QR-LRL detection technique employs OSIC method for detection but in order to mitigate the problem of error propagation in OSIC, it tries all the constellation points at the least reliable layer. For 4×4 MIMO system, the complete algorithm is summarized in Table I. The channel matrix $\mathbf{H}$ is ordered

TABLE II
ENLARGED QR-LRL ALGORITHM

$function[V_{1,2}Dist_{1,2}] = V_{LRL,MRL}(\mathbf{y}, \mathbf{H}_{ordered})$
$[Q, R] = qr(\mathbf{H}_{ordered})$
$\hat{y} = Q^H\mathbf{y}$
$for\ j = 1 : |C|$
$\hat{x}_{(4)} = C(j)$
$\hat{x}_{(3)} = M\left(\frac{\hat{y}_3 - R_{34}\hat{x}_{(4)}}{R_{33}}\right)$
$\hat{x}_{(2)} = M\left(\frac{\hat{y}_2 - R_{23}\hat{x}_{(3)} - R_{24}\hat{x}_{(4)}}{R_{22}}\right)$
$\hat{x}_{(1)} = M\left(\frac{\hat{y}_1 - R_{12}\hat{x}_{(2)} - R_{13}\hat{x}_{(3)} - R_{14}\hat{x}_{(4)}}{R_{11}}\right)$
$V_{LRL} = [\hat{x}_{(1)}, \hat{x}_{(2)}, \hat{x}_{(3)}, \hat{x}_{(4)}]^T$
$dis_{LRL}(:, j) = ||\mathbf{y} - \mathbf{H}_{ordered}V_{LRL}(:, j)||^2$
end
$for\ j = 1 : |C|$
$\hat{x}_{(3)} = C(j)$
$\hat{x}_{(4)} = M\left(\frac{\hat{y}_3 - R_{33}\hat{x}_{(3)}}{R_{34}}\right)$
$\hat{x}_{(2)} = M\left(\frac{\hat{y}_2 - R_{23}\hat{x}_{(3)} - R_{24}\hat{x}_{(4)}}{R_{22}}\right)$
$\hat{x}_{(1)} = M\left(\frac{\hat{y}_1 - R_{12}\hat{x}_{(2)} - R_{13}\hat{x}_{(3)} - R_{14}\hat{x}_{(4)}}{R_{11}}\right)$
$V_{MRL} = [\hat{x}_{(1)}, \hat{x}_{(2)}, \hat{x}_{(3)}, \hat{x}_{(4)}]^T$
$dis_{MRL}(:, j) = ||\mathbf{y} - \mathbf{H}_{ordered}V_{MRL}(:, j)||^2$
end
$V_{1,2} = [V_{LRL}V_{MRL}]$
$Dist_{1,2} = [dis_{LRL}dis_{MRL}]$
$end\ function$

using post detection SINR, i.e. $||\mathbf{G}||^2$ (where $\mathbf{G} = \mathbf{H}^{-1}$). Therefore, the ordered channel matrix is given as

$$\mathbf{H}_{ordered} = [\hat{h}_{(N_t-1)^{th}RL}, ..., \hat{h}_{MRL}, \hat{h}_{LRL}] \tag{4}$$

In table, M is a mapping function which maps the detected symbols to the nearest constellation point. BER performance of this algorithm approaches to ML performance for hard detection. Post detection SINR based ordering of $\mathbf{H}$ involves matrix inversion which results in higher complexity (of the order of $O(N_t^3)$ for the large antenna systems. Since all the constellation points are applied only at LRL, therefore the problem of EVS may perceived in the detection of further layers.

In order to get rid of this problem , threshold value is derived at LRL where the candidate vector set corresponding to each bit cannot be empty. This threshold value is used to derive LLR values for the further layers suffering from EVS. After calculating LLR at LRL using (4), threshold value is given by

$$Thres = \frac{1}{log_2|C|}\sum_{k=1}^{log_2|C|} Th(k) \tag{5}$$

where, Th is evaluated as

$$Th(k) = max[Th^+(k), Th^-(k)] \tag{6}$$

given, $Th^+(k) = \min_{\mathbf{x}\in P(k,(m))^+} D^+(x), m = 1, 2, \ldots, |C|$ and $Th^-(k) = \min_{\mathbf{x}\in P(k,(m))^-} D^-(x), m = 1, 2, \ldots, |C|$.

TABLE III
ENLARGE VECTOR SET AT 3^{rd} LAYER DETECTION

end
$V_3(:, k, i) = [\hat{x}_{(1)}, \hat{x}_{(2)}, \hat{x}_{(3)}, \hat{x}_{(4)}]^T$
$Dist_3(:, k, i) = ||\mathbf{y} - \mathbf{R}V_3(:, k, i)||^2$
end
end
$V_{cand,3}(:, 1 : C) = (min(V_3(:, 1, :)).....min(V_3(:, C, :)))$
$V_{S3} = [V_{1,2}V_{cand,3}]$
$end\ function$

V. PROPOSED SCHEME

Consider the system model mentioned in section III. Likewise in QR-LRL scheme, Enlarged QR-LRL also utilises ordered $\mathbf{H}$ that tends to mitigate the interference. Therefore, the received vector is given by:

$$\mathbf{y} = \mathbf{H}_{ordered}\mathbf{x}_{ordered} + \mathbf{z} \tag{7}$$

where, $\mathbf{H}_{ordered}$ is the ordered channel matrix (given by (4)) and $\mathbf{x}_{ordered}$ is ordered transmitted vector represented as follows:

$$\mathbf{x}_{ordered} = [\hat{x}_{(N_t-1)^{th}RL}, ..., \hat{x}_{MRL}, \hat{x}_{LRL}] \tag{8}$$

Instead of applying strict post detection SINR based ordering criteria to $\mathbf{H}$, since almost all the constellation points are applied at each layer, this algorithm employs simply SNR based ordering. This reduces the complexity to some extent as it avoids inverse of $\mathbf{H}$ matrix. The complete algorithm for Enlarged QR-LRL has been discussed in Table II and Table III. For the simplicity, 4×4 MIMO system has been considered.

For the detection purpose, first the ordered channel matrix is decomposed using QR decomposition method. Application of each constellation point at LRL and MRL is possible due to the upper triangular structure of R matrix obtained from QR decomposition of $\mathbf{H}$. V_{LRL} and V_{MRL} denotes the two vector set obtained by applying all constellation points at LRL and MRL respectively. These vector sets will not suffer from the problem of EVS as all the constellation points have been applied here. $V_{1,2}$ is the combined vector set defined as $([V_{41}....V_{44}], [V_{31}.....V_{34}])$ and the combined distance vector $Dist_{1,2}$ consists of the distance values for $V_{1,2}$.

For the detection of third layer, $V_{1,2}$ act as the enlarged vector set. U vectors from the enlarged vector set with the

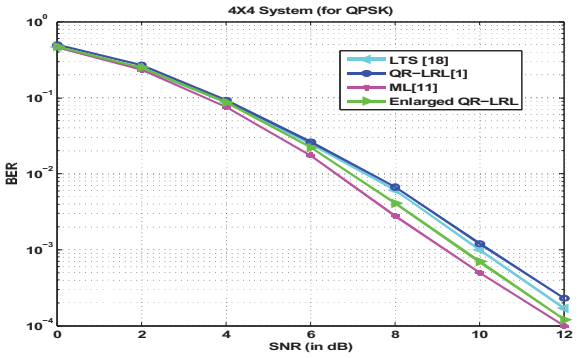

Fig. 2. BER Performance for 4x4 system with QPSK Modulation scheme

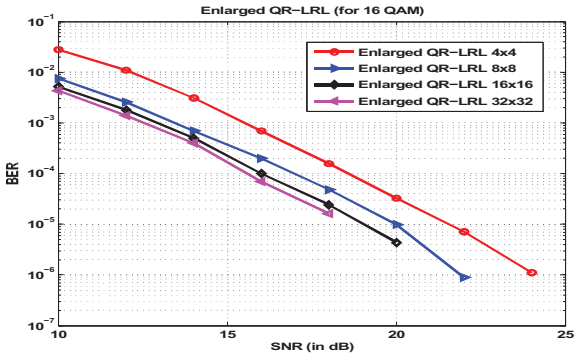

Fig. 3. BER comparison for different diversity order with 16-QAM modulation scheme

least distances in distance vector $Dist_{1,2}$ are chosen in order to avoid error propagation, where U$\leq |C|$.

$$V_{1,2}(i,j) = [\hat{x}_{(3^{rd}RL)}, \hat{x}_{(2^{nd}RL)}, \hat{x}_{(MRL)}, \hat{x}_{(LRL)}] \quad (9)$$

Considering these U vectors, detection of third layer (2^{nd}RL) is carried out by applying each constellation point at 2^{nd}RL, while $\hat{x}_{(4)}$ and $\hat{x}_{(3)}$ are symbols chosen same as x_{LRL} and x_{MRL}. V_3 denotes the resultant candidate vector set corresponding to the third layer detection. Now, V_3 is arranged by grouping vectors that uses same constellation point at 3^{rd} layer and than $V_{cand,3}$ is formed by choosing group wise minimum distance vectors from V_3 according to $Dist_3$. Again for the detection of further layer the candidate vector is enlarged by combining $V_{cand,3}$ vectors with that of $V_{1,2}$ and whole process is repeated until the last layer is detected.

After the detection of each layer, LLR values are raised in the same way as discussed in section III and then these LLR values are fed to TURBO decoder to retrieve the input symbols in case of soft output detection. The value of U is generally chosen small (here, $U = 1$) due to the least error propagation property of QR-LRL. The complexity of this algorithm increases with the higher order modulation. We have implemented this algorithm for the massive MIMO systems.

VI. Simulation Results

The massive MIMO system taken into account for the simulation purpose consists of different order of transmitting and receiving antennas i.e. 4, 8, 16 and 32. It is assumed that the perfect channel information is known at both transmitting and receiving end. The system model considers that the channel is Rayleigh block faded. 1/2 rate Convolutional TURBO code (CTC) has been used as channel encoder and CTC decoder is used to decode the detected soft output.

Fig. 2 evaluates the BER performance of 4×4 MIMO system with QPSK modulation. ML detector shows 10^{-3} BER at 9.2 dB (apx.) SNR while LTS, QR-LRL and Enlarged QR-LRL provide same BER at SNR of 10 dB, 10.2 dB and 9.6 dB respectively. This verifies that BER curve of Enlarged QR-LRL overlaps the ML curve. Fig. 3 shows the comparison of the system using Enlarged QR-LRL with 16-QAM modulation for the different diversity orders. From the

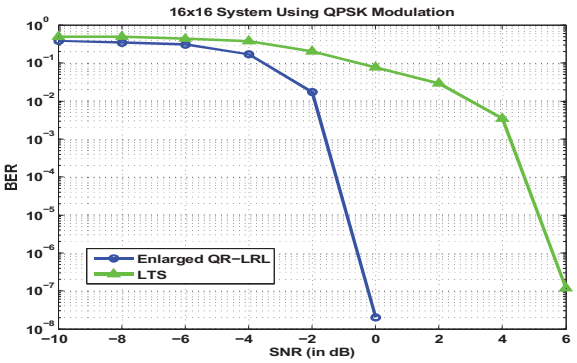

Fig. 4. Soft output BER comparison of 16x16 system with QPSK as modulation scheme

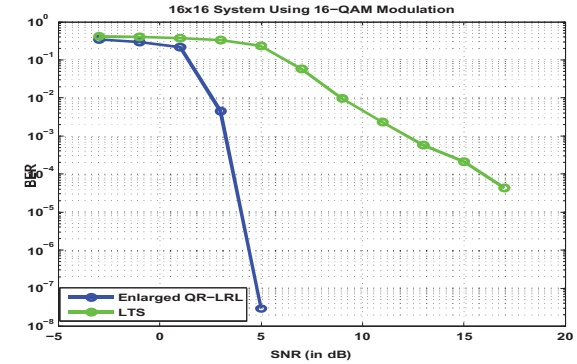

Fig. 5. Soft output BER comparison of 16x16 system with 16-QAM as modulation scheme

TABLE IV
Complexity Comparision of different detection schemes for MIMO systems of different diversity order(Real operations)

Method(with 16 QAM)	8×8	16×16	32×32
QR-LRL	9056	52,148	3,35,744
LTS(with ordering)	24,644	1,35,082	7,64,297
Enlarged QR-LRL	11,648	52,736	2,72,384

TABLE V
COMPLEXITY OF $N_t \times N_r$ ENLARGED QR-LRL ALGORITHM

Operation	No. of **M**
$\|\|h_i\|\|^2_{i=1,2...N_t}$	$2N_r$
$QR_{decomposition}$	$4N_t^2N_r$
$Q^H y$	$4N_tN_r$
$\|\|d-Rx\|\|^2@LRL$	$8(N_t(N_t+1)/2)$
$\|\|d-Rx\|\|^2@MRL$	$8(N_t(N_t+1)/2)$
.	
.	
$\|\|d-Rx\|\|^2@N_t^{th}RL$	$8(N_t(N_t+1)/2)$
$s=(6N_tN_r+4N_t^2N_r+8(N_t(N_t+1)/2)\|C\|(\sum_{i=3}^{N_t}L_i+2))$	

curves it is perceived that as the diversity order of the system increases, the BER performance of the system gets refined.

The comparison of Soft BER performance of LTS and Enlarged QR-LRL with QPSK modulation scheme is shown in Fig. 4 and with 16-QAM modulation scheme in Fig. 5. The figures distinctly show that Enlarged QR-LRL attains BER of 10^{-4} at SNR of -1.5 dB (for QPSK) and 3.5 dB (for 16-QAM) while LTS attains same BER at SNR of 4.5 dB (for QPSK) and 12 dB (for 16-QAM). Hence, the proposed scheme shows the gain of around 6 to 8.5 dB than that of LTS.

VII. COMPLEXITY ANALYSIS

Table IV and V shows the complexity analysis of MIMO system with different detection schemes in terms of number of M Multiplications[13][16]. $|C|$ denotes the number of constellation points and m indicates the QR-m. QR decomposition is used in the algorithm in order reduce the complexity as R matrix is used for multiplication with constellation points instead of taking inverse of H.

Table V gives the complexity analysis for $N_t \times N_r$ system using Enlarged QR-LRL and Table IV shows complexity comparison for 8×8, 16×16 and 32×32 MIMO system using 16-QAM modulation scheme which clearly shows that the QR-LRL becomes more complex as diversity of the system increases in comparison to Enlarged QR-LRL due to the inverse of H involved in QR-LRL. Similarly, a huge complexity difference can be observed between Enlarged QR-LRL and LTS detection scheme.

VIII. CONCLUSION

In this paper, detection algorithm of Enlarged QR-LRL has been implemented for the massive MIMO system for hard as well as soft output detection. The proposed method outperforms the conventional detection schemes both in terms of BER performance and complexity. The problem of EVS, encountered while performing soft output detection, has been mitigated by applying all the constellation points at every layer. In simulation results we have compared hard/soft BER performance of proposed scheme Enlarged QR-LRL with LTS which clearly shows that the proposed scheme gives near ML performance along with low complexity for different modulation schemes.

IX. ACKNOWLEDGEMENT

The work has been carried out as a part of the activity under the project Mobile Broadband Service Support over Cognitive Radio Networks sponsored by Information Technology Research Agency (ITRA), Department of Electronics and Information Technology (DeitY), Govt. of India.

ABSTRACT

Purpose

The ability to make business model innovation has been known for more than a decade. The support and the ability of BMI provides for companies wanting to push their business can be seen in increasing number of cases, in the literature. The technology now provides the next phase of BMI with persuasive technology. The purpose with this paper is to explore the possibilities and challenges that arise with the servitization, BMI and persuasive business models, in relation to understanding, development and implementation.

Design/methodology/approach

This paper is based on a qualitative case study using a deductive approach. This is combined in a participatory action research and insider-as-researcher framework. The point of view in the case is from both the business and the researchers point of view. The discussion section is fully from the researchers' side.

Findings

The ability to find and work with new business models are matured in both technology and business organizations. The competences in the business requires structure through a more visible generic framework for SMEs' to follow. New frameworks and competences are needed to maintain a required pace of implementation for all sizes of businesses.

Keywords: Business model innovation, Servitization, persuasive business models, Big Data.

INTRODUCTION

Emerging trends indicates that the aftereffect of globalization has changed how manufacturing organizations operate and expand their businesses on a global scale. This can be explained by looking at how the competitive situation is forcing these manufacturing organizations to shift their business models towards differentiating away from commoditization that arises from development countries with low labor costs [1, 2]. The difficulty on competing against the exportation of low cost commodity products is typically associated with fixed costs that are bound to operations. Meanwhile manufacturing organizations from development countries are more flexible and able to expand their market share by competing on exporting low costs products [1, 3].

In addition to this, the ripple effect of globalization indicates that the manufacturing organizations has removed boundaries between countries, economies and industries, resulting in technologies that are ever fast changing. At the same time, the requirement of processes needed to be redesigned and communication to become faster and available at any given place and time [3]. Another perspective shows customers changing how they interact with technology, requiring organizations to rethink their way of approaching how value is offered to their customers [1, 4].
In an effort to counteract, this requires manufacturing organizations in the industrialized countries to rethink their way of doing business in order to survive, be competitive and create profit [5, 6].

The historical events indicate that organizations that have focused on delivering desirable tangible products, on a transactional basis have met the specific needs of the customer. However, the value delivered through the goods-dominant view has changed, to a more service-dominant view [7], were intangible values, exchange processes and relationships are primary factors to consider in the long-term strategic perspective for organizations to be successful [6, 8]. In addition, the increasing trend and use of the terminology; the

service-dominant view has been influenced by changes in the customers´ demand through requested goods and services in integrated solutions [5]. This new transactional view has changed the way, in which manufacturing organizations focus less on manufacturing products and more on adding value to their customers through service. Some of the aspects related to this are technology improvements, intellectual property, etc., that the manufacturing organizations differentiate and diversify their value propositions after [9].

Recent literature reveals new ways to gain revenue streams on improved product-service offerings for traditional manufacturing organizations by focusing on system solutions [10]. Relating this to the globalization effect only highlights the importance of innovating on the service offerings with the customers centered in the development process, hence escaping commoditization, whereas goods-dominant focused manufacturing organizations spread to low-labor countries to survive [11].

Another way to diversify businesses to avoid the commoditization is to focus on identifying new trends occurring within the ecosystem. The literature study conducted in relation to this article suggests that data is one of these new trends, in which the data plays an important part on identifying value to the customers [12]. More so, data acts as the gateway to optimize service business models, create new business models and to better understand what customers' value [13].

Research shows that up to 64 per cent of organizations in 2013 are heavily investing, or planning to invest in big data technology [12]. According to this study, there are challenges with adopting big data, and it is not concerning the technology, but rather about where and how big data creates value. According to [12], the synthesis of current literature on big data suggests two areas as for how big data creates value. The first idea, concerns big data used for the incremental improvement and optimization of existing services, and second, new products and business models can be innovated based on the use of data.

Recent trends indicate that organizations are actively focused on redefining their value offerings to the customers, through the use of business models innovation [14]. This typically results in incremental improvements and cost reduction to the current products or services offered. However, on rare occasions it happens that organizations decide to conduct significant changes to their business model with a focus that extends further beyond the value proposition including more aspects of the business e.g. Ryanair, IBM, and Apple etc. [15]. Further research indicates that Business Model Innovation (BMI) is important and relates this to the organizations ability to create breakthrough and game-changing business models that redefines markets [15]. These business models usually commercialize new ideas and technologies. [16] argues that business models play an important role regarding technology, its success and ability to transfer value to the customer.

The purpose with this paper is therefore to describe how to counteract commoditization through business model innovation by shifting between business models of a European Electronics Manufacturer that follows a product-oriented logic towards service-oriented logic offering solutions for their customers, using persuasive service-business models.

METHODOLOGY

The applied research method for this research, has been participatory action research (PAR). The data collection and timing is considered a cross-sectional study with qualitative data gathered from primary, secondary and tertiary sources from unstructured and semi-structured interviews.
There is no single definition on action research (AR), but the definition by [17] is adopted as an approach in which the action researcher and the client collaborate in the diagnosis of a problem and in the development of a solution, based on the diagnosis.
The researchers participated in the companies daily routine from a management perspective, with the purpose to describe and change the behavior. The ontology is seen as an idealist approach that produces a reality created by the researchers, but with the AR being almost instantly is tested and shared with actors for a common understanding towards issues, that in turn creates a snowball effect of new issues and insights. This bottom up effect creates an abductive strategy to understand more complex problems that at first

glance not is revealed through qualitative data collection. This approach compliments the AR research strategy with the iterations for thicker data collection and deeper understanding.

The implications from the AR research method, is that the researchers have to be more rigorous in documenting the research, and look for the theoretical justification on the action part of the research. The close collaboration with management of the company allowed for this less linear approach to the problem where the action part of the research related to more knowledge sharing of the possibilities of persuasive business models, than the more direct approach of an end-product within a certain time-frame and budget.

Throughout the different phases of the research, described as fact finding and analysis, coordination of the action planning, action taken of implementing the knowledge etc., and the evaluation, great care was taken in order to avoid the over involvement of the researchers. This was done by confronting in an informal way with findings, before sharing on workshops etc., and thereby avoiding the consulting role of the researchers. Therefore, no action the researchers has taken throughout the study, has been based on time- or budget goals. This in turn also lengthen the research period due to ownership issues within the organization.

CASE STUDY OF A EUROPEAN ELECTRONICS MANUFACTURER

The following section deals with the case study of a European Electronics Manufacturer (EEM) in relation to the emerging trends presented above. In addition to this, the business model cube and process of business model innovation is also related to the case study with the purpose of drawing parallels to the transformation process from a product-oriented logic towards service-oriented logic. However, the purpose of the research conducted on this case company was to introduce the concept of service business models as complementary to the current business model.

The EEM, founded in 1933 is an international manufacturing organization of advanced power management controllers, power control units and protection equipment for both land and marine. Today, the EEM employs over 600 employees in 11 subsidiaries, half of these placed in the headquarters with a turnover reaching in the access of 85 mio. EUR.
One of the strategy goals besides increasing the turnover by a fixed percentage each year is to avoid increasing the fixed costs, which is approximately half of their turnover.
Another strategic goal is to increase their market share by investing resources in business model innovation.

