} is predefined threshold value, that is obtained using same statistic procedure for only noise case by Monte simulation. Fig.1 shows the variation of J_{max} versus the number iteration for noise only case. This plot shows that magnitude of J_{max} versus iteration in ascending order and threshold set based on required probability of false alarm. This procedure is called Monte-Carlo based thresholding, which is used in radar signal detection[9]. Threshold is estimated based on best path determined for noise only case with $\sigma_w^2 = 1$. For example fixed P_{fa}=0.01, threshold is set as $M_i * P_{fa}$=10, where $M_i = 1000$, is the number iteration Monte-Carlo simulation is run. Finally for noisy signal threshold is found by multiplying the previously obtained threshold for noise only case with variance of noise in received signal.

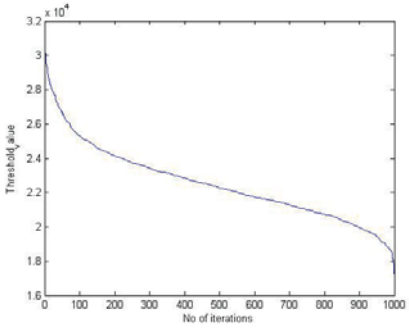

Fig. 1. Threshold estimation curve

III. Cooperative Spectrum Sensing and System Model for Time Frequency Detector

Some of the limitations in single CR receiver are as follows. limitation of sensitivity due to energy constraints, as the different primary user will be employing different modulation schemes, data rates and transmission powers [1, 12]. Due to shadowing and deep fading, effect of hidden node problem and missing of primary receiver is predominant. Hidden node phenomena occurs when path between the primary transmitter to secondary receiver is shadowed by tall building or large obstacles, while primary user may be at the vicinity of CR, than CR may fail to notice the PU and access the licensed channel and causes the significant interference to the primary user. This scenario is depicted in the Fig.2. To over come the problem of deep fade and hidden node problem in single node based receivers CR system, widely used distributed detection methods in Radar signals is incorporated as cooperative spectrum sensing in Cognitive radio scenario. Cooperative sensing enhance the robustness of detector to the fading and shadowing by using the diversity concept. In cooperative sensing, multiple CR sensors are scattered in network and they individually sense the spectrum and sensed information is sent to fusion centre, where decision is made [1][10].

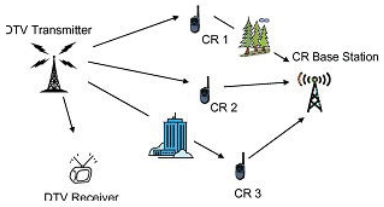

Fig. 2. Coopertive enviornment scenario in shadowing and fading effect shown[12]

Cooperative sensing is classified into soft combining (Data fusion) and hard combing (decision fusion) [1]. In Soft combining also called data fusion method, some M cognitive receivers collect the raw data from primary user and process or amplify and send it to the fusion center. In fusion center simple combining techniques based on diversity, like maximal ratio combining (MRC), square law combining (SLC) and equal gain combining (EGC) are used in decision making at fusion center. Recently weighted optimal linear combining techniques based on convex optimization are proposed in [1] [13]. In this case CR receivers does not require complex detection process. But, the bandwidth of communicating channel between CR and fusion center should be at least same bandwidth as of primary user and CR.

Hard combining or data fusion method, each cooperative CR receivers, make the binary decision based on local observation and each user sends the single bit or multi-bit decision to the fusion center (FC). Then the fusion rule at the FC user OR, AND or Majority logic combination in decision making [1][14]. This method requires low bandwidth control channel. However it performance is better, only if the control channel is error free, as only hard decision like 0 or 1 are sent. And also assumed that, SNR statistics is known at local CR sensors.

A. System model for cooperative sensing [1]

In Cooperative sensing, it is assumed to consist of M CR nodes and then hypothesis test is given as

$$H_0 : \mathbf{y_m} = \mathbf{w_m}, n = 1, ..., N \tag{9}$$
$$H_1 : \mathbf{y_m} = \mathbf{x_m} + \mathbf{w_m}, n = 1, ..., N$$

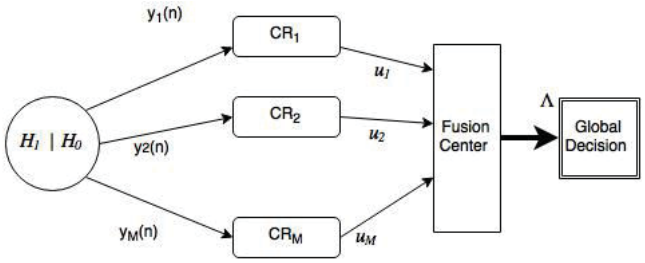

Fig. 3. System model for coopertive sensing

Above case, received signals at different CR are supposed to be independent of each other and $\mathbf{y}$ is defined as $\mathbf{y} = [\mathbf{y}_1^T, \mathbf{y}_2^T, ..., \mathbf{y}_m^T]$, then test statistics based on log-likelihood ratio is defined as

$$\sum_{i=1}^{m} u^{(m)} = log \prod_{m=1}^{M} \left(\frac{p(\mathbf{y_m} \mid H_1)}{p(\mathbf{y_m} \mid H_0)} \right) v \tag{10}$$

In above case, $u^m = log(\frac{p(\mathbf{y_m}|\mathbf{H_1})}{p(\mathbf{y_m}|\mathbf{H_0})})$ is the log-likelihood ratio(LLR) for mth receiver [1][15]. Because received data for all secondary receivers are assumed to be independent, optimal fusion rule tends to sum local LLRs. By considering noise vectors are independent $\mathbf{w_m} \sim \mathbb{N}(0, \sigma_m^2 I)$ and primary signal vector are also independent $\mathbf{x_m} \sim \mathbb{N}(0, \gamma_m^2 I)$. After neglecting the constants than LLR is written as

$$\sum_{m=1}^{M} \frac{\|\mathbf{y_m}\|^2}{\sigma_m^2} \frac{\gamma_m^2}{(\sigma_m^2 + \gamma_m^2)} \tag{11}$$

The statistic $\frac{\|\mathbf{y_m}\|^2}{\sigma_m^2}$ may be considered to be soft decision from time-frequency distribution detection of mth CR receiver. Optimal strategy like ECG, MRC and linear weighted optimal sum can used for detection. As paper uses the time-frequency based local detectors discussed in previous case, so large data handling becomes difficult and require large bandwidth, if soft-decision methods are used. In this paper only hard combining methods used for global decision making, as it is simple to implement and require low bandwidth.

In case of Hard combining individual receiver makes its own decision and sends the binary decision to fusion center. The test statistic of the local time-frequency detector can be represented as

$$J_{max} = \max_{w(m) \in W_D} J_m = \sum_{n=0}^{N-1} SM(n, w_{max}(n)). \tag{12}$$

Let local statics $u^m \in (0, 1)$ of the mth receiver. At the common fusion center, all single bit decisions are fused together according to following logic rule. Above (12) depicts that PU signal presence, when there exists at least n out of m CRs inferring as H_1. Otherwise it decides as absence of PU. OR rule corresponds to $n = 1$ and AND rule corresponds to $n = M$. Suppose all decision are independent, than the probability of false alarm for and Probability of detection for OR, AND and N out of M (majority) rule is given as

OR rule:

$$P_d = 1 - \prod_{m=1}^{M} (1 - P_{d,i})$$

$$P_{fa} = 1 - \prod_{m=1}^{M} (1 - P_{fa,i}) \tag{13}$$

And rule:

$$P_d = \prod_{m=1}^{M} (P_{d,i})$$

$$P_{fa} = \prod_{m=1}^{M} (P_{fa,i}) \tag{14}$$

IV. SIMULATION RESULTS AND ANALYSIS

Primary signals used for testing performance are taken from signals used in Project 25(P25) which is suite standards for digital radio communications used by federal, state, province and local public safety agencies in North America[16]. Fig.4 shows the time frequency representation of two types of TETRA signals, one is Compatible 4 level frequency modulation (C4FM) that transmit digital data over a 12.5 kHz channel other is Compatible quadrature phase shift keying (CQPSK), that transmits signal over 6.25KHz channel. For both signals settings are done as for the P25 standard. Fig 4 (a-d) are the time-frequency plots of clean primary signals and noisy primary signals at -10 dB SNR. Using S-method with $L = 16$ and hamming window of size of 32 with Primary signal samples of $N = 512$ are used to plot the T-F representation. Clean primary signal without any additive noise are represented by Fig.4 (a) and (c), clearly shows the concentrated plot of pure C4FM and CQPSK. Fig.4 (b) and (d) shows the noisy primary signals in which noise is spread over all the time-frequency plane. Joint time-frequency based sensing overcomes noise uncertainty problem encountered in ED, as noise equally spread in both the plane.

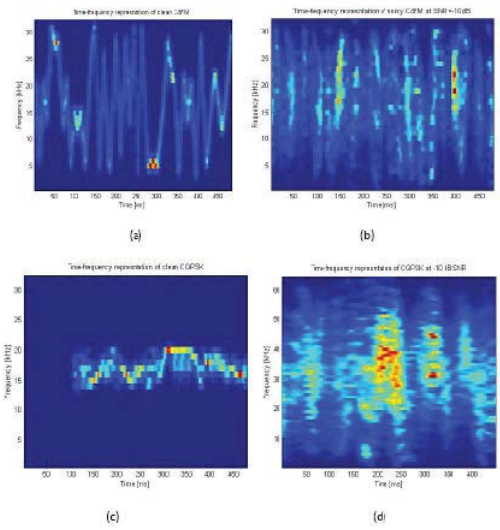

Fig. 4. Time-frequency representation of Primary signals

For simulation of cooperative scenario, environment shown in Fig.3 is considered. Previously mentioned CQPSK is used as

primary signal. Simulation are done for AWGN and Rayleigh fading case with number of receiver $M = 1, 3$ and 5 average of SNR=-5 dB. For S-method detectors, number of samples taken as N=256, window length W=32 and L=16. Fig 5(a) and(b) shows the ROC curves for hard combing based OR and AND logic cooperative sensing using the S-method based detection for both AWGN and Rayleigh Channels . As the number of receiver increased from $M = 1, 3, 5$ in case of OR logic probability detection for both channel type increases and for the case of AND probability detection decreases. From previous discussion it is known OR logic more conservative towards detection, but some time it may lead to false detection of noisy signals as primary signal. Where as AND logic is more biased towards the probability of false alarm, at the cost of low probability of detection. Most of the case OR logic is preferred over the AND logic, because of high probability of detection capability, which is stringent condition in case of Cognitive radio. So results are phenomenon, in which space, time and frequency dimension are considered to find vacant spectrum, because spectrum can be vacant in any of three dimension, this is first that kind approach. Results are validated based on simulation and still it requires the proper mathematical model. This type of detectors are very suitable for the wide band time-varying spectrum scanning. With respect to complexity requirement hard combining method are simple, but requires the individual receiver to have good signal processing capability of detection.

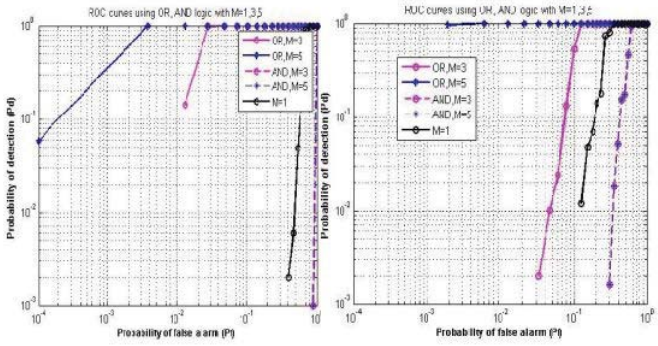

Fig. 5. ROC curve using OR, AND Logic with M=1,3,5 (a) AWGN Channel (b) Rayleigh Channel

V. CONCLUSION

Paper investigates cooperative sensing based on time-frequency detectors. This is first of the kind, where time, frequency and space dimension simultaneously used to detect the spectrum. S-method, which is combines the good characteristics of STFT and WD overcomes the problem of cross-terms appearing in time-frequency representation used as tool for detection. As S-method is obtained from STFT, hardware implementation is feasible compared to quadratic WD. All our results are based on monte-carlo simulation, so proper mathematical model for time-frequency based cooperative sensing need to be investigated.

***Abstract*—This paper aims at identifying available free space (White band) for transmission of data, by measuring the spectrum using commodity software defined radio (SDR). Measurements are taken using low cost SDR over a wide spectrum, at different locations and during different time of the day. Standard energy detection based spectrum sensing technique is used on both GNU radio and MATLAB to test the validity of the obtained results. For measurements, an automatic framework is developed and implemented on commodity hardware. The analysis of spectrum from 400-900 MHz shows that in sub-urban areas, 92% of band in underutilized and maximum 17-18% of band is utilized in the evening (7 PM-8 PM). In rural areas, 96% of band is underutilised and maximum 13-14% of band is utilized in morning (10 AM-11 AM). This is also the first ever measurement based identification in the Central India region.**

***Index Terms*—White spaces, TVWS, GNU radio, spectrum sensing, energy detection**

I. Introduction

Increase in data volume due to rising domestic demand and ongoing Govt. of India initiatives such as Digital India is expected to fuel the telecom networking market in India [1]. Microsoft, Google and Facebook are planning to bring WhiteFi technology in India that can provide internet connectivity to a large section of the Indian population, thus, giving a boost to the Digital India initiative [2]. Cost effective connectivity to rural India has been well recognized by Governments around the world and other stakeholders for addressing the digital divide and explore new business opportunities [3].

One such white space band, the Television white space (TVWS) refers to the frequencies made available for the unlicensed use at locations where the spectrum is not being used by the licensed TV services [4]. TVWS can provide potentially low cost solution and connectivity that makes it appropriate for rural applications. It is time to start exploring the spectrum present in India and find the white spaces at different locations and at different times. The high penetration and free space propagation of the lower ultra high frequency (UHF) band in the range of 400-860 MHz is ideal for long range transmission. In other parts of the world, the overall usage of the spectrum in the range of 470-590 MHz is as low as 4.54% in Singapore [5], 6.2% in Auckland [6], 17.4% in Chicago [7] and 22.57% in Barcelona [8]. Hence, it is appropriate to do measurement based studies in India.

In India, according to the Indian National Frequency Allocation Plan (NFAP), 2011 [9], the spectrum band from 400-900 MHZ is mainly used for Fixed, Mobile and Broadcasting services. The digital broadcasting services is operated in the 585-698 MHz. Currently 470-590 MHz band is used in analog TV transmission [10]. Currently state broadcaster, Doordarshan has more than 1400 terrestrial transmitters [11]. The operating frequency of Doordarshan is characterized in three bands : VHF Band-I, VHF Band-II and UHF Band-IV [11]. Doordarshan plans to completely convert its transmission from analog to digital by the end of 2017 [12]. This will complete India's digital switchover. These bands are likely to be either unlicensed like in the UK [13] and in Africa, where the regulators have made these bands unlicensed, or lightly licensed.

In the Indian context, an investigation of TVWS has been done in Delhi [11] and Southern India [14]. IIT Bombay research group and Tata Teleservices in association with the WhiteSpace Alliance will implement test bed at several parts in India for broadband in TVWS [15]. Feasibility and applicability of IEEE 802.22 for TVWS transmission over COST-207 channel models has been studied at IIT Indore [16]. In this paper, frequency spectrum from 400-900 MHz is analyzed at different times. The readings were taken at sub-urban and rural areas around Indore (India), which represents significant area of Central India. There are about 650 villages and rural communities which are sparsely populated in distributed communities over a coverage area of 4500 square kilometre. Thus this region is appropriate for adoption of survey of white space, with Indore serving the nearby villages and rural communities using TVWS.

In order to measure and identify spectrum availability, some of the popular techniques for detection of the spectrum are energy detection, cyclostationary detection and locking detection [17]. In this paper, an energy detection based approach is used due to its low complexity and simplicity. Spectrum sensing is done in two ways; using MATLAB and by using GNU Radio to test the validity of obtained results. For both MATLAB and GNU radio implementations, we used SDR (Software Defined Radio) as a receiver. In this work, an RTL-SDR is used since, it is a commodity low cost SDR and commercial devices for TVWS are expected to have similar low cost devices.

The rest of the paper is organized as follows: Section II describes the spectrum sensing and overview of RTL-

SDR. Section III describes experimental set up for spectrum measurement including algorithm for PSD calculation and measurement locations. Section IV provides analysis of spectrum utilization at different locations and at different time, and finally conclusion are drawn in section V.

II. Spectrum Sensing and Overview of RTL-SDR

The objective of spectrum sensing in this paper, is primarily for measurement and identification of white space in particular frequency bands. However, the findings can also be used for licensed band for cognitive radio (CR). In CR, there is one primary user or licensed user, who can use band at any time instance, and the secondary user or unlicensed user can use the band when it is not being used by the primary user. The technique of energy detection involves calculation of power spectral density (PSD) of a set of samples in a determined frequency band. The PSD shows the strength of the variation of signal as a function of frequency. For our setup, the samples are taken in an interval of 2-MHz spacing. After collecting the samples, the PSD of the samples is calculated.

RTL-SDR is a popular, low cost hardware in the range of INR 2000 that can receive wireless signals. The RTL-SDR dongle features the Realtek RTL2832U chip, which provides I-Q samples through the USB interface [18]. It can receive and demodulate various wireless signals across a broad frequency range. Thus, it is used as a receiver which has specifications as follows:

- SDR frequency: 24-1700 MHz
- SDR bandwidth: 3.2-MHz (better to use 2.4-MHz)
- Antenna input: 50 ohms

The low cost of RTL-SDR is also one of the reasons to use it for the spectrum detection purpose. With Communication System Toolbox™ support package for RTL-SDR Radio, one can use MATLAB to design and prototype systems that process real time wireless signals. Using MATLAB, one can measure the spectrum at a center frequency and for a smaller bandwidth. In this paper, we have proposed a method by which we can use MATLAB to obtain the spectrum for a range of frequencies based on users need. GNU Radio is an open source software development tool kit that provides signal processing blocks to implement software radios. It is also used to obtain the spectrum for the same range of frequencies as it is used for MATLAB and hence we reconfirm our finding from two independent measurement processes.

III. Background Preparations

In this section, we describe the experimental setup, automation for spectrum measurement, algorithm for calculation of PSD of received signal in MATLAB and GNU radio, and measurement locations.

A. Experimental setup

We used RTL-SDR as a receiver which is a low cost hardware that provides I-Q samples through the USB interface. It has a maximum bandwidth of 3.2-MHz. We used laptops with 2.5-GHz Intel Core i5-3210M microprocessor with 4 GB 1600 MHz DDR3 RAM and AMD Radeon HD 7670M (1 GB DDR3 dedicated) video graphics for processing of received data from RTL-SDR. Fig. 1 shows the experimental setup.

Fig. 1. Experimental setup

B. Automation

The PSD of received samples in the band of 400-900 MHz at different time duration requires automation of code. We created a function which performs scanning of spectrum for 1-hour duration and again the code will restart after 3-hour to get the desired spectrum. The code runs at 3 different times so as to get the analysis of the spectrum has done in morning, afternoon and evening. The results from both MATLAB and GNU radio are stored in a file or file on host machine.

C. Algorithm for PSD calculation in MATLAB and GNU radio

In MATLAB and GNU radio, using a loop, center frequency is changed after taking 500 readings for the same center frequency with the bandwidth of 2-MHz ensuring that not many samples are lost. The next scanning is therefore done after an interval of 2-MHz ensuring that the whole range of 400-900 MHz is covered. Scanning of 2-MHz bandwidth at a center frequency, on our setup, takes about 0.8 seconds. An ensemble of 500 readings has been taken at a particular centre frequency and averaged to get the data at their center frequency. The code is run again and the data is stored for different centre frequency and thus we obtain PSD of the received signal. The pseudocode for PSD calculation is given in Algorithm 1.

D. Measurement location

Regions selected for our measurement are the sub-urban area and rural area located in outskirts of Indore and around Indore. The locations are sub-urban Mundla Nayta (Indore) where some residential area is located including Silver Spring township, rural Harnya Khedi village where IIT Indore is located and another rural Simrol village where IIT Indore permanent campus is located. The experimental locations are shown in Fig. 2. These locations form a triangle and are approximately 20 KM away from each other.

Algorithm 1 Pseudocode for PSD calculation in MATLAB and GNU radio

```
intialize: maxfreq=900 MHz, minfreq=400 MHz, fspan=2 MHz, ensemble=0, nxtfreq=0, count=0;
while nxtfreq < maxfreq
  count ← count+1;
  nxtfreq ← minfreq+span;
  while ensemble < 500
    scan minfreq to nxtfreq;
    save data in temp(ensemble);
    ensemble ← ensemble+1;
  end
  temp ← average(temp);
  P(count) ← PSD(temp);
  minfreq ← nxtfreq;
  ensemble ← 0;
end
```

IV. Observation and Analysis

In this section, we analyze the spectrum usage of 400-900 MHz at different locations and at different time in terms of PSD. We choose -110 dB as the noise threshold for our measurement by repeated measurements in known bands.

A. Spectrum utilization in Simrol

Fig. 3 (a) and (b) show the spectrum utilization measurement in morning (10 AM-11 AM) and afternoon (2 PM-3 PM) respectively with the help of MATLAB. The band ranges from 870-890 MHz is throughout occupied as it is a GSM band and rest of the band is sparsely occupied in compliance. Hence, on an average 10-11% and 11-12% of band is used in morning and afternoon. It has been observed that the spectrum utilization calculation by using MATLAB and GNU radio gives same results which validate our analysis of spectrum utilization. As MATLAB has higher precision as compared to GNU radio, we used MATLAB analysis for rest of the measurements. Fig. 6 (c) shows the contiguous bandwidth (maximum 160 MHz) available for Simrol. Fig. 7 shows the cumulative distribution power, which shows that 96% of bandwidth is available.

B. Spectrum utilization in Harnya Khedi

Fig. 4 (a) and (b) show the spectrum utilization measurement in morning (10 AM-11 AM) and evening (7 PM-8 PM) respectively with the help of MATLAB. The figures show that the band between 870-890 MHz band is less occupied as compared to sub-urban location and rest of the band is equally occupied as in sub-urban location. On an average 13-14% and 10-11% of band is used in morning and evening respectively. Fig. 6 (b) shows the contiguous bandwidth (maximum 110 MHz) available for Harnya Khedi. Fig. 7 shows the cumulative distribution power, which shows that 98% of bandwidth is available.