The current concern in the organization is to limit the costs meanwhile expanding their business. This proves to be difficult at times regarding projects at certain sizes in which some departments do not have the necessary resources to handle, and therefore must decline requests from customers.

The competitive situation on the market is changing with emerging new manufacturing organizations from development countries starting to develop and match products for power management solutions. This situation is therefore seen as a great indication for the EEM to change their current business model. However, internally in the organization it is not a concern for most employees due to the mindset that the EEM is able to provide better service, know-how and quality than its competition. In contrast to this some employees acknowledge that it is only a matter of time before this is no longer the case, and therefore change is necessary for the EEM to gain a better and stronger position on the market.

The EEM describes their customers as being conservative towards change to technology, whereas some customers are not interested in this. Although, it can be argued if the customers do not know what effect new technology can have on their products or if they simply do not need it. In either case, it is a mental barrier for the EEM to sell their newest products, meanwhile they are forces to prolong the life cycle of old products. This means that retrofitting and aftersales are very difficult to accomplish even though, the newest products hardware provide great efficiency in relation to the old products.
The customer base is consisting of above 6000 customers with a Pareto rule (20 percent of the customers stands for 80 percent of the revenue).

The service perception prior and after the Turnkey System Solution projects (TSS), was characterized as a sidekick to the actual physical products. Service had been an Achilles heel for EEM, where increasingly more complex products ends up at customers fixed on price. This combined increases the support workload on the organization and a dedicated unit now functions as a barrier for the developers. This increases the fixed

cost and questions the ability for the EEM to deliver products that fits the needs for their customers.
The mantra for the organization has been to select partners that mount and integrate the EEM products and maintain the products after the installation is done. These partners are closely related to the EEM and are trusted partners. Managers in the organization therefore sees service as something that the "others" should do and not the core competence at the EEM.

One service that the company is aware of and is not that proud of is the old products and the ability for the customers to always have the opportunity to order old and in some cases technical obsolete products. These old products also demand special customization, and this customization demands resources and the service does only in large scale products come with a fee.

The administration at the EEM has a hard time tracking the efficiency of the support department and lacks transparency of the time spend on service and support

DISCUSSION - THE EEM'S TRANSFORMATION PROCESS

This discussion will focus on the capabilities and process of getting to acknowledge and use service for more than "just" basic service and support to customers.
The first step is to establish an ambidextrous service organization that has the responsibility to handle all of the EEMs service and support and to create service business models that are complementary to the current business model. Although this seems to be the challenge for the EEM to realize due to their internal misalignment between departments with different agendas. The internal research provided the researchers with several barriers towards the terminology of service, mostly related to current culture, hinted at a product-oriented logic, but also towards resistance in not knowing what changes might have as influence on the employees' daily activities.
It is therefore seen as problematic to align the service organization with the current, AS-IS business model at the EEM, because of existing sub-cultures.

In order to reach scalability on the service organization and have simplicity of the structure, it is important that the departments can agree on both the level of service that is delivered and the technological platform to develop from. The standardization is a natural step for the EEM in relation to their evolvement into a larger organization, having to control a larger fleet of employees and products.

THE EEM ON SERVITIZATION

The terminology of service at the EEM is defined and understood as relation to basic support of products and in rare occasions as intermediate services [18] provided as complementary to technical project support. However, service is not defined or agreed upon internally among the different departments and therefore the service offerings varies from department to department, what kind and what level of service is provided by the EEM. In some cases, service is seen as an opportunity to close a deal with new customers, meanwhile experiencing customers approaching the EEM for specific services as solutions.
In relation to the product-oriented perspective, the EEM is not capable, to fully understand the concept of Servitization and certainly not aware of what possibilities there exists beyond basic service and support on their own or customers' products.

THE EEM ON DATA GATHERING TECHNOLOGY

At the current state, the EEMs products allow for data gathering technology to be applied, but it does not currently play an important role regarding intermediate services, also in relation to provide consultancy in complex and technical environments. To specify, the EEM has awareness on the need for data to create new opportunities, hence to start doing business model innovation. However, they need the technology to do so. The new technology also has to accommodate for future services and old ones currently present at the EEM. Therefore, the technologies related to both products and services has to be managed through a technological platform as support for the activities in the PSS to provide value through service business models. Such a technology platform can be viewed as the Smart Monitoring (Remote Monitoring – system/Conditioned monitoring) that consists of different hardware and software components allowing the organization to receive and send data with the outcome of delivering valid and reliable information to

customers that value this. This will require the organization to have a data management system that can capture and categorize data, then transform this into values, either visual (graphs or diagrams), or as numbering tables.

It is essential for the EEM to invest resources into technology, as this is the key driver for creating service business models using data. In addition to this, it is also important that the EEM have the capabilities through human resources to maintain the business intelligence unit that sorts and analyzes data into usable and decision making information to act on.

THE EEM ON NEW BUSINESS OPPORTUNITIES

The EEM has experienced a new opportunity to shift from being sub-supplier towards entering the role of project entrepreneur in high-scaled projects interacting with the high-end and decision making customers. This shift, demands more of the EEM in terms of resources required to fulfill the role of project coordination, product specifications, power systems design etc.

As the project entrepreneur of these large scale projects, it provides the EEM with an opportunity to expand the scope of supply to more than products, because they are also responsible for part of service and support. This is what the EEM defines as Turnkey System Solutions (TSS).

Although, these type of projects does not come without challenges. To specify, the organization do not have the necessary training or understanding of what possibilities follows selling TSS projects, and to the extent of what value the customers can receive from services that becomes available from this.

There is also the issue regarding TSS projects that changes the market situation in which the EEM competes against own customers, bidding on the same projects.

CONCLUSION

The case study clearly indicates that there is a need for establishing a framework to structure and maintain service business models at the EEM. The researchers' will argue that such a framework will help create a functioning service organization to offer not only customized solutions for their customers, but the standardization of service, which is needed. It will also be an opportunity for the EEM to merge their technology platform with such a framework to ensure alignment between developing persuasive technologies and transform this into value for the customers through service business models. To specify, the EEM will need to invest resources into the data gathering technology in order to enable the receiving, storing and analyzing of data. This data has the potentiality to visually explain the customers' behavioral patterns that in turn can be useful to create or update the value proposition with new knowledge on how the customers' actually use the EEMs products. By modifying the value proposition, new opportunities might arise that leads to new services to offer the customers, hence the persuasive service business model approach.

The EEM stands as the only organization on their market to act and focus on service business models using data as the source of value creating activities. It is therefore an important first step in the transformation process for the EEM to not only understand the importance of avoiding commoditization by evolving into another way of doing business and delivering value to customers, but also to act on clear defined issues within and outside the organization that needs attention. This is not only of great concern but it is also vital for the survival of the EEM to start readjusting their organization to create the necessary alignment and shared understanding on what is needed to successfully go through such a transformational journey as proposed in this article.

Abstract*— The Balearic Islands have one of the best telecommunications infrastructures in Spain, with more than 1500 Radio Base Stations (RBS) covering a total surface of 4.991,66 km². This archipelago has high energy consumption, with high CO_2 emissions, due to an electrical energy production system mainly based on coal and fossil fuels which is not an environmentally sustainable scenario. The aim of this study is to identify the processes that would reduce the energy consumption and greenhouse gas emissions, designing a target scenario featuring "zero CO_2 emissions" and "100% renewable energies" in RBS. The energy costs, CO_2 emissions and data traffic data used for the study are generated by a sample of RBS from the Balearic Islands. The results are shown in terms of energy performance for a normal and net zero emissions scenarios.

Keywords*— renewable energy; efficiency; net zero; radio base stations; CO2; DVB; Balearic Islands.

I. INTRODUCTION

The energy model of the Balearic Islands is based on imported fossil fuels; almost 97% comes from imported fossil fuels, and the rest comes from *renewable energy sources*, which include the biomass and waste materials and products. Estimating the solar and wind energy they prove to occupy only the 1 % of the total energy production. Transportation has got the biggest impact on the energy consumption – about 54% goes to transportation and 23% of the total energy consumption is destined for air transport [1].

The electricity production requires 46% of the gross energy production, with a global efficiency of 37%. The Balearic Islands energy generation and distribution system is composed of two independent electrical networks, Mallorca-Menorca and Eivissa-Formentera. The Mallorca-Menorca system has been recently connected to the mainland with 2 submarine cables 250 kV High Voltage Direct Current (HVDC) with a maximum power capacity of 400 MW, covering a total distance of 250 km. This provides about 23% of the energy. The main generation system is composed of two thermal power plants responsible for, respectively, 43% and the 23% of the demand on each of the two island subdivisions and a combined cycle central that started last year. The rest is generated in 4 small distributed generation plants [2]. The principal thermal coal power plant, with a nominal power of 510 MW, constitutes the basis of the system. The other power plants assume the peaks of demand in the islands. The described *production model* produces a high amount of CO_2 emissions, because it is based on a coal power plant steam-cycle. The government's Energy Planning Project intends to reduce the *global energy consumption* by 3%, and increase by 10% the use of renewable energy sources (RES) [3].

This paper analyzes the energy consumption for the Balearic radio base stations (RBS) employed to support voice, video and data traffic.

II. CURRENT RBS SCENARIO IN THE BALEARIC ISLANDS

Currently, there are three types of RBS in the Balearic Islands serving the urban, tourist, and rural scenarios. These can be fed by connection to power grid, or isolated powering by a set generator and a set of batteries. An exceptional type of BS serves the island of Cabrera and is powered by a mix of renewable energy sources (RES) with a set of batteries. Finally, there are up to 3 DVB-T stations that lack the infrastructure and are isolated from the power grid and powered by a set generator instead.

A. Mobile and DVB Communications: Data & Energy

Figure 1 shows the time distribution for the load on the three types of RBS analyzed for urban, rural, and tourism voice traffic in the high season period. Figure 2 shows the mobile data traffic for the same period and the same categories. A similar

intensity of traffic per hour can be observed for all three types of traffic. While, the voice traffic is more abundant during the day, tourism mobile data has larger peaks during the night hours.

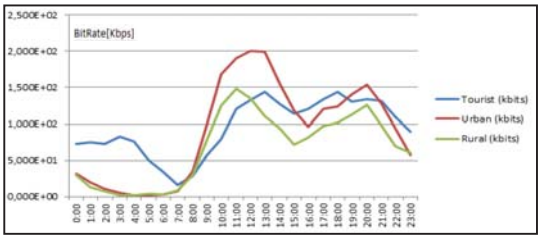

FIGURE 1. Distribution of voice traffic within a day

FIGURE 2. Distribution of traffic Data within a day

[7] provides information about the voice-video-HSDPA annual traffic for the three types of users in the period from 13 May to 14 June. The distributions and variations are shown in Figure 3.

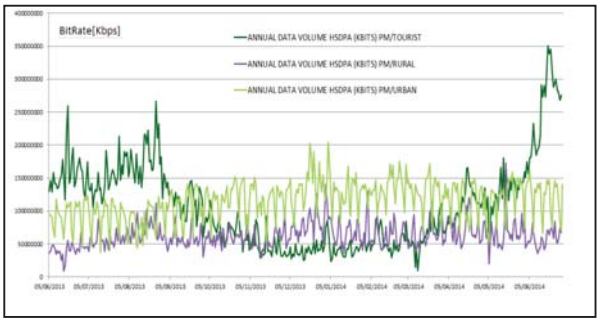

FIGURE 3. Distribution of annual all traffic data downlink at RBS

The rural traffic is more or less uniform throughout the year, while the urban traffic decreases slightly in the summer. During the tourist season, the traffic increases following a parabolic function and then decreases for the rest of the year. The distribution of the annual uplink traffic at the RBS is available in [14]. It follows the same pattern as the downlink traffic, but the data are an order of magnitude smaller. Figure 4 shows the mobile traffic fluctuations in terms of annual energy consumption at the RBS. The energy consumption due to rural mobile traffic stays at the same level throughout the year. The energy consumption due to tourist mobile traffic is higher during the summer months, with an increase in energy consumption for urban mobile traffic during the winter months.

Table 1 shows an estimate of the order of reference variables of mobile telephony, with an annual consumption of up to 58.7 GWh. The RBS consumption depends largely on the number of carriers holding the station by sector; typically rural stations often have up to one, while tourism and urban stations usually have 3 carriers per sector.

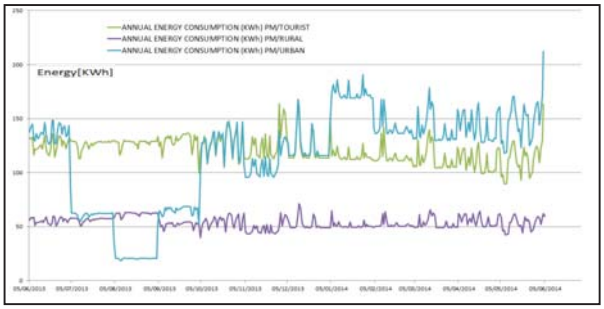

FIGURE 4. Estimation of annual Energy Consumption at RBS

Table 1 shows that tourism traffic during the summer season is the highest consumer of RBS energy. The number of RBSs at the Balearic archipelago is approximately 1586 for mobile communications, and for DVB-T is 64 [7], [8]. Table 2 shows the annual energy consumption of the DVB-T BSs for the various types of traffic. It shows that the rural traffic makes the larger consumer of DVB-T base station energy.

Table 1. Mobile Communications: Data & Energy.

	Annual Data (PBitps) Mobile Communications	Annual Consumption (GWh) Mobile Communications
Urban Station	21,1	28,8
Tourist Station	35,8	32,5
Rural Station	9,4	7,4

Table 2. Digital TV & Radio annual energy consumption.

	Annual Consumption (MWh) TV DVB-T/S
Urban Station	-
Tourist Station	249,616
Rural Station	593,059

The annual curve consumption of the rural DVB-RBS is shown in Figure 5. The DVB-T stations are running 7 x 24 hours constantly.

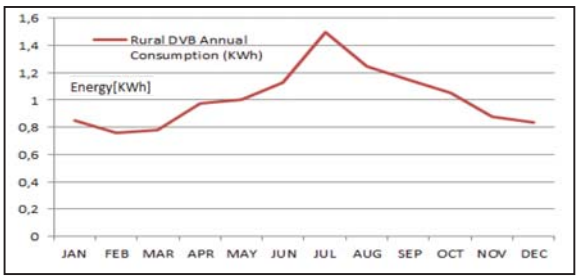

FIGURE 5: Estimated Annual Energy Consumption at DVB- RBS.

III. MODEL RBS VS ENERGY CONSUMPTION

Eq. (1) defines a model for the estimation of the RBS energy consumption. There is a linear correlation, quite similar to the one featured by the energy management systems used for buildings and industrial applications. We can relate the energy consumption to the unitary production, or to a climate variable. Then the linear function model can be defined by two independent variables, $Z\ (x, y)$, which reflect the amount of

datatraffic and the temperature on the days of the region where the study was done (Balearic) [9], [10].

$$Z(x,y) = M \cdot x + N \cdot y + C \quad [1]$$

Where, Z is the electric energy consumption in kWh; M is the unitary consumption in kWh per Gbps; x is given in Gbps; N is a factor defined by the cooling requirements in (18ºC) [kWh/ºC]; y is the temperature averaged for the days (18º) [ºC]; C is a constant in kWh.

There would be a direct relation between the energy consumption and the temperature for the DVB-RBS, which has a constant data traffic throughout the year. The cooling requirements, are known as cooling degree-days (CDDs). We assume that the need for cooling of the RBS would be on the days when the average temperature is above 18ºC. We have made some linear approximations with a polynomial of first order. The correlation index is quite good, however, there are some factors that influence more the temporary energy consumption (e.g., weather, data traffic) [7]. We can improve the approximation by adjusting slightly (1) to achieve (2).

$$Z(y) = N \cdot y + C \quad [2]$$

Eq. (2) does not satisfy the scenario of variable data traffic with variable consumption. We propose instead an alternative variable **α**, which is the *efficiency unitary*, to define the relationship between the electric energy consumption and data traffic vectors. Consequently, we redefine the model efficiency as in (3):

$$\alpha(x,y,z) = M \cdot x + N \cdot y + G.z + C \quad [3]$$

Where, α is in kWh/GBitps; M is the unitary consumption; x is the energy consumption in kWh per month; N is unitary consumption in kWh per Gbps; y is the data traffic in Gbps; Z is the CCD factor in (18ºC) [kWh/ºC] per month; C is a constant in kWh/Gbps. The consumption can then be estimated as in (4):

$$Z[kwh] = \alpha . Y \quad [4]$$

The coefficients $M, N, G, and\ C$ are obtained using the *least squares method* on the empirical data by using Eq. (1) and Eq.(2). When there are more than two explicit variables, the best option is to choose a matrix solution. We calculate the coefficients of a regression for the general matrix case as per the matrix in Table 3.

Table 3. System variables theoretical analysis

$\propto_i$	X_i	Y_i	Z_i	$\propto'_i$	e_i
$\propto_1$	X_1	Y_1	Z_1	$\propto'_1$	e_1
$\propto_2$	X_2	Y_2	Z_2	$\propto'_2$	e_2
.	.	.	.	.	.
.	.	.	.	.	.
$\propto_N$	X_N	Y_N	Z_N	$\propto'_N$	e_N

Where $\alpha'_i = M \cdot X + N \cdot Y + G \cdot Z + C$ is the theoretical efficiency of our model and $\emptyset = \alpha_i - \alpha'_i$ obtains the residuals. The squares function of the residuals is:

$$\emptyset = \sum_{i=1}^{N} e_i^2 = \sum_{i=1}^{N} (\propto_i - M \cdot X - N \cdot Y - G \cdot Z - C)^2 \quad [5]$$

M, N, G and C are calculated so that $\emptyset$ yields minimal empirical values for X, Y, Z. We calculate the derivative and equate to zero the result. For lack of space the elaborate calculations are omitted from the paper. Details can be found in [17].

IV. Simulation Analysis

The expressions for calculating the coefficients are used as the basis for generating the simulation data that is summarized in Tables 4, 5, 6, and 7. The data was processed by the Application Mathematical Software utility Language R.

Table 4. Urban Scenario : Mobile

Coefficients:	M	N	G	C
	0,0002653	-0,0002471	-0,0002056	0,94762
Equation:	α= 0,0002653.X −0,0002471.Y-0,0,0002056.G+0,94762 Z[KWh] = α.Y			
Multiple R-squared:	0.9829	Adjusted R squared:	0.9766	p-value: 2.067e-7

Table 5. Tourist Scenario: Mobile

Coefficients:	M	N	G	C
	0,0007316	-0,0003171	-0,0011118	-0.1240318
Equation:	α= 0,0007316.X −0,0003171.Y-0,0011118.G-0,1240318 Z[KWh] = α.Y			
Multiple R-squared:	0.8958	Adjusted R squared:	0.854	p-value: 0.0002984

Table 6. Rural Scenario: Mobile

Coefficients:	M	N	G	C
	0,0007369	-0,0004460	-0,0004112	0.5340732
Equation:	α= 0,0007339.X −0,0004460.Y-0,0004112.G+0,5340732 Z[KWh] = α.Y			
Multiple R-squared:	0.9632	Adjusted R squared:	0.9494	p-value: 4.43e-6

Table 7. Rural Scenario: Dvb – t/s

Coefficients:	M	N	G	C
	-	-	1,975	846,552
Equation:	α= 1,975.G+846,552 Z[KWh] = α.Y			
Multiple R-squared:	0.8101	Adjusted R squared:	0.7911	p-value: 6,623e-5

Eq. (4) shows that the model of energy consumption is equal to the alpha model for the total transmitted data (voice, video and data). We can then define the transmission efficiency as:

$$\propto_{effic} = \frac{Energy\ Consumption}{bits\ transmitted} =$$

$$\frac{Transmision\ Consumption + Cooling\ Consumption}{bits\ transmitted} =$$

$$\frac{Transmision\ Consumption}{bits\ transmitted} + \frac{Cooling\ Consumption}{bits\ transmitted} =$$

$$\propto_{effic} = \propto_{TC} + \propto_{CC} \quad \textbf{[6]}$$

Note, that the lower the numerical value of α, the greater the efficiency of the transmission system. Eq. (5) is a generic definition to establish the standard operating conditions for the transmission stations under study. The coefficients $(M, N, G, and\ C)$ are obtained by the method of least squares, carrying out the process of calculating the statistical values with language R [11], [12].

The DVB-T model shows that there is only variability in the consumption of the RBS depending on the weather, since this effectively only depends on the temperature. In fact, only the constant term is affected by the maximum amount 1.98Gd 547 kWh better compared to the constant term 860 kWh. Figure 6 shows that the distribution of residuals is very homogeneous in urban and rural stations, whereas it is fluctuant in tourism RBS and therefore a loss of homogeneity can be deducted.

	Median Residuals:	p-value:	Multiple R-squared
Urban MT-RBS	-0.00048	2.067e-7	0.9829
Tourist MT-RBS	0.02093	0.0002989	0.8938
Rural MT-RBS	0.000421	4.436e-6	0.9632
Rural MT-DVB	-27.54	0.001905	0.6354

The model then would be most appropriate to describe the urban or rural RBS, where there is more efficiency in the data transmitted per energy unit. In strict statistical terms, the overall mean of the residuals in the tourist stations is bigger than the rural and urban RBS taking a bigger *p value* and, therefore, a lower value determination.

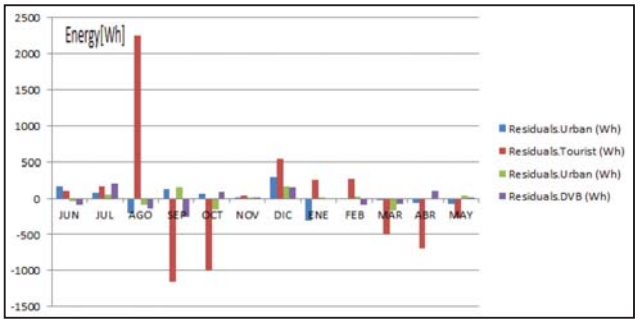

FIGURE 6: Residuals of data processing from the case study.

Table 8 shows a summary of the *correlation index* or determination referred Multiple R - Squared and as this should be inversely proportional to the level of significance or p-value and have a value of the Median Residual value close to 0.

TABLE 8. Statistics Summary from the case study.

	Median Residuals:	p-value:	Multiple R-squared
Urban MT-RBS	-0.00048	2.067e-7	0.9829
Tourist MT-RBS	0.02093	0.0002989	0.8938
Rural MT-RBS	0.000421	4.436e-6	0.9632
Rural MT-DVB	-27.54	0.001905	0.6354

Eq. (3) is the point statistical estimate of an RBS with regard to its efficiency: energy consumption, traffic data (voice-video-data) and the meteorological conditions (cooling degree days 18°C). This same argument applies to the Eq. (1) and Eq. (2) in their respective cases. Eq. (4) can be used for obtaining the punctual efficiency on the DVB RBS, setting the parameter *Y* as a function of the number of Gap fillers, and the bit rate. For example, for 7 MUX Gap Fillers, the monthly total data is Y = 361.065 Gbits.

V. NET ZERO ENERGY IN BALEARIC ISLANDS

A sustainable system can be achieved if the RBS is powered by renewable energy [1, 2]. The total number of RBSs in the Balearic islands is about 1586 - only two of these are not connected to the power grid, whereas out of the total of DVB-T RBS about 63 are connected to the power grid. That means that only one DVB-T RBS is isolated from the power grid. Photovoltaic and wind energy, incorporated in the RBS powering may contribute to the electrical system energy balance. A proposed configuration for both types of RBS would be a combination of *photovoltaic and wind micro turbine* with a storage capability of dual energy backup. Optionally, if space would be available, a set generator may be installed in the RBS for the case when the power grid would be a bit unreliable. For the isolated RBS, the dual energy backup may be implemented by an electrochemical battery as the primary energy backup, while the secondary energy backup may depend on use of a Fuel Cell, or bio fuels such as bio diesel or bio gas. The RBSs are almost in all cases located on the top of the roofs of the highest buildings or in windy sun-exposed isolated areas, which gives a good basis for the use of renewable energy an RBS power source.

By using the same methodology as in previous studies [3,13], according to the hourly simulation, we can determine the future net zero energy in the entire Balearic telecommunication system. The archipelago has areas with more than 2,000 hours equivalent peak wind and photovoltaic panels integrated architecturally with over 1250 equivalent peak solar hours (PSH) per year [14]. On the other hand, statistically the micro cuts duration of power grids in urban areas are about half hour whereas in rural areas is about 6 hour so we sized battery for a time duration of two times the minimum required that is 12 hours with a depth of discharge of the batteries of 25%. Figure 7 shows the energy import and export period for the first quarter of the year. There is a positive balance of annual renewable energy.

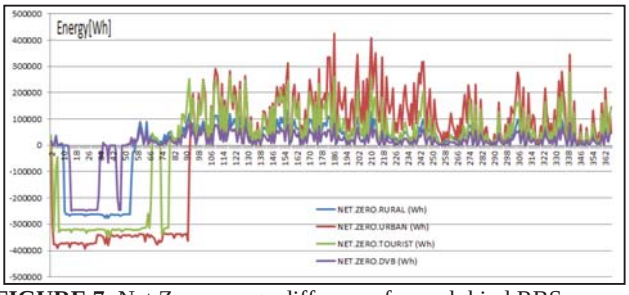

FIGURE 7: Net Zero energy difference for each kind RBS.

Table 9 shows the parameterization zero balance for each type of station, and the result of the minimum possible set balance, based on the installed capacity with commercially available solutions. If all types of stations were fed by renewable energy, the balance model will be under zero from a positive balance of the RES and the distributed energy. Moreover this would affect the environment with no shedding up to 51233.85 tons of

carbon per year, 50526 Tons of CO2 for the Mobile RBS and 707 for the DVB RBS. These statistics are shown in Table 10.

Table 9. Net Zero Energy features for each kind RBS

	Wind Power Install [KW]	Solar Power Install [KWp]	Battery Store Install [KWh]	Energy Import [KWh]	Energy Export [KWh]	Energy Balance [KWh]
Urban MT-RBS	36	9,6	87,840	34,693	35,312	+0.693
Tourist MT-RBS	30	8,5	87,840	23,69	23,712	+0.022
Rural MT- RBS	12	7,4	87,840	12,594	14,252	+1.658
Rural DVB-RBS	9	3,2	15,420	6,019	8,313	+2.294

Table 10. Net Zero energy global features and effect to power grid.

	Global Wind Power Install [KW]	Global Solar Power Install [KWp]	Annual Net Zero Energy [MWh]
Urban MT-RBS	19116	5066	+328,7
Tourist MT-RBS	20790	5877	+15,2
Rural MT- RBS	4092	2530	+565,4
Rural DVB-RBS	576	203	+146,8

VI. CONCLUSIONS

This paper described a model for calculating the dependency between data traffic and energy consumption of the RBS for a scenario on the Balearic Islands. The goal was to present a net zero balance model that can lead to sustainable telecom infrastructure of environmentally friendly nature. The model can be applied universally but the values for the variables would be based on the regional specifics.

Promoting and investing on renewable energies to combat CO_2 emissions is the way to go forward. A setup of a mix of wind micro turbines, and photovoltaic and distributed energy, would stop the discharge of more than 50,000 tons of emissions per year. The overall *zero balance* in the Balearic archipelago is overall positive in the order of 1 GWh as if it were a distributed micro generation, which strengthens the own power grid provide to it some stability. Accordingly, the transmission efficiency is due to be constant since the RBS-DVB would transmit uniformly and the system efficiency would only depends significantly on the efficiency of the cooling of the station itself. This would require an efficient as possible cooling system.

Mobile communications operators with more than 500 RBS in Balearic archipelago could make use of a bidirectional flow of electricity by a dual smart meter so instead that it plays role of net zero agent, it would perform the role of a producer and consumer agent. This opens the road to new business possibilities.

The result of the energy zero net balance would be a saving in primary energy costs or electrical energy coming from the conventional central generator per kWh in electrical renewable energy at the exit point and also a decrease in CO_2 emissions given the CO_2 gr per kWh embedded by the conventional central generator since these would start to be generated by renewable energies.

VII. ACKNOWLEDGMENTS

We would like to acknowledge Mr. Antoni Font Bauza from *Comunitat Autonoma Illes Balears* (CAIB) for the information about DVB-T Radio Base Stations. Special thanks to Mr. Jaime Homar Ferrer de Sant Jordi from Telefonica Spain delegation Baleares for the support during the paper elaboration. Finally, we would like to thank the Spanish Institution Colegio Oficial de Ingenieros de Telecomunicación COIT (Madrid) and the Technical department.

***Abstract* - Cloud Radio Access Network (C-RAN), Multiple Input and Multiple Output (MIMO) and Heterogeneous and Small Cell Networks (HetSNet) support on-demand network bandwidth, heterogeneous device connectivity and optimal usage of network resource operators. The traditional architecture of radio access network supports signal processing and radio frequency functions at the cell sites. This incurs an additional installation and maintenance cost that is not eco-friendly to the environment. Cloud Radio Access Network (C-RAN) combines the features of cloud computing and radio access network where the centralized baseband units are responsible for signal processing and Remote Radio Heads (RRHs) deployed at cell sites are responsible for operations of radio frequency. C-RAN supports Green Technology in which the base station reduces the percentage emission of Carbon Dioxide (CO_2). This article provides a comparative analysis of interference management in HetSNets.**

Keywords: HetSNet, Macro cell, Femto cell, Interference Management, Spectrum Management

I. INTRODUCTION

C-RAN and MIMO technologies have been proposed for future wireless networks along with Heterogeneous and Small Cell Network (HetSNet) where small cells deployed to facilitate Cell On Edge (COE) mobile users [1]. Due to the constraints in radio resources, the mobile users in COE area increase the transmitting power to communicate with the macro cell, otherwise it could lead to call drop. Handoff latency and rate of call drop indicate the performance parameters used by network operators. Small cells are less expensive, easy to install and eco-friendly that support low power transmission. Heterogeneous cells use micro, femto and pico cells [2] [3] with existing macro cell sites to increase the coverage and connectivity in the network. Heterogeneous cell structure depends on cell size, and the antenna position [1]. MIMO technology uses multiple antennas at the transmitter and receiver to increase the coverage area and mitigate multipath fading. The advantages of Heterogeneous and Small Cell Network are as follows:

(i) The deployment of small cells reduces the distance between COE mobile users and micro Base Stations (BS). This reduces the transmission or reception power of mobile users
(ii) Flexible deployment enables the HetSNet to adapt with efficient spectrum management
(iii) Uses power control mechanisms to save the energy and bandwidth constraints [4] in the network

II. INTERFERENCE MANAGEMENT IN HETSNETS

Heterogeneous and Small Cell network of different sizes are installed to enhance and expand the network capacity. The deployment of femto cells in heterogeneous networks not only reduces the cost of installation [5] but also minimizes the micro cellular interference effect on MUE. In HetSNet, the spectrum allocation for small cells [6] and macro cells are same, and this leads to Interference between the cells. There are two types of interference in HetSNets [3] – (i) Cross-Tier interference and (ii) Intra-Tier Interference. Cross-Tier Interference [7] exists between the femto cell and macro cell whereas Intra-Tier Interference exists between the femto cells in the same tier due to densely deployed cells at smaller distance. Separate spectrum allocation for each cell avoids interference but reduces the network capacity and increases the control channel overhead [3]. Table 1 provides the comparative analysis of three spectrum sharing access modes (Open, Closed and Hybrid) in HetSNets. Intra-tier interference is more harmful in closed access mode due to leakage from walls or windows the small cell causes interference to nearby small cell [3] and only a sub-set of subscribed user's access the network.

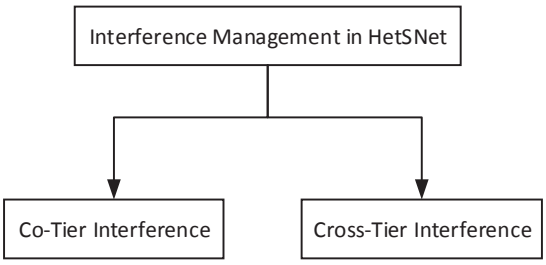

Figure 1. Types of Interference in HetSNet

Table 1. Comparative analysis of Open, Closed and Hybrid spectrum sharing access modes in HetNets [3]

Feature	Open Access Mode	Closed Access Mode	Hybrid Spectrum Sharing
Resource Usage	In Open Access mode, any user can use the resources from small cell.	In Closed Access mode, users can use the resources from the small cell that have subscribed to that particular cell. It is sometimes called Closed Subscriber Group.	This is a combination of Open and Closed Access modes. On demand certain users from outside are allowed to use the network facility. The allocation of subscription is handled by the operator with an approval from the subscriber [3].
Security	Security is the major concern in this method as this mode is open to use for any subscriber	This mode provides better security as only subscribed users are allowed to exploit the services.	This mode also provides better security services as subscribed and certain allowed subscriber from outside are all handled by the operator.
Cost Factor	Easy to install and less expensive.	Expensive compared to Open Access Mode.	Complex and expensive.

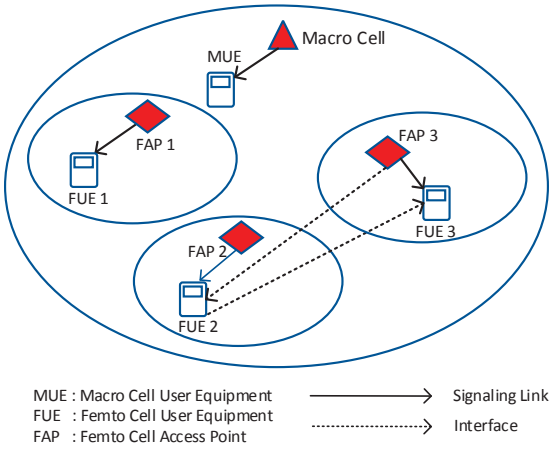

Figure 2. Intra-Tier Interference (Co-Tier)

In Figure 2, FUE 2 causes interference at FUE 3 in the uplink, and FAP 3 causes interference at FUE 2 in the downlink. To mitigate uplink interference the transmit power of FUE should be controlled by the serving Femto cell. Thus, the FAPs should automatically sense the surrounding environment and interfering Femto cells. If the power of FUE is more than the threshold limit, then it should be minimized to avoid interference with the adjacent Femto cell UE or FAPs. Similarly in the downlink, the Femto cell FAP should be able to control its power adaptively. Intra-tier interference for uplink power from femto cell is given as follows:

$$P(femto) = P(UE) + P_{Loss} + D \quad \ldots\ldots\ldots\ldots (1)$$

$P(UE)$ = Power transmitted by Femto UE
P_{Loss} = Path Loss between FAP and FUE
D = Distance between FAP and FUE

Power in femto user equipment is given as follows:

$$P(FUE) = \left(\frac{P(Interference,\ Max)}{No.\ of\ Users_{Femtocell}} \right) + P_{Loss} + WP_{Loss} \quad \ldots\ldots\ldots\ldots (2)$$

Where WP_{Loss} = Wall Penetration Loss.

Cross-Tier interference is due to the interference between the components of macro cell and femto cell networks.

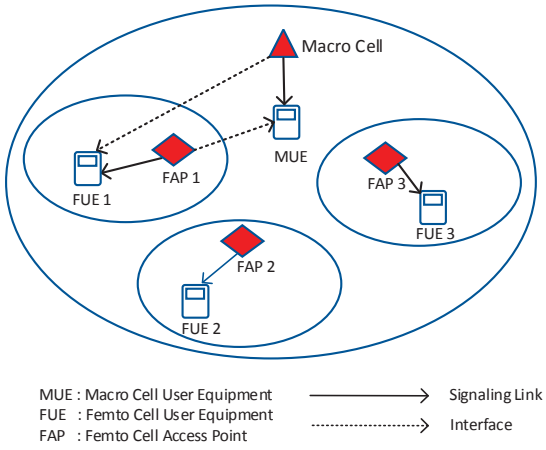

Figure 3. Inter-Tier Interference (Cross-Tier)

The cross-tier interference occurs due to the high power downlink transmission of the femto cell, and the macro cell user is in the vicinity of FUE. Hence, it becomes difficult for MUE to choose the optimal network path. Similarly, if the macro cell user at Cell on Edge (COE), transmits at high power in the uplink channel, then the interference occurs in the nearby femto cell

UE. Inter-tier interference can be reduced by using separate spectrum for macro cell base station and femto cell, but it results in reduced spectral efficiency and spatial reuse. Two schemes that primarily control the power transmission in High Speed Downlink Packet Access for Femto cells [3] are:

(i) Geostatic Power Control Scheme
(ii) Adaptively Power Control Transmission

In Geostatic Power Control Scheme, the power of the network element(s) is controlled from the cell location. In Adaptively Power Control Scheme, the power is controlled with respect to the data rate transmitted by the network element [3]. If more data is to be transmitted, then the power of network element is increased, otherwise the power is reduced to avoid interference. OFDMA femto cells can also be used to mitigate inter-cell interference since the carriers allocated to macro cell base station and femto cells are orthogonal to each other, and hence the interference is avoided. In cross-tier interference, the power transmitted [7] by femto cell base station in downlink channel is given as follows:

$$P(femto) = P(macro) + G + PathLoss\left(f_{FemtoBS}^{MacroBS}, g_{FUE}^{FemtoBS}\right)$$

$$where\ f\ and\ g \in \left(\gamma_{fading}, \zeta_{noise}, \alpha_{attenuation}\right) \quad \ldots\ldots\ldots\ldots (3)$$

$P\ (femto)$ = Downlink power from Femto BS
$P\ (macro)$ = Transmit Power from Macro BS
G = Transmitter Antenna Gain

The power transmitted by femto UE in uplink channel [7] is given as follows:

$$P(FUE) = \frac{P\left(Intfr_{Max}\right)}{No.\ of\ Users_{Femtocell}} + PathLoss\left(f_{FemtoBS}^{MacroBS}\right) \quad \ldots\ldots\ldots\ldots (4)$$

$P\ (Intfr_{Max})$ = Maximum Allowed interference or power to be transmitted from femto cell users to macro base station

The signal to interference and noise ratio gets affected due to interference. Ideally it should be high but due to path loss, wall penetration and interference between cells reduces the interference and noise ratio.

$$SINR = P \Big/ \sum_{i=1}^{n} Interference_i + N \quad \ldots\ldots\ldots\ldots (5)$$

P = Signal Power, $Interference_i$ is the interference for n users,
N = Noise Signal

III. INTERFERENCE MANAGEMENT TECHNIQUES

In HetNets, there are various interference management schemes to enhance the network performance. To handle interference, the messages are shared between the macro cell and nearby small cells with respect to time and frequency domains. Different cells in HetNets deployment are connected to the core network via different backhaul interfaces. Macro cell is connected via S1 interface, pico cell via X2 interface and femto cell via Internet IP [8]. Synchronization between the macro cell and the nearby small cell is taken into consideration to access frequency channel carrier, otherwise contention occurs in the same channel. In X2 interface, the narrowband transmit power, overload indicator and interference indicator messages are shared. In RNTP, the active cell informs the nearby cells to lower the transmit power for certain channel interval so that there is no conflict between the accessing cells. In overload indicator, the information SINR is shared between cells, and in high interference indicator the users cannot use the same channel and cause interference since the advance channel allocation is fixed within the time interval. The messages are not shared at Internet IP that is used for femto cell [8]. The distributed antenna system is used to avoid interference. Here, the spatial antennas are placed at *2*Pi /N* where *N* is the number of sectors. However, the hardware installation is expensive, hence the network operators usually use the coordination mechanisms [9] to minimize interference.

The cloud radio access network needs to function in coordination with the small cells, which reduces the handover delays during the peak traffic hours. The effect of cooperative interference [6] is significant in the deployment and defining the baseband pool matrix of the HCSNets.

Table 2 gives the comparison between the interference management techniques in HetNets. Recently, Heterogeneous Cloud Small Cell Network has been proposed to improve further and revolutionize the small cell network technology. In HCSNet, the small cells are centralized at BBU pool to handle the signal processing tasks. This approach improves latency and spectral efficiency in the cellular network. Synchronization reduces interference that is controlled by BBU pool. Hence, HCSNet provides enhanced and utilization of radio resources in the network. In low traffic conditions, the BBUs are enabled to sleep mode to save the energy in Heterogeneous Cloud Radio Access Network (H-CRAN). Spectrum allocation is the key feature to reduce interference in Heterogeneous and Small Cell Network. If the spectrum is allocated in shared mode, then the major part of allocation is utilized by macro cell, and the minor part of allocation is used by femto cell. To attain improved spectral efficiency, frequency reuse factor is considered [6].

In H-CRAN, the frequency allocation is handled by the centralized BBU pool. This avoids interference between the multi-tier cells of the network. In order to cancel interference in C-RAN and H-CRAN, Inter-cell interference (ICIC) and Coordinated Multipoint (CoMP) schemes are used. Fractional frequency reuse at the edge of cells reduces the rate of interference and transmission power to establish the communication channel.

Table 2. Comparison between the Interference Management [3] [10] Techniques in HetNets

Interference Cancellation	Interference Avoidance	Distributed Interference Management
This method is applied at the receiver side. After decoding the signal, the interference will get subtracted from the desired Signal.	This method focuses on intelligent networking and sharing the information between the small cell and macro cell. This could either reduce or increase the power and serve the end user.	This technique provides distributed mechanism to mitigate interference. Adaptive power control or selecting the small cell with high SINR and lowering the small cell power induces the interference.
As the number of users increase, interference cancellation of becomes tedious.	This technique is complex to implement on small cells.	Time consuming and complex.

For the cell edge users, the macro cell transmits at higher power to communicate with adjoining components through the air interface. This further causes interference at femto cell base station. Cell Range Extension (CRE) is applied where the edge user is in proximity to femto base station instead of macro cell base station.

In recent developments, inter-cell interference is reduced at a satisfactory margin level by using Almost Blank Sub frames (ABS). This method extends ICIC, where the multi-tier cells share messages pertaining to frequency usage prior transmission in the time domain. A sub-set of channel frames are free so that the small cells can transmit in the domain network. This reduces the cross-tier interference. Macro cell synchronizes with user equipment so that interference is reduced at a minimum level [11]. Coordinated Multipoint avoids cross-tier interference. Here, the multiple cells coordinate with each other based on geographic location. This enables the cells to adapt and schedule the transmission and reception of signals to enhance the coverage and connectivity in the network [12]. In LTE-A and 5G communications, this feature is being considered to minimize the interference in the network.

IV. SIMULATIONS

Simulations are performed for a small heterogeneous network consisting two macro base stations, six femto base stations and 200 number of heterogeneous user nodes. We assume that each macro base station supports an average of 60 Macro UE nodes. Each Femto base station is associated with 10 Femto UE nodes. Figure 4 and figure 5 represents the average downlink throughput rates with respect to the average transmission powers of the macro and femto base stations. The throughput levels of the femto UEs increases with time and increasing the transmission frequency of the femto base station.