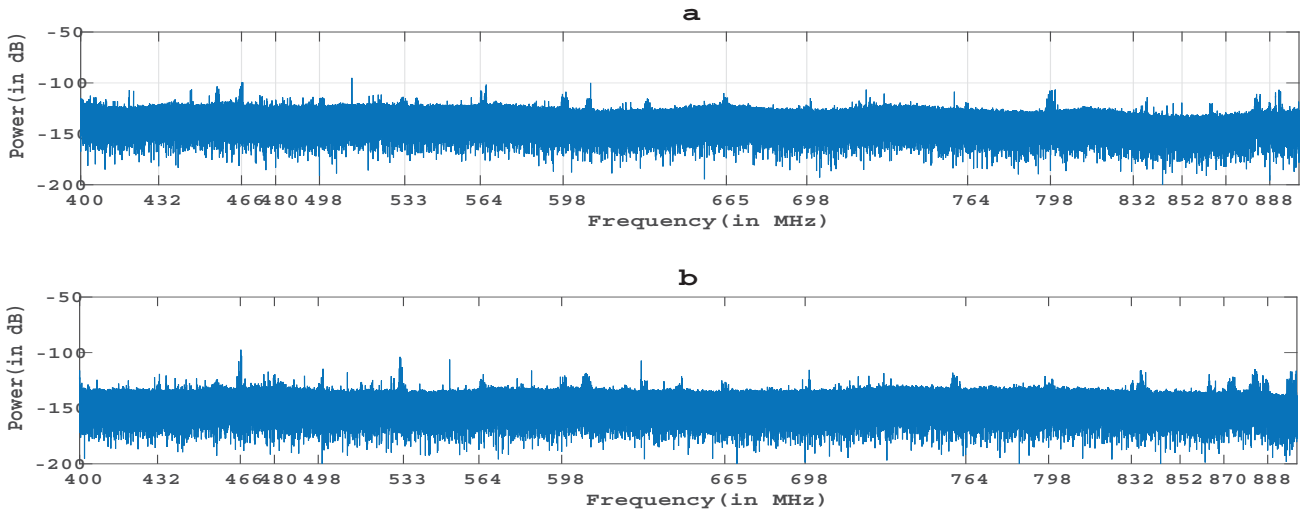

Fig. 4. a) Morning (10 AM-11 AM) and b) Evening (7 PM-8 PM) measurement using MATLAB in Harnya Khedi

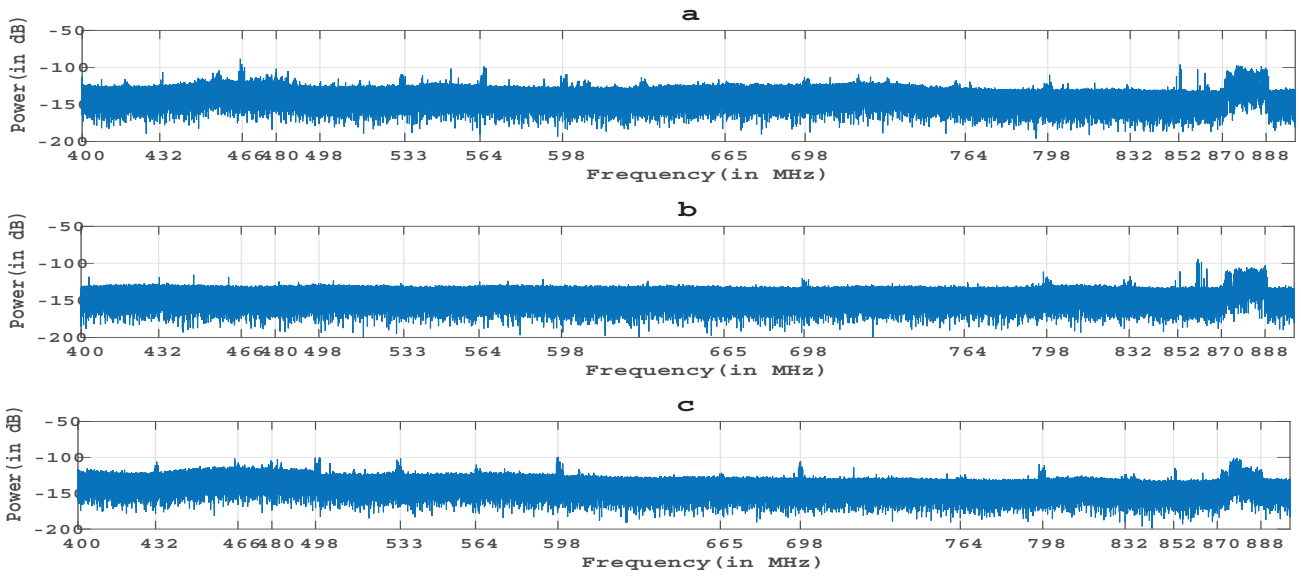

Fig. 5. a) Morning (10 AM-11 AM), b) Afternoon (2 PM-3 PM) and c) Evening (7 PM-8 PM) measurement using MATLAB in Mundla Nayta

C. Spectrum utilization in Mundla Nayta

Fig. 5 (a), (b) and (c) show the spectrum utilization measurement in morning (10 AM-11 AM), afternoon (2 PM-3 PM) and evening (7 PM-8 PM) respectively with the help of MATLAB. Figures show that again the band between 870-890 MHz is occupied and rest of the band is sparsely occupied. On an average 13-14%, 7-8% and 15-16% of band is used in morning, afternoon and evening respectively. Fig. 6 (a) shows the contiguous bandwidth (maximum 140 MHz) available for Mundla Nayta. Fig. 7 shows the cumulative distribution power, which shows that 92% of bandwidth is available.

V. Conclusion

In this paper, we measured and analyzed the spectrum utilization of band range from 400-900 MHz in sub-urban and rural area of Indore. The analysis show that in sub-urban regions 92% of band is unutilized and maximum use of band is in the evening. However, in rural areas 96% of band is unutilized and maximum use of band is in the morning. The analysis also show that the band except 870-890 MHz

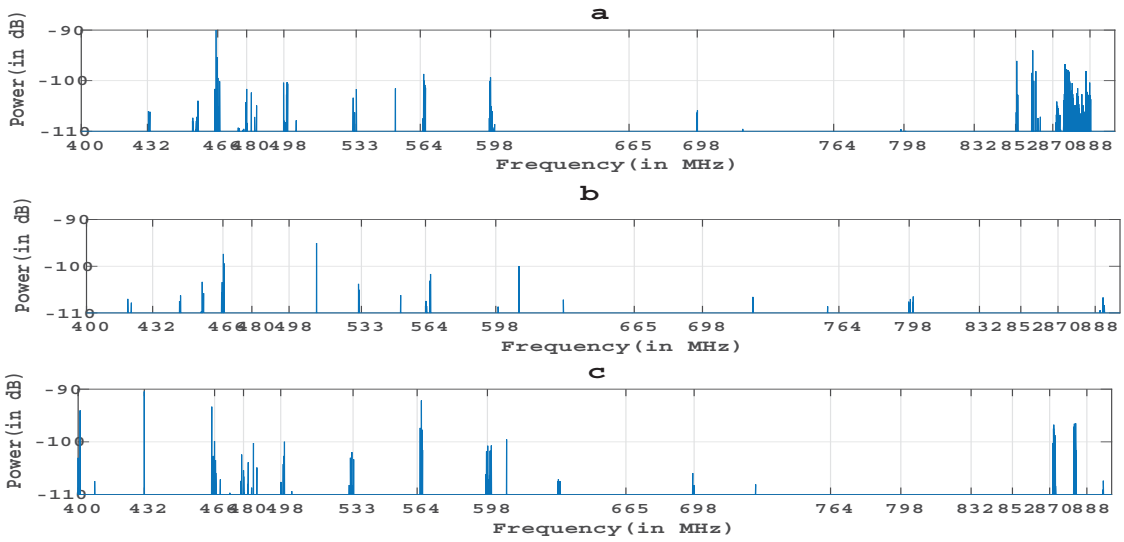

Fig. 6. Contiguous bandwidth available for a) Mundla Nayta, b) Harnya Khedi and c) Simrol

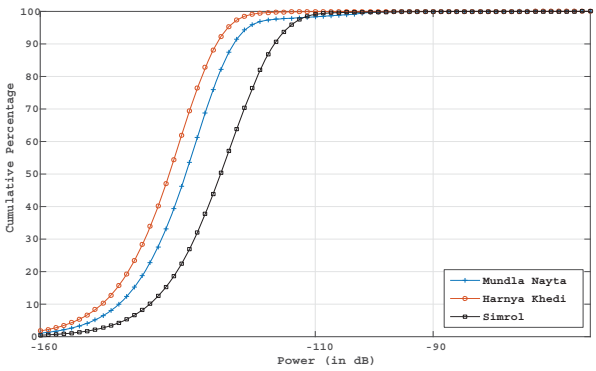

Fig. 7. Cumulative distribution of power

is not occupied contiguous. The largest value of maximum available contiguous band in sub-urban and rural region is 140 MHz and 160 MHz respectively. Hence, there is a vast availability of white space bands, that may be utilized for wireless communication for rural broadband.

***Abstract*— This paper focuses on the use of UWB radar imaging for stroke detection. In particular, we optimized the use of the RAR algorithm, originally proposed for breast cancer, to the case of stroke detection. Moreover, we extend it to the multistatic case. Both modified RAR and multistatic RAR are then combined with a novel artifact removal algorithm based on PLSR (Partial Least Square Regression) processing. The paper shows the effectiveness of the proposed solution in terms of improved stroke localization accuracy and number of false positives.**

Keywords—beamforming algorithms; UWB radar imaging; PLSR; brain stroke detection

I. INTRODUCTION

Brain stroke is one of the main causes of disability in the world. Detecting a stroke as soon as it occurs (for example, after a trauma) would be extremely important to better manage the emergency (for instance, by optimizing the priorities in case of more than one patient) and in reducing the number of unnecessary high resolution imaging diagnoses. This would be possible with a stroke detection device that is low cost and transportable so that it can be carried on site by first response paramedical teams or in the ambulance. More traditional high resolution medical imaging tools such as CT (Computed Tomography) and MRI (Magnetic Resonance Imaging) scanners, are not compatible with these requirements (portable and low cost). Microwave imaging (MWI) is an emerging diagnostic branch based on the observation that different tissues, or the same tissue in different functional conditions (i.e. cancerous and healthy) have different dielectric properties in the microwave band. MWI allows to design less complex and costly devices, which might be transportable. Moreover, it is less invasive with no risk associate to patient exposure to ionizing radiations.

Currently, there are two main MWI approaches: microwave tomography and UWB radar. The microwave tomography determines morphological (location, size and shape) and electromagnetic characteristics (permittivity, conductivity and magnetic permeability) of any abnormal examined tissue. The output is the reconstruction of the complete dielectric profile of the crossed tissues. One limitation of this technique is that the tissue reconstruction requires the solution of a very complex mathematical inverse problem. Relevant works on stroke detection via a MWI tomographic approach has been done by a research group at Chalmers University [1], [2].

In this paper we focus on the UWB radar approach, [3]. A lot of work on the use of UWB radar imaging has been done for breast cancer detection [4]-[7]. If a low complexity beamforming algorithm, such as the Delay & Sum (DAS), was first proposed in [4], more complex and powerful beamforming algorithms have been proposed more recently, such as the MIST (Microwave Imaging Space-Time) proposed in [5] and optimized for a multistatic approach in [6]. An important recent work is [8], in which authors propose the RAR (Robust and Artifact Resistant) algorithm, based on an adaptive weighted sum via correlation exploration. The backscattered signals exhibiting high correlation are combined, reducing the algorithm sensitivity to clutter.

Recently several works have started to consider the application of UWB radar imaging also to stroke detection, [9]-[12]. Processing and pre-processing algorithms proposed for breast cancer cannot be applied in a straightforward way to stroke detection for two main reasons: 1) Requirements are rather different: for breast cancer accuracy is more important than device complexity and response-time. In case of stroke detection, a fast response, the low complexity and cost of the device are more important than accuracy; 2) The scalp generates strong artifacts to backscattered signals and attenuates wave penetration inside the brain.

Works on UWB radar for stroke detection has mainly focused on antenna design [9]-[10] or anatomical head phantom [11]. In most of these works the DAS algorithm is used [11]-[12], which allows to keep the complexity low. However, DAS offers limited capability for discrimination against clutter. As it has been shown in [13], artifact removal algorithms, such as the one based on Wiener filters, which are effective when combined with a more complex processing algorithms (such as the MIST applied for breast cancer detection in [5] and for our application in [14]) are not applicable to DAS. Therefore, in [13], the use of a novel approach for artifact removal, based on PLSR processing, has been proposed and its effectiveness has been shown.

In this paper, we propose the combination of this artifact removal algorithm with a modified version of the DAS algorithm, namely the RAR [8], which has been originally proposed for breast cancer. As it will be shown in the paper, the direct application of the original RAR algorithm and a state-of-the-art artifact removal algorithm such as the one based on Wiener filter [5] to stroke detection does not provide good results. Therefore, we have first optimized its use to the

stroke detection. Then, we have extended it to a multistatic case to further improve the achievable performance. Modified RAR, multistatic RAR, combined with the PLSR-based artifact removal algorithm, are compared with the DAS algorithm in terms of accuracy of stroke localization, presence of false positives and also computational complexity, using backscattered signals acquired by a FDTD (Finite-Difference Time-Domain) applied onto a 3D and 2D head model.

The paper is organized as follows: Section II presents the system environment; Section III describes the considered artifact removal algorithm, while in Section IV the proposed processing algorithms are presented; performance results are reported in Section V.

II. System Model

In this study the backscattered signals are generated by FDTD software and are assumed to be noiseless, which is an acceptable assumption for the purposes of this paper. We have considered 8 UWB antennas, located in different positions along head surface. Each antenna transmits a UWB pulse into the tissue and receives signals transmitted by all antennas and backscattered by the tissue discontinuity, according to a multistatic approach.

The transmitted pulses have a bandwidth that extends from 1 to 4 GHz, a good trade-off between radar spatial resolution and waves attenuation inside the human brain.

The head has been modeled as a 3D multilayered structure, considering the stratification in different layers, simulating the actual biological head structure, and the dispersive properties. The 3D model consists in the layer of the skin, the skull and the brain matter. The dispersive properties are incorporated in the FDTD model, based on 2th order fit to Cole-Cole model.

We have also assumed the presence of a coupling medium between the antenna system and the head, in order to ease wave propagation inside the tissues. The coupling medium is a mixture of different liquid substances with dielectric constant similar to skin. This liquid increases electromagnetic energy transmission inside the skull and reduces the reflection contribution.

Table I shows the main parameters of the different head tissues considered in the model for the computation of the backscattered signals, at center frequency of 2.5 GHz.

TABLE I. Head Tissue Properties At Center Frequency of 2.5 GHz [15]

Tissue	Dielectric constant	Loss tangent	Conductivity (S/m)
Skin	37.952	0.28184	1.4876
Bone	11.352	0.25597	0.40411
White Matter	36.107	0.24699	0.24699
Coupling Medium	43		

For validation of our methods we start with a 2D (planar) elliptical head model. Fig.1 shows a planar section of the head model and the antennas system around it.

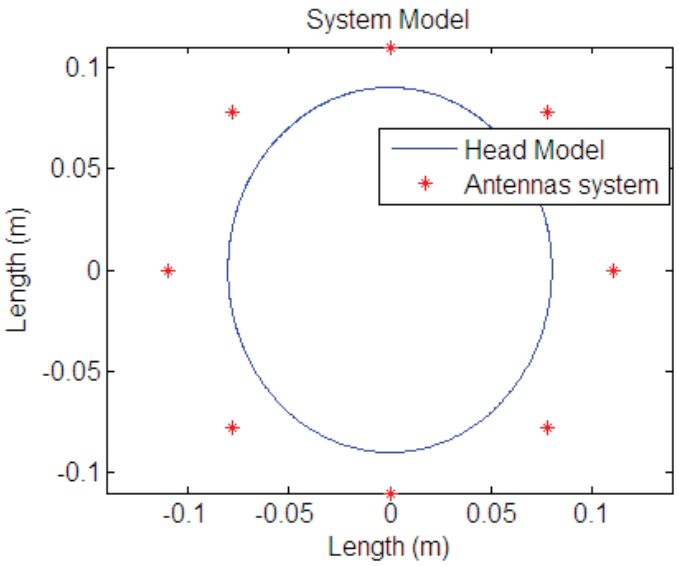

Fig 1. System model. The ellipse represents planar section of the 3D head model. The antennas, in red, are arranged along the head surface

III. PLSR-based Artifact Removal Algorithm

The UWB backscattered signals contain a lot of useless information (artifacts), including the reflected signal from the skin-coupling medium interface, coupling between antennas, antennas mismatch and clutter. Artifacts have magnitude larger than lesion contribution, leading to false positives or negatives. Therefore, they must be removed, by an artifact removal algorithm, before applying any image reconstruction algorithms.

In [13], an artifact removal algorithm based on statistical regression technique, PLSR, has been proposed. As shown in [13], the PLSR processing allows to achieve better performance compared to artifact removal algorithm originally proposed in [5], with a drastically reduced computational complexity. To apply PLSR, the artifact on each channel was estimated as a linear combination of the artifact in all other channels, utilizing the maximization of correlation as constraint and relying on the assumption that the artifacts are similar, but not identical.

Before passing the backscattered signals to the pre-processing algorithm, a first "cleaning" of the signals is performed by a simple low pass filter, because the stroke response is mainly on low frequencies of the spectrum, [13].

IV. Processing Algorithm

In this paper, we have considered the RAR algorithm, proposed in [8], for processing the backscattered signals. RAR is a modified version of the DAS. The idea is to introduce a weight factor that gives more relevance to the most significant signals, i.e. those signals with the greatest information content.

This allows to reduce the effect of the artifacts that have not been removed by the artifact removal algorithm.

The algorithms build a map of backscattering energy, applying a beamformer to each return signal. The head is divided in focal points, which are associated with the intensity

of corresponding pixel in the energy map. The signals are time-shifted to align them so that, if a scattering object exists at focal point, the energy will be relatively high, since signals are summed coherently. Conversely, if lesion is not in focal point, i.e. focal point is a healthy tissue, signals are summed incoherently, leading to low energy value.

A. RAR algorithm

Let N be the number of antennas and L the number of focal points. The steps described below are repeated for each focal point, thus the energy map is achieved by L loops, involving 4 steps.

Step 1: Preprocessed signals are time-shifted to align them approximately in time. Then, a windowing truncation is provided to eliminate useless information while preserving stroke response.

Step 2: A coherent summation of these time-shifted signals is calculated as in (1):

$$Sum(n,l) = \sum_{i=1}^{N} X_i(n,l) \tag{1}$$

where $n=1,\ldots k$ is the sample number and X_i is the i^{th} signal, after previous step.

Step 3: A weight factor is introduced, adaptively combining neighboring pairwise Pearson's correlation coefficients, calculated as follows:

$$c_i(l) = \sum_{n=1}^{k} X_i(n,l) X_{i+1}(n,l) / \sqrt{\sum_{n=1}^{k} X_i(n,l)^2 \sum_{n=1}^{k} X_{i+1}(n,l)^2} \tag{2}$$

The weight factor in [8] is calculated as:

$$wf(l) = \prod_{i=1}^{M} c_i(l) \tag{3}$$

where M is the number of relevant correlation coefficients normalized between *0-1*.

In the original algorithm proposed in [8], $M=N/2$, i.e. only half of the correlation coefficients, among the ones with higher values, are considered in (3). However, as it will be shown in the next Section, in our case we need to consider $M=N$, at least for the monostatic version of the algorithm. In the calculation of the weight factor all the correlation coefficients, normalized between *0-1*, are considered. In the following, we will refer to "modified RAR" to the algorithm that has this slight modification. Note that the last correlation coefficient is calculated between X_N and X_1 signals, because the antenna array is circular.

High correlation is expected at stroke location. The neighborhood pairwise correlation ensures that the correlation between two antennas, for each location, measures the reflection from the same scatterer.

Step 4: Finally, the energy of l^{th} focal point is

$$I(l) = \sum_{n=1}^{k} wf(l) \cdot Sum(n,l) \tag{4}$$

A high value of *wf* occurs when a stroke is in a l^{th} focal point, increasing the energy related to this focal point and giving more relevance to the stroke.

Conversely, when there is no stroke in l^{th} focal point, *wf* is low, decreasing the energy associated to the artifact.

B. Multistatic RAR

In this Section we present the multistatic extension of the RAR algorithm.

When a multistatic approach is used, we have *NxN* channels. We consider $C<NxN$ channels, selected a priori, according to distance between the i^{th} transmitting antenna and j^{th} receiving antenna. We use N mono-static channels Xij with $i=j$, when the transmitter coincides with the receiving antenna, and $2N$ multi-static channels between each transmit antenna i and nearest neighboring antennas $i+1$ and $i-1$.

Step 1- Step 2: These steps are the same of the monostatic case.

Step 3: Correlation coefficients for monostatic channels are calculated by (2), whereas for multistatic channels ($i \neq j$) we use (5) for $j=i+1$ and (6) for $j=i-1$.

$$c_{ij}(l) = \sum_{n=1}^{k} X_{ij}(n,l) X_{i+1,j+1}(n,l) / \sqrt{\sum_{n=1}^{k} X_{ij}(n,l)^2 \sum_{n=1}^{k} X_{i+1,j+1}(n,l)^2} \tag{5}$$

$$c_{ij}(l) = \sum_{n=1}^{k} X_{ij}(n,l) X_{i-1,j-1}(n,l) / \sqrt{\sum_{n=1}^{k} X_{ij}(n,l)^2 \sum_{n=1}^{k} X_{i-1,j-1}(n,l)^2} \tag{6}$$

The normalized correlation coefficients are sorted in descending order in a vector, called P vector.

The weight factor is achieved by multiplying correlation coefficients of neighboring pairwise transmitting-receiving antennas in the P vector and selecting the N higher values. The N higher values are chosen as a good trade-off between complexity and reliable performance. A lower number of the selected correlation coefficients would involve a worst discrimination between stroke and other scatterers, increasing the false positives. Whereas, a greater number of the selected correlation coefficients would lead to information loss.

Step 4: Finally, the energy of l^{th} focal point is given by (4).

V. Results and Final Remarks

In this section, the performance of the different beamforming algorithms namely the RAR algorithm in [8], modified RAR (as explained in Section IV), multistatic RAR and DAS algorithm are shown.

The performance has been evaluated considering a spherical bleeding (hemorrhage) with a diameter of 20 mm, placed in different positions of the head.

The metrics used for performance assessment, in terms of accuracy of stroke localization and amount of clutter versus stroke intensity, are:

- the absolute distance between the actual location of the stroke and the location of the maximum energy value in the

backscattering energy map, used to assess the localization accuracy. The stroke is localized with more precision when this distance is low.

- Signal-to-mean-ratio *SMR*, to validate if the stroke energy is high enough to classify it as a detected stroke, written as follow:

$$SMR = 10 \log_{10} \frac{mean\,(P_{stroke_region})}{mean\,(P - P_{stroke_region})} \quad (7)$$

where P_{stroke_region} is the average energy value of the stroke region and P-P_{stroke_region} is the average energy value of the remaining tissues. A higher value of this metric implies that stroke intensity is stronger than background region and results in a low amount of clutter.

Furthermore, an important aspect to take into account is the algorithms computational complexity.

The RAR complexity and the modified RAR complexity are comparable. Whereas, the complexity increases by introducing the multistatic RAR, since more channels are considered.

Table II reports the complexity as magnitude order, in terms of basic mathematical operations. As shown, the multistatic RAR complexity is higher than DAS complexity, due to the weight factor calculation.

TABLE II. ALGORITHMS COMPLEXITY

Metrics	**Processing algorithms**			
	RAR [8]	***Modified RAR***	***Multistatic RAR***	***Multistatic DAS***
Complexity	10^4	10^4	10^5	10^4

First of all, we assess the performance of the modified RAR and multistatic RAR using a state-of-the-art artifact removal algorithm based on Winer filter [5].

Fig. 2 shows the energy map, in a planar section, obtained with this frame. In Fig. 2, the external ellipse is the head contour, while the internal black circumference is the bleeding extension. The energy output is represented as colored pixel, according to values in dB scale.

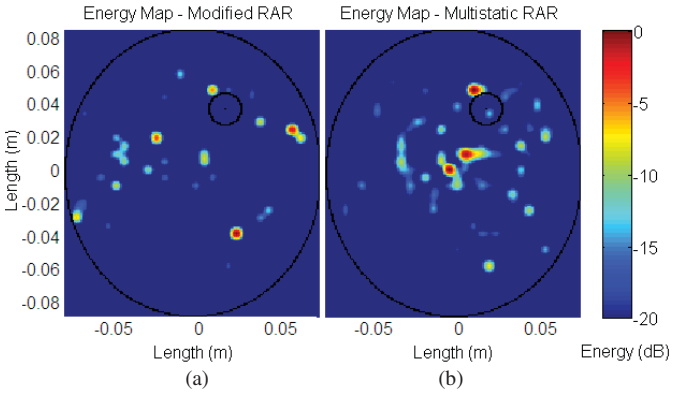

Fig. 2. Energy map obtained with the artifact removal algorithm based on Wiener filter and the (a) Modified RAR algorithm and (b) Multistatic RAR algorithm.

Fig. 2 clearly shows that, even if the RAR algorithm has been proposed for breast cancer detection to make the DAS processing less sensitive to the clutter, its performance are still poor when combined with a typical artifact removal algorithm also used for breast cancer. Therefore, we propose the use of the an artifact removal algorithm based on PLSR as described in Section III.

Fig. 3-4 show the backscattering energy map, in a planar section, obtained with different processing algorithms considering two different positions of the stroke. Table III-Table IV summarize the metrics values achieved for each of the compared algorithms, where Distance represents the absolute distance metric.

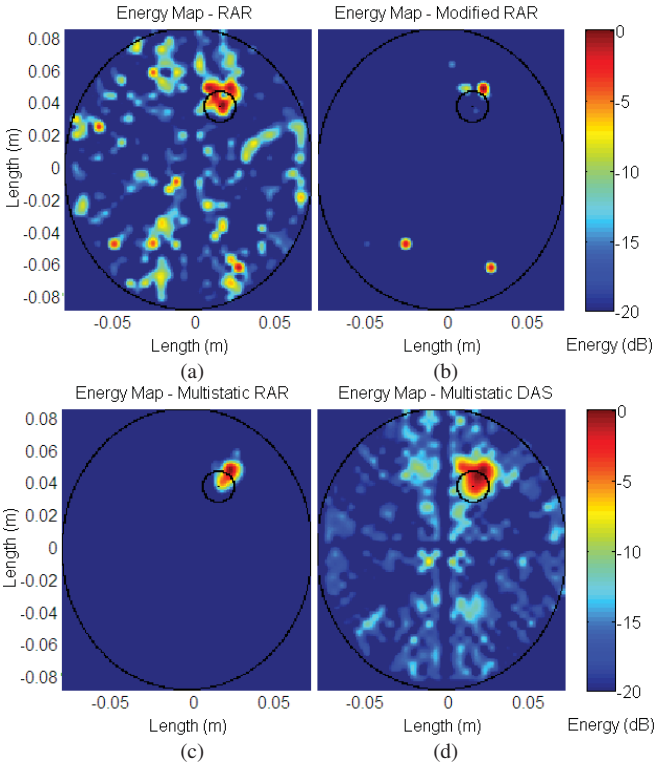

Fig. 3. Energy map obtained with the artifact removal algorithm PLSR and the (a) RAR algorithm proposed in [8], (b) Modified RAR algorithm, (c) Multistatic RAR algorithm and (d) Multistatic DAS algorithm.

TABLE III. METRICS PERFORMANCE FOR FIG. 3

Metrics	**Processing algorithms**			
	RAR [8]	***Modified RAR***	***Multistatic RAR***	***Multistatic DAS***

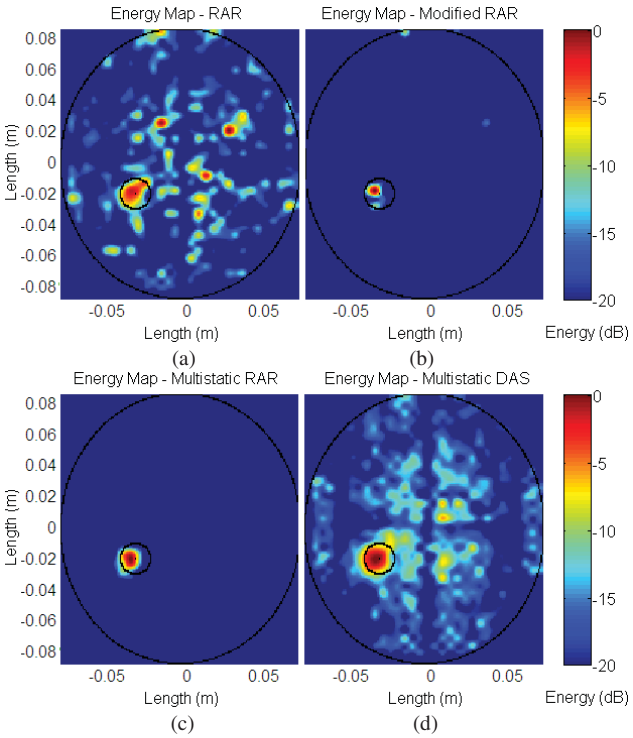

Fig. 4. Energy map obtained with the artifact removal algorithm PLSR and the (a) RAR algorithm proposed in [8], (b) Modified RAR algorithm, (c) Multistatic RAR algorithm and (d) Multistatic DAS algorithm.

TABLE IV. METRICS PERFORMANCE FOR FIG. 2

Metrics	**Processing algorithms**			
	RAR [8]	***Modified RAR***	***Multistatic RAR***	***Multistatic DAS***
Distance [mm]	72.1113	4.9999	4.9999	4.9999
SMR [dB]	6.8847	21.4698	32.353	8.8298

From Figs. 3-4 and Table III-IV, we can conclude the following:

The original RAR algorithm cannot be directly applied to our case of stroke detection. The stroke is effectively located, but the number of false positives is unacceptable. By considering all the correlation coefficients in the weight factor, as in the modified RAR, it is possible to greatly reduce the number of false positives. It is worth noting that in the case of breast cancer application of RAR, 48 antennas were considered. In our scenario, only 8 antennas are considered. Therefore, considering all correlation coefficients do not lead to a dramatic increase of the complexity as it would be in case of breast cancer.

The multistatic extension of RAR algorithm is able to locate the stroke with high accuracy and the number of false positives is extremely low. This is expected as the multistatic approach allows to acquire more information about the target, avoiding strong reflections from undesired scatterers, as clearly shown in Fig. 3. On the other hand, the multistatic approach is computationally heavier. However, it is also worth noting that in our proposed extension of the RAR, we consider a number of correlation coefficients lower than the total number of correlation coefficients, as opposite to the monostatic case where all coefficients are needed.

Finally, with respect to a multistatic DAS algorithm, the accuracy in stroke localization of the multistatic RAR is the same, but the multistatic RAR can drastically reduce the number of false positives, leading to more precise information. Moreover, this performance improvement is achieved with a low increase of the computational complexity, as previously shown in Table II.

In conclusion, the results show the effectiveness of the proposed combination, artifact removal algorithm based on PLSR and a multistatic RAR, for stroke detection.

Email: rajarshim@ieee.org

***Abstract*—Recent survey predicts that the number of smart phone users will cross two billion worldwide by early 2016. In order to support high QoS requirements, ITU proposed IMT-2020, which is setting the stage for 5G wireless technologies. The 5G technologies aim to support broadband data rate more than 5 Gbps, latency less than 1 ms for high mobile user. Establishing and maintaining a successful wireless communication link among the users with simultaneously achieved all objectives becomes challenging. The backhaul of nearly all wireless access networks is fiber-optic. In order to support these tremendous amounts of data, optical network has been evolved in respective way. These technological advancements and deployments are creating a new landscape in access networks, with an integration of wireless and optical technologies. As optical fiber has penetrated the access network and the latest wireless standards have demanded smaller, higher bandwidth cells, fiber connectivity has become key. This paper studies the various wireless technologies to support high QoS and the impact of optical backbone network correspondingly. In particular, the development of optical networks will be discussed with advancement of wireless networks to support high performance communication. In this study, participation of both the networks will be considered to understand several efficient mechanism (*e.g.* spectral, energy, deployment, routing, transport etc.) of networks.**

***Index Terms*—Green communication, optical network, cognitive network,**

I. Introduction

Recent survey predicts that the number of smart phone users will cross two billion worldwide by early 2016. The usage of number of smart terminals (smart phones and tablet PCs) has proliferated the mobile Internet applications, which explored mobile traffic. It is predicted that mobile data traffic will grow more than 1000 times compared with the end of 2010 beyond 2020. In early 2012, in order to support high quality-of-service (QoS) requirements, ITU proposed IMT-2020, which is setting the stage for 5G wireless technologies [1]. The focus of 5G technologies is to enable a seamlessly connected society in the 2020 time frame and beyond that brings together people along with things, data, applications, transport systems and cities in a smart networked communications environment.

Network densification, miscellany of node types, split of control and data plane, network virtualization, heavy and localized cache, infrastructure sharing, concurrent operation at multiple frequency bands, simultaneous use of different medium access control and physical layers, and flexible spectrum allocations can be envisioned as some of the potential ingredients of 5G [2]. The prominent technologies of 5G includes massive MIMO, cloud computing, software-defined network, cognitive radio, distributed antenna system and others technologies, which are differ in their characteristics, operation, application, requirements, purpose etc. These technologies are diverse in nature and coexist in the same environment to provide ubiquitous network coverage. Users can connect to any available wireless network depending on their requirements. With the increased drive from the industry for a fully connected network, there is also a need to design heterogeneous wireless network (HetNet) architecture to interconnect these different wireless networks. These interworking mechanisms are of prime importance to achieve ubiquitous access and seamless mobility in HetNet environment.

The data produced at wireless access network are transported through optical fiber link. Thus, optical networks are facing increased levels of heterogeneity, from types of services to the types of transmission technologies. Over the years, capacity of optical network increases from 10 Gbps to 100 Tbps and more. Like wireless networks, optical network is also evolved to fifth generation. During this evolution, optical network incorporated several technologies such as enhancement mechanism (rate, bandwidth, wavelength), transmission mechanism (dense wavelength-division-multiplexing (DWDM), optical CDMA (OCDMA), Coarse WDM (CDWDM)), architecture (time-division-multiplexing passive-optical network (TDM-PON), long reach PON, Ethernet PON (EPON), WDM-PON), switching (optical circuit switching (OCS), optical burst switching (OBS), optical packet switching (OPS)) and other techniques. Figure 1 shows a typical service architecture of wireless network with optical backbone, where all the 5G wireless technologies are connected directly with the optical network.

The successful development of wireless network depends on the successful transmission of data traffic through optical fiber *i.e.* optical network. Thus, optical network is responsible for transmission of data traffic and make available for usage of wireless user. In this paper, we will discuss the participation of optical backbone network for successful wireless communication.

II. Participation of Optical Network in 5G Technology Development

In this section, we will discuss several 5G wireless network technologies, which are proposed to improve QoS and quality of experience (QoE) of application. Simultaneously, we will provide the details of participation or importance of optical

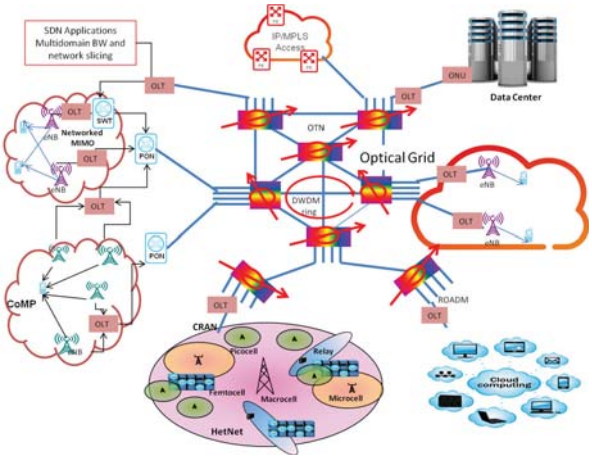

Fig. 1. A typical service architecture of wireless network with optical backbone.

network component to enable the services/applications by improving quality of transmission (QoT).

A. Coordinated Multipoint Transmission Technique

Intercell interference is one of the reason by which wireless users experience outage. Coordinated multipoint (CoMP) transmission technique exploits this scenario to improve the performances of the user, first developed for LTE Advanced. Its aim is to enhance the overall system performance, utilize the resources more effectively and improve the end user service quality by dynamic coordination or transmission and reception with multiple geographically separated eNBs. They dynamically coordinate to provide joint scheduling and transmissions as well as proving joint processing of the received signals [3]. To enable CoMP, very close and highly detailed feedback is required on the channel properties in a fast manner. It should be able to provide a very low level of latency, as required by 5G standard. Expected traffic load and and participation of more number of eNBs required additional processing, which increase delay. For deployments with the same sites topology, backhaul latency and capacity, and scheduling and processing capabilities, the configuration of the processing also has an impact on the performance of CoMP. To achieve physical layer cooperation, high speed and delay sensitive communications channels are required between eNBs [4]. Time synchronization is particularly critical in time division duplexing (TDD) systems to avoid interference between the downlink and uplink of adjacent cells and enable enhanced features such as enhanced inter-cell interference coordination (eICIC) in CoMP.

To enable CoMP, the backhaul network must fulfill stringent capacity requirements (several Gbit/s backhauling capacity per eNB) and latency requirements (round-trip latencies between eNBs less than 1 ms). It turned out that even standard future optical technologies, like WDM-PON, do not allow CoMP in a satisfactory way [5]. Optical network units (ONUs) (and hence eNBs) are attached to one optical line terminal (OLT) via a remote node (RN). The eNBs/ONUs are assigned to OLTs based on their proximity and the RN is positioned such that the fiber lengths between the ONUs and the RN are minimized in each PON (Fig. 1). Thus, fiber propagation delay for a fiber of length, link capacity of WDM, wavelength tuning time (influences the actual link capacity and link delay) and inter-ONU data exchange are the main parameters of optical network which influence the CoMP performance. More eNBs under cooperation are limited by backhaul performance.

B. Massive MIMO & Networked MIMO

Networked MIMO has been proposed to increase wireless efficiency. It is also consider as multi-user MIMO, which has ability to reduce inter-cell interference (ICI) and improve the system spectral efficiency by coordinating multiple eNBs. In a networked MIMO system (Fig. 1), each BS is equipped with a smaller number of antennas, but interference cancellation is realized by significant data and channel state information (CSI) sharing across the cooperating eNBs over the backhaul links and joint downlink transmission to the scheduled users. Performance of networked MIMO system bottleneck with out of cell interferences, feedback overhead, control channel overhead (increased reference signal overhead), backhaul link latency (delayed CSI and data sharing) and etc [6].

In case of massive MIMO, very large antenna array is used at each eNBs to serve large number of users simultaneously. Excess antennas simplified multiuser processing, reduce transmit power and minimize the effect of fast fading. It generally uses time division duplexing to enable channel estimation. The gain of massive MIMO system limited by pilot contamination (need more coordination), interference, spatial correlation (it reduces effective DoFs as increasing number of antennas) and channel aging affects (energy-focusing ability of narrow beams) [7].

C. Small Cells

Recent study shows that the data traffic generated from the indoor user is two-third of the total wireless traffic. Thus, to increase coverage and data rate at low-power for indoor users, wireless networks introduced a new type of access technology, named femtocell (HeNB). HeNBs are a low-cost, low-power base-station deployed by the end-users [8].

Femtocell needed backhaul to connect with the core network. HeNBs are deployed on an already existing and working cellular infrastructure, and may use same licensed spectrum of macrocell BS (MeNB). Due to this, HeNB users suffer interference from the serving MeNB and the neighbouring MeNBs. Femtocell backhaul needs QoS for delay-sensitive traffic and provides enough capacity. Femtocells backhaul are local ISP networks, which are controlled by same or different service provider. Femtocells are prone to backhauling energy costs and delay limitations. Frequency and time synchronization are essential to guarantee that transmitted signals use their specific allocated channels and comply with license regulations and system requirements [9].

Gigabit passive optical network (GPON) uses passive splitters within the fiber network and allows one single feeding optical fiber to provide service to multiple network nodes. WDM is used in GPON to allow the use of a single optical fiber

for both uplink and downlink. WDM-PON utilizes specific wavelengths for specific optical network components or links, while they all use the same physical infrastructure. X-GPON or 10-GPON as the next generation of GPON can achieve data rates of 10 and 2.48 Gbps for downlink and uplink, respectively. However, fiber may not always be available or the associated installation and/or operating costs may be much higher than that of DSL. It is also important to note that considering the need to keep up with the increasing traffic demands, installing wired backhaul in all new small cell sites may not be cost-effective.

D. Distributed antenna system (DAS)

DAS is a single facility system usually in a large building, sports facility or other places where cell signals cannot penetrate like tunnels for cars or mass transit. A smaller DAS may pick up cell signals from an outdoor antenna to connect indoor antennas to the cellular systems of various carriers through a network of coax cables and amplifiers. That might work for small systems, but not for systems with large numbers of users. These systems generally connect to fiber backhaul like a cell tower and distribute signals inside the facility digitally over fiber.

Radio over Fiber technology (RoF) is an integration of wireless and fiber optic networks. A fiber based DAS installations are being increasingly used in a variety of locations including public buildings, airports, stadiums and subways. In these in building wireless systems a base station (BS) includes the centralized equipment where the radio signals are converted to optical signals, which are then transmitted via optical fiber to specific remote node locations [10].

E. Cloud-assisted radio access network

Cloud computing is becoming increasingly important in todays business due to benefits such as greater flexibility, increased security, scalability, and low cost [11]. Hetnet (Fig. 1) consists with densely installed small cells such as micro/pico/femto along with macrocells. The network operator and the end users or third parties can deploy small cells with open and closed access modes. Here, it mainly focuses on operation, maintenance, and management of cells to provide services by efficiently using network resources instead of sending users' and small cell data to cloud for processing, which is generally the case in cloud RAN (C-RAN).

Cells are connected to the cloud through high-speed optical fiber. Monitoring, configuration, optimization, and mobility control operations are generally centralized in the cloud. This centralized nature allows the network operators to manage the networks in a more efficient way. Since, the traffic demand vary dramatically, the cloud based architecture helps the network operator to allocate resources on demand and coordinate cells efficiently to provide services with seamless coverage, high data rates, and low latency. Effective joint optical and radio resource management can be implemented in order to satisfy the stringent delay requirements of the emerging mobile cloud computing applications and increase the overall cell throughput [12]. The flexibility and efficiency of the underlying optical network infrastructure as well as the cloud computing infrastructure become more and more crucial. In order to achieve required flexibility and efficiency, coordinated provisioning of data centers (DCs) and optical network interconnection among DCs is essential. Performance of the fiber (guaranteed for immediate and ongoing performance for the life of the network) is critical to deliver user experience in cloud computing promises. For guaranteed performance of fiber, 0.4 dB losses per km should not be good enough in todays demanding world. Many vendors that have built their data centers for optimal performance are delivering guaranteed 0.2-dB loss.

F. Software Defined Network

Software defined networking (SDN) is a new networking paradigm where the forwarding plane is decoupled from the control plane. In SDN, network intelligence is logically centralized in the control plane, and the forwarding plane is abstracted from the control plane to perform service delivery. This separation provides user more control over network and supports more flexibility in the deployment of new services and protocols at a much faster rate, higher network utilization, lower energy consumption, better QoS and higher revenue. Moreover, SDN has triggered significant interest in network functions virtualization (NFV), which decouples network functions from proprietary hardware appliances. Therefore, network functions run flexibly in software to accelerate service innovation and provisioning. Both SDN and NFV aim to advance a software-based approach for more manageable, agile, utilize and innovative networks [13].

This require dynamic backhaul configuration in order to configure and control the routing and transport data across the BSs. Due to provisioning of network visualization, the topology of network will need to be dynamically configured. The required flexibility and capacity in the backhaul network for our approach can be provided by optical backhaul networks based on WDM-PON [14]. In this direction, software-defined optical network (SDON) has been proposed, which composed of WDM equipments, optical transport network (OTN) switches, reconfigurable optical add-drop multiplexer (ROADM), and their supporting fiber network with the help of are flexible grid and elastic rate transponders [15].

G. Load balancing, Infrastructure & Data Sharing

With all the above 5G technologies, networks can support different kinds of traffic of diverse requirements. The users (UE) can be categories as static-indoor UE with high QoS, static-outdoor UE with high QoS, low mobility outdoor UE, high mobility outdoor UE and etc. In order to support these different kinds of traffic without outage and service blocking, network needs to provide coverage with required QoS. Virtually, UE should not be outside of coverage and services at any point of time. The network should successfully communication with anyone at anytime, anywhere with anything.

Today's network is a heterogeneous one and several service providers exist in the environment operating on same/different spectrum. It is very difficult for a particular service provider to

support UE satisfactory, since user's location is random. Thus, to provide better service to UE, different service provided needs to cooperate each other. With the cooperation, they can share each other networks and can also maintain proper balancing on traffic load. However, these tasks are huge and complex, and need a proper understanding and agreement among the service providers. Therefore, network needs to configure themselves accordingly to support UE. This configuration can happen simultaneously at UE and network side, which can change time to time depending on requirements, network, location etc. Thus, reconfigurability is an important requirement in future generation network.

III. Reconfigurability in Both the Network

In the previous section, we have discussed several issues of 5G technologies, where both the networks participated differently. The requirements of networks specification varies widely with applications. To supports a particular application or service, network has to configure themselves based on the service's QoS. Since, different application has different QoS, network has to reconfigurable themselves. Thus, reconfigurability is the key in next generation network.

In wireless network, software defined radio (SDR) emerges to support reconfigurability. SDR is is a radio communication system where components that have been typically implemented in hardware (e.g. mixers, filters, amplifiers, modulators/demodulators, detectors, etc.) are instead implemented by means of software on a personal computer or embedded system. SDR is needed for next generation network. Since, spectrum is scarce resources and studies say the allocated resources are very much under-utilized, cognitive radio technology has been proposed to use this underutilized spectrum. A cognitive radio is an intelligent radio that can be programmed and configured dynamically with the help of SDR based transceiver. Its transceiver is designed to use the best wireless channels in its vicinity. Such a radio automatically detects available channels in wireless spectrum, then accordingly changes its transmission or reception parameters to allow more concurrent wireless communications in a given spectrum band at one location. This process is a form of dynamic spectrum management [16].

In a similar manner, optical networks have also evolved continuously, increasing their capacity due to the growing of internet traffic demand, thus setting the path for new approaches that allow them to become more dynamic and flexible. Such reconfigurable optical networks have the capability of being dynamically programmable by software thus enabling, among other features: configuration of different bit rates in the same optical transponder, selection of different modulation formats and forward error correction (FEC) algorithms, reconfiguration of the optical equipment parameters, depending on the quality of the transmission, and dynamic adjustment of the optical channel bandwidth. In a similar way, software defined optics (SDO) was introduced in optical network to enables cross-layer interactions through the construction of application-specific protocol stacks out of small reusable services. The dynamic reconfigurability of multiple modulation and ability to adapt various transponder provides software-defined optical transmission (SDOT). To extend this idea, cognitive optical network (CON) has been proposed to enables high data rate lightpaths and to compensate a variety of dispersion impairments and to enable more agile optical networking, [17]. The impairment compensation and transmission performance monitoring/ measurement (e.g., optical signal-to-noise ratio (OSNR), chromatic dispersion (CD), polarization-mode-dispersion (PMD), and bit error rate (BER)) to improve QoT can be done efficiently in CON. It also supports unified signaling to address different application's bandwidth reservation requirements and also able to provision dynamic wavelength services with a rate adaptive optical reach and flexible subwavelength services with rapid mesh restoration [18]. The state-of-play for optical telecommunication equipment contributes with either rigid passive-optical multiplexing devices that do not offer the required degree of flexibility and dynamicity, or, in the other extreme, highly complex networking subsystems such as ROADM as found in metro-core networks, whose high cost and energy consumption is prohibitive for metro-access [19].