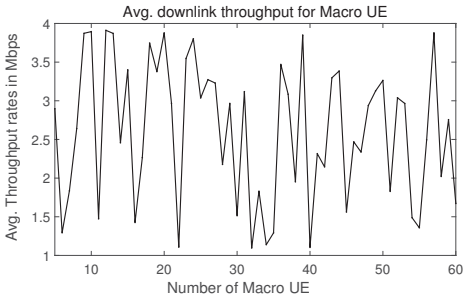

Figure 4. Average throughput rates for Macro UE

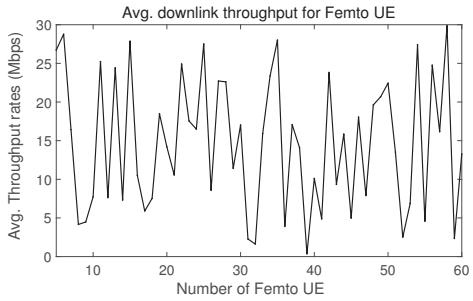

Figure 5. Average transmission power of the Femto UE

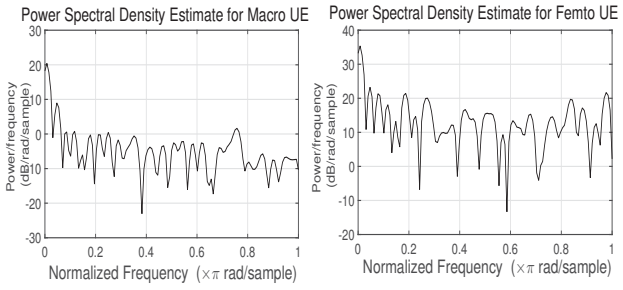

Figure 6. Macro UE and Femto UE transmission power levels

Figure 6 illustrates the macro UE and femto UE transmission power levels which are currently connected to reduce the cell outage and reduces the interference levels at the cell-edge. Femto cells configured using in-band and out-band frequencies. The macro BS transmits the signals with a strength of 46 dBm. It has been observed that that the performance of femto BS is high when it transmits the signals at the same frequency of the adjacent macro base station.

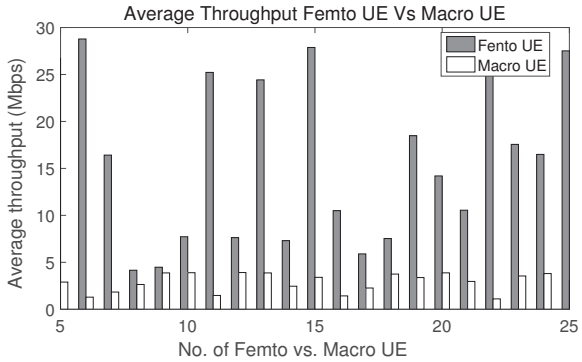

Figure 7. Comparison of Average Throughput rates for the Macro and Femto UEs

The comparison of average throughput rates for the adjacent macro and femto UEs using the in-band and out-band frequencies has been provided in figure 7. It has been observed that the femto base stations increases the throughput rates for the adjacent femto UEs by selecting the appropriate frequencies as per the density of macro UEs in the neighborhood. This technique reduces the effect of interference between the macro-macro UEs, femto-macro or macro-femto UEs.

V. CONCLUSIONS

Heterogeneous Cloud and Small Cell Network (HCSNet) has been proved to improve and revolutionize the small cell network. Since, HetNet is not a centralized approach, there arises delay, low latency and less spectral efficiency in the network. In HCSNet, the centralized BBU pool handles the signal processing tasks for small cells. This approach further improves the latency and spectral efficiency. Synchronization improves as the BBU pool handles the active cells in the network. Since, interference reduces the channel allocation, the HCSNet provides superior functionality and utilization of radio resources and thus helps to reduce undesired behavior of the network. In the emerging technology of LTE-A and 5G multi-cellular networks, HCSNet enhances the network performance.

Abstract— **With the rapid escalation of vehicles and their usage in recent years, finding a vacant car parking space in most efficient manner and to save customers' time is becoming more and more difficult. Parking problems are becoming omnipresent and increasing at an alarming rate in every city. Lots of research and development is being done all over the world to implement efficient parking management systems. This project proposes a fully automated parking system which does not require any new infrastructure. It aims to provide optimum solution for parking management in minimum cost which will help parking owners as well as the customers. The project describes the overall system architecture from hardware to software implementation.**

Keywords— Internet Of Things (IOT), Near Field Communication (NFC), Parking Automation, Precise Payment, QR Code.

I. INTRODUCTION

Automation is necessary while we are trying to survive in the Era of smart world. Automation provides perfection and efficiency. In this paper, we are focusing on parking automation, as the current parking system is facing many problems. Here we are considering problems faced by both, users and the parking owner which will lead us to a hassle free automated parking system. [2]

A user has to deal with numerous problems like long parking queues, high rates, waste of time and energy in search of an empty parking slot, manual mistakes during payment etc. On the other side, even the parking manager faces issues; he has to recruit more and more people to handle huge traffic especially at rush hours of the day and has to maintain a database manually which is a very tedious job. [3][6]The solution to these problems is parking automation; it allows a vehicle to communicate directly with the parking system without any human interference which thus provides an efficient parking system that benefits both, user and the owner. [2]

We use the concept of IOT (Internet of Things) for the interaction between two objects. Internet of things is defined as a conceptual network of anything and everything in this world. [9] Using IOT as a base concept, attempts are being made worldwide to develop an automated parking system which will help in reducing the human error involved in the process and also save the time and fuel of the customers looking for a parking in malls, theatres, companies, etc.

In our project, we are trying to implement parking automation based on the concept of the Internet of things using NFC (Near Field Communication) to reduce the overheads in current systems. NFC allows two devices to communicate with each other using radio frequency. NFC connection is established by bringing two devices together for less than a second. NFC varies in ranges but typically it is favourable for distances less than 10 cm. [1]

Another cost effective technology that we are using in our project is the technology of QR codes. QR codes are nothing but machine readable symbols which can be described as array of white and black squares typically which can be used for storing some information. [10]

II. MOTIVATION

The incident described below is a real time situation faced by all of us. It motivates us to develop an automated system for parking to overcome all the problems.

It was a Sunday. Mr. Joshi decided to visit a mall along with his family in the evening. They started around 5 p.m. for the mall which was 8 kilometres away and reached at the entrance in 20 minutes. Mr. Joshi saw that about 4 cars were standing in front of his car and thus was a bit disappointed as he had to wait in the queue. They realised that the cars were not moving the reason being - no person attending the increasing queue. After around 10 minutes, the attendant arrived, made entries in a register specifying the time and vehicle number and let them enter the parking.

After entering this 3 storied parking, they had to now search for an empty parking slot which was indeed a challenge. Mr. Joshi's wife suggested that they should try searching for a parking slot near the lift as it will be easier to carry bags once they are done with their shopping. There were others too who

wanted the same, hence it led to congestion and he ended up wasting more time and fuel.

Finally they found an empty slot, but before they could park their car, another car driver parked his vehicle in that slot. This further led to a greater disappointed and they had to then search for another empty slot and park there. The only way to find their car after they were done shopping was by remembering the pillar number near the car, which if forgotten would've led to hours of searching all over again. The amount Mr.Joshi paid did not consider the no of hours he was in the mall moreover it was a manual cash transaction which obviously could have been prone to human errors.

III. Literature Survey and Current Issues

Various solutions have been presented as a prototype for automatic parking till date. In the following section, we will introduce some solutions and summarize them based on the themes of implementation.

A. Mechanical Parking Using Microcontrollers

This is the most popular prototype for automation of parking. Various international papers suggest building multi-storeyed mechanical parking system for automation purpose which will be then controlled using microcontrollers.

Use of rack and pinion model along with Bluetooth is suggested in the method by Harmeet Singh, Chetan Anand, Vinay Kumar and Ankit Sharma [3]. Here, the parking process starts when driver turns his Bluetooth on. The Bluetooth reader fetches the owner's unique number and then microcontroller is fed with appropriate commands, thereafter, assigns an empty parking slot. The mechanical system which consists of rack and pinion lifts the car and transports it to a predetermined parking space in the parking garage.

Harsh Kotak, Prithvish Mamtora, Dhruv Mehta and Grishma Vithalani suggest using a rack and pinion model along with NFC. [6] The user establishes communication by tapping his NFC enabled smart phone against an automated terminal nearby. The NFC Reader terminal fetches UID of the NFC enabled smart phone then commands the microcontroller and the microcontroller assigns an empty parking slot. The mechanical system which consists of rack and pinion lifts the car and transports it to a predetermined parking space in the parking garage.

Mr. John Nair, Mr. Nimesh Gupta, Ms. Rakhee Mahadik and Mr. Chintan Chauhan are also using a rack and pinion model along with NFC. [8] The driver taps his NFC enabled smart phone at an automated terminal nearby. The NFC Reader terminal fetches UID of the NFC enabled smart phone then sends the commands to microcontroller and microcontroller assigns an empty parking slot. The mechanical system which consists of rack and pinion lifts the car and parks it to a predetermined parking space in the parking.

B. Parking automation using Bluetooth

Bluetooth technology is used for improving the prototype of automated parking. Here in one of the paper by Harmeet Singh, Chetan Anand, Vinay Kumar and Ankit Sharma Bluetooth is used as a communication channel between parking and user. [3] The Bluetooth reader fetches the owner's unique number and then commands the microcontroller which, thereafter, assigns an appropriate parking slot.

C. Parking automation using NFC

To further improvise over Bluetooth technology, NFC (Near Field Communication) is introduced where communication between parking facility and user is allowed using NFC enabled devices. Harsh Kotak, Prithvish Mamtora, Dhruv Mehta and Grishma Vithalani suggest using NFC. [6] The driver taps his NFC enabled smart phone at an automated terminal nearby. The NFC Reader terminal fetches UID of the NFC enabled smart phone then commands the microcontroller and microcontroller assigns an empty parking slot.

Mr. John Nair, Mr. Nimesh Gupta, Ms. Rakhee Mahadik and Mr. Chintan Chauhan suggest an approach using NFC. [8] The driver establishes communication by tapping his NFC enabled smart phone against an automated terminal nearby. The NFC Reader terminal fetches UID of the NFC enabled smart phone then commands to microcontroller and microcontroller provides an empty parking slot.

D. Parking automation using GPS

GPS technology is used to allocate a parking slot to the user. On a forum discussion author proposes to use GPS (Global Positioning System) to locate the user and then allocate a vacant parking space near to the user with the help of Bluetooth. [4]

TABLE I. Issues In Current Automated Parking Systems

No.	Theme of Implementation	No.	Issues
1.	Mechanical parking using microcontrollers	i.	The database has to handle large amount of data.
		ii.	As the mechanical components used are quite slow, at rush hours, it would lead to congestion at the entrance.
		iii.	The setting up of a new infrastructure involves a lot of cost.

		iv.	Maintenance of the mechanical components is costly too.
		v.	There is no mention of a manual override for the mechanical system.
2.	Parking automation using Bluetooth	i.	When compared to other wireless communication technologies like NFC, Bluetooth consumes relatively more power.
		ii.	Bluetooth has trouble dealing with interference while the data is being shared especially when several other devices are in proximity.
		iii.	Setting up of connection manually every time some data has to be sent consumes a lot of time.
		iv.	In the proposed solutions so far, directions to the allocated parking slots are not provided, thus, the problem of time wastage in finding the allocated parking slot along with the wastage of fuel still remains.
3.	Parking automation using NFC	i.	Once the parking slot is allocated there is no mechanism mentioned which would ensure that no other car would be parked before the user himself parks the car in his allocated slot.
		ii.	There are no directions provided to reach the allocated slot.
		iii.	Generally, people prefer having a parking that is closer to the entrance of the mall, there is no solution mentioned yet which would address this requirement.
		iv.	As there is no redirection provided at the entrance,the parking manager ends up hiring lot of people who then guide the cars to their respective allocated parking slots.
4.	Parking automation using GPS	i.	This technology is very power hungry,lasts only 8-12 hours before needing a recharge.
		ii.	The GPS signal does not pass through solid structures effectively, thus, it might create problems for basement parkings.
		iii.	Absolute miniaturisation is not possible whilst maintaining positioning accuracy.
		iv.	Factors like Inconsistencies of atmospheric conditions, multipath issues, clock errors and man-made electromagnetic interference cause a 5m-10m error in GPS.
		v.	There is a demand of continuous internet connection.

IV. PROPOSED SYSTEM AND RECOMMENDATIONS

We are using NFC technology to register vehicle user with automated parking system. Every time a user enters the parking, he has to tap his NFC enabled smart phone against the NFC reader available at the parking entrance. Once the communication link is established, system transfers a file to the user which contains suggested available parking slots along with the date and time stamp. For example:

Available Slots: A1, B13, C8.
15 August 2015, 13.56.

Now the user is given all the liberty to park at any parking space. He may or may not choose from the suggested list. All he has to do is scan the QR code pasted on the wall of parking slot which he will be choosing. As soon as the customer will scan the QR code, the parking number encoded in QR code will be sent to parking system using the internet available with user's smart phone. This parking slot will be marked as occupied by system till the time the vehicle exits.

Now while leaving the building or mall, user can check their car's current location by a kiosk machine after tapping the phone on it. While leaving the parking premises, user has to tap his phone on a cash counter to pay the parking fees. To calculate parking fees, entry timestamp will be compared with the current system time and accordingly the amount to be paid would be deduced from the account. Here, account used for the transactions will be any e-wallet which user wishes to use. [5]

Once the user exits, the parking slot will be marked as empty. If at all the internet connectivity fails and system is not prompted with the parking slot ID, at the exit point NFC readers will fetch this data and the parking slot will be treated empty there onwards.

The highlights of system proposed in this project are no need of new infrastructure and minimum setup cost. This system can be implemented in any parking within the span of 3 to 4 days. This system does not involve any kind of human interference. Aim of our proposed system is to achieve full automation using minimum resources. This proposed solution resolves the issues discussed above.

The flowchart for proposed parking automation system is as given in Fig.1:

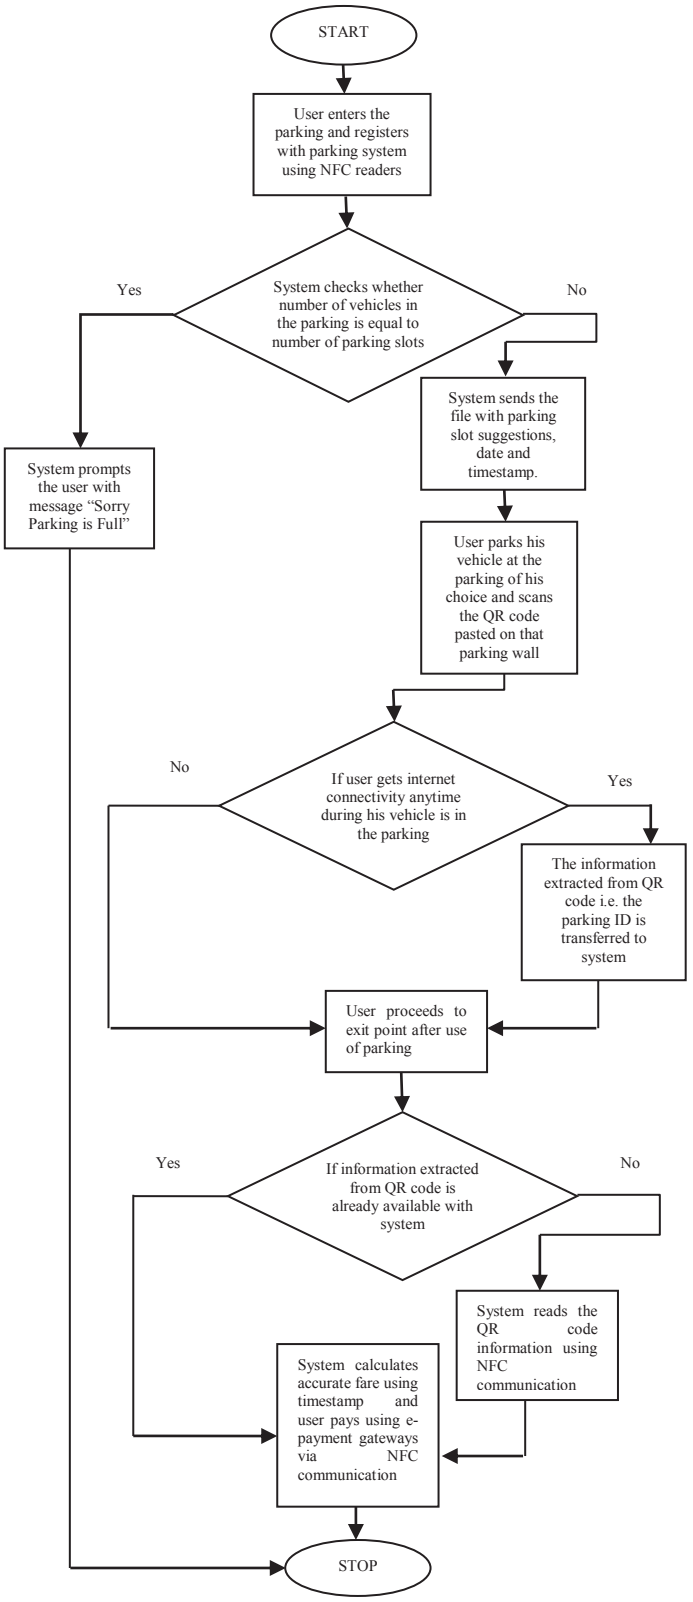

Fig. 1. Flowchart for proposed parking automation system

V. CONCLUSION

Thus, we have presented a detailed description of our Automated Parking System. It helps overcoming the shortcomings of the current parking systems. The biggest challenge that one faces in a system is the high cost involved in building new mechanical infrastructures. In this system, we have provided an automated parking without introducing any mechanical system in the existing infrastructure. Also, using NFC for suggesting parking spaces minimizes the system errors and makes it hassle-free for users as there is no need for them to wait in long queues. Precise payment with trouble free redirection to parking spaces gives this system an edge over other current systems. Being a low setup cost system, it provides an efficient way of optimizing space and performance.

***Abstract*—This paper presents an overview and review of major issues involved in wireless mesh IP video surveillance systems. These include but are not limited to security, signal degradation and diversity, and quality of service. Finally, we share research directions the team is taking. The pivotal system of this discussion paper has been proposed elsewhere [1] as a model for the Internet Protocol (IP) mesh video surveillance systems complete with the performance evaluation of AODV and OSPF routing protocols in a wireless mesh video surveillance system. The discussion highlights past and current research, and reveals some scope for further collaborative research.**

Keywords—IP mesh video surveillance, security, QoS, dynamic spectrum access, MIMO, antenna selection,

I. Introduction

In recent times, internet has hosted applications from diverse sectors from telecommunications to commerce. Video surveillance has taken a cue in harnessing the benefits of transmitting information over the Internet. Relative to most applications that use the internet as a transmitting medium, emphasis is always placed on the quality of service (QoS) while security has not enjoyed as much attention. Internet being an open architecture is built on standard interfaces, protocols and basic data format. When used as a medium for transmitting IP video surveillance data, it is exposed to security threats, especially when embedded in wireless mesh networks.

Wireless mesh networks (WMN) have the advantage of extending network services to areas where wired networks or conventional wireless networks cannot be installed. WMN are mainly made up of mesh routers and mesh clients, but they are capable of providing network access to both mesh and conventional clients. An example of a network service that has traditionally been deployed on wired networks is the surveillance video system. Wired surveillance video systems have their advantages, but they also suffer from challenges which can be overcome by deploying the surveillance video system on a wireless mesh network. The performance of mesh surveillance video systems can be severely affected if a large number of nodes are placed in close proximity, this is because the bandwidth available for supporting the nodes will now be limited.

Another area of concern in wireless mesh IP video surveillance quality of service provision involves dynamic spectrum access (DSA). Video surveillance has earned high relevance globally, due to recent trends in security and the need to gather visual information for decision making. The need to get real-time video data with high resolution is a key consideration in all IP video surveillance systems. However, this is degraded by congestion in wireless networks. This congestion is attributed to the recent surge in the deployment of wireless communication technologies, introduction of various bandwidth demanding multimedia services and the current paradigm of spectrum allocation i.e. the static spectrum allocation technique. [2]

The rest of the paper discusses the issues under study, the directions envisioned and scope for possible collaboration. Section II discusses the IP video surveillance system from an Internet security point of view. Aspects of related quality of service provisioning approaches are the subject of Sections III and IV. In Section V we take a bold step and propose a game theoretic take on the deployment of IP cameras linked to mesh routers and access gateways.

II. IP Security

A. A Security Perspective on Surveillance Modelling

Much research focuses on quality of service (QoS) provisioning without paying any attention to security. The Internet being an open architecture is built on standard interfaces, protocols and basic data format. When used as a medium for transmitting IP video surveillance data, it is exposed to security threats. These are threats to confidentiality, integrity and availability in IP-based video surveillance systems.

A security assessment of the proposed mesh IP video surveillance system [1] can be guided by the CIA triad model

This work is a re-look at aspects of the concurrently published work by C. S. Lubobya [1] from the multiplicity of perspectives represented in the wireless communications laboratory. His work is supported by the University Science, Humanities and Engineering Partnerships in Africa (USHEPiA) Fund.

C. S. Lubobya is investigating wireless Internet-based crime monitoring and traffic control systems from a unified perspective. This is a joint research project between UCT and the University of Zambia.

O. Osanaiye interests himself in multi-stage security boosting for service availability in cloud computing. His work has opened up collaborations with the UCT Department of Computer Science as well as the University of South Australia

E. Okumu is developing a novel cross-layer approach to antenna selection in cognitive radio MIMO systems.

H. Ohize is developing a new MAC protocol for optimal spectrum identification, co-ordination and scheduling in Ad Hoc cognitive radio networks.

V. Moyo is improving cognitive radio energy efficiency by using game theory enhanced distributed cooperative sensing.

[2]. CIA being confidentiality, integrity and availability are the critical components of security that must be considered during the design and implementation of the system.

B. *Confidentiality*

Rajpoot & Jensen [3] describe confidentiality as the ability to protect data and information transmitted over a network against unauthorized access. It involves taking control and ownership of packets which are always at risk from attackers capable of monitoring to capture sensitive data packets. Information sent from the IP cameras to both the local and remote servers therefore needs a high level of confidentiality. Eavesdropping is a common attack against confidentiality of IP information.

C. *Integrity*

It is essential that data sent in the mesh network remains unaltered by an unauthorized user. The wireless links in the network can be used by an attacker to compromise the system through altering of configuration to achieve virtually any aim. According to Sayyad et al. [4], authentication of communication links between two parties is not a guarantee that messages transmitted cannot be altered; therefore the mesh IP video surveillance system must be protected to maintain the integrity of its data system and configuration.

D. *Availability*

Availability in this context is the ability to access the resources in form of information from the local and remote servers when needed. Several malformed packets can be used to disrupt, damage or disable network functionality [5] to the detriment of the proposed system design objectives. DDoS attack has been identified as one of the major cause of unavailability of service while congestion leads to delay in accessing resources [6].