IV. Energy efficient communication

Over the year, energy efficient (EE) communication has earned tremendous interest in recent years due to ever increasing number of devices operating in dense cells, while demanding high data rates with high QoS and QoE. Ever increasing demand of data traffic in recent year forced everyone to redesign the network. According to some estimates, the global information communications technology (ICT) ecosystem consumes around 1100 to 1800 Terawatt-hours of electricity annually, which is roughly equal to the electricity used by Germany and Japan combined. Worldwide telecommunication networks (which include wire-line, wireless and core networks) are responsible for more than one third of this energy consumption due to increased coverage and user subscriptions. To meet these challenges, green evolution is becoming an urgent need for wireless networks. It should be noted that the word Green has been coined to focus on reducing CO2 emission and energy efficient systems are considered as green as long as they introduce less gas emissions. A study by GreenTouch indicates that despite the data traffic growth in the next decade, wireless networks can be made Green by reducing their overall energy consumption by almost 90% in the year 2020 with significant economic and environmental impact [20].

Wireless network is a heterogeneous one, where it is ranging from technologies characterized by networks for few UEs with small coverage area (e.g. bluetooth) to networks with larger coverage and hundreds of users (e.g. LTE), which are diverse in nature and coexist in the same environment to provide ubiquitous network coverage. Energy saving mechanisms are comparatively easier for homogeneous environment than heterogeneous environment. This is mainly due to conflicting design goals of different spectrums. In HetNet, establishing and maintaining a successful wireless communication link to simultaneously achieve all the QoS objectives becomes challenging since the energy consumption requirements of

the user and network are different for different objectives. Thus, there is a need for tradeoff techniques to achieve energy efficiency in each protocol layer [21]. A green framework has been proposed for energy-efficient communication in wireless network with energy-cognitive cycle, where the awareness are categories as network awareness and access point awareness module [22].

Similarly, EE issue have been a current topic in optical network. There is no easily defined bound on the energy consumption of optical transmitters and receivers. In determining the bound on energy consumption in transport systems, it is necessary to consider the energy of the optical transmitters and receivers used in the end terminals and in intermediate repeaters. Second-generation optical systems using optical amplifiers have enabled the energy per bit to be reduced to approximately 10 nJ/b/1000-km. In optical network, the energy per bit in the system is determined by the total power consumption of each item of equipment is divided by the number of wavelengths (40) and by the bit rate (40 Gb/s) [23]. The transmission system comprises n identical optically amplified links. Each link has length L and the overall length of the system is nL. A WDM transmitter/receiver (TX/RX) pair at the interface between each link provides regenerated signals at each wavelength for injection in the next link of the system. Energy consumption exist at many levels in optical transmission systems, from inefficiencies at the device level in optical amplifier pump lasers and their cooling systems, at the circuit level in the tradeoff of efficiency for speed in high-speed electronic circuits used in transmitters and receivers, and at the system level in terms of multiplexing and management overheads. The key strategies for reducing energy consumption include improving the energy efficiency of switching, devising methods to reduce the quantity of switching infrastructure in the network, development of low-energy transport technologies, and reducing the energy consumption of the access network [24].

OFDM is a promising technique is used for transmission in wireless network. Similarly, optical OFDM [25] is used in optical network. Therefore, immense amounts of research upon OFDM-based elastic optical networks with fine granularity spectrum splitting mechanism. Subcarrier multiplexing and WDM-PON [26] is a promising solution to support RoF for the convergence of optical and wireless networks [27].

V. Conclusion

The heterogeneity in network is required to support, secure and sustain users. These needs motivate networks to be reconfigurable, flexible, adaptable dynamically to the various components of the networks in both optical and wireless domain. In any situation, the network should transparent to the user. Recent research efforts show that the developments in both the networks are looking for common platform to converge and easily transform from one domain to another domain.

***Abstract*—There is an upsurge in bandwidth-intensive and data-centric applications in cellular wireless networks, witnessing a shift in focus from voice to data services. 5G cellular networks are envisaged to provide very high data rates, high reliability, reduced latency and stringent quality of service, while supporting a diverse range of services. To satisfy these requirements, 5G systems will involve new innovative methods on the Radio Access Network (RAN) and Core Network side. With this, there will also be tremendous impact on the backhaul network to connect the RAN nodes to the Core. This paper reviews 5G wireless network requirements and the wireless backhaul concepts, and discusses the evolving technologies and protocols that can meet the 5G backhaul network challenges.**

I. Introduction

According to Cooper's law [1], the maximum number of "conversations" (voice or data) that can theoretically be conducted over a given area in all of the useful radio spectrum will get doubled every 30 months. Witnessing the trend (Figure 1), there are plethora of bandwidth hungry applications which makes the traffic transition from voice-centric to data-centric [2] quite evident. According to industry estimates, the global mobile data traffic is expected to reach 11.2 Exabyte per month by 2017 [2], [3], as shown in Figure 2. This is due to two reasons: a) increase in the number of Internet-connected devices such as smartphones, tablets etc., which is expected to be more than 4.2 billion by 2017 (Figure 2) and b) deployment of Machine to Machine devices in very large numbers.

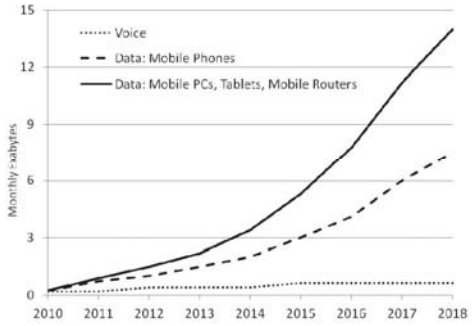

Fig. 1. Global Mobile Traffic (Source: Ericsson Mobility Report [2])

According to the Next Generation Mobile Networks (NGMN) Alliance, 5G networks are envisaged to enable fully mobile and connected society [4]. To attain this objective with billions of connected devices, Gigabit-level traffic will be generated. It is predominantly because 5G networks are expected to support diverse range of applications like Internet of Things (IoT), tactile internet, smart wearable, ultra-reliable communications like automated traffic control/driving, public safety, e-health, and many more real-time applications. Interestingly, there will be distinct and much more stringent quality

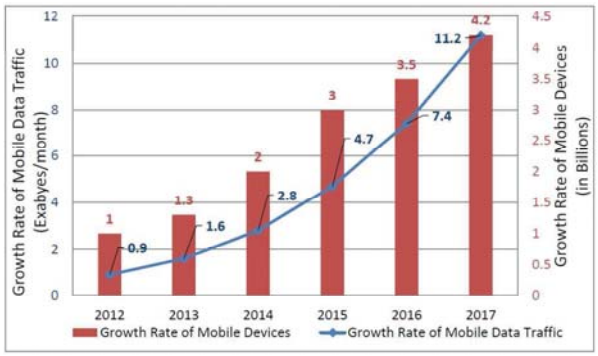

Fig. 2. Growth Rate of Mobile Data Traffic and Mobile Devices [3]

of service requirement for each application, in terms of latency, reliability and energy consumption, compared to 4G networks.

Ultra-Dense Network deployment is one of the technology enablers to meet the 5G requirements. It has several heterogeneous serving nodes, belonging to different Radio Access Networks (RANs). However, increased number of cell edges and significant variation in traffic density in both spatial as well as temporal domain leads to complex interference and mobility management [5]. Therefore, 5G networks need extremely robust and self-organized coordination mechanisms [6], [7] for efficient resource allocation, interference and mobility management. This calls for significant changes to be made in not only access and core network, but also backhaul. As revenues are not growing in proportion to the traffic growth, both cost minimization and capacity improvement are crucial. We review the mobile backhaul concepts and the 5G requirements which makes the backhaul issues crucial. We also discuss the candidate solutions, i.e., evolving technologies and protocols, to meet the backhaul challenges in this paper.

II. Backhaul Technologies

While *Access Network* is the communication link between mobile devices and the transmitting node, *Backhaul Network* (also known as "last mile" network) provides connection between the transmitting nodes i.e., Base Station (BS) and the *Core Network*, i.e., switching nodes as Radio Network Controller (RNC) and Packet Data Gateways.

In Global Systems for Mobile Communication (GSM) network (2G), backhaul link is between BS Transceiver Station and BS Controller, while in Universal Mobile Telecommunications System (UMTS) network (3G), it is between NodeB and RNC. In case of Long Term Evolution (LTE), i.e., 4G, network controller functionality is embedded in eNodeB due to the flat architecture and therefore, backhaul is between eNodeB and Evolved Packet Core nodes including Mobility Management Entity, Serving Gateway (S-GW) and Packet Gateway (P-GW).

Initially, mobile backhaul networks were rolled out as Time Division Multiplexed (TDM) based leased lines and microwave radio links. However, these are issues like: low bandwidth support, high installation costs and inefficient performance for converged data services. Most importantly, they are not scalable, specifically when required to support 1000-fold traffic. Table I summarizes the evolution of cellular technology with supported data rate and backhaul technology. Next, we review the popular wired and wireless backhaul technologies.

TABLE I. EVOLUTION OF BACKHAUL WITH THE EVOLUTION OF CELLULAR TECHNOLOGIES[1] (ADAPTED FROM [8])

Time Frame	Generation	Standard	Peak Data Rate	Backhaul Technology
Before 1999	1G	GSM	10 kbps	TDM
1999	2G	EDGE	200 kbps	TDM
2002	3G	WCDMA	384 kbps	ATM
2005	3G	HSDPA	3-21 Mbps	ATM
2009	3G	HSPA+	42 Mbps	ATM/IP
2010	4G	LTE	>60 Mbps	IP

A. Wired Backhaul

The physical transmission medium for wired backhauling could be either copper or optical fiber.

1) Copper, DSL: Technologies like E1/T1 and Digital Subscriber Line (DSL) widely use copper as the data transmission medium. DSL is predominantly deployed for residential broadband services and is suitable for delay insensitive cellular traffic backhaul for indoor scenarios. Very High Speed DSL2 (VDSL2) is one variant of DSL which provides data rate around 100 Mbps over short distances.

2) Optical Fiber: Optical fiber outperforms copper based backhaul in terms of capacity. A Passive Optical Network (PON) is a point to multipoint fiber based architecture which deploys an Optical Line Terminal (OLT) at service provider's end and a number of Optical Network Units (ONUs) near end user. Passive optical splitter near OLT enables single fiber to serve multiple termination points. Downlink signals are broadcasted, while uplink signals are TDM. Driven by passive components such as unpowered splitters and filters, PON offers high reliability and low cost compared to active networks. The PON data stream is converted to Ethernet/Wi-Fi at the subscriber's location and its range is about 20 kms.

Gigabit PON (GPON) and Ethernet PON (EPON) are two prominent standards. GPON uses optical Wavelength Division Multiplexing (WDM) so that a single fiber can be used for both downlink and uplink data. The latest version, Next Generation PON2 (NG-PON2) [9] uses Time and WDM and unlike other variants, uses active filters and tunable lasers in the ONU. It offers 40 Gpbs and 10 Gbps for downstream and upstream respectively. EPON is fully compatible with Ethernet standard. Its extension 100 GbEPON can support 100 Gbps data rate. Thus, Ethernet networking technology being scalable, turns out to be a carrier grade transport technology for mobile backhaul.

[1] EDGE: Enhanced Data for Global Evolution; WCDMA: Wideband Code Division Multiple Access; HSDPA: High-Speed Downlink Packet Access; HSPA: High-Speed Packet Access; ATM: Asynchronous Transfer Mode; IP: Internet Protocol

B. Wireless Backhaul

Compared to wired backhaul, it is easier and faster to deploy. The operational frequency distinguishes the different wireless backhaul options. Different frequency bands have different channel characteristics, which classifies the use cases and deployment scenarios for wireless backhaul options.

1) Satellite Backhaul: Satellite network is expected to evolve to provide terabit/sec of throughput. It is useful for broadcast/multicast services and can provide ubiquitous and reliable connectivity for non-real-time services, especially in remote/rural areas. Higher delay is one issue when real-time services are considered. It is due to long round trip time over a geostationary satellite, which can be improved with medium earth orbit satellite solutions. Very Small Aperture Terminal (VSAT) technology supports delay sensitive as well as IP based multicast applications. Thus, the technological advancements are expected to reduce cost and latency constraints to ensure the feasibility of satellite backhaul.

2) TV White Space Backhaul: It is the unused part of the TV band transmission, typically lying in the range 470-698 MHz. This allows radio signals to traverse distances of about 10 kms, which is much more than conventional mobile bands that starts at 800 MHz. Hence, the deployment costs are less. TV white space backhaul is an ideal candidate to provide rural broadband services at low cost.

3) Free Space Optics (FSO): It is a Line-of-Sight (LoS) technology that uses invisible beams of light (using LED/LASER) to provide optical bandwidth connections that can send/receive voice, video, and data information [10]. This optical connectivity does not require expensive fiber-optic cable or radio frequency spectrum licensing, which reduces the deployment cost and time. It is upgradable and has open interfaces, which allows using equipments from any vendor. FSO is immune to interference due to very narrow beam transmission, and offers speed of about 2.5 to 10 Gbps using WDM for short range, 20 meters to 8 kms. However, FSO communication gets severely affected by fog and atmospheric turbulence, which may cause scintillation and beam wander.

4) Microwave: Traditional microwave backhaul operates on carrier frequencies between 6 GHz and 42 GHz, which is a licensed spectrum, and offers data rates upto 1 Gbps. It is specifically useful for remote locations, where physical links are not feasible. While its operational cost is low, initial deployment cost is high. Microwave radios can support native Ethernet transport, statistical multiplexing and adaptive modulation. Long range transmission of about 10 kms is possible with highly directive antennas, due to moderate pathloss.

5) mmWave: Millimeter wave is a new generation of point-to-point microwave radio, operating in 60, 70/80 and 90 GHz bands, where each band offers up to 9 GHz spectrum. 60 GHz band is unlicensed, while its inexpensive to obtain license for other two bands. Therefore, faster and low cost deployment is feasible. These high frequency signals undergo heavy path loss and attenuation due to atmospheric absorption and rain. High signal attenuation results in reduced interference between mmWave transmissions. Path loss compensation can be achieved by either increasing transmit power (hardware and regulation constraints) or using highly directional antennas (improves security and is feasible). However, due to highly

directional antennas with small beamwidth, multipath benefits like diversity cannot be exploited. Hence, it is difficult to implement spatial diversity multiplexing techniques like MIMO and LoS is essentially required. Yet, mmWave backhaul can support data rate up to 10 Gbps, over 10 km range and is suitable for dense urban scenario.

III. Towards 5G

Massive growth in mobile data demands, number of wireless devices, diverse range of applications, ubiquitous connectivity and drastic changes in end user's expectation are the key factors driving the 5G technological advancements [4]. Additionally, very high data rates, energy efficiency, high reliability and very low latency requirements are predominant. In addition to integration of these characteristics, flexibility to adapt to the changing scenarios is required. This section discusses the key enablers for 5G and the evolving technologies which will play a significant role in the 5G roll out.

A. Key Enablers

Ultra-Dense Deployment involves several low power BSs (small cells), complementing the existing macro cell network, to meet the high traffic demands. These low power BSs can be pico cell, femto cell (for indoor scenarios), Remote Radio Heads (RRHs) or WiFi Access Points (APs). Such infrastructure, also known as Heterogeneous Network (HetNet) provides 1) efficient spectrum utilization, due to aggressive spectral reuse across multiple cells and 2) higher area spectral efficiency, due to reduced distance between users and serving nodes and the availability of dense network of BSs. The coexistence of both networks is preferred over complete replacement because both have their use case specific beneficial attributes. For instance, while macro cell network manages connectivity with high-speed users to ensure minimum handovers, small cells connects with low/medium speed users to provide higher data rates and efficient resource utilization.

Flexible Centralized Processing: With ultra-dense HetNet deployment, there are overlapping cellular footprints and each user lies in the coverage area of more than one BS, which makes association as well as mobility decisions crucial [11]. Also, the increased number of cell edges makes multi-cell interference management complicated. Additionally, temporal and spatial variation is user traffic density requires mechanisms for adaptive load balancing and interference-aware resource allocation. This calls for flexible and adaptive self-organized mechanisms [7] to be implemented in a centralized manner, which can be beneficial for both RAN as well as network [13]. At RAN level, joint Radio Resource Management (RRM) and Inter Cell Interference Coordination (ICIC) algorithms can be implemented by centralized processing. At network-level, centralized processing can enable dynamic resource allocation and network configuration based on the variation in user traffic demands. Additionally, BSs can be turned off during low load conditions to achieve energy efficiency. Hence, network operators can perform use case specific optimizations on a large scale to meet network-centric objectives.

B. Cloud Based Mobile Networks

Self-Organized Networking (SON) solutions typically operate at coarse time scales and optimize RAN performance by control plane coordination without impacting fine time scale scheduling in data plane. Significant gains are obtained using SON algorithms for RAN optimization in cellular networks [12]. Considering 5G requirements, more sophisticated RAN optimization can be performed by data plane coordination across BSs at fine timescales. Coordinated Multi-Point (CoMP) transmission is one such approach, where BSs from multiple cells coordinate their data transmissions such that interference is minimized and throughput gains are maximized. Performance gains now depend on how efficiently the centralized coordination is implemented.

Cloud-RAN (C-RAN) [13] enables efficient implementation of centralized coordination by decoupling processing from transmission, within the data plane. In C-RAN, all BSs (i.e., BaseBand processing Units (BBUs)) are aggregated in a centralized data centre (cloud), where all baseband processing is performed, while the Radio Frequency (RF) transmission is handled by RRHs which are distributed in a region to meet coverage requirements. RRHs or set of RRHs are generally referred to as Radio Access Units (RAUs). Centralized processing in C-RAN provides higher capacity due to aggressive reuse of resources, enhanced cooperative gains, better interference management, green infrastructure, reduced capital and operational expenses, easier traffic load balancing and flexibility through software defined virtualization of communication networks and protocols. Note that HetNet with cloud computing is known as Heterogeneous C-RAN (H-CRAN).

The communication link between BBU pool and RAUs is known as *fronthaul* which is required to support high data rates. At present, only fiber links support about 10 Gbps for TD-LTE with a 20 MHz bandwidth. Optical fiber coupled with WDM and/or TDM is used for signal distribution from BBU to RAU with high reliability and low latency. Signals can be transported in two ways: 1) digitized radio signals through Common Public Radio Interface (CPRI) [15], or 2) analog radio signal through Radio-over-Fiber (RoF) [16] technology. Digitized radio signal transmission experiences less degradation and can transport signals over longer range compared to RoF. However, it requires large backhaul bandwidth to carry the sampled radio signals of the order of 10 Gbps.

C-RAN decouples BBU pool from RAUs in terms of physical connectivity, but there are two issues adversely affecting the performance gains. First, there is a one-to-one logical mapping between a BBU and an active RAU. Thus, distinct radio frame for each cell is required. It enables techniques like CoMP and dynamic Fractional Frequency Reuse (FRR) to be used for capacity enhancement. However, such schemes are applicable only for static users. For non-stationery users, traditional Distributed Antenna System (DAS) technique can be used to allow transmission of the same radio signal to multiple small cells and provide increased coverage and diversity gain, while avoiding frequent handovers. Second, a single BBU is capable of managing load of multiple cells by serving them via a DAS, in case of sparse traffic. However, this will require mapping a BBU to a set of RAUs. Thus, to serve both static and mobile users, and handle variable load conditions in an energy-efficient manner, flexible backhaul is required which can also support "one-to-many" logical mappings between BBUs and RAUs. Authors in [14] propose a C-RAN system with flexible backhaul architecture, where the physical backhaul remains

the same but logical connectivity between BBUs and RAUs is configurable to adapt to varying user and traffic load profiles, and uses RoF technology for backhaul.

C. SDN in Cloud-Based Mobile Network

Performance of cloud based mobile network can be further enhanced by using Software Defined Networking (SDN). Traffic and energy optimization can be achieved by dynamically using SDN concept on backhaul/fronthaul. SDN enabled network [17] decouples data and control plane and uses OpenFlow Application Programming Interface (API) for interaction between the two. A software based controller aggregates the control plane functions, maintains an abstract view of the network topology and provides API to network operators. The operators can control the data traffic flow and handle congestion by effective traffic management and optimized resource allocation. Thus, SDN makes network devices (switches/routers) programmable and enables segregation of traffic flows, routing of flows to specific services and efficient resource management.

With the introduction of switching hardware in the fronthaul and flexible mapping between BBUs and RRHs, traffic optimization in RAN and energy optimization in BBU pool can be achieved jointly. Emerging SDN approaches facilitate transition from source-to-destination traffic routing to context-aware traffic routing and manage the complex traffic management, by providing programmable data plane. Most of the SDN related works consider wired networks and gradually, SDN concepts are being implemented in wireless networks, specifically backhaul segment. It is being investigated that unified control of radio interfaces via SDN [18] can enable flexible spectrum and capacity management.

D. RAN as a Service (RANaaS)

There is a trade-off between centralized processing requiring high capacity fronthaul links as in C-RAN, and decentralized processing using traditional backhaul. This trade-off can be exploited by the novel *RAN as a Service* concept [13], which provides flexibility in centralizing RAN functionalities based on the requirement and network characteristics. Figure 3 shows the flexible functional split of radio protocol stack between RANaaS platform and RAUs. The left side shows conventional LTE implementation where all functionalities up to admission and congestion control are implemented at BS (RAU). On the right side, C-RAN approach is shown where only radio front end is implemented at RAU, while all other functions are centralized. RANaaS is a midway approach which centralizes only some of the functionalities. For instance, when high capacity backhaul is available, lower layer functions can be shifted to RANaaS platform to achieve higher degree of centralization. However, implementation of such a functional split [13] is challenging for RAN, due to various constraints like latency, backhaul, etc. Latency issues may arise due to virtualization of RAN resources.

IV. Heterogeneous Backhaul for Cloud-Based Mobile Networks

A typical backhaul for 5G network may have a combination of one or more of the components discussed in Section III.

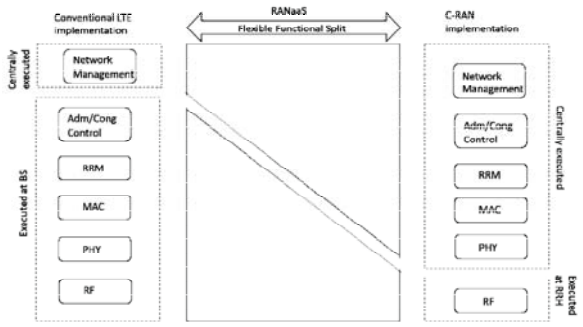

Fig. 3. Flexible Functional Split (Adapted from [13])

Backhaul for cloud based ultra dense HetNet must be able to handle different types and degrees of centralized processing, from conventional LTE to RANaaS platform to C-RAN implementations. The envisaged architecture for 5G networks with heterogeneous backhaul and RANaaS is shown in Figure 4. This section discusses the concerns and crucial aspects involved in provisioning heterogeneous backhaul [19], which is envisaged to enable 5G.

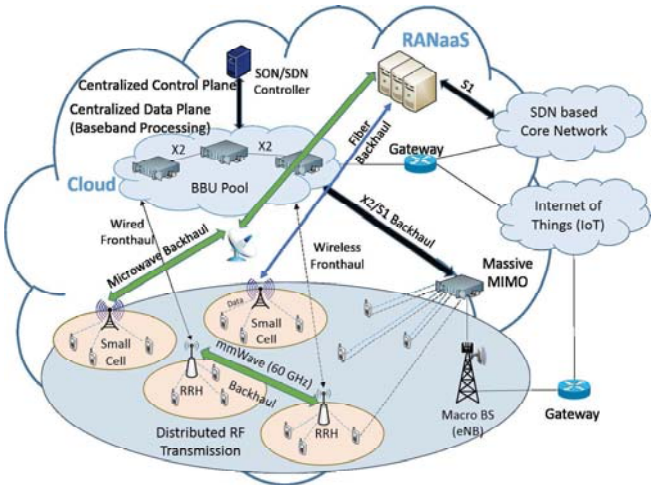

Fig. 4. Envisaged 5G Architecture with RANaaS, SDN-based C-RAN and Heterogeneous Backhaul

A. Heterogeneous Backhaul Challenges

The main challenges identified in design and optimization of backhaul are as follows:

Heterogeneity: In an ultra-dense network with diverse deployment scenarios, heterogeneous backhaul is required because different technologies discussed in Section II are suitable for different deployments. At the same time, it is not feasible to have a completely unified backhaul deployment throughout. Considering the data rate requirement and transmission range, fiber based backhaul seems to be the best choice. However, with deployment cost and geographical location considerations, it is not feasible to lay down fiber everywhere. Easy availability makes DSL backhaul a suitable option for indoor backhaul. TV white space and satellite backhaul seems to be the perfect choice for rural broadband services. FSO and

Millimeter wave backhaul/fronthaul is suitable for road side lamp posts, river side and inter-site connections. The non line of sight coverage can be ensured and transmission range can be increased by multihop concatenation of these links, at the cost of additional latency.

Data Rate: The data rate support expected from backhaul will depend on the degree of centralization in RANaaS. In case of full centralized processing like C-RAN, very high bandwidth backhaul will be required. Due to the heterogeneity of backhaul options and variable capacity, the flexible functional split in RANaaS needs to give consideration to the data carrying capacity of the available backhaul.

Latency: Latency is a function of the distance between user and RANaaS, the number of nodes in the end-to-end link and the amount of processing at each node. Processing and protocol latency can be reduced by improving the processing capabilities at each node.

B. Joint Access and Backhaul Design

5G networks are evolving towards an ultra-dense network, where small cells connected to RANaaS platform, may be deployed at unconventional locations. There will lead to different deployment scenarios, each requiring a different backhaul solution, resulting in heterogeneous backhaul infrastructure. It is crucial to ensure that backhaul does not become a bottleneck in meeting the end-to-end requirements in terms of throughput and latency. While RANaaS provides flexibility in sharing the functionalities between small cells and RANaaS, it makes sense to explore access and backhaul design issues jointly.

One instance, when centralized processing is shifted from RAU towards RANaaS. This is likely to happen when high capacity backhaul like fiber, mmWave etc is available. Let the use case be of uplink data transmission, which typically requires decoding at BS to reduce bandwidth requirement and re-encoding for transmission towards RANaaS. In such case, decoding process can be skipped at small cell and the received samples can be forwarded to RANaaS directly. This reduces the hardware requirement, reducing the deployment costs. In addition, latency and energy consumption will reduce.

Another instance, when centralized processing is shifted from RANaaS towards BS or RAU. Let the use case be frequency domain RoF approach for downlink. In a typical RoF architecture, time domain signals from multiple users along with overhead are transmitted from centralized controller to RAU. With the FFT/IFFT functionality shifted to RAU, it is possible to transmit data in frequency domain on per-user basis. This reduces overhead and hence, the capacity requirement on backhaul. User specific transmission also makes the implementation of adaptive beamforming easier.

V. Conclusion

To support multitudes of data-centric applications, demanding high reliability and very low latency, 5G networks are expected to deploy ultra-dense HetNet with cloud-RAN, which mitigates inter-tier interference efficiently and improve cooperative processing gains. Corresponding upgradation in capacity and latency is expected from backhaul network, to ensure a sustainable end-to-end user experience. With SDN implementation, the data and control plane decoupling enables efficient traffic and energy optimizations, which is useful for both RAN and backhaul. We review different backhaul technologies and their suitability for different deployment scenarios. We discuss the backhaul related challenges in cloud-based architecture and infer that heterogeneous backhaul solutions will meet the 5G requirements. With the implementation of *RAN as a service*, degree of centralization will vary, impacting the data rate and latency requirements for backhaul. This calls for a flexible functional split and joint optimization of access and backhaul, so that backhaul dose not pose any constraint and end-to-end performance is achieved.

Cybersecurity for M2M Smart Grid

Sarmistha De Dutta, Prof. Ramjee Prasad
sd56@columbia.edu, prasad@es.aau.dk

Abstract –
The Smart Grid is the next-generation electrical power system that combines OT (Operations Technology) and IT (Information Technology) for the efficient generation, delivery, and consumption of electrical energy. More and more utility companies around the world have started to evaluate, plan, and implement Smart Grid technologies by deploying Advanced Metering Infrastructure (AMI) and other electronic communications technologies that enable the utility to monitor and analyze their networks and provide customers with a more reliable and efficient power system both at the smart grid level and micro grid level. Data that is generated by the Smart Grid is now referred to as 'big data' - data that is high in volume, velocity, variety or a combination of all three. This data is very useful as it allow utilities to gather higher resolution consumer energy usage data compared to the legacy centralized electrical power plant and distribution grid.
As Smart Grid implementation gains momentum and utilities are collecting high-volumes of data, consumer concerns about the security and privacy of this data are forcing utilities to identify and address the increasingly important issue of securing this data without compromising the efficient delivery of electricity. We aim to provide a brief overview M2M communication and its history, its application in the Smart Grid, security issues affecting M2M data on the Smart Grid and some available solutions to detect and prevent cyber threats.

Index Terms – Smart Grid, M2M, Cyber Security, AMI

INTRODUCTION

With the start of the new millennium, the term Machine to Machine (M2M) communications has become increasing prevalent in our everyday lives. However, the concept of M2M has its roots in the term 'Telemetry' which originated over 150 years ago. Telemetry in its original form was the collection, transmission, and monitoring of data, over wires. The first official occurrence of data telemetry dates back to 1845 when live data was transmitted between the Russian Tsar's Winter Palace and the army headquarters. Another breakthrough application of telemetric data was in 1912 when the Commonwealth Edison implemented a telemetry system using telephone lines to transmit operational data on electric power plants throughout the city and use this data to monitor electrical loads on Chicago's power grid.

We have made great strides in the field of telemetry over the past century and nowadays telemetric data is used in solutions across a wide-range of fields such as medicine, meteorology, aerospace communications, and managing retail sales transactions. [1] Another notable application of data telemetry came in the 1980's with the introduction smart homes. By the 1990s', a new business model evolved out of the basic concept of telemetry, M2M. [2]

Figure 1: Evolution of M2M

While telemetry was typically limited to the use of radio signals, M2M was able to transmit and measure sensor data from remote sources harnessing newer technologies such as wireless sensors, mobile devices, wireless networks, and the Internet. [2]. With the advent of this decade, M2M communications has become synonymous with another evolving concept, the Internet of Things (IoT). The IoT is a system of devices such as sensors, smart appliances or intelligent electronic devices (IEDs) installed at strategic locations on the M2M communications network that transmit and receive data which is then collected, analyzed, and accessed through a gateway such as the Internet.

M2M communications is used in a whole slew of industries ranging in such diverse fields as transportation and medicine. An increasingly popular application of M2M communications technology is in the energy sector, namely the Smart Grid (SG). The Smart Grid allows utility companies to integrate two-way M2M communication and electricity flows. Sensors and advanced control mechanisms are used to capture then analyze real-time data on power delivery, generation, and consumer usage. This information allows utility companies to manage energy supplies and demand as well as customer billing more efficiently. However, along with all these undeniable benefits comes the realization that this advanced communications and OT/IT infrastructure which is responsible for the enhanced Smart Grid is also its Achilles heel by increasing susceptibility of the power grid to destructive cyber events. The underlying technology that empowers the SG also

makes it vulnerable to cyber attacks which can also be detrimental to the health of a nation's power delivery system. [16]

M2M COMMUNICATION ARCHITECTURE

Machine to Machine (M2M) communication is the flow of data from a machine, over a wire line or wireless network, and through a gateway to another machine where it can be collected, analyzed, and these results be used for informed decision-making and applied to a wide range of services. [3]

A high-level overview of the M2M communication architecture, as per the European Telecommunications Standards Institute (ETSI) model, considers three main domains:

- M2M Device Domain – connects intelligent M2M devices to M2M gateways
- M2M Network Domain – connects M2M gateways to M2M applications
- M2M Application Domain – provides the middleware layer where the M2M data is used in business software applications

An M2M device can range from a simple temperature sensor to a highly intelligent computer system. The M2M communication is initiated by extracting data from a remote data collection device either in response to a request or automatically. Refer to Figure 2 for a simple visual depiction of the M2M architecture. [4, 15]

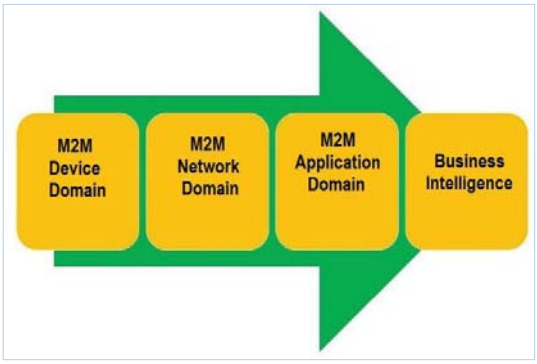

Figure 2: M2M Architecture

After the data is extracted from the remote device, it is then transported using a wired/wireless network, PLC (power line communications) lines, or communication satellites, to the M2M application where it undergoes processing. Meaningful information is extracted from these results which is in turn utilized by different business services.

Though telephone lines may be used if a line is readily available and satellites are practical for monitoring equipment in remote areas, cellular networks provide the best, cost-effective method of M2M communication in today's increasingly mobile environment. [3]

As the M2M ecosystem expands and industry leaders are jumping on the M2M bandwagon, there is an increasing need to bring standardization to this new area. The wireless standard groups such as IEEE, 3GPP, and ETSI are already studying the effects of increasingly wide-scale usage of M2M devices on existing networks.

SMART GRID CONCEPTUAL MODEL

The Smart Grid, a popular application of M2M communications, is the next-generation electrical power system that integrates OT (computers/network for power delivery) with IT (computers/network for business processes). The OT platform allows utilities to manage energy resources, plan for emergencies, and maintain the grid load based on data received from among other sources, the Supervisory Control and Data Acquisition (SCADA) system. While the IT platform is used by utilities to manage their business and administrative processes. [17] This grid infrastructure utilizes increased use of telecommunications and digital technology for an automated, decentralized, consumer-interactive but also environmentally sustainable generation, delivery, and consumption of electrical energy. In a nutshell, the SG is a more efficient electricity delivery system. [5]

The National Institute of Standards and Technology (NIST) Smart Grid Conceptual Model defines the Smart Grid as consisting of seven distinct domains: Bulk Generation, Transmission, Distribution, Customers, Operations, Markets, and Service Providers. The first four domains, cover the generation, storage, delivery of electricity, and support bi-directional flow. The latter three domains manage this electricity flow and provide data or services to power utility companies and their customers.

The IEEE-based Smart Grid model [6] shown in Figure 3 displays the two-way data and electricity flow between each domain and demonstrates how they are inter-connected to create an intelligent and dynamic power grid. [7]

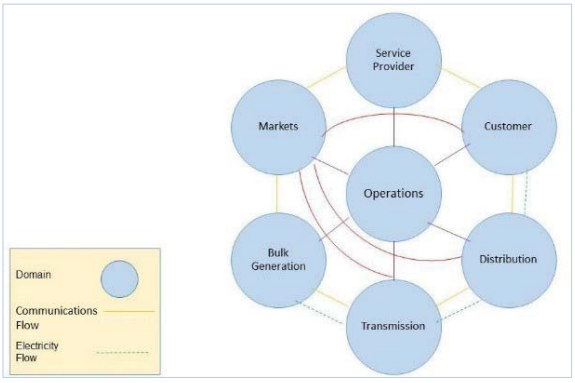

Figure 3: Smart Grid Conceptual Model

Energy is generated in the Bulk Generation domain from both centralized, traditional sources as well as distributed energy resources (DER): renewable variable sources - solar, wind; renewable non-variable sources - hydro, biomass, geothermal;

non-renewable and non-variable sources such as nuclear, coal and gas.

In the Distribution domain, electricity is distributed to utility customers (home, commercial, industrial) who are connected to the electric distribution network through intelligent M2M field devices such as smart meters. The Advanced Metering Infrastructure (AMI) is an integrated system of smart meters, meter data management systems, and gateways that allows communication between the customer and utility company. Using a real-time, two-way communications network, customers can sell back unused energy to the power grid, thus helping balance the supply and demand of power usage. The SCADA system remotely controls, monitors, and acquires real-time data every 2-5 seconds from distributed substations. This data is then used by utilities to evaluate the condition of the power delivery network every few minutes and take the necessary actions to ensure a reliable supply of power. [17]

Through the Operations domain, information such as energy consumption data collected from the consumer is further processed and provides key business intelligence. Integrating the AMI with the traditional distribution infrastructure has led to a more efficient power grid. In the Service Provider domain**,** third-party service providers such as web portals allow end-customers to exchange data with their utility company and empowers the consumer to better manage their energy consumption. [7]

The first 'smart meter' was publicly deployed in the 1990s' and since then utility companies around the world have started evaluating, planning, and implementing Smart Grid technologies by deploying Advanced Metering Infrastructure (AMI) and other digital communication technologies. This allows the utility to monitor and analyze their distribution networks and provide customers with a more reliable, available, and efficient power system whether at the smart grid level or micro grid level.

The sources of data [14] generated by this intelligent Smart Grid are as follows:

- AMI (Smart Meters)
- Distribution automation (Grid)
- Third-party Data (Data external to Grid)
- Asset Management (Firmware for smart device or Operating System)

A key component of the SG is the "smart meter". Metering is just one of the many M2M business application that utilities are using to exploit the full potential of the Smart Grid. The smart meter is a device that is used to store data related to power consumption and provides insight into the trends in electricity usage. Data from smart meters is now collected at 5-15 minute intervals as opposed to the monthly readings of the past. [9]. This is just one of the sources responsible for the explosive growth in Smart Grid data is shown in Figure 4, provided by the Electric Power Research Institute. This graph helps us better visualize the vast volumes of data that the utility must be able to analyze in order to realize the full potential of the Smart Grid.

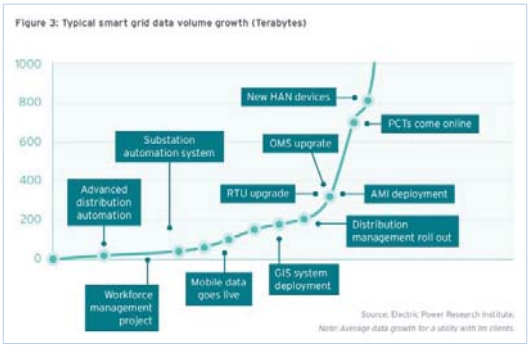

Figure 4: Smart Grid Data Growth
(Source: Electric Power Research Institute)

SECURING THE SMART GRID

The widespread blackout affecting parts of the US in August 2003, though not a result of a cyber attack, still gave us our first experience of the fallout from a possible attack. The Smart Grid is a much more complex system compared to its predecessor, the legacy power grid. The very components that are responsible for its 'intelligence" also make it more vulnerable to cyber threats. Improving cyber security, power system security, and protecting consumer data while being able to balance power grid performance with cost is a tightrope that utility companies will have to learn to manage if they wish to fulfill the true potential of the Smart Grid.

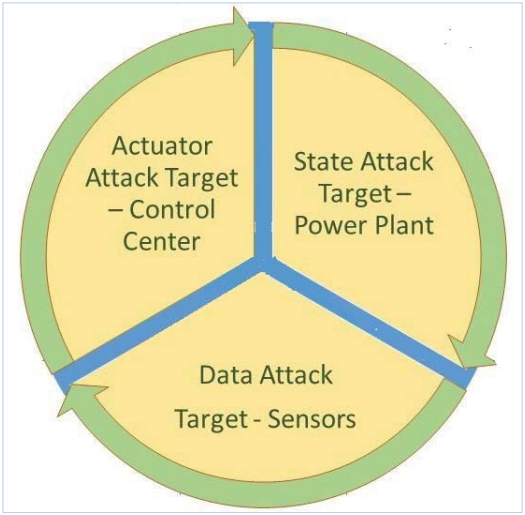

Figure 5: Smart Grid Security Cycle

Vulnerabilities in the Smart Grid range from access to and manipulation of smart devices such as IEDs with malicious intent, proliferation of malware, denial of Service (DoS) attacks, hacked smart meters, deliberately modified sensor and SCADA systems data, to the unauthorized modification of routing in wireless networks and these can all disrupt grid operations. Concerns about customer data protection and privacy are also equally important. As utility companies plan

to expand their Smart Grid operations, they must also address the problem of data security. Security controls must be correctly designed and implemented in order to provide consumers with an efficient yet secure power delivery system. In order to be truly effective these security controls will have to satisfy the unique needs of both the OT and IT platforms. [10, 11]

As Smart Grid implementation progresses around the world, the OT/IT platforms are increasing overlapping and utilities are collecting increasing volumes of Smart Grid data. Applying big data analytics to smart meter data, network sensor data and operational voltage load SCADA data will allow utilities to detect cases of electricity theft, anomalous behavior, and even predict malicious events that can lead to the disruption of power delivery. [11, 15]

Utility companies are also working with agencies such as NIST, NERC CIP (North American Reliability Corporation – Critical Infrastructure Protection), US Dept. of Energy (Office of Electricity Delivery and Energy Reliability), and IEEE among others to develop a Smart Grid security framework which will encompass remote access, authentication, encryption, and privacy of meter data and customer information thus ensuring that Smart Grids provide consumers with an efficient but safe and secure energy supply chain. [12]

BIG DATA ANALYTICS FOR THE SMART GRID

As the volume of data from the SG grows over time, utilities will have to collect, store, and mine data, then apply predictive analytics for utilities to further develop their business and manage both their operations and customer base more efficiently and effectively.

Utilities can analyze this data using the following types of Smart Grid analytical tools:

- Meter Analytics
- Grid Analytics
- Asset analytics
- Renewable Energy Integration

Utilities will increase their budget for Smart Grid data analytics as shown in the Pike Research report [Figure 6] and demand is expected to increase globally by $34 billion through 2020 with maximum growth in the Asia Pacific region. [8]

Data that is generated by the Smart Grid is now referred to as ‘big data’ which simply means data that is high in volume, velocity, variety or a combination of all three. The data generated is very useful as it allows utilities to gather consumer energy usage data at a more granular level compared to the legacy centralized electrical power plant and distribution grid. This is beneficial to the entire energy sector including energy retailers, distributors and generators as it not only allows consumers to have a better understanding of their own energy consumption, but also allows energy companies to interpret the detailed consumption patterns of their consumers and plan more accurately for future energy needs while also incorporating alternative energy sources such as wind, hydro, and solar energy, as well as the impact of micro grids on the power infrastructure. [9]

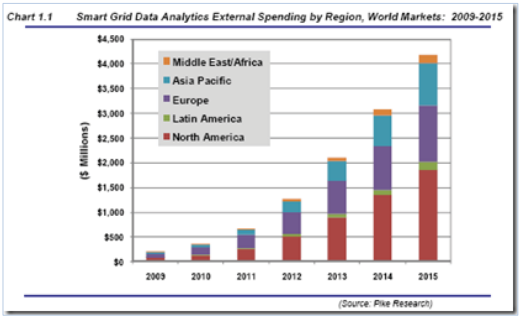

Figure 6: Smart Grid Analytics Market Distribution (Source: Pike Research)

Only if we can effectively collect and analyze these volumes of grid data generated by smart meters, sensor captures, appliances, and electric cars and then act upon the results in real-time, can we exploit the full potential of the Smart Grid. However, this requires building statistical models that extract useful information and identify patterns hidden within the generated M2M data, allowing the grid operator to use these results and forecast future grid behavior. [15]

These predictive models can help utilities optimize the Smart Grid. The field of Smart Grid data analytics, both traditional and cloud-based analytics is just evolving and applying predictive analytical techniques to mine and analyze Smart Grid data and then make intelligent decisions has not yet been fully exploited. An analytical tool can play an important role in analyzing the data generated by the Smart Grid and ensure that it operates at peak performance. [15]

However, along with optimizing performance, data-mining tools can also be used to secure the SG and prevent potential cyber attacks. A crucial M2M security application for securing the Smart Grid is authentication. For example, a lack of proper security controls for authentication can easily compromise the integrity of smart meters, a key component of the Smart Grid.

Key industry players such as ABB, NIKSUN, eMeter (Siemens), IBM, General Electric to name a few have recognized the global market demand for Smart Grid data security analytics solutions and each are a making their own niche in this rapidly expanding market are shown in Figure 7. Each vendor is developing their own technology to effectively and efficiently transform the data generated by the various components of the Smart Grid into data that is useful to utilities who would like to ensure a secure Smart Grid for its customers. [13]

However, it is important to note that these same techniques that are supposed to protect the SG can also be used by individuals for personal and illegal gain. For example,

statistical models for tracking home energy consumption can also be used to detect unusual behavioral patterns which can then by exploited by criminals.

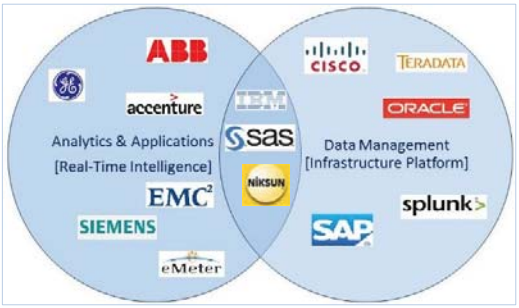

Figure 7: Top Vendors - Smart Grid Data Analytics

Some of the analytical tools offered by these vendors are listed in Table 1 below:

Vendor	Analytics Tool
ABB	ABB Utility Analytics
Capgemini	SES Platform
EMC	Smart Grid Analytics
eMeter	EnergyIP
GE	Grid IQ Insight
IBM	Netezza data warehouse appliance
Oracle	Utilities Meter Data Analytics
NIKSUN	NetDetector, NetVCR, NetMobility, NetOmni
SAP	Smart Meter Analytics
SAS	SAS®Analytics
Siemens	PSS®ODMS
Teradata	Active Smart Grid Analytics (ASA) Platform

Table 1: Analytical tools for Securing the Smart Grid

CONCLUSIONS

This paper has provided a brief overview of the evolution of M2M communication, its application in the Smart Grid, and the importance of M2M data analytics to ensure an optimally performing and secure power distribution system. For the Smart Grid to benefit from M2M communications and the IoT, it is paramount that security controls are deployed without compromising consumer privacy.

In our next paper, we plan to survey the security analytics currently available for M2M data across different components of the Smart Grid and help better understand the tradeoff between Smart Grid security and consumer privacy.

ACKNOWLEDGMENTS

We would like to thank NIKSUN Inc., one of the leading lights in the cyber security industry, for providing support while writing this paper.