TABLE I.

Attack	Features	Mitigation
DDoS	Flooding service with malicious packets using compromised vulnerable nodes on the internet.	Firewall, NIDS
Unauthorized access	Illegal access to system components due to non-centralized authentication in meshed ah-hoc network.	Access Control List (ACL), Password security
Eavesdropping	Intercepting or viewing IP video over without the knowledge of the administrator	Encryption of traffic, Virtual Private Network (VPN)
Masquerading	Pretense of an entity to be another entity e.g. illegal IP camera or server in the network.	Device authentication
Man-in-the-middle- attack	Secretly relays or alter communication between two nodes.	Encryption, VPN.

III. Diversity Approach

The surveillance video system is an example of a network service that has traditionally been deployed on wired networks. Wired surveillance video systems have their advantages, but they also suffer from challenges that can be overcome by deploying the surveillance video system on a wireless mesh network. However, the performance of wireless mesh surveillance video systems quickly gets severely bandlimited as the density of nodes in a geographic area increases. Incorporating cognitive capability in mesh routers, for instance, can alleviate the problem.

This will enable the mesh routers to access radio spectrum in frequency bands not assigned to them, availing more bandwidth for transmission purposes [7]. The main challenge now is how to meet the QoS requirements for the surveillance video system. This can be accomplished by deploying multiple input multiple output (MIMO) antenna systems.

A. *MIMO*

The cognitive mesh routers can be equipped with multiple antennas, and MIMO techniques can be used to improve the spectral efficiency and diversity [8] [9]. There is a hardware complexity and cost factor in this approach. Antenna selection techniques then address the latter difficulty.

B. *Cross Layer Antenna Selection*

Hardware complexity and cost reduction requires astute antenna selection that maintains the gains of MIMO [10] – [12]. Cross layer antenna selection that uses information from the data link and physical layers offers performance benefits when compared to physical layer based antenna selection which uses only information from the physical layer [13]. Throughput based antenna selection, which uses information from the data link and physical layers can be used to select cognitive mesh router antennas and optimize the link throughput. In turn, throughput based antenna selection results in increased performance of the surveillance video system in the following areas. This approach optimizes the system throughput for the mesh IP video surveillance system, and reduces packet re-transmissions, which results in lower end-to-end delay. In addition, throughput based antenna selection reduces the error rate, resulting in less jitter as packets are more likely to maintain the correct arrival sequence.

IV. DSA in Mesh IP Video Surveillance

There is a need to get real-time video data with high resolution, a key consideration in all IP video surveillance systems. However, this is mitigated by congestion in wireless networks. This congestion is attributed to the recent surge in the deployment of wireless communication technologies, introduction of various bandwidth demanding multimedia services and the current paradigm of spectrum allocation, i.e. the static spectrum allocation technique. [14]

Static spectrum allocation is rather inefficient in congested networks [15], as it hamstrings the recovery of any and all

disuesed spectral bands. Additionally, this technique fails to identify underutilized though active bands thereby resulting in apparent pseudo-spectrum scarcity [15]. Consequently, a dynamic spectrum access (DSA) approach for Mesh IP video surveillance system is proposed as a work in progress. DSA is made feasible with Cognitive Radio (CR) technology.

The CR prototype aims at devising spectrum sensing and management techniques, thereby allowing the IP cameras to intelligently locate and use frequencies other those in the 2,4 GHz ISM band. DSA concept is receiving the most attention among researchers and industry players as a more lasting and sustainable resolution to the challenge of spectrum scarcity [17-19]. This will in turn increase spectrum usage efficiency and reduce congestion currently being experienced in certain frequency bands e.g. ISM bands. However, canvassers of this technology are currently confronted with the complexities involved in the development of a fully functional CR system. This is attributed to the complex requirements for the integration of the major building blocks of CR namely Spectrum Identification (Sensing), Spectrum Access, Spectrum Sharing and Spectrum Management [20]. Therefore, in this paper, we propose an intelligent frequency-shifting self-managed IP Mesh video surveillance systems**.**

This is realized in two ways: (1) A new approach for spectrum sensing is devised without alteration to the de facto Mesh IP video surveillance systems design. (2) We propose distributed MAC protocol design. This will enhance self-organization and co-ordination for spectrum access in the Mesh IP network.

A. A new approach for spectrum sensing for Mesh IP video surveillance systems.

The success of our Mesh IP video surveillance systems model design, is pegged on the ability of the CR to accurately make spectrum occupancy decision based on it spectrum sensing results. The conventional energy detector is best suited for our Mesh IP video surveillance applications but its performance is greatly deteriorated under noise fluctuation and low SNR regimes [21]. This can be attributed to its fixed threshold approach and its lack of prior knowledge of the noise variance. In this design, we adopt an adaptive threshold energy detection technique with noise variance estimation based on the recursive one-side hypothesis test (ROHT) algorithm and the constant false alarm rate (CFAR) principle, as seen in the work of Nixon and Dlodlo in [21]. Simulation results indicate that this technique improves spectrum occupancy detection as seen in the receiver output characteristic curve (ROC) of [21].

B. Proposed Distributed MAC protocol design for DSA Mesh IP video surveillance systems.

The proposed mesh IP network consist of video cameras organised in a mesh topology or wireless ad-hoc network topology. The mesh IP network co-exist with the licensed users network also known as primary users (PU). In the spirit of improving channel access, we propose an efficient MAC protocol for enhancing spectrum access, thereby avoiding co-tier and cross-tier interference. Existing Medium Access Protocols (MAC) such as the 802.11 and others were designed for homogenous spectrum access. The introduction of DSA technique has, however, compounded the realization of an efficient MAC protocol. With respect to known solution the use of dynamic common co-ordination channel DCCC is the most patronized solution. DCC facilitates a variety of co-ordination operation such as transmitter-receiver handshake, channel access negotiation, topology change, routing information updates to cooperation among the Mesh IP videos [22]. The contribution here is the proposed dynamic control channel selection scheme. We develop an Ant Colony System (ACS) based control channel selection scheme. By ACS we make reference to the mimicry of pheromone laying behaviour of real ants to find the shortest route between their nest and a food source. ACS technique is popular in literature as Ant Colony optimization [23]. By drawing similarities, we propose the use of such technique in achieving the goal of coordination among the IP video cameras.

V. SENSING POWER: A GAME THEORY VIEWPOINT

For a case where the IP cameras, the mesh routers (MRs) and the mesh gateways (MGs) are within buildings with easy access to power, the amount of energy spent on sensing the ISM bands that the devices use for communication may not be a factor worth consideration. However, where there is no steady source of power, such as in ad hoc wireless networks, it becomes important to reduce the amount of power spent on sensing. In such a scenario, for the IP cameras to ensure reliable communication with the MRs and also on the communication between the MRs and the (access point (AP) with reduced power requirements, there is need for performance enhancing algorithms and protocols to be in place.

A Game Theory [24] based algorithm can be used to improve the energy used for sensing idle spectrum between the IP camera and the MR and between the MR and the AG. The IP cameras connecting to a single MR can be modelled as players with a number of strategies each. A strategic form game is a tuple (A, S, u) for multi IP cameras. Where: A = {1,2,…,a} is the set of IP cameras from the first IP camera to the ath IP camera shown in Figure 2 ; S = {S1,S2,…,Sa} where Si is the set of actions available to IP camera i; u = {u1,u2,…ua} where ui is the utility function for IP camera i [25]. The objective of the game would be establish a strategy that would result in each IP camera use less time and energy for sensing, if the sensed information is shared. The algorithm used by the IP cameras can be extended to the MRs if there is a number of MRs that need to connect to an MG.

VI. The Networking Viewpoint

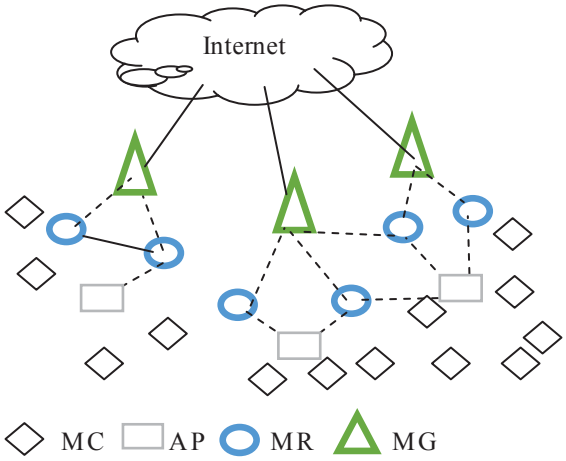

Fig. 1. Wireless Mesh Network Infrastructure [26]

A previous paper [24] analyzed and simulated the performance analysis of video surveillance applications through Wi-Fi networks, using three network topologies: wireless tree, star and wired tree topologies. It was shown there that the wireless tree topology had the best throughput performance of 100% better than star and wired tree topologies. It reduced packet losses to less than 5%. The wireless tree is is assumed in the concepts presented here. This is good news for remote as well as congested built-up areas, or for increasing the capacity of a backbone network. The next step is to investigate its performance in other IEEE 802.11 family of standards and cases where mobility introduces stochastic fading and shadowing.

A concurrent paper from this lab [26] presents an mesh IP video surveillance model that stipulates routing protocols that optimize throughput, reductions in packet loss, end-to-end delay and jitter. The routing protocol of choice is found to be OSPF. A concerted investigation of the effect of mesh topologies and routing algorithms on these metrics is also proposed.

VII. The 5G Prospect for IP Video Surveillance

The wireless communications research laboratory in the Communications Research Group (CRG) takes a multifaceted view of the questions in wireless mesh IP video surveillance systems. This paper discussed some of them, highlighting briefly what has been identified as problems, some solutions recently tested, those under investigation, as well as challenges that open up areas of collaborative research.

A systems engineering approach has been illustrated by this discussion as one approach to tackling the complicated challenges involved. The approach involves teaming together from diverse schools of thought that are collectively brought to bear on the problem at hand. It is viewed as the surest way to realize system-wide optimization of wireless mesh IP video surveillance systems embedded in the emerging 5G heterogeneous environment.

Other perspectives that the laboratory is investigating include the big question as to how much autonomy we want our networks, their components, and user devices to have. The question quickly brings up the Internet of Things and the Internet of everything paradigms in the heterogeneous 5G environment. To what extent must wireless mesh IP video surveillance systems make decisions about security issues and traffic conditions? When decisions regarding suspected crime are made by a network of things, who would take responsibility for the crime report and verification in a court of law? Our interest in this area has opened up avenues for collaboration with the Council for Scientific and Industrial Research (CSIR) in South Africa.

dominique.noguet@cea.fr

***Abstract*—White space communications have attracted a particular interest after some national regulators have authorized TVWS unlicensed secondary usage. The IEEE 1900.7 working group has defined a specific air interface tailored to these applications. The standard, expected for publication in 2016, is based on an Filter Bank Multi Carrier (FBMC) physical layer and a CSMA-CA MAC sublayer. To our knowledge, this is the first time a radio standard is based on FBMC technology. This paper provides a brief description of the technology considered by the IEEE 1900.7 working group, providing also a more global perspective related to White Space research and standardization. Then, the paper provides preliminary simulation results of the IEEE 1900.7 system and uses more usual Cyclic Prefix-Othogonal Frequency Division Multiplex (CP-OFDM) technology as a comparison baseline.**

Keywords—IEEE 1900.7; white space; dynamic spectrum access; physical layer; MAC; use cases

I. INTRODUCTION

In the recent years, there has been a worldwide concern related to spectrum shortage. As an example, in June 2010, the White House issued a Presidential Memorandum stating that the National Telecommunications and Information Administration (NTIA) shall collaborate with FCC to make available a total of 500 MHz of Federal and non-federal spectrum over the next 10 years, suitable for both mobile and fixed wireless broadband use. One of the means to make new spectrum available is through sharing, and the Digital Switch Over (DSO) in TV bands, which has resulted in making the so-called TV White Space (TVWS) UHF spectrum available, was the first actual example where such a mechanism has been allowed. TVWS availability depends on TV broadcast frequency usage profile, thus changing across time and space. TVWS usage relies on unlicensed secondary Dynamic Spectrum Access (DSA) under the principle on a non-harmful interference with incumbent users [1].

In the USA, the FCC proposed rules for the Unlicensed Operation in the TV Broadcast Bands [2], with the final set of rules in 2009 [3] and an additional notice in 2011 [4], along with additional memorandum [5][6]. In Japan, MIC has published rules for secondary operation in TV white space [8]. In Europe, the Ofcom UK was the first regulator to establish rules for TVWS usage [8] [9]. Subsequently, Ofcom organized a nation-wide trial where several technologies were assessed [10]. Following up the approval of the European Parliament and Council the first Radio Spectrum Policy Programme (RSPP) in March 2012 [11], the European Commission released a Communication [12] in which shared use of TV White Spaces in the 470-790 MHz band is identified as a major opportunity. Then, regulatory actions have taken place in this area. In a first report, European Regulation (CEPT) has defined technical considerations for TVWS operation in Europe [13]. Then, ECC Report 159 established technical and operational requirements for the possible operation of cognitive radio systems in the "white spaces of the [470-790] MHz band" [14]. CEPT thoroughly addressed the way forward in European TV White Spaces, assessing both geolocation database and spectrum sensing as enabling technologies and setting out technical requirements for the use of TVWS. Finally, ETSI established some requirements for TVWS equipment in answer to the R&TTE Directive and delivered the EN 301 598 Harmonized EN [15].

Alongside these regulatory harmonization initiatives, a set of bodies developed technology standards to enable the implementation of TVWS radios. First, the CogNea consortium developed the ECMA392 TVWS standard for WLAN-like application [16]. Then, IEEE802.22 [17], and more recently in IEEE802.11af [18] issued standards for WRAN and WLAN applications respectively. Finally, IEEE802.15.4m has been developed to address WPAN operation in the TVWS [19].

All broadband TVWS standards (ECMA392, IEEE802.22, IEEE802.11af) are based on Cyclic Prefix - Orthogonal Frequency Division Multiplexing (CP-OFDM) physical layer (PHY), often inherited from previous standard developments such as IEEE 802.16e or IEEE802.11a. These standards have been adapted to make them suitable for TVWS operation. However, because of the very stringent requirement on Adjacent Carrier Leakage Ratio (ACLR) to ensure interference free operation for incumbents, and the dynamic nature of DSA, it was shown in the literature that CP-OFDM was probably not the best choice for TVWS PHY, although probably the fastest in terms of market readiness [1]. For this reason, IEEE DySPAN Standards Committee (formerly known as SCC41) created an ad hoc group on White Space (WS) Radio in March 2010 "to consider interest in, feasibility

Authors would like to acknowledge the support of the European FP7-318563 CRS-i project.

of, and necessity of developing standard defining radio interface (medium access control and physical layers) for white space radio system". Subsequently, the 1900.7 working group on "Radio Interface for White Space Dynamic Spectrum Access Radio Systems Supporting Fixed and Mobile Operation" [20] was created.

The IEEE 1900.7 standard, which is aimed at being issued in 2016, is the result of a clean slate analysis where the working group tried to identify the most suitable technology for TVWS. The standard is based on a Filter Bank Multi Carrier (FBMC) PHY and a contention based CSMA-CA MAC. [21] describes the scenarios and approaches followed by the IEEE 1900.7 working group.

In this paper, a first set of performance evaluation of the IEEE 1900.7 draft standard is carried out though simulation. Simulations are performed considering some parameters of the draft standard. First, the principles of IEEE 1900.7 FBMC PHY are recapped. Then, section III explains the MAC mechanisms of the IEEE 1900.7 standard. Then, in section IV, some performance evaluations are described.

II. Physical Layer

The rules established by regulators, like in the US [4][6], in the so-called TV white space allow opportunistic unlicensed operation in the UHF TV bands. These rules aim at ensuring opportunistic communication systems (white space devices) to coexist with TV broadcast signals and wireless microphones (referred to as 'incumbent systems' hereafter). The coexistence scheme is enforced with a priority mechanism where opportunistic systems must guarantee that no 'harmful interference' will be incurred to the incumbents. In this context, harmful interference is defined in a twofold way. Firstly, co-channel communication between incumbent and opportunistic systems is prohibited. This means that opportunistic systems must be able to assess the presence of incumbent signals and access only channels vacant from any incumbent. Besides, opportunistic systems have a limited amount of time to evacuate the channel when an incumbent is switched on. Secondly, adjacent channel leakage ratio (ACLR) is limited in order to prevent an opportunistic system from interfering with an incumbent operating in another channel, and in particular in adjacent ones. In [6], ACLR is restricted to be at least 55dB. Similar requirements are considered in other countries (e.g. in the UK [8]). Such a high ACLR requirement is specific to the TVWS context. For instance, ACLR requirement is 10dB stronger than required for LTE systems [22].

CP-OFDM has proven to be very effective for mobile wireless communications and is a first guess when broadband wireless PHY is at stake. By dividing a frequency selective fading channel into a large number of narrow-band flat fading sub-channels, CP-OFDM systems can easily compensate the effects of the channel using a simple one-tap frequency domain equalizer. However, CP-OFDM cannot meet the ACLR requirements unless the transmitter flexibility is sacrificed or spectral efficiency is compromised. This is due to the square temporal filter of CP-OFDM, or in other words the sinc kernel function in the frequency domain, which has very high sidelobes (-13dBc). On the other hand FBMC modulation has shown very good simulated ACLR performance in the context of TVWS [1]. Through an implementation on a flexible hardware TVWS transmitter, [23] shown that FBMC modulation can meet ACLR levels prescribed by the FCC's coexistence requirements. The actual implementation was aimed at assessing the performance under real hardware impairment conditions, such as limited dynamic Digital to Analog Convertors (DAC) [24].

Another way of comparing ACLR performance of FBMC vs CP-OFDM, is to measure respective power levels for a given interference level in adjacent channels. This was performed in [24] where the power of FBMC was 9dB higher than with CP-OFDM to meet quasi-error free video reception in the adjacent channel. The benefit of this 9dB margin can be estimated in terms of range (or coverage). For instance, considering a fixed station TX power of 36dBm (4W), a 12dB reception SNR, a -86dBm receiver sensitivity, the transmission range when using 470 MHz central frequency is given in Table I.

TABLE I. Range comparison for equivalent -55dBc ACLR

Propagation condition	FBMC 36dBM	CP-OFDM 27dBm
Okamura-Hata (Urban)	0,93 km	0,53 km
Okamura-Hata (Suburban)	1,56 km	0,89 km
Free Space Loss	63,72 km	22,61 km

FBMC was introduced in the 60s by [25][26]. It is a multi-carrier approach, but unlike CP-OFDM where the *sinc* kernel filter ensures subcarriers orthogonality with respect to the FFT operator, FBMC uses a prototype filters that filters each sub carrier. A proper design of the prototype filter enables to trade time and frequency localization, and thus to control ACLR. Because the prototype filter's response spreads each subcarrier over several adjacent subcarriers, another dimension is used to 'restore' orthogonality. In the framework of IEEE 1900.7, the offset QAM (OQAM) approach was used. OQAM consists in a complex to real conversion where real and imaginary parts of each complex symbol are multiplexed in consecutive time samples into Pulse Amplitude Modulation (PAM) symbols (Fig. 1). In order for this pre-processing not to impact data rate, the PAM symbols are up-sampled by a factor of 2.

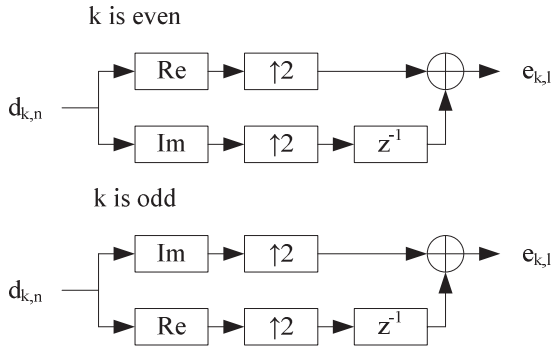

Fig. 1. OQAM pre-processing.

Then, the output real numbers are multiplied by an offset QAM sequence to form a new complex symbol: $h_{k,l} = (-1)^{kl}(j)^{k+l} e_{k,l}$. These symbols are consequently filtered through a polyphase network *G(z)*. The FBMC modulator and demodulator are shown in Fig. 2.

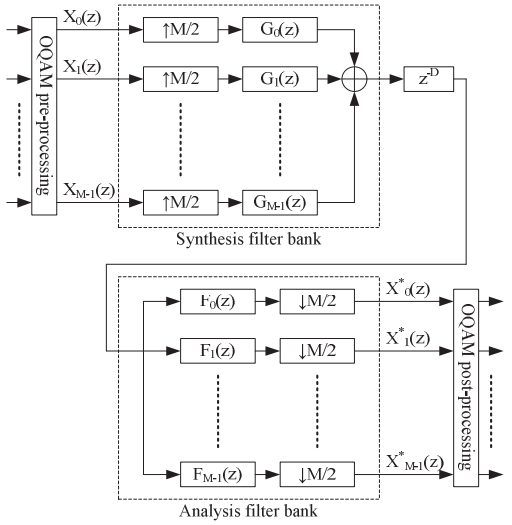

Fig. 2. FBMC modulator and demodulator using a polyphase network.

One of the main shortcomings of FBMC was supposed to be its implementation complexity. However, recent results have shown that a flexible approach was possible with very limited complexity overhead. First, on the transmitter side, it has been shown that an additional filter is required on top of CP-OFDM and shall be implemented as a digital filter for the sake of flexibility. In this context, [24] concluded that the complexity of the filtered CP-OFDM TX could be as high as or even higher than the one of the FBMC TX, which does not require this additional filtering. Similarly, the complexity of an FBMC receiver has been compared to the one of CP-OFDM. [27] has shown that the computational complexity of the FBMC receiver was only around 30% higher than the one of the CP-OFDM RX. In addition, the proposed block-wise processing approach requires FBMC symbols to be stored, which impacts the size of the memory (2.5x the one of an equivalent CP-OFDM RX). However, such memory sizes can be implemented at a very limited footprint and cost on current silicon technology nodes.