Persuasive Technology and Business Models - Profiting from Big Data

Morten Karnøe Søndergaard • Peter Lindgren • Niels Einar Veirum [1]

Abstract Recently, there has been growing interest in research on Big Data since more and more information is becoming available to us every day. This is caused by the concurrent rise of new mobile technologies and social networks, which allow us to virtually share everything, with everybody, everywhere – and anytime. These smart technologies might also be used to persuade human beings to change their behavior. The following article aims at presenting an easily understandable way to approach these new developments. Since Big Data can be used to measure specific behavior, this results to the ability of designing for specific changes. Businesses use different persuasive technologies to persuade users, customers and network partners to change behavior. Operating more than one value proposition, both tangible and intangible value proposition, in combination seems to be crucial to the success of a persuasive business model. We will give a short introduction into the area of persuasive technology and business models. Based on our experience with persuasive technologies we then conclude that it is key for all agents to relate to ownership, since enabling an intervention to the benefit of the public or to a private company, might result in spin-offs.
Keywords Persuasive Technology • Business models •Big Data • Interventions

1 Background

Big Data has been buzzing in the last decade. The term in itself describes any voluminous amount of structured or unstructured data that has the potential to be mined for information. Big Data, despite of a long history, has become a current top priority on the agenda, simply, because more information is becoming available to us every day. Mostly, this is caused by the concurrent rise of new smart technologies (mobile phones, tracking devices, sensors etc.) and social networks which allow us to virtually share everything, with everybody, everywhere – and anytime. The new reality of Big Data and its accompanying technologies has created feeding grounds for new integrative business models, which target behavior and design in a

Peter Lindgren - peterli@auhe.au.dk,
Niels Einar Veirum - nielseinar@auhe.au.dk.

[1] Stanford Peace Innovation Lab, Department of Business Development and Technology, Aarhus University, Denmark

whole new manner. This article present a clear-cut and easily understandable way to approach this new scene.

2 An introduction to persuasive technology

A subset of Big Data is data closely related to human behavior. It can be indicators on consumer trends or any kind of workflows or life style habits individuals perform on a daily basis. This means that you can use Big Data to measure specific behavior and as you can measure them, you can also start designing for specific changes.

Persuasive technology design is a promising discipline when trying to move from rather abstract levels of data mining to concrete interventions that can influence human actions and change the reality behind the data. Persuasive technology can, for example, take the form of a smartphone app, a web app or an embedded functionality in tools or appliances, often backed by cloud services and data sources.

In the persuasive technology design loop you define the target behavior you want to change, the technology platform you want to use and the data metrics that will indicate your failure or success. You then quickly build and deploy technology prototypes, measure the impact of various approaches and start optimizing on the most promising solutions. Behavior design is of course about motivating individual human beings to do the target behavior in question. Often you will fail if this is the only path you follow. In most cases it is smart to design interventions with the aim to make it easier for the individual to do what she is already motivated to do. However, the most crucial part is building technology such as mobile apps that can trigger her just in the right moment, when she is motivated and has the ability to perform the desired action.

In order to make behavioral changes persistent you will strive to incorporate the new actions in tiny habits, that closely connect to familiar situations in your target group's daily life. And you will try to invoke social amplifiers within the target group, like engagement and good emotions communicated within the group. It is very important for a sustainable impact that the individual and the group find the achievements meaningful. In that respect, you furthermore need sustainable business models inviting to engage by paying forward the gained benefits of the intervention to stakeholders and also by paying back rewards to support continuous improvements.

3 Persuasive technology and business models

The huge possibilities of designing persuasive business models embedded with persuasive technology were introduced in 2013. [2] Increased competition and diminishing life cycles of business models force business to think out of the box and find new ways of business – especially for those business that are locked in increasing red ocean business model ecosystems. However, in order to rapidly develop a persuasive business model ecosystem both the businesses and their business models are forced to become even more agile, dynamic and smart in bundling technics.

In this context the persuasive business model becomes highly related to the multi business model approach [3] as most businesses using the persuasive technology need a combined bundle of two or more business models. We found in earlier research that persuasive technology is especially deeply anchored in the competence dimension of the business models either in the business' own business models or in the users', customers' or network partners' business models. While most persuasive business models seem to come with a kind of tangible value proposition – a product, a service or a process of products and services – they are often coupled to "intangible" value propositions related to human activity, in particular socio-economic activity. [1]

Operating more than one value proposition, both tangible and intangible value proposition, in combination seems to be critical to the success of a persuasive business model but it can easily become blurred in the perception of the user, customer or network partner. However, if persuasive business models are constructed with smart and easy to operate technology embedded they have higher potential for success. Also, it seems persuasive business models that make the user, customer and network partner personally involved in the moment of action have higher possibilities of success.

While persuasive business models can make for a better world [2], they also have to engage in business model ecosystems that make profit in order to be sustainable. In fact, this raises significant challenges and ethical questions in relation to persuasive business model leadership and management. It is crucial that business models are clearly communicated as for-profit business models to avoid misunderstandings when entering business domains, which are largely influenced by charity organizations and others that flag different values.

4 Perspectives

We admit that we are just starting to see the contours of this vast possibility space and that we are still exploring the best methods for cultivating it.

A promising future perspective is to build a more integrated innovation process that concurrently analyze Big Data, innovate business models and implement persuasive technology. But how could that be orchestrated?

The possibility that – at least at this stage – seems to be most aligned with our experimental ambitions to act agile and learn along the way, is the loosely coupled set of methods we identified, which can act on the same entities and models from different perspectives.

Still the interconnections in a business ecosystem rapidly grow to a complexity level incomprehensive for the human brain. Therefore, the possibility which immediately comes to mind, is to carefully link all sub-processes to one giant design loop, ensuring that every aspect gets the appropriate awareness in all iterations. We are working towards this direction through our standardization efforts [4] and hopefully they will pave the way for an integrated digital business-modeling environment.

An effect might even be methods cross-fertilizing each other. For example, machine learning strategies that initially were introduced to discover patterns in Big Data sources might also be able to reveal a superior combination of business model components, when the business models and their elements over time become part of the common data repository as well.

Until now, it is a great challenge to make these generic methods grasp the complexity of a special case in a specific domain and local context. Last but not least it should be underlined that using the same methodology over a variety of cases in different urban contexts might eventually spark the cross-domain solutions that are greatly needed today.

5 Conclusions

Aiming to roadmap the way from abstract notions of Big Data to concrete positive business-models, this article has outlined a number of key elements. The first key is to grasp and map the possibility space. Translated into the company's or public entity's everyday setting this means a focus on available data combined with present and urgent issues should be a top priority. As example, if a municipality has the opportunity to harvest and collect data on potential heart patients, systemizing and

monetizing this data might prevent heart failures from occurring at the same rate, which means saved lives, optimized health quality and money saved. Before such concrete results are obtained, a phase of implementation is indispensable, which includes finding the right triggers to hit. Providing the right set-up can be learned or the service can be bought and implemented. Nevertheless, it is a possibility at hand to all agents, private as well as public, if equipped with ample visions. Finally, and perhaps, most vitally, if we judge from or cases, it is key that all agents relate to ownership. Doing an intervention to the benefit of the public or to a private company, might result in spin-offs. The intervention in its own right becomes a business, and the legal issues this might entail should be dealt with in the very early stages of intervention. The most pivotal issue with Big Data is not making a business out of it, rather it is ensuring that business fits into the existing landscape.

GET IoT- Green computing and Energy harvesting Technology in Internet of Things (IoT)

Jetendra Joshi, Anshumali Singh, Lakshya Gourav Moitra and Manash Jyoti Deka
Dept. of Electronics and Communication engineering
NIIT University, Neemrana, Alwar, Rajasthan-301705

Abstract— **The Internet of Things (IoT) refers to a system of future where every day physical objects are connected by the Internet in one form or the other. The promise of the Internet of Things (IoT) becomes a part in our everyday lives, but there are many challenges regarding the security issues and also we are concerned about the low energy consumption solutions that support the pervasive components at play in IoT. The security and energy efficient approach will really play an important role in the Internet of Things. We conducted a literature review about IoT, which includes features, architecture, and security aspects in IoT. This paper aims to study and use the relevant green computing and energy harvesting methods and select the most likely candidates for IoT use.**

Keywords— Green Networking; Data Center; Virtualization; Intelligent transport systems (ITS); V2X communications; Cloud computing (key words)

I. INTRODUCTION

With the swift development of Internet technology and communications technology, our lives are gradually leading a world full of hypothetical space present in a virtual world. Activities like chatting, shopping, work, etc. can be done easily in virtual world provided by network. Since we live in a real world, all our activities cannot be fully implemented through the services in the imaginary space. It is the constraint of imaginary space that limits the development of Internet to provide better services. To eradicate these constraints, a new technology is required to accommodate imaginary space and real-world on a same scaffold. We name this platform as IoT or Internet of Things. Now-a-days, the sensor network technology is demanding new internet technology derived from low-cost sensors and wireless communication. It will bring huge changes to the future society, change the way of life and business models [1]. In section II we have taken a brief description on the concept of IoT architecture and applications. In section III, the system security and privacy issues has been discussed. In section IV, we have used the various green computing techniques in IoT. Energy harvesting techniques in IoT is given in section V lastly we have Section VI that concludes this paper and gives a glance of future work. Lastly, we have given the references used.

II. IOT: ARCHITECTURE AND APPLICATIONS

The developing network of physical objects that constitute of an IP address for connection of internet, in order to build a communication channel for communication between these objects and other devices which are internet enabled, is known as IoT or Internet of Things. Any physical object, for example a person with a heart monitor implant, a biochip transponder inside a farm animal or a built-in sensors inside an automobile, etc. or any other natural or man-made object ,to which an IP address is assigned and provided with the intelligence to transmit data over a network, can be referred as a thing in IoT. The Internet of Things most closely related with machine-to-machine (M2M) communication in manufacturing and power, oil and gas utilities, as products with M2M capabilities are referred as smart.

A. Architecture of IOT

IoTs can be divided into three important layers [1] Viz; Perception, Network and Application. Perception layer or recognition layer collects data/information and analyses the physical world. Middle layer is known as Network layer or wireless sensor networks, which is liable for the early preparation and transmission of data, collection and polymerization. The application layer bids these overhauls for all the industries. Central Nervous system role was played by the network layer that handles overall services in the IoTs, as it aggregates with upward application layer and makes the link downward of perception layer. Various basic networks including, mobile/ private network, wireless/wired network allow the elementary connection. Business applications constitute of this new network of IoTs [2].

B. Applications

A survey done by the IoT-I project in 2010[3] identified IoTs application scenarios which are gathered in various domains and they are: Smart Home and city, transportation, Lifestyle, Retail, Agriculture, Smart Factory. This survey had its foundation on 270 responses from 31 countries and the schemes which got the most interest were: smart home, smart city, transportation and health care[3] .In this paper, the focus will be briefly on the IoTs applications in medical (health care) [4], smart home[5], intelligent community security system (smart city)[6].

- *IoT in Medical Application*

  Remote Monitoring and Management Platform of Healthcare information (RMMP-HI) [4] facilitates monitoring and management of the diseases for their prevention and early detection. In spite of restrictions of

location, time, and user' movement, RMMP-HI can gather human body medical information timely with the help of different body medical sensors laden in the human body or neighboring space and excerpt useful information by data encryption, storage, comparative analysis and transformation. When exceptional sight is found, users are notified to take early treatment; this allows the early detection and prevention. Short range wireless communication sensor module will gather the various information about the human body parts and transmit this information to 3G mobile phone or home gateway. This medical information is notified and transmitted to data storage and processing center timely. Then the important health guidance will be given back to the patient, family members of patients or medical institutions after systematical preparation of trained system or the scrutiny of professional medical staff in health service center. In the case of emergency, first-aid notification is communicated to a nearby medical institution by health service center to provide faster and better emergency services to the patients.

- *IoT in Smart Home*
  Reading of remote meters can be achieved through these smart home systems. That means, the data related with home power, telecommunications, gas and water can be transmitted automatically to their corresponding utility company to enhance the efficiency of the work. In addition, by virtue of smart home systems, windows, home ventilation, doors, lighting, air conditioning etc., can be operated and controlled remotely. Entertainment equipment's like radios and televisions can be connected to common channels which are distant.
- *Intelligent Community Security System*
  The intelligent community security system (ICSS) [7] controls several subsystems, such as Vehicle Management Subsystem (VMS), Surrounding Security Subsystem (SSS), Central Information Processing System (CIPS), Property Management Subsystem (PMS), Fire and Theft Prevention Subsystem (FTPS) etc. The Vehicle Management Subsystem [7] in ICSS adopts IPR, technologies in sensor network and RFID. Image recording can be done by RFID card and video camera which is provided to the vehicles. The vehicle license knowledge will be transmitted to the CIPS, when it enters the communities. The visitors are provided with the temporary parking places. The SSS (Surrounding Security Subsystem) contains electronic access controls, electronic fences and rotatable monitoring cameras. It can be used to avoid illegal enter or intrusive behavior into communities. The subsystem can find the exact location of the accident by making use of sensing terminals which can automatically omit untrue signals. The rotatable cameras will track the people or objects by IPR technology; simultaneously they triggers alarm to the handheld devices of the security personnel and CIPS through the sensor network [6].
- *M2M*
  Machine-to-Machine (M2M) communications illustrate machinery, algorithms and technologies that enable networked devices (wireless/wired) and facilities to interchange information or control data seamlessly, without explicit human intervention. M2M communications are expected to reform telecommunication operators business due to emergence of new networked applications, which will draw in new clients and increase the data flowing in their networks, producing more billing opportunities. The Internet of Things (IoT) with its wide dimension of applications that rely on everyday objects becoming intelligent connected devices [9] is a major driver for M2M applications. The National Intelligence Council predicts that food packages, furniture, and even paper documents can have internet connectivity by 2025 [10]. IDC envisions 212 billion "things" by the end of 2020, where 30.1 billion are expected to be connected autonomously [11]. On the other hand, the sensing and connectivity abilities of smart phones and their pervasiveness in people's lives make them critical pieces of this IoT and future applications.
- *ITS*
  Cooperative intelligent transport systems (ITS) are treated very important for enabling technology to improve road safety, traffic competency and driving practicality. There is in circulation a trend to deploy this new technology in vehicles to enable them to transmit information/data through hotspots with other nearby entities by direct short-range communications (DSRC), such as vehicle-to-vehicle (V2V), vehicle-to-infrastructure (V2I), vehicle-to-pedestrian (V2P) and vehicle-to-anything (V2X). Indeed, new market predictions [12] clearly indicate that the connected vehicle market will be worth 39 billion USD in 2018, and that more than 50% of the vehicles sold worldwide in 2015 will have communication efficiency. It is envisage that every new vehicle will be connected in multiple ways by 2025. This new reality of intelligent transport systems will ascend different types of vehicular communications (VC) and telematics services to the emergence of innovative rapid road safety operations, driver convenient services, smart mobility and traffic management services.
  Certainly, this technology dejectedly depends on wireless communications, several threats and attacks can cause an impact on its functioning and entertain the safety of the compound ITS entities and users. Typical attacks on ITS consist denial of service (DoS) attacks, Sybil attacks. Subsequently, various security

requirements should be established to abide these attacks, including reliability, confidentiality, integrity, non-approval and data entrustment in order to empower the materialization of future autonomous (or driverless) vehicles [13].

- *Smart Grids*
  The Smart Grid (SG) [14], the intelligent power grid, can be seen as the largest realization of the IoT network in the next future. The whole power grid chain, from the energy power plant generation to the final electricity consumers, which consists of conveyance and circulation of power networks, will be filled with comprehension and two-way communication capacity to monitor and regulate the power grid anywhere, at a fine granularity and a very high accuracy. The aim of the Smart grid is to keep a real time balance between energy formation and utilization, by allowing an exquisite examining and control over the power chain, thanks to the large number of the two-way communicating smart objects (smart meters, smart appliances, sensors, actuators, etc.)[15]

III. SECURITY CONCERNS IN IOT

Internet of Things virtually is a network of real world systems with real-time interactions. The development of the initial stage of IoT, is M2M (Machine to Machine), having unique characteristics, deployment contexts and subscription. Unattended operation without human intervention is possible for long periods of time by the wireless area network (WAN) or WLAN. Though providing improvements in social efficiency it creates an array of new problems concerning breach of privacy and that information security [16]. Front-end sensors and equipment receives data via the built-in sensors. They then transmit the data using modules or M2M device, thus achieving networking services of multiple sensors. This methodology involves the security of machines with business implementation and node connectivity [16]. Machine or perception nodes are mostly distributed in the absence of monitoring scenarios. An intruder can easily access these devices which imply damage or illegal actions on these nodes can be done. Possible threats are analyzed and are categorized to unauthorized access to data, threats to the Internet and denial of service attack. Back-end IT systems form the gateway, middleware, which has high security requirements, and gathering, examining sensor data in real time or pseudo real-time to increase business brilliance. The security of IoT system has seven major standards viz; privacy protection, access control, user authentication, communication layer security, data integrity, data confidentiality and availability at any time.

IV. GREEN COMPUTING

Green Computing can be defined in various frame of references. Green computing helps environmentally, socially and politically with respect to adequate and productive use of energy. In order to accomplish competitive edge in terms of an energy-cost saving strategy, and reduction to carbon discharge. Green computing represents environmentally possible ways to recede power and environmental e-waste [17]. Various goals of green computing are to reduce the use of lethal and harmful materials. Green computing also helps to build the energy efficient environment and also recycling of factory waste. Such practice includes the productive utilization of server and its constituents as well as reduces the power consumption [18].
Advantages of Green Computing:

1. Lower energy utilization from green computing techniques which also help to reduce the content of carbon dioxide discharge.
2. Less energy is required to produce, use, and dispose of products in order to preserve energy and resources.
3. Saving energy and resources saves capital.
4. Green computing contributes in changing government policy to strengthen recycling and lowering energy use by individuals and businesses.

There are a number of approaches for green computing. Some approaches illustrate as:

1) *Product longevity*: The PC manufacturing process is one of the important process that accounts for 70% of the natural resources used in the life cycle of a PC. The biggest contribution to green computing is to increase the equipment's lifetime.
2) *Data center design:* Data center facilities consume a lot of energy. The U.S. Department of Energy calculates that data center energy requirements for their facilities are 100 to 200 times more energy than standard office buildings.
   According to the U.S. Department of Energy, the primary areas on which energy efficient data center form best practices are given below:
   Information technology(IT) systems
   Environmental conditions
   Air management
   Cooling systems and Electrical systems.
3) *Software and deployment optimization*: It consists of algorithmic efficiency, resource allocation, terminal servers and virtualization. With feature of virtualization, a system administrator could add up several physical systems into virtual machines on one single and powerful system. The effect of virtualization will help in unplugging the original hardware and decreasing power and cooling consumption.
4) *Power management*: The ACPI or Advanced Configuration and Power Interface, is an open industry standard, which allows an operating system to directly dominate the power-saving aspects of its underlying hardware. When the system is inactive for longer time then the system automatically turn off peripherals such as monitors and hard drives after set

intervals. In addition, a system may hibernate, when majority of the components are turned off.

Various techniques can be classified at different levels:

1) Hardware and Firmware Level
2) Operating System Level
3) Virtualization Level
4) Data Center Level

Hardware and Firmware level techniques implemented at the manufacturing time of a machine. These techniques consist of all the optimization methods that are applied at the initial phase when the designing of the logic, circuit, architectural and system levels is done. Next level is Operating System level mechanisms which consists of methods that take care about programs at operator level. Finally the Virtualization level techniques are enhanced to use the concept of Virtual Machines (VMs) to manage power. In this number of VMs are generated on a physical server, so that reduce the amount of hardware in use and improve the utilization of resources. Data Center level mechanisms are taken into effect at various data centers and these centers consist of different methods which are used to manage workload across physical nodes.

V. ENERGY HARVESTING

Ambient energy harvesting or power harvesting, is the phenomenon of deriving usable energy from natural and human-made sources that surround us in the everyday environment. From the previous calculations we can conclude that the low end of power usage for an IoT node that remains useful is at 124μW. This means the node hibernates for a second and is activated by an outside trigger for processing and data communications that will not last longer than one tenth of a second. We need to scrounge for ambient power sources that can fulfill this energy requirement [19].

A. Small Solar Cell Outdoors

A small solar cell fixed outdoors can easily give 150mW [20]. It will need a battery to function in night time or cloudy days. It has to be installed into a visible place that is free from shadow. This means it will have to survive in different weather conditions from snow to direct rain and withstand dust accumulation.

Solar cells in inside use are often overlooked as toys or completely ignored. A small unit in unfavorable angle to an incandescent lamp can create 51μW [21]. If we install three of these we hit our power target of 124μW. This is very promising. But we cannot assure that the lamps will be on all the time. So we will have to install some kind of battery or capacitor that charges from the solar cell and powers the IoT node when lamps are off. This might lead to considerable problems in buildings that become empty for longer periods of time.

B. Magnetic coupling with a nearby power line

A very simple power source is to gather energy from power lines that are embedded inside walls. They offer high power when the IoT node is directly on top of the power line. This solution can easily feed even a high power processor. Unfortunately this solution suffers from the square distance law. When there is a small increase in the distance from the power line that reduces the power available for the magnetically coupled node. Also rather unexpectedly this solution suffers from a version the same problem as the indoors solar cells.

C. Harvesting Radio Singnals

Most of the available radio signals need a huge antenna to be gathered efficiently. That naturally is not a realistic option for an IoT device. The most realistic case is a smallish (10x5 cm antenna) 10 m from Wi-Fi antenna. This gives roughly 4 μW if the base station is transmitting continuously. This is not enough unless we either go up with the signal strength or use a really large antenna. If we go up in size of the antenna we also start creating shadows behind us where the Wi-Fi signal is weaker for other listeners. This becomes quickly a problem when the number of IoT nodes goes up. It is also hard to create a design that won't create problems for other IoT nodes by damping their transmissions. Even though there are some products on offer that might be used for IoT power use, it seems the solution is not feasible with the current processor technology.

D. Magnetic capture of vibration

A very promising technology is the magnetic capture of vibration. The principle is simple. A magnet is hung from a spring or similar structure and placed inside a coil. When the magnet vibrates due to outside forces it will create alternating current in the coil surrounding it. An example installation produced from a 0.85 mm movement over 180μW [22] of power. This fulfills the requirement set earlier nicely. This kind of energy harvesting has been used to power measurement systems in bridges. The vibration created by trucks passing powered the measurement nodes in the bridge.

E. Piezo capture of vibration and strain

Energy in piezoelectric elements is captured from vibration as well as compression. For example, [22] a human walking over a large piezoelectric plate can easily produce 8W during the passing. If we expect the human to pass the plate in half a second producing 4 J and our energy needs derived from 124μW are 0.446 J per hour leads to conclusion that we need one human every 9 hours to pass the plate to keep the IoT device running. This is a very reasonable expectation. As there is so much excess energy available from the piezo plate it is logical to pair the plate with a small NiMH battery. This can be kept topped from the element to compensate for the self-discharge current.

F. Thermoelectric capture

In thermoelectric capture the idea is to gather energy from a temperature difference or more specifically heat flow. The elements are small and the output is a simple DC current. As an example Seiko wristwatch produced 22 μW @ 1.5 °C from human body heat [24]. Scaling that up by 10x surface or 10x

temperature difference we can easily get 220μW which compares favorably with our target of 124 μW. This would be continuous power. Unfortunately buildings are usually designed to minimize places where there can be heat flow between large temperature differences. So finding places where there units can be positioned will prove troublesome.

G. Air Movement

Air movement does not need to be gathered with large and visible propellers. Piezoelectric wind turbines can gather energy from passing air rather innocuously. This kind of turbine can be inside ventilation ducts and it can gather energy from the random air current inside building. Small piezoelectric wind turbines can easily get 200μW from random air movements. Leaving sufficient extra energy to keep a battery topped. Currently available models are designed for larger energies and are unfortunately bigger than an AA battery, but there is no reason why the technology could not be scaled down and some manufacturers seems to be experimenting with the small turbines.

VI. Conclusion

In the first part we concluded that the IoT architecture and application are explained in details. Later we study the various application scenarios and also study the various security concerns in IoT then at last we study the various green computing techniques in the IoT. We also demonstrate multiple ambient energy harvesting solutions and list their power output and their problems. From these it becomes evident that ambient vibration and light are the most likely sources to use for true IoT devices. Next step would be to build a demonstration system to measure the power output from vibration and light sources and to gather better insight into how these kinds of systems operate and what are their limitations in true IoT use.

***Abstract*— Nowadays, there is great interest in developing telemedicine technologies. These technologies will provide health care from distance swiftly and lightly, as well as reduce the expenses for activities, such as rehabilitation. Telemedicine applications are possible due to the advances in information technologies and the ever-expanding communication network infrastructure. The network characteristics bandwidth, packet loss, latency, jitter and policies are crucial for the performance of tele-rehabilitation systems. Because in tele-rehabilitation human lives are at stake, guaranteeing the Quality of Service (QoS) is important. In this paper, an approach for assuring the QoS for information transmission in tele-rehabilitation systems is proposed.**

Keywords—capacity; communications; delay; jitter; networks; policies; protocols; telemedicine; tele-rehabilitation; quality of service;

I. INTRODUCTION

In the recent years, a great advancement in the development of technological and rehabilitation methods was observed. By combining rehabilitation and the advancements in Information and Communications Technologies (ICT), tele-rehabilitation arises. This is a subpart of telemedicine, consisting of a system for controlled rehabilitation "via the Internet" – an actual application possibility with a promising development in the future. A tele-rehabilitation system is a bilateral system, consisting of master and slave devices, which interact through a bidirectional communication channel, as shown in figure 1.

Various communication media can be used in tele-rehabilitation: transmission lines, wireless transmission or the Internet. Depending on the different environments, based on their performance, a decision for using TCP (Transmission Control Protocol) or UDP (User Datagram Protocol) for transporting the information has to be made.

TCP provides reliable two-way communication and guarantees data delivery at the cost of retransmissions and long timeouts that are detrimental to the performance of real-time applications, such as teleoperation. UDP does not require reception acknowledgments, eliminating unnecessary waiting time, which makes it appealing for teleoperation.

In tele-rehabilitation, improved quality video-assisted telecommunication services and devices, such as videoconferencing, webcams and telepresence, assist in treatments. Sensors and body monitoring data, voice, sounds, medical images and information related to telehaptics (the sense of touch), as well as virtual reality, can also be transmitted for rehabilitation purpose. Moreover, with the massive utilization of portable smart terminals, such as smartphones, laptops and tablets, web-based approach and mobile applications are becoming ever more common and can potentially be used for tele-rehabilitation.

In tele-rehabilitation, human lives are at stake. Hence, the consequences of an error or delays in information transmission could be serious. This is the reason why reliable techniques of networking must be developed and applied [1]. Particular stress should be laid on the importance of availability and reliability of the communication networks. Interruptions in network operation, e.g. introduced by a power cut, could cause errors or delays in the transmitted data. These specifics pose strong requirements for the bandwidth, delay, jitter, reliability and availability of the network connection for tele-rehabilitation.

Five fundamental network characteristics are crucial for the performance of tele-rehabilitation systems. Bandwidth is a fundamental requirement that there is enough capacity in a network path for all of the packets to get through unimpeded. Packet loss is the amount of packets, which do not arrive correctly at their destination, and it should be less than 1-2%. Latency is the time delay between an event occurring on one site and the remote end seeing it. For a voice transmission with good quality, a latency of less than 150 ms is needed. Jitter is the time variation of latency among the packets, which can result in packets arriving in different order than transmitted. Jitter should be under 50 ms. Policies are introduced by network elements like firewalls and Network Address

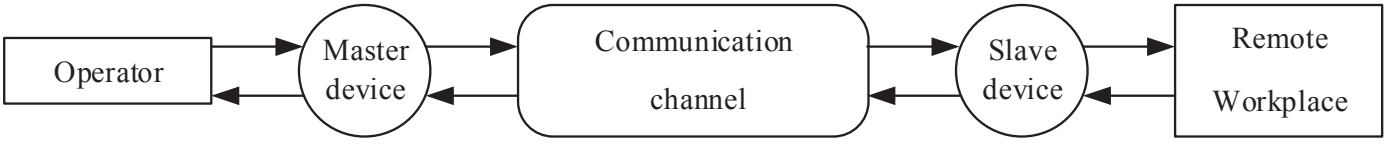

Fig. 1. Tele-rehabilitation concept

Translation (NAT) devices. If the traffic is encrypted for security, some additional aspects should also be considered.

The rest of the paper is organized as follows. In the next section, some telecommunication approaches for tele-rehabilitation purposes ensuring the required QoS are considered. In addition, in this section the problem definition and motivations are presented. In section III, various categories of telemedicine data and their Quality of Service (QoS) requirements are described. The proposed approach for assuring the QoS for information transmission in tele-rehabilitation systems is described in section IV. Finally, we conclude the paper in section V.

II. State of the art

In this section, some telecommunication approaches for tele-rehabilitation purposes guaranteeing the required QoS are considered.

In [2] to overcome instability, caused by unknown and varying time delay, an event-based teleoperation system is employed for synchronization of the robot and the operator. The developed teleoperation system could be easily adjusted to be useful for a tele-rehabilitation robot. UDP is used for sending operator commands and forcing feedback. Additionally, the size of packets for UDP compared to TCP puts less load on the communication channel. To avoid breakings in the control cycle, a server application monitors the control cycle's duration.

The effect of time delay can be reduced with latency tolerant control methods as presented in [3]. The proposed architecture is evaluated with three models of the system components: a master device, a slave device and a communication system. The master includes a controller and the human operator, which are connected via a high-delay medium to the slave model. The master side is where the "human operator" or the replacing automatic control device is located. The surgical staff can be found here, providing the control signals for the actuators of the slave. The communication system includes a transmitter, a receiver and a communication medium. In the deriving cascade setup, the time delay can be partially alleviated using appropriate predictive controllers, tuned to the master and slave systems [3].

In [4], the authors discuss the importance of provisioning QoS and information security in the field of medical care, focusing on the use of data communications, Internet, cloud and Smart Ubiquitous Computational Devices (SUCDs). They present possible scenarios, related to remote control of Medical Surgical Robots via the Internet. The main idea is to lay stress on the importance of QoS provisioning and cyber security in the field of telemedicine, which also applies to tele-rehabilitation.

To assess the convenience of the remote tele-laboratory technique, different configuration architectures have been tested in [5]. For each of these configurations, experiments have been performed, consisting of 400 remote movements of a robot. These experiments use TCP and UDP protocols. Performance details, obtained from these experiments, show that the configuration with UDP is fastest and the most convenient one for traditional tele-robotic applications. A new software protocol, called Interoperable Telesurgical Protocol (ITP), has been developed, which is open and meant for sharing. The first data interface in ITP is a packet of 84 bytes, using the UDP network protocol for fast transmission. The small size of the ITP packet makes it suitable for high packet rates.

In [6], the Secure ITP enciphers communications between the master and slave. The communications use TLS (Transport Layer Security), DTLS (Datagram TLS) protocols and the AES (Advanced Encryption Standard) cipher.

Analysis of the possibilities for providing real-time services for bilateral teleoperation systems on existing wireless infrastructures, using only application layer measurements without any information from the network layer, is presented in [7]. Since teleoperation systems should have a video feedback channel, the influence of video transmission on the transmission quality in the other two periodical channels is analysed. Based on the delay variation measurements of the two opposite directions, data channels identify WLAN (Wireless Local Area Network) problems.

The packet latency is observed and analysed in [8]. Teleoperation latency becomes noticeable to human users for delays above about 200ms, starts to be annoying at around 500ms, and significantly impacts the performance of tasks at 1s and longer. In order to provide true telesurgical care, software systems need to be in place to protect the integrity of the signal and minimize the latency of data transmission between the surgeon and the patient. One way to protect remote surgery's connectivity is to send information over multiple communication pathways or routes.

An investigation into the use of SIP (Session Initiation Protocol) protocol for a telemedicine transition system was proposed in [9]. According to standard computing platforms and operating systems, it is easier to integrate SIP protocol into the application program. Second, SIP is an extensible protocol. Therefore, it is able to run a wide range of applications with a variety of media formats and loads. In the SIP protocol, a number of criteria have been developed for instant messaging, resource management, media streaming (video) and online friend management applications.

In [10], a robotic tele-rehabilitation system has been developed to perform both interactive and cooperative bilateral rehabilitation. The system has been evaluated using four computer games, each with different specification of the data transmission and event management. In addition, robotic teleoperation techniques have been implemented to evaluate the performance and stability of the force reflecting strategy in the cooperative bilateral configuration. The internet communication between the robots has been performed through sockets, using the TCP/IP protocol stack.

A classification of the security threats against mobile surgical tele-robotic systems is presented in [11]. Communication networks security is an active research area and many existing strategies may be also applicable to tele-rehabilitation systems. Identifying those, as well as developing

novel, specialized mitigation strategies, and analyzing their impact on system's performance, security and safety, is an emerging research question.

III. Problem definition

Based on the specifics of tele-rehabilitation and the resulting requirements on the network performance and QoS, a method for conforming to these demands for information transmission in tele-rehabilitation systems should be provided. The approach has to satisfy the requisites for bandwidth, latency, packet loss, jitter, policies, reliability and availability of network connection.

IV. QoS requirements

The data for telemedicine, which is transferred through a communication channel, can be divided into five main categories with different QoS demands:

- Voice;
- Video;
- Data from sensors;
- Teleoperation;
- Virtual reality.

A. Voice over IP (Internet Protocol)

In order to digitize human voice effectively, a sampling rate of 8 kHz with 8 bits per sample is needed, which results in a minimum data transfer rate of 64 kbps (kilobits per second). The delay must be less than 100 – 150 ms. Some notable low bit rate compression algorithms used are ITU G.723.1 and G.729A. It is common to use silence compression to reduce the payload dramatically.

B. Video

The type of video, which is most important in telemedicine, is the video, which is transmitted in real-time. The throughput in raw format, without compression, varies depending on three main features – resolution, frame rate and bits per pixel. For video with resolution 1920×1080 pixels, 30 frames per second, RGB (Red, Green and Blue) color components and 8 bits per pixel per color, a total video stream with data rate of 1.5 Gbps in raw format is produced. Techniques, which compress individual frames, have been developed. In addition, motion prediction is used to compress the data even further. Most of the time, the throughput for video transmission is dependent mainly on the motion within the images. Factors, such as resolution and scanning rates, are not so relevant. A full-resolution HDTV (High-Definition TeleVision) stream, compressed with the MPEG2 method, requires 19.3 Mbps of data bandwidth. For online video streaming with 720p resolution, a 2.4 Mbps channel is required.

Every computation for compressing and decompressing the video adds delay to the total transmission delay. The greater the compression ratio used, the greater the latency introduced. The total delay requirement for video transmission is less than 150 ms.

C. Data from sensors

For this type of information, the requirements for throughput and delays are not so stringent. However, high requirements for data integrity are set. Efficient transport protocols are needed to provide correctly received sensors' data.

D. Teleoperation and Virtual reality

This category includes a mix of video, voice, text, sensors data and remote device commands, which are to be multiplexed and transferred through the communication channel simultaneously in real-time. A list of provisional network requirements for teleoperation and virtual reality can be identified. These QoS requirements include [1], [4]:

- reliability and integrity;
- an acceptable end-to-end delay;
- multiplexing of various data rates resulting in high network bandwidth;
- low data error rate (BER – Bit Error Rate);
- low latency;
- constant jitter.

Studies show that the acceptable limit of time delay in terms of a surgeon's perception of safety is roughly 330 ms [1]. A study in [1] shows how the interactive Internet gaming is affected by the end-to-end delay. The results are presented in table 1.

TABLE I. Perception of interactive Internet gaming as a function of end-to-end delay [1]

End-to-end delay	***< 50 ms***	***50-100 ms***	***100-150 ms***	***100-150 ms***	***> 200 ms***
Perception	Excellent gameplay	Good gameplay	Noticeably decreased gameplay	Significantly effected gameplay	Intolerable gameplay

V. Approach for assuring QoS for information transmission in tele-rehabilitation systems

Because of the various transport protocols and telemedicine technologies existing, we propose adaptable and scalable framework for tele-rehabilitation. Its main functions are:

1) providing abstraction and generalization of the transmitted data among telemedicine devices from different vendors. This way, the network infrastructure is transparent;

2) Data Tunneling for meeting various QoS requirements;

3) M2M communication capabilities for tele-rehabilitation devices from different vendors;

4) General and scalable application software for all telemedicine technologies;

5) Adaptation of the transport layer for reaching target QoS requirements.

The proposed framework is illustrated on figure 2.

The layer "Generalization" has the main responsibility to set the parameters for each data stream generated by a tele-rehabilitation device. It controls tele-rehabilitation devices, or more specifically – their output data streams. Another main responsibility is to adapt or translate different teleoperation and

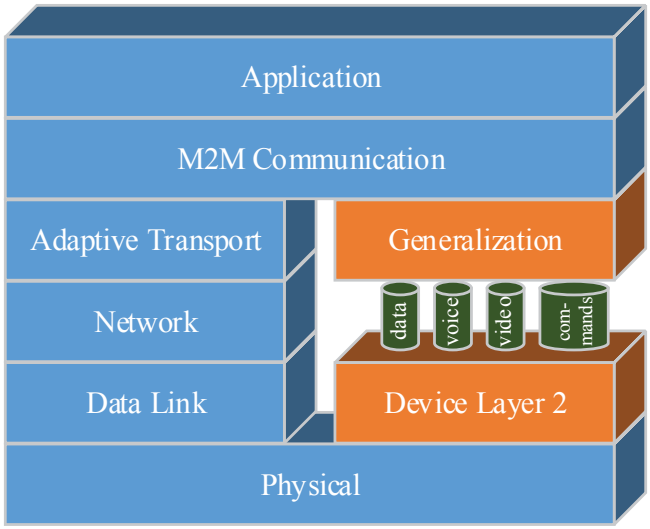

Fig. 2. Proposed framework for assuring QoS for information transmission in tele-rehabilitation systems

sensors data streams, which are sometimes unique for the device itself. The layer gives a compatibility function for all tele-rehabilitation devices to work together.

The main responsibility for the "M2M Communication" layer is to give tele-rehabilitation devices abilities to share and request data from each other, which is needed for taking an overall decision by a given tele-rehabilitation device. This functionality can be realized as a sublayer of the Application layer.

"Application" layer is the man-machine interface, which sets QoS requirements for the data streams. It works also like a SIP server to negotiate data stream parameters between different vendor-specific or technology-specific devices. Another function is to track communication KPIs (Key Performance Indicators), such as delays, throughput, error rate, latency, etc. This acts as a feedback for the "Generalization" and "Adaptive Transport" layers, so they can further modify data and communication parameters and thus meet QoS requirements.

The "Adaptive Transport" layer has the task to fulfill the QoS requirements for every data stream on the transport layer by using various transport protocols – existing or novel. For transporting information, which is insensitive to delays but should be received with no errors, TCP can be used, for example for controlling a remote workplace or receiving measurements from sensors.

Because of the broad development of the Internet and associated IP networks and protocols, this is one of the candidates for providing such transport. In this case, one appropriate protocol for transporting media in real-time is SIP in addition with Session Description Protocol (SDP) and Real-time Transport Protocol (RTP) or Secure RTP (SRTP). For a transport protocol, either TCP, UDP, Stream Control Transmission Protocol (SCTP) or any other suitable implementation can be leveraged.

By implementing this multilayer framework, we separate the communication channel functions from the tele-rehabilitation devices functions. Hence, tele-rehabilitation technologies can be developed independently from the network infrastructure. This method will be a common interface for all tele-rehabilitation technologies, providing network communication capabilities.

With the use of data tunneling, QoS requirements for the transmission of different information types are met. For meeting stringent QoS requirements, a tailored protocol on the transport layer can be developed. The M2M communication capabilities assure compatibility between tele-rehabilitation devices from different vendors. This unity enables general and scalable application software for all telemedicine technologies.

The information with particular requirements for network performance can be separated into different traffic flows. Each of these flows should use a distinct stack of protocols, tailored to fulfilling the requirements posed by this type of information.

As the technologies and services in the networks evolve, backward compatibility should be maintained, so that devices from both newer and older generations can interoperate together.

VI. Conclusions and Future Work

The proposed communication framework for tele-rehabilitation systems with QoS guarantee provides abstraction and generalization of the transmitted data among various tele-rehabilitation devices. Hence, the network infrastructure is transparent to the communicating devices. Data tunneling is leveraged for meeting various QoS requirements. M2M communication capabilities are added for interoperability. Adaptation in the transport layer protocols is a means to reach target QoS requirements.

As a result, the framework can serve to develop generalized and scalable application software for all tele-rehabilitation technologies.

The communication between tele-rehabilitation systems has to be designed in such way, so that it allows compatibility between devices from different vendors and of various generations, and provides openness of the underlying protocols and methods.

The next steps in the development of the common communication framework for tele-rehabilitation systems would include a more elaborate selection and design of the protocols in each layer should be performed. After a protocol stack has been chosen, the integrity of the whole stack shall be tested and evaluated. This can be done by simulating the interoperation of separate protocols and devices or by implementing the stack in tele-rehabilitation systems and devices.

Acknowledgment

***Abstract* — There is a huge demand for automation infrastructures that increase the efficiency and the commercial potential for the agricultural sector. One approach to achieve these objectives is deploying Internet of Things including its embedded wireless sensor network platform. However, deploying wireless sensors in the fields far from the farms provide some challenges in terms of transmit power, path loss, and lack of power. This paper explores the possibility to deploy an efficient low power adaptable wireless link which interfaces the Internet of Things infrastructure located on the farm. This new adaptable link element offers many benefits such as adaptable transmit time, powered from a sustainable source, and a variable size payload based on the farmers need.**

Keywords—IoT; WSN; adaptive wireless links; solar power in WSN

I. INTRODUCTION

Nowadays, there is huge demand from the agriculture business to incorporate Internet of Things (IoT) based on Wireless Sensor Networks (WSN) into the farming infrastructure to automate, control and monitor most of the agricultural aspects. These aspects includes elements such as crop production monitoring, detect and control diseases, unmanned animal farm production, and food transportation and distribution. Especially, in the area of detecting and controlling diseases it is important that the IoT nodes and their embedded resource-constrained sensors are able to send selective messages. Each message must contain crucial information for one particular disease or insect attack in order to detect it at an early stage and thereby handle it in time. A study which shows the importance of this approach has been carried out in cooperation with the Research Centre for Cultivar Testing (COBORU) [*1*].

Today's wireless communication infrastructure enables fast and reliable message exchange between nodes even at a long distance. However, for the farm infrastructure the most crucial and important element is to keep the system running with limited power options. Hence, most of the agriculture applications cover large areas where there is no power infrastructure, i.e. the farming applications use resource-constrained sensor network types which are powered from sustainable sources such as solar power and wind power. The challenges for the solar based system are: the size of the solar panel, the size of sensor enclosures, and the sizes of the antennas. These parameters need to be minimized; however, small solar panels means less power and small antennas means its radiation efficiency is reduced. Important factors to minimize these parameters are the choice of network topology and the number of packets sent and received. Thus it is important to cooperate with the plant disease forecasting experts to proper design the protocols and packet types which minimize the link budget. It is noted that the transmission energy cost primarily depends on distance between the IoT devices and the size of packet to be transmitted, whereas the receiver energy costs primarily depends on packet size.

The main focus for this paper is to provide a solar powered IoT system which is able to stay alive for a long time without any maintenance or service. To provide such viable and sustainable system, an adaptive approach is taken where the parameters of the WSN link adapts the needs for a particular agriculture application.

II. RELATED WORKS

A similar work has been published by Hancke et al. Their work explores smart systems to improve and automate many of the processes such as collect rainwater and control intelligent buildings in smart cities. They discuss deployment of a ZigBee WSN in the smart city and they elaborate over the limited range problems [*2*]. A paper from Z. Nakutis et al. presents an idea of RF-169 utilization in IoT Infrastructure, but no detailed link budget calculation and system life-time span in relation to the node energy consumption. However, they studied network infrastructure including system architecture, redesign of protocol (type of packets) and regulations for the 169 MHz ISM band [*3*].

III. THE CONCEPT AND THE CHALLENGES

In this section the challenges for long range coverage is discussed in the light of minimizing the energy consumption, deploying IoT technologies, and adding adaptive link behaviour. The discussion and exploration is elaborated by a case study. A typical farm equipped with IoT technology is illustrated in Fig. 1. The farmhouse contains a collection of IoT devices which monitor and control their environments.

An example could be the grains contained in the barn are monitored for vital parameters such as temperature, moisture, and light exposure. The measured data are transferred (wireless) to the coordinator (gateway) that stores and processes these. To be able to access these data the coordinator offers an interface to a user management system (e.g. based on a Cloud IoT system).

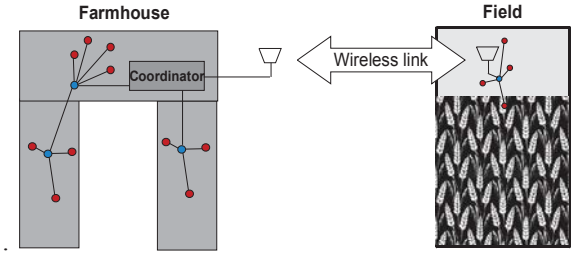

Fig. 1.A typical farm equipped with IOT's

In general, such systems are implemented by deploying a simple Wireless Sensor Network (WSN) like e.g. a ZigBee network and run the IoT devices on top of this [2]. However, the IoT devices deployed in the fields cannot be part of such a network because the WSN network is not able to cover the huge distance from the farmhouse to the fields. As discussed, to overcome this challenge an efficient adaptive wireless link is needed which adjusting the radio parameters, selects the information to be transmitted intelligently, and deploys new power sleeping technologies for the processing part. These aspects will be elaborated in the coming sections.

A. A case study regarding a common disease in vegetable farming

This section provides a selected case that elaborates over the possible choices for the adaptive link parameters. One of the most common destructive diseases in vegetable farming is the "leaf spot" disease which is caused by the Cercospora beticola Sacc. foliar pathogen. It attacks sugar beet leafs. This infection happens when a spore in a process of germination is formed on the leaf. And this process can occur only when propitious favourable weather conditions like warm and a high humidity level exists. The spores in the process of germination enter the respiration plant cells. After a few days they form small spots with a red border, visible black spots and gray coating conidia. Those conidia, which are a major dispersal diseases factor, spread from parts of leaf when it rains. Especially, when the temperature is above 17°C (optimum 27°C), the disease spreads very quickly to the neighbour leafs and plants which results in all the vegetable crop fields is infected in a few days. Thus, selective temperature, humidity, and rain conditions in the fields must be monitored frequently to handle this disease in time. Thus, this is an example of selecting important selective information to be repeated with just the right repetition interval.

B. Radio and sensor hardware choices

To relate the simulations performed in this paper to the real world settings tiny transceivers have been explored and hardware RF test modules have been build [*4*]. Parameters from these circuits are used as input for the simulations.

A transceiver module has been build with the CC1120 device (from Texas Instruments). It has a programmable transmit power up to +15dBm and sensitivity limit of -120 dBm at 1200 bps (Fig. 1 left side). To increase transmission range between two communicating nodes an external PA [*4*] with up to +30dBm transmit output power has been explored and assembled as shown on Fig. 2 right side.