TABLE II. IEEE 1900.7 PHY MODES

Mode	*N*	Intercarrier spacing	Channel 2MHz	Channel 8MHz
4K	4096	3.75 *KHz*	504 (1.86MHz)	2016 (7.56MHz)
1K	1024	15.00 *KHz*	124 (1.86MHz)	504 (7.56MHz)
0.5K	512	30.00 *KHz*	64 (1.92MHz)	252 (7.56MHz)
0.25K	256	60.00 *KHz*	32 (1.92MHz)	124 (7.44MHz)

The IEEE 1900.7 standard specifies two different sizes for the prototype filter: K=3 or K=4 governing the level of protection of adjacent channels. Also, for the sake of flexibility, several modes are proposed. They consider different number of carriers, and two channelization modes (2 or 8MHz). Thus, IEEE 1900.7 can be used in any country authorizing TVWS operation and can cover medium to broadband channels.

The block diagram of the IEEE 1900.7 transmitter is shown in Fig. 3. The transmitter architecture is composed of two main elements: forward error correction block and data mapping and modulation block. Forward error correction (FEC) is implemented using a standard convolutional encoder. The code may be punctured to support variable encoding rates. The convolutional code is segmented by blocks of fixed size. The trellis is closed at the beginning and the end of each FEC block. The output of the encoder is forwarded to a bit interleaver of size multiple of the output length of the encoder.

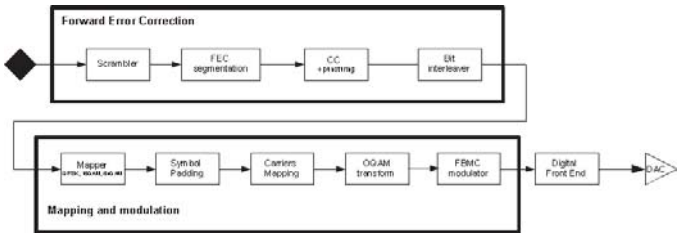

Fig. 3. Block diagram of IEEE 1900.7 baseband transmitter.

The second block maps and modulates the encoded bits to the multicarrier modulation. The coded data are mapped to QPSK, 16QAM or 64QAM modulation symbols, depending on the desired data rate. Symbols are then padded to make the transmitted burst length an integer multiple of multicarrier symbols. The generated block of QAM symbols is mapped to active carriers and modulated to an offset-QAM before being transformed into a time domain signal using FBMC waveform. A modulation and coding scheme (MCS) index is defined to describe the combination of the modulation and coding schemes that are used when transmitting data.

III. MAC SUBLAYER

The MAC sublayer is based on a Carrier Sense Multiple Access with Collision Avoidance (CSMA-CA) approach using "Request To Send" and "Clear To Send" (RTS/CTS) handshake mechanism. A basic network operates in a master-slave mode. In the master-slave mode, a device is designated as master (network coordinator) and others are associated with the master as slaves. The master coordinates channel access in the master-slave mode.

A. CSMA/CA RTS/CTS

With CSMA/CA each user can access the channel with equal priority through contention at each time instant. It is the access protocol adopted for IEEE 802.11 [23].

A node with a packet to transmit should first sense the channel. If the channel is sensed to be idle for a time period greater than the distributed inter-frame space (DIFS) time, the node sends a RTS packet. If the RTS packet is received without collision, a CTS is sent back to inform all nodes in the cell that the channel is reserved. All nodes defer their transmissions for the duration specified by the RTS: this mechanism is called virtual sensing.

If the channel is sensed as busy, a backoff procedure is invoked. Under the hypothesis of an error free transmission, collisions may only occur on RTS packets and transmission of data packets can proceed without interference from other nodes. The frame transaction of IEEE 1900.7 consists of a RTS/CTS frame exchange, a single frame, and the associated acknowledgement frame if requested by the ACK policy as shown in Fig. 6. When the I-ACK mode is invoked, an immediate acknowledgement frame is requested after the data packet (if it is decoded correctly). Otherwise, data frames are transmitted successively without acknowledgement (N-ACK mode).

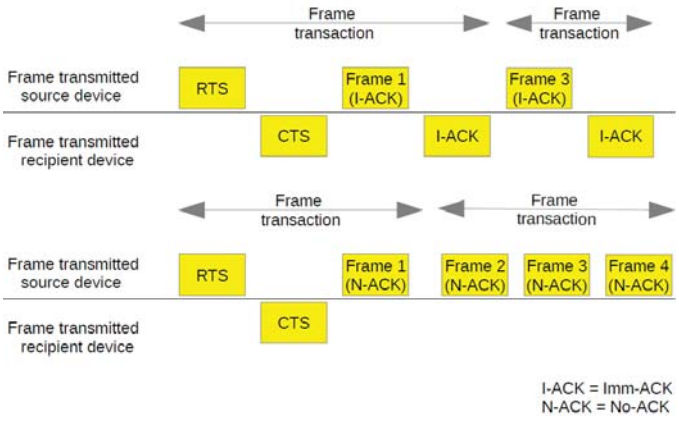

Fig. 4. Frame transaction examples.

B. Time structure of a MAC frame

The basic timing structure for a frame exchange is a superframe. The superframe is composed of 256 medium access slots (MASs) as shown in Fig. 7. Each superframe starts with a beacon period (BP). The BP is composed of 16 beacon slots. All nodes which share the same channel follow the same superframe structure.

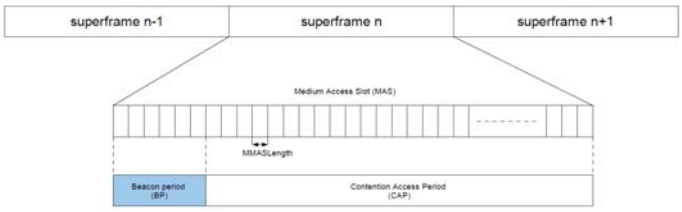

Fig. 5. Time structure of MAC frame.

The network coordinator device indicates its presence in a network to other devices by transmitting beacon frames. This allows other devices to perform the network coordinator discovery and network join procedures.

TVWS operation requires that before the completion of the master discovery procedure, a device does not know the operating channels. This results in a channelization combinatorial far too large to be discovered through blind scanning. In IEEE 1900.7 the data carried by a beacon frame is designed to speed up the discovery process. Additionally an optimized channel switching mechanism is implemented to maintain the connectivity when a new channel map is requested by higher layers.

IV. Performance Evaluation

A. PHY Layer

The IEEE 1900.7 PHY has been specified to be very flexible in terms of spectrum profile allocation. For instance, the 2MHz profile (see TABLE II. was designed to cope with 6MHz and 8MHz TV channelization in order to fit best to regulation worldwide. This profile also enables narrower spectrum allocation. Fig. 6 shows an example of 2 fragments of 2MHz each separated by an unused 2MHz fragment, using the IEEE 1900.7 FBMC PHY (0.25K and 1K profile as per TABLE II.). LTE CP-OFDM spectrum profile is given as a reference. The reference system uses 1024 carriers and a guard interval (GI) of 72 samples, similar to 10MHz LTE signal. The figure illustrates the much focalised spectrum localization of IEEE 1900.7 vs CP-OFDM based systems in the edges of the spectrum and in the gap.

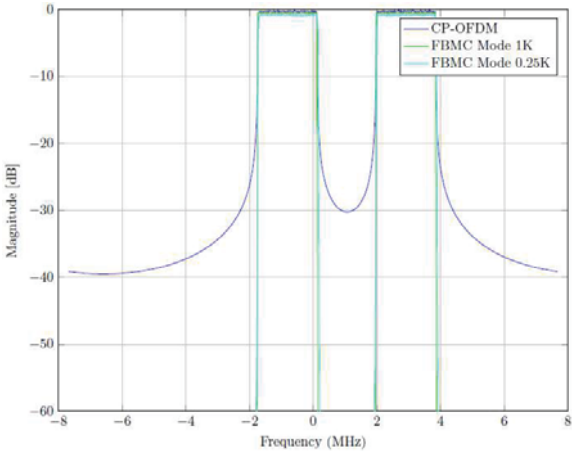

Fig. 6. IEEE 1900.7 spectrum profile example

Fig. 8 and Fig. 8 give PHY layer complete (TX-RX) performance evaluation considering a Frequency Spreading FBMC (FS-FBMC) architecture of the receiver [28][29]. With such a receiver the whole RX processing, including channel estimation and equalization is performed in the frequency domain. Performance evaluation are provided for a static LTE "Extended Typical Urban" channel model which is a 9 tap channel (delay spread of 5*us*) as defined in TABLE III. Results are given for a QPSK considering a coding rate 1/2 (Fig. 8) and 64QAM (Fig. 8) considering a coding rate 2/3 under a perfect channel estimation assumption.

TABLE III. LTE "EXTENDED TYPICAL URBAN" CHANNEL

Tap index [samples]	**0**	**1**	**2**	**3**	**4**	**8**	**25**	**35**	**77**
Relative power [dB]	-1	-1	-1	0	0	0	-3	-5	-7

The Mode 1K gives significant performance gain compared to CP-OFDM (~1.5dB). It can be explained by the high performance offered by the Frequency Spreading RX scheme demonstrated in [29]. When the size of the FFT is reduced (carrier spacing is increased), a good performance level compared to LTE CP-OFDM is maintained. This suggests that carrier spacing could be significantly reduced when FBMC is considered giving the waveform a significant advantage for resilience to Doppler shift.

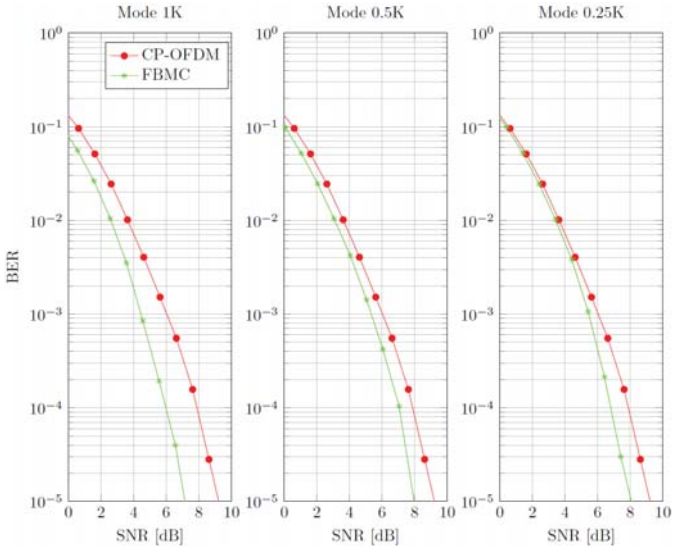

Fig. 7. IEEE 1900.7 QPSK 1/2 vs CP-OFDM

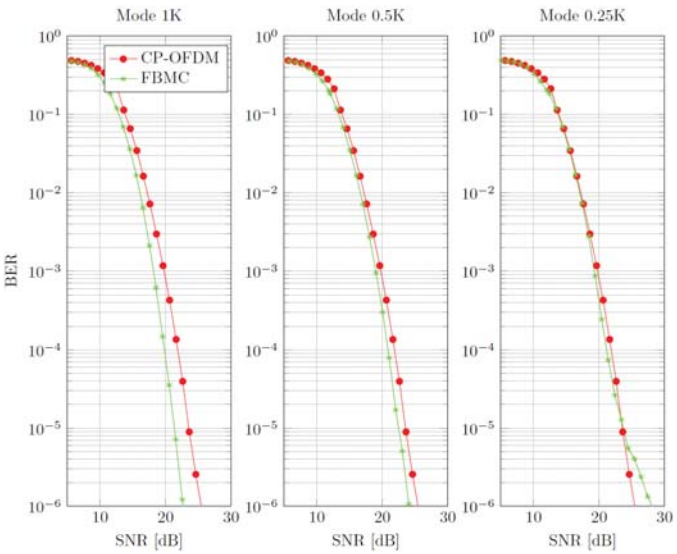

Fig. 8. IEEE 1900.7 64QAM 2/3 vs LTE CP-OFDM

B. MAC sublayer

Performance evaluation of CSMA/CA RTS/CTS MAC sublayer can be analytically derived from the Markov chain model of [30] under the following assumptions:

- No hidden nodes and capture effect.
- Failed transmissions only occur as a consequence of a collision.
- All nodes are saturated and always require to send packets.
- For any given user, the probability of collision, is constant and independent of the past collision history.
- The probability of collision does not depend on the backoff stage at which the transmission is made.
- All nodes have the same data rates and the same amount of time to transmit.

The closed form of the saturation throughput is given in [30]. Based on these assumptions, we evaluate the performance of the proposed PHY-MAC sublayers. The saturation throughput of the IEEE 1900.7 access method is estimated by considering perfect channel conditions for the PHY (no noise, no fading): failed transmissions only occur as a consequence of a collision. The evaluated MAC-PHY saturation throughput is an upper bound that gives the maximum achievable throughput on a shared channel with a given configuration. We assume that the MCS configuration for the acknowledge frame is the same as the MCS configuration used for the data payload transmission. As far as signaling packets like RTS or CTS are concerned, the MCS index 1 (QPSK, Coding rate ½) is used. As these messages serve for virtual carrier sensing, they should be decoded by all the nodes within the cell.

The achievable throughput in the case of two packet sizes 1500 bytes and 8x1500 bytes for various network load and PHY mode has been evaluated for 8MHz bandwidth. Assumption is made that the payload packets are sent using the MCS index 4 (16QAM coding rate ¾). The load of the network varies from 1 to 20 nodes trying to simultaneously access the channel. Results are depicted in Fig. 9.

Significant performance improvement is achieved when payload size is large. Indeed in case of large packet size, the overhead introduces by the handshake mechanism becomes more and more negligible. The 0.25K mode is the most efficient due to the small size of the FFT. This mode is particularly interesting for small packet size as the duration of the burst is shorter than with the 1K mode and the number of padding bits to fill a multicarrier symbol is reduced. Conversely, the 1K mode is more robust to large delay spread making this configuration interesting for long range scenarios while 0.25Kmode would be better for medium to small cell size.

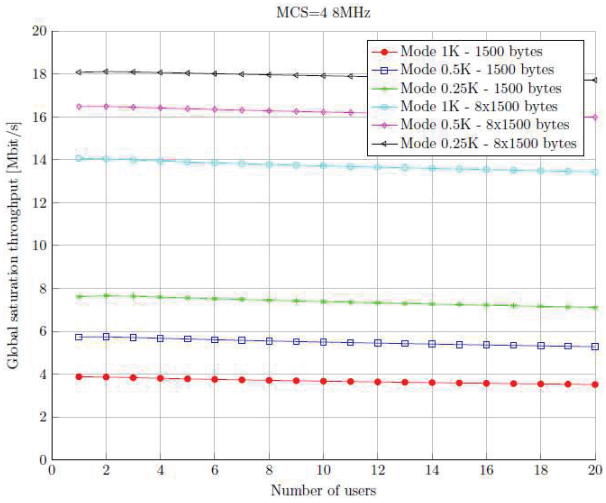

Fig. 9. Achievable throughput in Mbit/s for various mode aussming 8MHz bandwith.

V. Conclusions

In this paper, preliminary performance evaluation of some IEEE 1900.7 profiles has been provided. It was shown that the FBMC PHY used in the standard outperforms classical multicarrier PHY such as LTE 10MHz CP-OFDM. Thanks to the properties of FBMC, the IEEE 1900.7 standard has very good ACLR performance, and is well suited to fragmented spectrum operation. The steep roll-off of the FBMC spectrum also allows higher transmit power, when considering FCC spectrum masks, resulting in larger coverage. The standard is aimed as being published in early 2016.

***Abstract*—Identifying the person utilizing voice / speech utterance or Biometric based on voice is gaining importance in recent scenarios, for applications like, access to shared machine from a distance through phone. Here, the person is first identified among a list of people and then a personalized service is provided by the machine. But this research area, faces threats from the attackers, who utilizes voice disguise, to steal personal information / resources of a target. Therefore, this paper studies the effect of three types of voice disguises, along with the normal speaking on speaker identification performance. Out of the three voice disguises, two are variants of imitative type, namely, Synchronous and Repetitive Synchronous speaking, and one is the Fast speaking type. A method has been proposed to measure the reliability of the test speech data, which helps in the selection of reliable speech part from the total test speech data, and which will then participate for identification process. Experimental results showed the overall better performance of the proposed method over the conventional speaker identification method.**

***Index Terms*—Reliable Frame Selection, Robust Speaker Identification, Biometric Based on Voice, Voice Disguise.**

I. Introduction

Determining the person who has spoken a given speech utterance from a group of people is referred to as *speaker identification*. It is also known as Biometric based on voice. It falls under the broad *speaker recognition* area, which in general, deals with finding out the speaker of the given speech utterance [1], [2], [3]. Speaker identification can be classified as *closed* or *open*. It is termed as *closed*, when it is known in advance that the given test speech utterance has been spoken by one amongst the N group of people. On the other hand, when the speaker of the given test speech utterance can be one, not belonging to the N group of people, it is referred to as *open*. In an open speaker identification, the task is to first determine whether the speaker belongs to the group of N people or not, if yes, then the speaker identification process is continued, otherwise the test speech utterance is discarded. Speaker identification can be further classified as *text-dependent* or *text-independent*. When the speech data utilized during the training of speaker models is different from the test speech data, it is referred to as *text-independent* and *text-dependent* otherwise. It is not difficult to understand that the open speaker identification is tougher than the closed and text-independent is more difficult than the text-dependent speaker identification [4], [5]. In this work, closed text-independent speaker identification system has been studied and for simplicity, will be referred to as just speaker identification in the rest of the paper.

With the rapid advancement in technology, speaker identification research has the potential to capture the current consumer electronics market. It can be combined with the mobile phones to gain access to information from remote places. Here, the person is first identified from a group of people and then a personalized service/information is given to him/her. In an office/home environment, a person can be uniquely identified by a shared machine, like robot or television to give customised services to the user. But this research faces challenges due to the mismatched training and test conditions, which greatly decreases its performance [5], [6], [7]. "Non-electronic voice disguise" is one, out of many factors, like environmmental noise and electronic voice disguise (a typical example is the "voice changer" software [8]) which contributes to the mismatched problem.

Non-electronic voice disguise (referred to as, simply, voice disguise in the rest of the paper) occurs when a person deliberately modifies his/ her own voice, either to sound like a target so that target's personal information or resources can be stolen, or to hide his/her own identity. It is very commonly utilized in crime scenes [9]. Therefore, researchers are now trying to develop robust speaker identification system against voice disguise. A new speech feature based on the AM/FM approximation of the speech signal, called *pykfec* (Pyknogram Frequency Estimate Coefficient) has been proposed in [10], and it has shown an overall better performance over the famous MFCC feature for voice disguise. Glottal and vocal tract characteristics of voice impersonators were studied in [11] to detect voice disguised speech data. The effects of different types of human voice modifications/voice disguise on the speaker identification performance has been investigated in [12], [13]. Frame selection has been carried out in speaker identification research for improving identification efficiency under mismatched conditions [14], but frame selection of the test speech data under voice disguise scenario has not been studied. Therefore, in this study reliable frame selection from

the voice disguised test speech data has been carried out. Here, instead of finding out the speaker of the given test speech data, speaker for each test frames were determined. The decision about the reliability or non-reliability of the frame is found out by the distance between the probability score of the selected speaker and other enrolled speakers and a threshold value. Finally, only selected reliable frames participated in the identification process using maximum likelihood rule[15]. Experimental results showed the favourable performance of this method over the conventional method for voice disguise.

The rest of the paper is organized as follows. The next Section describes the proposed frame selection method. Experimental results and discussions are decribed in Section 3. Finally, Section 4 concludes the paper with future directions.

II. Frame Selection Method.

The conventional Gaussian Mixture Model (GMM) based speaker identification system make a decision about who spoke a given test speech utterance $\vec{X} = \{\vec{x_1}, \vec{x_2}, \vec{x_3}, ..., \vec{x_T}\}$ amongst the S registered speakers using the following maximum log liklihood rule [15] :

$$\widehat{S} = \arg \max_{1 \leq k \leq M} \sum_{t=1}^{T} \log p(\vec{x_t}|\lambda_k) \tag{1}$$

In the proposed system, the decision about the speaker is calculated in the following steps:

1) Each frame is viewed as a classification problem and the speaker is found out on a frame by frame basis:
$$\widehat{S} = \arg \max_{1 \leq k \leq S} p(\vec{x_t}|\lambda_k) \tag{2}$$
2) To calculate the reliability/degree of confidence measure of the decision of the frame, the distance between the probability score of the selected speaker and other speakers were found out:
$$D_k = |p(\vec{x_t}|\lambda_{\widehat{S}}) - p(\vec{x_t}|\lambda_k)| \qquad k = \{1, 2, 3, ..., S\} - \{\widehat{S}\} \tag{3}$$
The larger the distance D_k between the selected speaker for the frame and the other speakers, the more is the confidence in the decision and vice versa.
3) In this step, each D_k is compared with a $threshold$, if $D_k \leq threshold$, the frame is discarded.
4) After the step 3, the less reliable frames will be discarded and the remaining frames will participate in the final decision about the speaker using the conventional maximum likelihood rule [15].

III. Experimental Setup and Results

A. Database and Speaking Styles

CHAINS corpus has been selected for this study. It is specifically developed for the speaker identification research [17]. It provides different speaking styles from the same speaker. This corpus gives an opportunity to capture the unique characteristics of the person, which remain intact in a variety of speaking styles and also facilitate the study of voice disguise.

It consists of approximately 36 person's voice recordings. Out of which, a bulk of people i.e. 28 (14 male and 14 female) were from the same dialect belonging to eastern part of Dublin, which raised the identification difficulty level and 8 (4 male and 4 female) were from different dialect belonging to either UK or USA. People's voice were recorded in 6 speaking styles. For this study, the following speaking styles were utilized:

1) Normal Speaking (Norm)
The speakers adopted their day-to-day speaking style for recording the text (fable/sentence).
2) Synchronous Speaking (Sync)
Speakers spoke a given text (fable/sentence) in synchronization with a co-speaker. It showed marked reduction in inter speaker variabilities for global timing and phrasing parameters.
3) Repetitive Synchronous Imitation (Rsi)
In this a person has been selected per sex, whose normal voice recordings (fable) served as a target for other speakers. The whole fable reading of the target has been broken into 19 sentences. Each sentence recording has been played repeatedly for 8 times with a gap of 0.5 sec. The speakers listened to the target and joined the repeating loop after the 2nd instance, speaking it for 6 times. The penultimate recording of the speakers were kept. It produced a very close match between the speaker and the target in prosody.
4) Fast Speaking (Fast)
Speakers listened to two sentences which has been spoken at a very fast rate from the normal speaking. Speakers then recorded their voice at approximately this fast rate. It produced complex changes in the speaker's voice.

,

Out of the above four speaking, two falls under the category of imitation, namely, Sync and Rsi. The Fast speaking falls under the non-imitative speaking styles. The Norm and Sync speaking has been recorded in a professional recording studio using Neumann U87 condenser microphone, whereas, Fast and Rsi speaking has been recorded in a quiet office environment using a shure SM50 head-mounted microphone. The spectrogram of the Norm, Sync and Fast speaking for a sentence is shown in Fig. 1, in the next page. From the Figure, it can be observed that Fast speaking shows good spectral differences from the Sync and Norm speaking of the same speech utterance.

B. Speaker Identification Experiments

Speaker identification experiments were conducted for the Baseline (Conventional GMM method [18]) and the proposed method. For both the Baseline and the proposed method, speech data were cut into smaller frames of frame size 25ms with a frame shift of 10ms. This can be done because, speech is a non-stationary signal and cutting it into smaller frames make it quasi-stationary. Features were then extracted

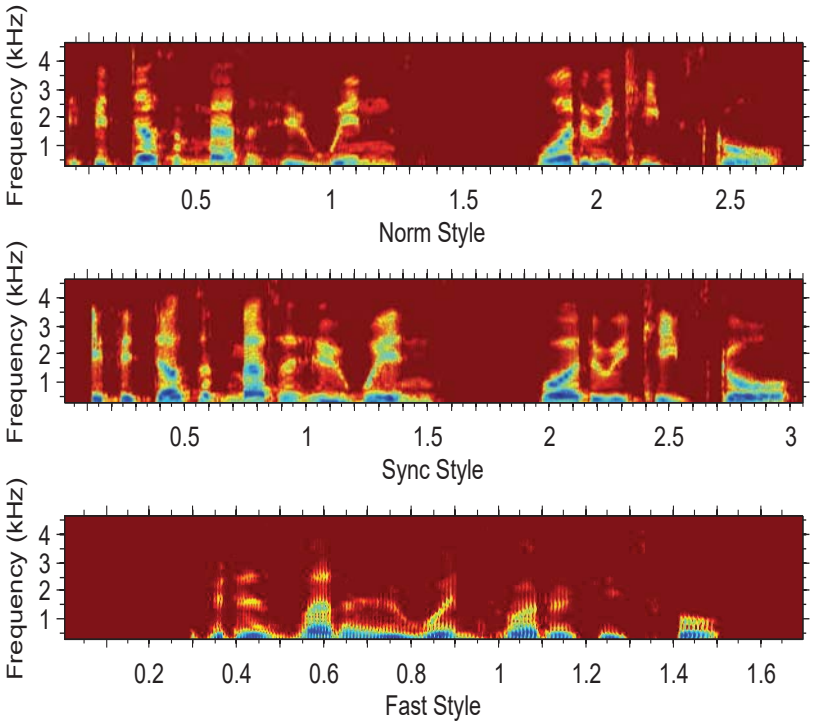

Fig. 1. *Spectrogram of the Norm, Fast and Sync speaking for the speech utterance If it doesnt matter who wins, why do we keep scores? [16]*

from these frames utilizing 12 liftered Mel-Frequency Cepstral Coefficients (MFCC), excluding the 0^{th} coefficient. Liftering is used to re-scale the lower and higher magnitude's cepstral coefficients to similar magnitudes. Cepstral mean removal method was also applied to compensate for channel variations. Speakers were then modelled utilizing 64 components GMM.

For training the speaker models, $\sim$ 70 sec of Norm speaking speech data were utilized. For testing, $\sim$ 30 sec of Sync, Fast, Rsi, along with the Norm speaking speech data were utilized. For this, the 30 sec of speech data were first segmented into 5 sec sentences, and $\sim$ 5 sentences per speaker were then utilized for testing.

The identification accuracy of the speaker identification system is found out using the following equation:

$$\frac{No.\ of\ correctly\ identified\ test\ utterances}{Total\ no.\ of\ utterances\ tested} \times 100\% \quad (4)$$

C. Results and Discussions

The identification accuracies obtained for the Baseline and the Proposed system were tabulated in Table 1. From the table, it can be observed that, the Proposed system showed similar performance for the Norm and Sync speaking test data for the threshold value of 0.03. For Fast speaking test

TABLE I
IDENTIFICATION ACCURACY (%) FOR BASELINE AND PROPOSED METHOD UNDER VOICE DISGUISED AND NORMAL TEST SPEECH.

Test Speech	Baseline(Conventional GMM)	Proposed	Threshold
Fast	80.75	81.22	0.1
Rsi	74.54	76.85 / 77.31	0.1 / 0.3
Sync	96.76	96.76	0.03
Average	84.02	84.94 / 85.10	NA
Norm	100	100	0.03

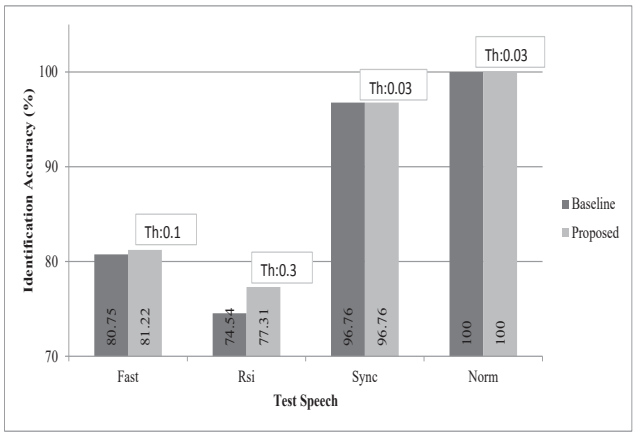

Fig. 2. Identification accuracy (%) of the Baseline and the Proposed method for voice disguised and normal speech test data.

data, the Proposed system showed a relative improvement of 0.58% for the threshold value of 0.1 over the Baseline system. For Rsi speaking test data, the Proposed system showed a relative improvement of 3.10% for the threshold value of 0.1 and a relative improvement of 3.72% for the threshold value of 0.3 over the Baseline system. The average of the identification accuracies across the different voice disguised test speech data also indicate the overall better performance of the Proposed System over the Baseline. For this initial study, the selected threshold value for frame selection has been chosen on a trial and error basis. Change in the threshold value also affects the identification accuracy as can be seen for the Rsi test data, where a threshold value of 0.1 yielded an identification accuracy of 76.85% and a threhold value of 0.3 yielded an identification accuracy of 77.31%. This suggests that, a careful selection of the threshold value can enhance the performance of the speaker identification system. The identification accuracies of the Baseline and the Proposed System for voice disguised and normal speaking test data is also plotted in Fig. 2. Here, for Rsi test speech, only the threshold value of 0.3 is used. It also confirms the better performance of the Proposed System for Fast and Rsi test speech data over the Baseline.

IV. Conclusion

A frame selection method for test speech data has been proposed in this paper. Here, instead of finding out the true speaker of the whole test speech utterance, the true speaker for each frame is determined. A degree of confidence measure is then calculated, using the distance between the probability score of the true speaker and the remaining enrolled speakers. The greater the distance, the higher is the confidence in the identification decision. Using this distance and a threshold value, frames were then categorized as reliable and non-reliable. Finally, only reliable frames participated in the identification of the test speech data using the conventional maximum liklihood rule.

Experimental results on voice disguised test speech data showed an overall better performance of the proposed system compared to the conventional GMM based method. However, for normal speaking test data, the proposed system has shown similar performance. In this study, the threshold value utilized for frame selection has been selected on a trial and error basis. However, an algorithm for careful selection of the threshold value can enhance the speaker identification performance and will be a subject for future study.

Abstract: **The foremost challenging issue in Cognitive radio networks (CRN) is spectrum sensing and allocation. Cognitive radio network consists of a collaborated frame of layer-wise multiple cognitive radios dynamically responding to the surrounding radio environment. The primary concern of dynamic spectrum sensing is identifying the number of primary users (PUs) and the spectral bandwidths currently used, to address the issues of harmful interference of secondary users (SUs) with the primary spectrum, co-existence of hidden primary nodes. In this article, we present a geolocation aware dynamic sensing (GLADS) scheme that defines a spectral sensing and management scheme based on the location of the primary users and the bandwidths of current usage to (i) detection of number of active primary users on the channel, and (ii) using this information to predict the number of hidden primary nodes on the channel.**

Key words: Cognitive radio networks, Dynamic spectrum sensing (DSS), dynamic spectrum accessing (DSA), angle of arrival (AoA),

I. INTRODUCTION

Cognitive radios (CRs) a disruptive technology that provides promising solutions to the spectral scarcities of the ever increasing network traffic in heterogeneous wireless networks. CRs adapt dynamic spectrum sensing (DSS) and dynamic spectrum accessing (DSA) techniques [1], with the support of multiple antenna systems of the secondary users. Cognitive radio technology is upgraded and enhanced from the existing basic Software Defined Radio with smart antennas technology. CRs are capable of sensing and identifying the unutilized parts of the licensed spectrum by the primary users (PUs) and provide an opportunistic and non-harmful interfering access to the secondary user nodes (SUs). These white spaces are the guard bands defined in space, time and frequency domains to resist the potential interference in the air space. DSA techniques preferred to enhance the spectrum agility aspects of the cognitive radio networks (CRNs). CRs use DSS technology to detect spectral holes to provide services at low prices thus empowering the network operators with increasing commercial benefits. Spectrum sensing techniques not only identify and protect the spectral bands used by the primary user nodes (PUs) but also detect the spectral holes to manage the secondary user nodes (SU) traffic. The *underlay* approaches allow simultaneous packet transmissions of the primary and secondary user nodes separated by protective masks while limiting the interference of the secondary user nodes merely to the floor level noise. The *overlay* approaches allow the secondary user nodes to act partly as the relay nodes and the other as the transmitting nodes. The *interweave* approaches use the opportunistic spectral access schemes (i.e.) to allocate if only if the channel is vacant.

Spectrum opportunity discovery techniques try to determine the exact geolocation of the primary users along with their signal strengths and the number of bandwidths they availed per each session. The mobile databases of PU nodes are used to detect the geolocation as these nodes are non-stationary entities. As the signal-to-noise ratio (SINR) values highly differ from primary and secondary nodes, the complexity lies in the proper selection of backup channels. The beacon periods are used to estimate the duration of quiet periods, reservation periods to allotted for packet transmission over multiple spectral channels. The conventional spectrum sensing algorithms concerning the frequency, space and time are being upgraded to use the code dimensions, frequency hopping schemes of the spectral bands [1]. The parameters such as angle of arrival (AoA) that differ with the space dimension radios and their signals from the primary and secondary antenna can better define the spectral opportunities. The work of [2] implements the particle swarm optimization algorithm to accurate the positions of primary transmitters in CRNs.

We present a geolocation aware dynamic sensing (GLADS) and cooperation scheme that defines a spectral sensing and management scheme in terms the location and the bandwidths of current usage by PUs to (i) detection of number of active primary users on the channel, and (ii) using this information to predict the number of hidden primary nodes, which suddenly tune their radios. CRs need to sense immediately such primary node activity and alert the secondary users availing these bands to switch immediately to the next available band.

II. RELATED WORK

Localization algorithms are optimized one at the local level within a small group of cluster/mesh and the other at the global scale for large size wireless network level. Since the cognitive network consists of one or many wireless regional area networks we implement global optimization for an entire region of the network. A two level collaborative spectral sensing scheme has been proposed in [3] which uses the sensing parameters obtained from the cognitive sensor nodes that are grounded to define the real-time parameters for PU and SU nodes with higher degrees of accuracy. The information from the ground nodes is updated at regular intervals with priorities as per their frequencies. The analysis of [4] sequential and probabilistic sensing models has been performed by which states that the random hopping algorithms perform better to sequential sensing models. The concept of client-base network of secondary users has been implemented in [5] that performs non-contiguous orthogonal frequency division multiplexing technique to evaluate the spectral accessibilities with a high degree of fairness.

The enhanced version of designing a network of cognitive radio nodes [6] which are mapped in terms their interference temperatures highly evaluated from multiple domains of the radio environment. The works of [7] consider the power constraints of communication and the resulting interference levels and proves that the hazardous interference between the primary and secondary nodes can be mitigated to consider levels. The positions of PUs and SUs are estimated in terms of binary detection indicators estimate [8] the error probabilities between the actual and measured distances. A technique of awarding grades based on the performance of the nodes using the weighted sequential probabilities has been proposed in [9] which addresses the sensing dysfunctional features at the secondary user node levels. An interference based resource allocation technique has been introduced in [10] that restricts the constraints of position estimations to pre-defined limits to enhance the sensing capabilities of the cognitive radio networks. The signal strengths received from the radio transmitters, the path loss and fading parameters are used to define the [11], actual positions of the nodes. Installation of multiple access points increases the hardware and computational complexity and cost of installation also.

The work of [12] implements the technique of localization using a single point in wireless networks. Multiple channel switching during the packet transmissions increases packet delays and packet drop rates in cognitive radio networks. To address this issue a three-way solution based on the cost, [13] delay and the hybrid techniques. Another way of efficient localization scheme has been proposed by [14] which improvises a technique of configuring the primary and secondary base stations in proper positions so as to all the cognitive radios as well as the primary users present at any part of the given network.

The concept of leader and follower has been used to judge the unused spectral bands in an effective manner so as to allocate to the secondary user nodes. The secondary user nodes that want to communicate are only allowed to scan the radio environment [15] and use the sidebands of the carrier signal so as to minimize the interference. The localization in cognitive radio networks supporting cooperative methods is defined in terms of the primary user based noise levels using Bayesian technique has been provided in [16]. The received signal strength parameters are used to implement constrained localization technique [17] to estimate the location of primary user nodes. Parameters such as the receiver signal strength, direction-of-arrival with some pre-defined bounds are implemented in [18]. The channel allocation scheme that preserves the rights of primary users with a constant rate of secondary node assignment rates has been proposed in [19]. The localization method based on the evaluations of linearization of RSS parameters has been proposed in [20]. The localization method based on the time of arrival rates of the communication (request-to-send, clear-to-send) messages, data and acknowledgement have been proposed in [21] that updates these parameters in a cyclic manner.

III. SYSTEM MODEL

Geo-location aware dynamic spectrum sensing (GLADS) technique is based on the parameters such as the RSS parameters, Distance or Time (DoA or ToA). The primary and secondary user nodes are assumed to be associated with the respective base stations. The works of [17] assume that the transmission powers of the primary nodes are unknown and each primary node can be heard by a minimum of four secondary user nodes. We extend this idea and introduce the concept of defining a primary grid with a primary base station (PBS) positioned at the origin, and two primary user nodes as access points to improve the efficiency of our estimations. The basic assumptions of GLAD protocol are given as:

(i) Primary beacon node or Primary base station located at a known fixed position in the grid transmits signals of equal strength in all directions.

(ii) The positions and transmission powers of the primary users are unknown excluding the immediate two neighbors.

(iii) The secondary user nodes are assumed to know their one-hop, two-hop and three-hop neighbor (if required) nodes and this information is periodically updated to the secondary base stations.

A. GLAD Setup Phase

Let P_{BS} be the primary base station be kept at the origin and it initiates the session by the beacon and let PU_1 be the first nearest primary user node (TV_{TX}) located at the distance R obtained by using the time of arrival method. A data that exists

in the database of the primary base station. PU_2, be the second nearest primary user node (TV_{TX}) located at a distance $\frac{4R}{3}$ from the first primary user node. These two primary user nodes are assumed to be the primary access points based on which the positions of other member nodes static/mobile and PU/SU member nodes are estimated. We consider the network to be a square grid and the first secondary user node be positioned at a distance $\frac{2R}{3}$ from the primary node.

(i) We define the following conditions: The primary node exists in the middle of the diagonal of the square consisting of four secondary user nodes situated at the four corners of the square grid.

(ii) The transmission range of second primary user node, PU_2 is assumed to be equivalent to the distance $\frac{2R}{3}(i.e.)TX_{SU} \approx \frac{2R}{3}$. For larger networks, the secondary user node mesh consists of two-hop and three-hop neighbors.

A Bayesian-based covariance channel occupancy model has been designed in [22] that estimates the theoretical and spatial covariance techniques to evaluate the states (active/sleep) of the primary antennas or nodes in CRNs.

Hidden Primary node Problem: GLADS addresses the issue of Hidden PU by obtaining the a maximum of two adjacent secondary nodes identifying the activities of the PU then a search algorithm for second hop neighbors of the respective PU is performed. If at least one secondary user/primary user identifies any activity, then the conformity of hidden primary node is made and located in the grid.

B. GLAD Functional Phase

We obtained the square grid of such secondary user nodes, one hop neighbors for each secondary user and this grid is extended for two hop and three hop neighbors as per the distance of the secondary user node from one another. This procedure is over the entire region of the network.

Let $\left(x_{PU_1}, y_{PU_1}, z_{PU_1}\right), \left(x_{PU_2}, y_{PU_2}, z_{PU_2}\right)$ represent the coordinates of PU_1 and PU_2, $\theta_{11} and \theta_{22}$ be the angles at the P_{BS} and PU_2 respectively. By applying the basic laws of vector analysis, the distance between the primary base station and second primary access point PU_2 is obtained as $2.021R$. R is the diagonal vector joining the distances cognitive radio nodes. To obtain the position of secondary user SU_i at some $\left(x_i, y_i\right)$, and SUj at some $\left(xj, yj\right)$, angles of arrival being $\theta_1 and \theta_2$ we define the distances using RSS,

$$d_i = \sqrt{\left(\left(x_{PU1} - x_i\right)^2 + \left(y_{PU1} - y_i\right)^2\right)} \text{ and}$$

$$d_j = \sqrt{\left(\left(x_{PU2} - x_j\right)^2 + \left(y_{PU2} - y_j\right)^2\right)} \quad \ldots\ldots\ldots\ldots (1)$$

And by using DOA methods are obtained as:

$\tan(\theta_1) = \frac{y_i - y_{PU1}}{x_i - x_{PU1}}$, the distance of the secondary user node SU_i from the primary node PU_1 $\tan(\theta_2) = \frac{y_j - y_{PU2}}{x_j - x_{PU2}}$, the distance of the secondary user node SU_j from the primary node PU_2.

Each secondary node individually and exhaustively searches for the transmission signals of the primary users in close by. If for any two secondary user nodes SU_i, SU_j the probabilities for finding a primary node obtained as $P\left(SU_i\right)$ and $P\left(SU_j\right)$ for the same primary node in the neighborhood, then by applying Bayes' conditional probability we have,

$$P\left(SU_i \mid SU_j\right) = \frac{P\left(SU_i, SU_j\right)}{P\left(SU_j\right)} \text{ and}$$

$$P\left(SU_j \mid SU_i\right) = \frac{P\left(SU_i, SU_j\right)}{P(SU_i)} \quad \ldots\ldots\ldots\ldots..(2)$$

$$\Rightarrow P\left(SU_i \mid SU_j\right) = \frac{P\left(SU_j \mid SU_i\right) P(SU_i)}{P\left(SU_j\right)} \quad \ldots\ldots\ldots\ldots.. (3)$$

By applying the Bayes chain rule for the given set of secondary nodes SU_i, SU_j in determining the probabilities of finding the same set of primary nodes as $\left\{X_{PU1}, X_{PU2}, \ldots\ldots\ldots X_{PUN}\right\}$ we have,

$$\begin{aligned} &P\left(X_{PU1}, X_{PU2}, \ldots\ldots\ldots X_{PUN}\right) = \\ &P\left(X_{PU1} \mid X_{PU2}, \ldots\ldots\ldots X_{PUN}\right) * \\ &P\left(X_{PU2} \mid X_{PU2}, \ldots\ldots\ldots X_{PUN}\right) * \\ &P\left(X_{PU3}, \ldots X_{PUN}\right) \end{aligned} \quad \ldots\ldots\ldots\ldots (4)$$

Above equation can also be written in the form

$$P\left(\cap_{k=1}^{n} X_{PUk}\right)=\prod_{k=1}^{n} P\left(X_{PUk} \mid \cap_{m=1}^{n} X_{PUm}\right) \quad \ldots\ldots\ldots\ldots (5)$$

where '$\cap$' represents the joint probability of finding the primary node, by applying the law of probability we marginalize the probability of the primary nodes as:

$$P\left(SU_i\right)=\sum_{m=1}^{k} P\left(SU_i \mid SU_j=SU_m\right)P\left(SU_j=SU_m\right) \ldots (6)$$

The net probability of each primary user node is measured from the probability estimation of at least four number of secondary user nodes. Application of conditional probabilities for this frame of SUs, the active/sleep states of the PUs can be determined. The size of the contention window is defined as per the obtained results to the SUs seeking the access to use the communication channel for packet transmissions.

Table1. Conditional probabilities truth table for locating PU

	$P(SU_i)$	**$P(SU_j)$**	**$(P(SU_i) \cap P(SU_j))$ = P(PU) detection**
$P(SU_i)$	T	T	T
$P(SU_j)$	F	T	F
$P(SU_i)$	T	F	F
$P(SU_j)$	F	F	F

IV. SIMULATIONS

In the proposed protocol we estimate and verify the positions of primary user nodes with respect to a minimum of four secondary nodes present in the immediate neighborhood of the primary node. Simulations have been performed by using MATLAB and the proposed protocol has been analyzed. Based on the conditional probabilities obtained from simulations, if the state of the primary node is true with respect to three at least and four immediate neighbors of a primary node, then that position is selected as the optimum center for the primary node as shown above.