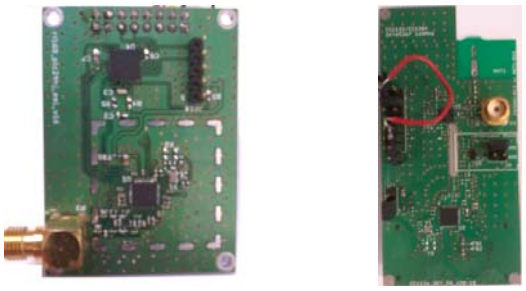

Fig. 2 A hardware RF modules based on the wireless CC1120 device

IV. AN ENERGY EFFICIENT ADAPTIVE WIRELESS LINK

The main challenges for creating an energy efficient link between a receiver and a transmitter are to overcome the path loss and to be able to supply power from a sustainable source. These challenges are explored and elaborated in the following sections.

A. Path loss

One of the most significant contributions to a wireless link loss is the path loss or free space loss, which accounts for the spreading of the transmitted energy as a function of distance. A commonly used formula that takes this into consideration is the Friis transmission formula (1).

$$\frac{P_r}{P_t} = G_r G_t \left(\frac{\lambda}{4\pi R} \right)^2 \quad (1)$$

Where: Pr and Pt are the received and the transmitted power respectively. Gr and Gt are the antenna gain for the receiver and the transmitter. λ is the wavelength and R is the distance between the receiver and the transmitter. Fig. 3 shows the formula (1) plotted with the path loss expressed in dB.

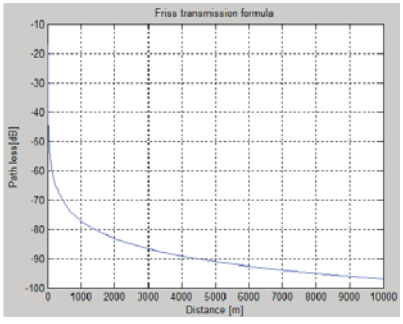

Fig. 3. Friis transmission formula with path loss on the y-axis and distance on the x-axis

As illustrated (Fig. 3) the path loss can be as large as 100 dB if the distance between the receiver and the transmitter is 10 km. However, the path loss is also a function of the Line of Sight (LoS) condition between the transmitter and the receiver. If an object is blocking the LoS it has impact on the path loss. Especially if the object is inside the first Fresnel-zone (Fig. 4) it has a considerably impact on the path loss [5] [*5*].

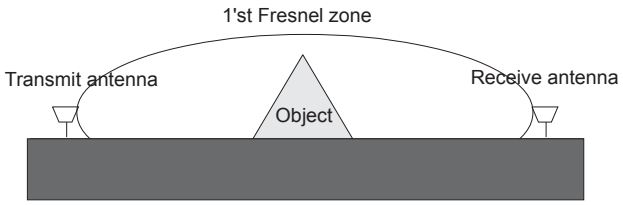

Fig. 4. The first fresnel zone with an attenuating object

Finally the curvature of the earth can disrupt the LoS condition. The distance where LoS is possible is stated in equation (2) as an approximation.

$$D \approx 4120\left(\sqrt{h_r} + \sqrt{h_t}\right) \quad (2)$$

Where: D is the LoS distance between the transmitter and the receiver in meters. The heights hr and ht are the antenna-heights in meters for the receiver and the transmitter over ground, respectively.

B. *Power source*

Many types of power sources exist; however, for low form factor IoT devices located in the field sources based on solar and wind power are attractable because they are cheap, they are available most of the time, and they are sustainable. An alternative could be batteries, but they need to be changed over time and the weather conditions have impact on their efficiency and lifespan. Nevertheless, re-chargeable batteries are needed to store the solar and wind power in non-productive periods such as at night time and under conditions with no wind.

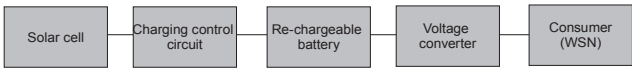

Fig. 5. A solar power system which interfaces a WSN

Focusing on a solar power system (Fig. 5) it has a solar cell which converts the solar energy into electricity. However, this process provides some challenges in form of low efficiency and it often provides an incompatible voltage for the battery and the WSN node. The efficiency for most consumer, market available solar cells is in the range of 17 - 20 percent and the produced power is approximately 15 mW/cm^2 [6][*6*]. Nevertheless, future solar cells expect a maximum efficiency of 46% [7][*7*].

Regarding the voltage incompatibility a charging circuit is often deployed as illustrated in Fig. 5. This circuit transforms the solar cell voltage and current to fit the battery parameters for the cost of an efficiency of approximately 60 percent [*8*][8]. The re-chargeable battery stores the power received from the charging control, but approximately 34 percent are wasted, i.e. the re-chargeable battery efficiency is approximately 66 percent [8]. Finally, the voltage converter adjusts the voltage so it fits the needs for the consuming IoT node (WSN) for the costs of approximately 50 percent [8] energy loss. Adding all the losses the final energy loss is given in equation 3.

$$E_{loss} = E_{solar} + E_{ch\,\mathrm{arg}\,econtrol} + E_{battry} + E_{votageconverter} \quad (3)$$

To be able to predict the produced energy from a solar cell data for the average sun hours and the energy intensity are needed. The PVGIS database [*9*] is a source that provides these information's. Assuming that the solar cell is mounted horizontal the solar radiation (Wh/m2/day) can be looked up in the database. An example for Copenhagen is illustrated in Table I.

TABLE I.

	Month			
	March	***August***	***September***	***December***
Wh/m2 /day	2810	4440	3170	384

C. *A simulation model*

A simulation model has been developed in a mathematical tool to be able to experiment and explore the most vital parameters in the adaptive wireless link. This model is primarily based on the equations discussed earlier in his paper in combination with some parameters as illustrated in Fig. 6.

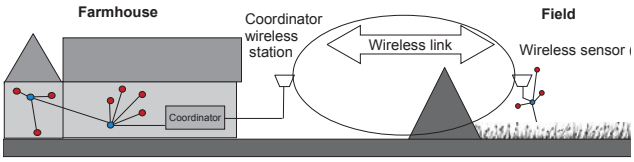

Fig. 6. The simulation model settings

The coordinator (and its user) communicates and exchange data with the farms IoT devices which are interconnected by a WSN network (Fig. 6). To be able to communicate with the external IoT devices located in the fields an energy efficient adaptive wireless link is established. In this model it is assumed that this link is attenuated by an object, which ranges into the first Fresnel zone.

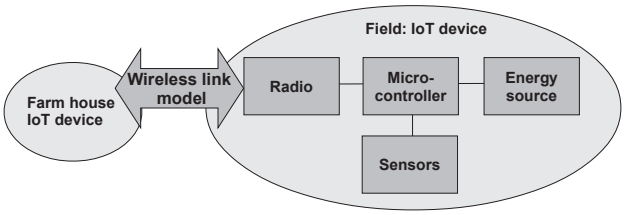

Fig. 7. Schematic of the simulated iot device

A block schematic of the simulated IoT device is presented in Fig. 7. The wireless link model implements equation 1 and 2 together with the attenuation provided by the object in the Fresnel path (Fig. 4). The following parameters are used for the model (Table II):

TABLE II.

Parameter	*Value*
Distance from the field to the farmer house	9 km
Height (over ground) of farm house antenna	4 m
Height of the antenna - the field IoT device	1 m
Attenuation of object in first Fresnel zone	20 dB
Antenna gain (Rx+Tx)	0 dB

The radio model (Fig. 7) covers a CC1120 device inclusive an external Power Amplifier (PA). The parameters for the radio and the power amplifier are given in Table III.

TABLE III.

Parameter	*Value*
Operating frequency	169 MHz
Sensitivity	-120dBm @ 1200 bps, BER=10E-2
Sensitivity (approximated)	-110dBm @ 1200 bps, BER=10E-5
Modulation	2-GFSK
Power amplifier output power	Max. 1 Watt
Radio consumed power RX	69 mW
Radio consumed power TX	150 mW
Microcontroller consumed power	3 mW
PA efficiency	50 %

The energy source (Fig. 7) is based on a solar cell with belonging components (Fig. 5). The data used in the simulation has been discussed previously and are summed-up in Table IV.

TABLE IV.

Parameter	*Value*
Solar cell (SZGD6030) area	60*30 mm (10 mm rim)
Solar cell efficiency	17 %
Solar power system efficiency (Fig. 4)	3.4 %
Solar radiation	Data from Table I

Regarding the wireless transmission protocol it approximates the popular ZigBee framework which is often used as the backbone in many IoT systems. Thus, each frame has an overhead of 31 bytes and a maximum payload of 127 bytes. These individual frames are combined into a super-frame that contains 16 of these. Additionally, it is assumed that the microcontroller provides a power saving mode (sleep mode) when no traffic takes place and it is assumed that the sensors have a very low power-consumption (i.e. it is ignored).

D. Elaborated simulation results

This section discusses and elaborates the elements in designing an energy efficient adaptive wireless link by using the previously discussed simulation settings. By focusing on the path parameters including the Friis transmission formula (1), the transmit power, the blocking object attenuation (Fig. 4), and the compensated receiver sensitivity (10 dB for changing the BER to 10E-5, Table III) the total received power can be estimated (Fig. 8).

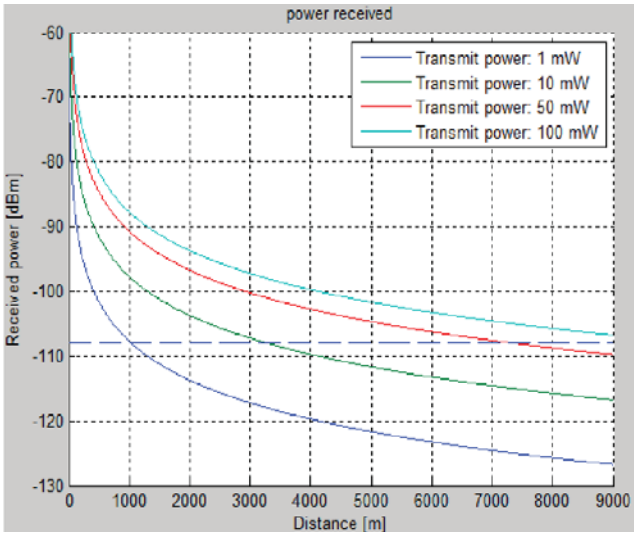

Fig. 8. The received power as a function of transmitted power and distance (a link margin of 12 db is included). The dashed line indicates the receiver sensitity level

From Fig. 8 it is notable that the received power (including the 12 dB link margin) allows a range of 1,2 km when the transmitted power is 1 mW (0dBm) and similarly, the range can be extended to 9 km when the transmit power is 100 mW (20 dBm).

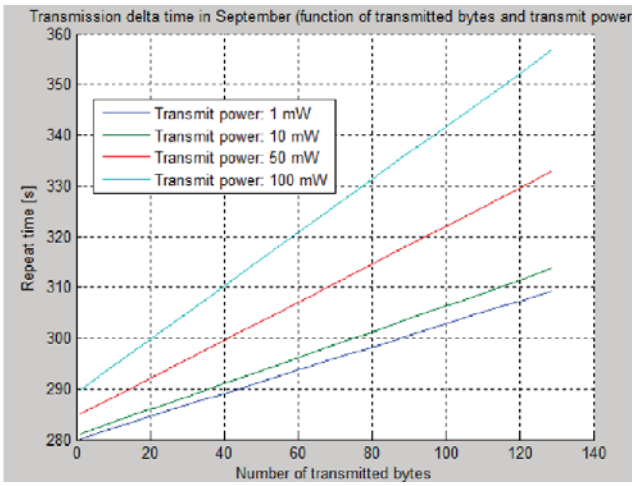

Fig. 9. The time between each transmission as a function of message length, transmit power and solar power available in september month (Denmark)

By using the average energy level provided by the solar cell to drive the IoT device it is possible to simulate the Repeat Message Time (MRT), i.e. how often a message can be send as a function of Message Length (ML) and the Transmit Power of the Field IoT Device (TPFID). This simulation result is presented in Fig. 9 where it is noted that it is possible to trade the MRT for ML. Some examples of this are provided in Table V.

TABLE V.

	TPFID [mW]	*ML [bytes]*	*MRT [s]*	*Comment*
1	100	127	356	Long range application, 9km (Fig. 7), long message
2	100	1	290	Long range application, 9km (Fig. 7), short message
3	1	127	310	Short range application, 1,2km (Fig. 7), long message
4	1	1	280	Short range application, 1,2km (Fig. 7), short message

As presented in Table V it is possible to trade ML versus MRT for a wireless IoT sensor located in the field, i.e. an adaptive link can be established. This can be very usable, e.g. if some overcast days limit the harvested solar energy it is possible to reduce the MRT and/or the ML to compensate for this, hence the link becomes adaptive. However, trading ML means sending a shorter message. Often this is possible as illustrated in the scenario (III.A) where only data about temperature, wind, and humidity are needed. These parameters occupy less than 10 bytes.

In general, the behaviour of an IoT device can be programmed into its embedded microcontroller, i.e. it behaves pseudo-intelligently. This behaviour can be programmed by the farmer remotely or the farmer can decide to overrule the pseudo-intelligence behaviour, i.e. manually setup the parameters for the IoT device. An example could be the time before harvest (September for many grain types in Denmark) where the farmer decides to monitor the humidity in the grain and therefore program the field IoT device to only transmit these data with a fixed time interval. Alternatively, the pseudo-intelligence system in the IoT device could monitor the available battery-power and transmit all data with some MRT. If the power drops (e.g. long period with overcast days) the pseudo-intelligence system could adjust the ML and the MRT to adapt to the new level of harvested power. So, if the field IoT devices has been running for some time without any harvested power the MRT and the ML can be adjusted so the battery last longer and when the solar energy is back on the parameters can be adjusted so the battery charges between the transmissions.

V. Conclusion

An energy efficient adaptive wireless link for farms based on IoT technologies has been explored and elaborated by using a simulation model. The model simulates the vital parameters in a wireless IoT link that is based on ZigBee-WSN technologies and real world hardware in form of the transceiver module CC1120 from Texas Instruments and a small form factor solar panel (SZGD6030). It has been found that it is possible to place a wireless IoT device far from the farm-controller by using the elaborated adaptive technologies. Hence, an IoT device placed 9 km from the farm-controller is able to transmit periodic messages every 6 minutes with a payload length of 127 bytes. This amount of payload is sufficient to transmit vital data like those presented and discussed in the disease scenario. Additionally, the presented simulation results support and enable the future design of an adaptive algorithm for IoT nodes. This algorithm could be able to scale the ioT node power consumption according to weather conditions and thereby behave adaptive with respect to the sustainable power available.

***Abstract*—The vowed gain in capacity within the available spectrum and power consumption provided by the Multiple Input Multiple Output (MIMO) systems make it appropriate for current day technologies. The massive MIMO system provides orders of magnitude enhancement in capacity and spectral efficiency. Earlier work shows number of detection techniques[1][8] for MIMO systems. In this paper, previous work of QR-LRL with the enlarged candidate vector set based MIMO detector i.e. Enlarged QR-LRL detector has been extended to Enlarged QR-LRL based massive MIMO detectors for hard/soft output detection. The problem of Empty Vector Set (EVS)[1][2][3] procured during the soft output generation has been worked out by earlier methods but they were inefficient in terms of complexity. Enlarged QR-LRL proposed in previous work solved the EVS problem with less complexity for the MIMO systems and achieves hard as well as soft ML performance. In this paper we have extended this algorithm for the massive MIMO systems where soft as well as hard output of proposed algorithm has been compared with the conventional schemes for the large number of antennas in terms of complexity as well as performance.**

***Keywords* - Massive MIMO; Soft output; Empty vector set; OSIC; QR-LRL; Enlarged QR-LRL.**

I. Introduction

To accomplish the increasing demand of high data rate, link capacity, reliability and spectral efficiency, various new technologies, like 5G, LTE, LTE-Advance, WiMax, etc, are using MIMO systems. In order to increase the throughput, these technologies require large number of antenna system. The systems using tens or hundreds of antennas are known as large/massive MIMO systems. Large antenna array bequeath surplus degree of freedoms and also scales down the power consumption at the base station thus generating essentially less electromagnetic interference. Beam forming, due to the large number of antennas, shun the fading dips in the transmitted signal. [5] discusses how massive MIMO act as a stockpile for number of research problems.

In the massive MIMO systems, the proper detection of transmitted symbols is a major call out due to the large number of antennas on the single terminal. Till now, number of detection techniques have been developed. ML detection[11] is known as optimal detection scheme but has highest complexity. Linear detection techniques, like ZF[6] and MMSE[7], shows degraded performance due to inefficient signal processing. Non linear detection techniques, like VBLAST[8] and QR-MRL[9], uses Ordered Successive Interference Cancellation (OSIC)[10] to mitigate the problem of interference through which linear techniques undergo. However, the later techniques show degraded performance due to error propagation, if the detection of first symbol is erroneous. To abstain from this error propagation in the detection of further symbols, QR-LRL[17] detection technique was introduced where Least Reliable Layer (LRL) is detected first by applying all the constellation points at LRL.

QR-LRL algorithm almost achieves hard ML performance but its complexity increases with the number of antennas. Layered Tabu Search (LTS) algorithm introduced in [18], approaches to ML performance and have low complexity in the massive MIMO systems even for the higher order modulations. These detectors suffer from EVS while generating soft output more firmly at lower order modulations. Various techniques like threshold based, multiple QR decomposition of channel matrix, transforming QR matrix and joint iterative detection and decoding[2][3][15][14] have been developed to mitigate EVS.

In this work, we are proposing the deployment of Enlarged QR-LRL in the massive MIMO systems for the generation of hard/soft output. This work, along with the proficiency of fixing the problem of EVS in case of soft output detection, also has less complexity for the massive MIMO systems than that of the conventional schemes[17][18]. With the enlargement of candidate vector set of QR-LRL, the problem of EVS is resolved while generating soft output and achieves almost hard/soft ML performance. At the same time it avoids multiple QR decomposition and also retains low computational complexity notably in the lower order modulation for the massive MIMO systems.

Rest of the paper is organised as follows. In section II, system model for the massive MIMO systems is introduced. Section III deals with EVS problem in the conventional detection schemes for the soft output generation in MIMO systems. Conventional schemes have been discussed in section IV. Soft output detection using Enlarged QR-LRL for large number of antennas is discussed in section V. Section VI cover the simulation results and complexity is analysed in section

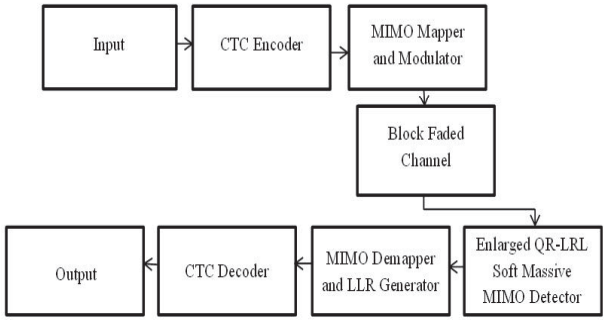

Fig. 1. Massive MIMO system model

VII. Paper has been concluded in section VIII.

II. System Model

The block diagram of massive MIMO system model for soft output generation is depicted in Fig. 1. Consider a system with N_t transmitting antennas at the base station and N_r receiving antennas at the receiver end[4][1][18]. $\mathbf{H}$ denotes the $N_r \times N_t$ block faded Rayleigh channel matrix. Here it is assumed that the complete channel state information is known at both transmitter and receiver end. The received signal $\mathbf{y}$ at the user end is given by

$$\mathbf{y} = \mathbf{Hx} + \mathbf{z} \tag{1}$$

$\mathbf{y} = [y_1, y_2, ..., y_{N_r}]$ denotes the received sequence, $\mathbf{x} = [x_1, x_2, ..., x_{N_t}]$ is the transmitted data sequence and $\mathbf{z} \sim CN(0, \sigma^2)$ denotes the circular symmetric Gaussian noise. Modulation alphabet, C, decides the order of modulation. MIMO mapper in Fig. 1, maps the single stream of data into N_t data streams. MIMO Demapper and LLR generator maps the modulated N_r data streams back to single stream of LLR values. In order to encode the input sequence and decode the soft detected sequence, Convolutional TURBO Code (CTC) Channel Encoder and Decoder has been used.

III. EVS Problem

In order to obtain the Log Likelihood Ratio (LLR) value for k^{th} bit of j^{th} symbol, where, $k = 1, 2, \ldots, log_2|C|$ and $j = 1, 2, \ldots, N_t$, distances $D^+(x) = \frac{1}{\sigma^2}||y - Hx^+||$ and $D^-(x) = \frac{1}{\sigma^2}||y - Hx^-||$ are calculated. x^+ and x^- belongs to the candidate vector set $P(k,j)^-$ and $P(k,j)^+$, corresponding to the k^{th} bit i.e. $b(k,j) = -1$ or $b(k,j) = +1$, respectively. σ^2 is the power of the transmitted signal. Therefore, LLR value can be calculated as follows:

$$LLR(b(k,j)|y) = \min_{x^- \in P(k,j)^-} D^-(x) - \min_{x^+ \in P(k,j)^+} D^+(x) \tag{2}$$

The problem of empty vector set arises when either $P(k,j)^+$ or $P(k,j)^-$ is an empty set. Due to this, LLR values cannot be obtained, thus curbing the generation of soft output values. Previously, multiple methods have been employed to overcome the problem of EVS. Best possible method to mitigate the problem of EVS is by applying all the constellation points at each layer.

TABLE I
QR-LRL Algorithm

$\hat{x}_{ordered} = \hat{x}(:, ind)$
$end\ function$

IV. Conventional Schemes

A. LTS Massive MIMO Detector[12]

LTS algorithm was developed specifically for the massive MIMO system by employing layering approach with the Tabu Search (TS) algorithm. In this algorithm, local neighbourhood is explored to detect a sub-vector that act as an initial solution for the detection of the further layers. The complete algorithm has been discussed in [18]. The complexity of this algorithm mainly depends upon i) Total number of local neighbours considered (maximum value depends on order of modulation) ii) δ, a constant ($0 \leq \delta \leq 0.5$) which is responsible for the switching between the OSIC detection and TS detection (OSIC and TS if $\delta > 0$ and pure TS if $\delta = 0$). As δ tends to 0, performance improves but leads to high computational complexity.

As this algorithm in case of the soft output detection, does not involves application of all the constellation points at any layer for the symbol detection, thus it diversifies the scope of formation of the empty vector sets. To resolve this problem, the detected vector $d = [\hat{x}_1, \hat{x}_2, \ldots, \hat{x}_{Nt}]$ is mapped to bit vector $b_i = [b_{i,1}, b_{i,2}, ..., b_{i,k}]$, where $k = log_2|C|$ and $b_{i,j} \in [-1, 1]$, $i = 1, 2, ..., N_t$ and $j = 1, 2, ..., k$. d_i^{j+} and d_i^{j-} are the detected vectors with j_{th} bit of i_{th} symbol forced to be +1 and -1, respectively. Now, if

$$||\mathbf{y} - \mathbf{H}d_i^{j-}||^2 - ||\mathbf{y} - \mathbf{H}d_i^{j+}||^2 > 0 \tag{3}$$

then j^{th} bit of i^{th} symbol is likely to be +1, otherwise -1. In order to shun the unbounded increase with the increase in number of antennas, authors in [18] introduced a normalization factor $(\frac{\lambda_{i,j}}{2})^2||h_i||^2$.

B. QR-LRL MIMO Detector[17]