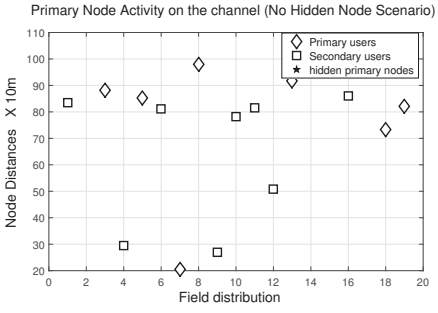

Figure 1 Distribution of PUs, Hidden primary users and Secondary users in a CRN

Figure 1 describes the distribution of nodes (PUs, hidden PUs and SUs) in a cognitive radio network. The primary and hidden primary nodes are located by the proposed GLADS technique, and the secondary nodes adjacent to such nodes are allowed to monitor the channel cautiously and increase their contention window from [0, 4] to [0,8]. The secondary users between the regions 6 -10 can use the communication channel for transmission and the secondary nodes nearer to the active primary channels are allowed switch to a contention window size to [0,8].

The following figure 2 shows the comparison of the proposed protocol with the existing location based and state based protocols.

(a) Finding the optimum centers for Primary and Hidden Primary user nodes in the GLADS Cognitive Radio Network

The primary user nodes are detected by considering the pairwise combination of conditional probabilities for four immediate neighbors as mentioned above.

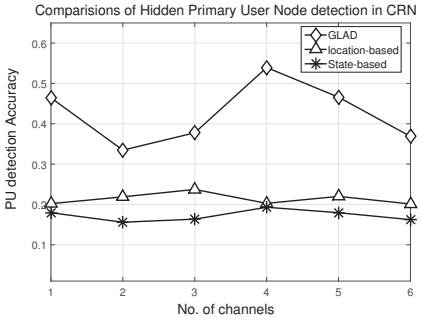

Figure 2 No hidden primary nodes Scenario in the proposed protocol

But for the identification of hidden primary node PU_h , we assume that between the four adjacent nodes $\{SU_i, SU_j, SU_k, SU_l\}$, if only two of the secondary nodes discover an active signal from the hidden primary node, then we consider the probabilities of the immediate second hop neighbor nodes which can listen and sense the activities of the primary node.

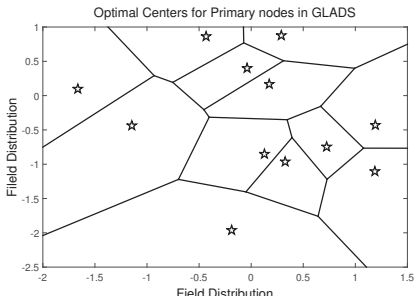

Figure 3 Optimal centers for Primary nodes in the proposed Protocol

If any one of the secondary nodes identifies a signal from this node alone and not by a different primary node towards PBS, then we assume such a node to be hidden primary node and is mapped on the field. The secondary nodes increase their contention windows to again [0, 8] to prevent the harmful collisions with the primary nodes. The field distribution is obtained as shown in the figure 3.

VII. CONCLUSIONS

Spectral sensing and intelligent based decision making is the fundamental aspect of cognitive radio networks. In this regard, this work defines the approaches for dynamic spectral sensing aspects of cognitive MAC. The geo-location aware spectral sensing technique is defined in terms of SINR and probability factors obtained from the grid of secondary nodes. The future work can be extended by including the parameters such as packet losses/communication channel. Inclusion of energy efficient spectrum sensing and access algorithms is required as the sensors have limited energy and memory resources.

***Abstract* - The number of older people in need of long-term care and assistance is increasing. It is estimated that by 2025 more than 20% of Europeans will be 65 or over, with a particularly rapid increase in the number of over 80s. Due to physical or cognitive impairment, many need assistance in their activities of daily living (ADL).**
One of the key challenges for Europe is to transform this longer life expectancy into longer active and healthy life years. Building on the existing European norms for quality long-term care services, it is necessary to develop an integrated quality framework for long-term care services which would cover very different types of care: all healthcare (both preventive and rehabilitative), social services, care for cognitive diseases, services delivered at home as well as support for carers as an integral part of the quality improvement process. The priority should be to develop a "person-centered" approach, creating a comprehensive system that would offer easily accessible and affordable continuous services allowing the users to enjoy a decent quality of life, independence and the chance to remain active in society.

I. INTRODUCTION

This paper looks at the impact of demographic ageing within the European Union (EU), which is likely to be of major significance in the coming decades [1]. It shows a clear shift towards a much older population structure that is already becoming apparent in several EU Member States. In response to the growing issue of ensuring the adequate care for the elderly people, European Commission has financed WeDO[2] project ("For the Wellbeing and dignity of Older people: European Quality Framework for long-term care services") which developed Quality care training package [2] with the aim of promoting quality long-term care services in Europe[3]. Based on the concepts of active ageing, everything should be done to enable the person to live autonomously for as long as possible.

The proposed and developed eWALL framework within eWALL project (project no. 610658: "eWALL for Active Long Living") described in this paper follows the norms and standards described in the two documents: "The European Quality Framework for Long-term Care Services"[3] and "The European Charter of the rights and responsibilities of older people in need of long-term care and assistance"[4] and focuses on providing outcome oriented and evidence based services for quality long-term care [2-4]. This way, elderly people in need of care and assistance stay involved and are empowered to define how their needs are met. At the same time, their caregivers are also given support in order to maximize the quality of the services provided.

This is planned to be done by creating a "Caring Home" environment, meaning an environment that "senses" intuitively the wishes and needs of the person that lives in the house, providing unobtrusive daily support, notifying informal and formal caregivers when necessary and serving as a bridge to supportive services in areas such as risk management and home safety, e-Health and lifestyle management and Activities of Daily Living (ADL) [5].

II. eWALL FRAMEWORK: ARCHITECTURE

Architecture of eWALL system involves an ecosystem of sensing devices, computing resources and display. It consists of two main subsystems: Sensing Environment and eWALL Cloud [6].

a. Sensing Environment is a smart environment centered on its human users in which a set of embedded networked artifacts, both hardware and software, collectively realize the paradigm of Ambient Intelligence, mainly by providing for context-awareness and personalization, adaptive reactivity, and anticipatory pro-activity. It can be Home or Mobile.

b. eWALL Cloud is a cloud environment that includes a set of hardware and software components used for aggregation of data coming from sensors, analyzing them and transforming them into specific formats suitable for the user/system that needs them and infers new higher-level knowledge by applying advanced reasoning on data.

Below, Figure 1 depicts the eWALL high-level architecture along with its main building blocks:

a. eWALL Devices are responsible for all explicit (direct interaction via audio/video devices) and implicit (collecting data) interaction with the end user in Sensing Environment.

b. Sensing Middleware is responsible for connecting, configuring, querying and reporting data from end user devices, for interconnection of Sensing Environment and eWALL Cloud, and for basic data storage [6].

c. Local Context Manager is responsible for handling low-level context data and processing, (indexing and adaptation, analysis of humans and non-A/V perception processing) [6].

d. Cloud Middleware is responsible for providing (1) all cloud communication infrastructure, (2) data abstraction and all data handling in cloud taking into account privacy and security concerns, and (3) for hiding the heterogeneity and distribution of cloud hardware environment and management of physical resources and the provisioning of virtual resources [6].

e. Horizontal Platform Services is a generic reusable set of services which eases the development of personalized services and applications (e.g. profiling, notification support, intelligent decision making, lifestyle reasoning provisioning and configuration) [6].

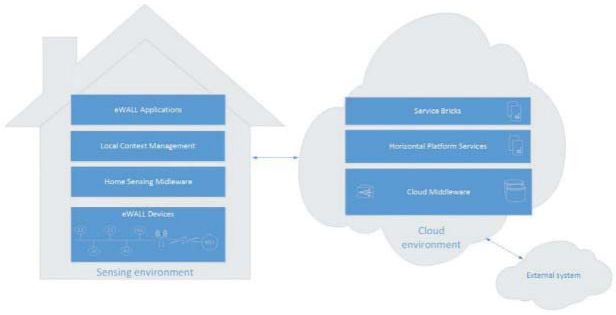

Figure 1: eWALL main building blocks [6]

f. Service Bricks are eWALL intelligent context aware service components, which together with applications act as a bridge between the end users and the eWALL back-end services [6].

g. eWALL Applications provide the interface between the user and the eWALL system. The eWALL Applications extract relevant data from Service Bricks and take care of visualization aspects of the data [6].

The most important components of eWALL system functionality are:

a. Intelligent Decision Support System (IDSS) is a software component responsible for decision-making activities in eWALL system. It uses inference to discover new relationships, automatically analyses the content of the data, and manages knowledge (i.e. perform reasoning based on corresponding or appropriate rules). It consumes low-level data (e.g. sensor data), or medium level data (e.g. processed data from service bricks) from multiple sources and makes high level, semantically meaningful data [7].

b. Lifestyle Reasoners (LR) are software components that process and store long-term data

that follows certain patterns or routines that define the lifestyle of the user. The aim of these components is to predict behavior and to detect (slow or fast) changes that might indicate a change in the user's health status. To do so, the lifestyle reasoners consume medium level data from multiple sources and derive semantically meaningful patterns [7].

c. Notification Manager (NM) is a software processing component that manages (i.e. storing, forwarding or deleting) all eWALL notifications. It is a single central block where all notifications are being managed, so the user is not overloaded by all information coming randomly from independent notification sources. The main role of the notification manager is to manage the notifications (alarms) and messages that originate from a specific set of processing blocks, e.g. service bricks [7].

III. eWALL FRAMEWORK: SERVICES

Using the data captured by the wearable and ambient environment sensors as well as user input information, several services are offered to cover the needs of our three primary target user groups: Elderly users with Age Related Impairments (ARI), patients suffering from Chronic Obstructive Pulmonary Disease (COPD) and elderly suffering from Mild Dementia (MD). Figure 2 below shows the spectrum of cognitive and physical impairments we aim to cover in the eWALL project. The proposed applications are shown to cover this entire spectrum. Daily Physical Activity (DPM) is beneficial for every individual and is the most general application. Cognitive Training (CT) is a preventive application for the ARI population and more a rehabilitation application for the MD population. Physical Training (PT) is similarly a preventive application for ARI and a rehabilitation application for COPD. Daily Functioning Monitoring (DFM) is targeted at MD patients, supporting independent living and peace-of-mind for informal caregivers. Healthcare Support (HS) is always present for COPD and in a later stage for MD patients. Each application has a number of possibilities for demonstrating personalization and intelligence in the eWALL platform [5]:

a. Daily Physical Activity application enables the system to learn the activity patterns of the user over time. Based on this, personalized goals will be set for each day of the week, which grow and change. Motivational messages will be provided based on the user's preferences and knowledge, current context (time, season, weather), and disease characteristics.

b. Daily Functioning Monitoring enables the system to learn a "normal" lifestyle pattern for the user, e.g. regarding sleeping, eating, social contacts. The system can warn informal caregivers in case of deviations from these normal values, based on the preferences of the informal caregiver (configurable).

c. Healthcare Support is a service that provides connections to professional care services and automatically initiates communication with a professional if certain events are detected.

d. Physical Training is a tool that provides exercise support to the user (e.g. video follow-along exercise). The system can follow progress over time, recommend exercises that the user likes and set the difficulty of exercises automatically based on progress and disease characteristics.

e. Cognitive Training is a tool that provides cognitive exercise support. Personalization and intelligence functions are similar to physical training (automatic selection of exercises, difficulty setting, automatic coaching or hints).

From the target end user perspective, the eWALL system consists of a set of messages, recommendations, reminders and suggestions delivered to him/her on a big screen (installed in the home) or on a portable device. From the caregivers' perspective, the system allows them to control the health status of their assigned end users, leveraging a set of technologies that allow collection of meaningful information on the target end user, to analyze them and to take actions accordingly. The ideal way to provide the above

mentioned functionality is by means of a web portal, which allows access from everywhere in a modality which is independent from the client operating system used [5].

IV. PERSON-CENTERED DESIGN

Articles [20] and [21] explain the importance of "person-centered" design in home care environments. Following the "Quality principles and Areas of Action" stated in WeDo guide [3], characteristics of eWALL are:

a. eWALL is customizable, accessible and easy to use. Different services can be "plugged in" using the concept of app market; the users define which applications they need and what they will do [8].

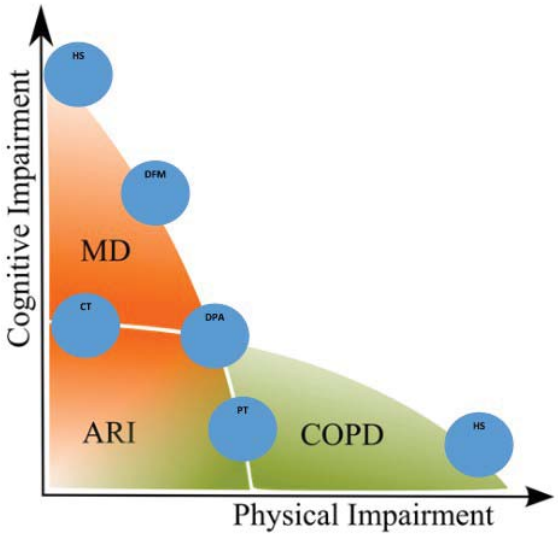

Figure 2: The spectrum of cognitive and physical impairments and the associated primary target populations with the proposed services: DFM (Daily Function Monitoring), CT (Cognitive Training), PT (Physical Training), Daily Physical Activity (DPA), and Healthcare Support (HS) [5]

b. eWALL provides adaptability since each of the services provided can be fine-tuned to correspond to the requirements of a specific user based on their cognitive and physical abilities or on their needs [8].

c. eWALL is unobtrusive: messages the platform delivers are clear and prioritized and should interrupt the personal flow of a user only when it is absolutely necessary [8].

d. eWALL provides continuous and reliable service, which is a prerequisite for a functional system and is mainly validated by technical partners [8].

e. eWALL is outcome oriented and evidence based, meaning it is oriented towards monitoring and improving a person's health, wellbeing and independence based on the information collected and the user's feedback.

f. eWALL is person-centered and respectful of human rights and dignity. Faced with impairment, many people seem to lose trust in their cognitive or physical abilities and they gradually abandon their former activities. As a result, their confidence and mood are affected and they often succumb in isolation [8]. This has an impact on their overall health and social life [22]. Among eWALL's main goals as a person-centered system is to attempt to restore these two emotional parameters, self-trust and motivation and empower the end users on a psychological level [9].

Overcoming the psychological obstacles described and empowering the end users to face their life and responsibilities by supporting independent living of senior citizens and compensating for prevailing age-related physical and cognitive impairments is certainly the utmost goal of eWALL and therefore, constitutes the most important high level goal.

V. CHALLENGES AND FUTURE WORK

In this paper, we proposed eWALL framework that provides long-term care for the elderly and assistance to their caregivers. Challenges faced were: (1) developing a comprehensive, ambient aware and dynamical system that would serve the elderly and their caregivers and (2) empowering older people and creating opportunities for participation using a person centered design.

Future work would continue to work on fostering human rights and dignity of elderly people. This can be achieved by expanding the existing system with services focused on preventing and fighting elder abuse and neglect which has been a growing issue [23].

Acknowledgement - We thank our colleagues from the eWALL project who provided insight and expertise that greatly assisted the work presented in the paper.

About Wireless Personal Multimedia Communications (WPMC)

The Wireless Multimedia Personal Communications (WMPC) was inaugurated as a global platform which aims at enabling collaboration in the field of wireless information and multimedia communications. The Wireless Multimedia Personal Communications (WMPC) International Symposium was started way back in 1998, with about 200 participants and about accepted 100 papers. Thereafter, in four years span, the number of participants has reached and exceeded 400 and the number of papers more than 300 for each Symposium. In every WPMC International Symposium, high-quality technical sessions, workshops, tutorials as well as product exhibitions are organized. Since the first WPMC in YRP (Japan), seventeenth WPMCs were held through the world in Asia, Europe, North and South Americas.

In the year 2007, this event was held in Jaipur (India). The quality of the presentations is also very high. It is indisputable that WPMC has become one of the major international conferences in the field of wireless Communications. Some of the themes of earlier Symposia were (i) Communications, Networking and Applications for the Internet of Things, (ii) Autonomous Communication and Networking for Promoting Human Living, and (iii) Orchestrating Wireless Personal Multimedia Communications for Digital Services etc.

Every year is witnessing rapid change in the field of wireless communications with the development and deployment of new technologies and solutions in the field of wireless technologies. Every aspect of wireless communications right from physical layer, resource management including alternative methods of spectrum management, interference management, IoT & M2M, smart antenna, MIMO, multimedia QoS & traffic management, visible light communications, cloud computing, security & privacy, vehicular networks, radio propagation & channel modelling, cognitive radio & SDR, mobile multimedia & mobile TV, wellness & health care, ICT for energy efficiency etc. WPMC is becoming more and more important every year. Against such a backdrop, it was truly gratifying that the 18th International Symposium of WPMC was held in Hyderabad during December, 2015. This Symposium was supported by National Institute of Information and Communications Technology (Japan), and YRP (Japan).

About Global Wireless Summit

The Global Wireless Summit (GWS) had been conceptualized in bringing together wireless media communication/personal communication, etc. The First GWS was successfully held in Princeton (USA), in 2013, followed by the Second one in Aalborg (Denmark), in 2014. As has been the tradition for this Summit, it continues to feature a high-quality technical program across a wide range of research in the wireless communications and related areas. Under the theme "Democratizing Communications", the GWS-15 brought together academia, industry and standardization bodies working on green and secure communication. The conference explored activities, trends and future challenges towards ICT globalization including energy and security issues in existing and future wireless technologies. The Global Wireless Summit-15 presented high-level technical sessions; tutorials, and special sessions on advance topics; workshops; and panel discussions.

Under the theme of 'Democratizing Communications,' the 18th International Symposium on Wireless Personal Communications (WPMC), and the 3rd Global Wireless Summit (GWS) are jointly organized, encompassing the 5th International Conference on Wireless Communication, Vehicular Technology, Information Theory and Aerospace & Electronics Systems (WirelessVITAE), The 12th World Wide Security and Mobility Conference (WWSMC), and the 3rd International Conference on Communications, Convergence, Content and Cooperation (IC5).

About Wireless VITAE

The Wireless Vehicular Technology, Information Theory Aerospace & Electronics Systems (VITAE) is the only international conference broadly addressing the wireless developments in the world by merging the communities from four different IEEE societies. The 1st Conference was held in 2009 in Aalborg (Denmark) followed by 2nd in 2011 in Chennai (India). The 3rd was held in 2013 at Atlantic City, NJ, USA. The 4th was co-located with GWS-2014 in 2014 at Aalborg (Denmark). The primary event in Aerospace, Information Technologies and Databases & Information Systems category centerpieces to Aerospace, Wireless Communication, Information Theory, Vehicular Technology and Electronics Systems issues. Wireless VITAE joined hands with GISFI to provide a platform to gather the different facets of the wireless into a single event and to exchange ideas and knowledge among the different research communities that address the various aspects of the wireless theme. The International Wireless VITAE conference is Global one that addresses the trends, challenges and future roadmaps within a conglomerate of existing and novel wireless technologies, including cellular, short-¬range, sensor and embedded ones. Cognitive and self-¬organizing networks, nano-sensors, positioning and localization, Internet of Things (IoT), positioning and localization, recent advances in information theory and its applications, space technology for very high data rates, and techno-¬economic aspects of telecommunications are part of the scope, among others.

Committee Members

RAMJEE PRASAD,

- Steering Board Chair/Co-Chair of WPMC, GWS, and Wireless VITAE;
- Founder Director, CTIF Global Capsule (CGC), Aarhus University, Herning, Denmark;
- Founder Chairman, Global ICT Standardisation Forum for India (GISFI).

Welcome Speeches

On behalf of the Steering Committee of the WPMC 2015, Global Wireless Summit (GWS) 2015, and Wireless VITAE 2015, it is my great pleasure to bid you all a warm welcome to these highly renowned events in the beautiful historic city of Hyderabad, India.

Under the theme of '**Democratizing Communications**,' the 18th International Symposium on Wireless Personal Communications (WPMC) and 3rd Global Wireless Summit (GWS) are jointly organized, encompassing the 5th International Conference on Wireless Communication, Vehicular Technology, Information Theory and Aerospace & Electronics Systems (Wireless VITAE), The 12th World Wide Security and Mobility Conference (WWSMC), and the 3rd International Conference on Communications, Convergence, Content and Cooperation (IC5).

Wireless communications have evolved over the years to open great potential for monetizing on multimedia data and diversified user-generated content, making them a ubiquitous means of connecting people and businesses. Democratization of hardware, software and connectivity is the necessary enabler to benefit all stakeholders and provide a stable platform for creating profits out of technology disruption.

The setting of WPMC 2015 jointly with GWS2015 was in the heart of the City of Pearls, as Hyderabad historically been known for its blooming pearl industry. Today, Hyderabad is also a major center for the technology industry. The WPMC and GWS2015 program featured an unusually distinguished group of keynote and invited speakers, as well as a strong technical program with novel research contributions from the relevant thematic areas from all over the world. In addition, an extensive list of social events were scheduled to allow for a break from the exciting technical sessions. Please, take the advantage of the many opportunities to network and expand your technical and cultural horizons.

I would like to extend my appreciation to my global colleagues for their dedication and effort to put together a strong event.

Ramjee Prasad,

Steering Board Chair/Co-Chair of WPMC, GWS, and Wireless VITAE

It is my great pleasure to host the 18th International Symposium on Wireless Personal Multimedia Communications (WPMC'15) in Hyderabad, India.

The WPMC symposia series first commenced in 1998, as a unique international conference dedicated to wireless multimedia communications aiming for global collaboration. In cooperation with YRP, we hold the symposium in a location in Asia, Europe, America or Australia each year.

This year's host country, India, has shown remarkable developments in the information and communications technology (ICT) field, in particular, in mobile phones, since the 10th WPMC Symposium held in Jaipur in 2007. During that time attention to wireless technology has also increased and a broad range of R&D activities have been advanced. Against such a backdrop, it is truly gratifying that the WPMC Symposium is being held here.

As Japan's sole national research institute in the field of ICT, the National Institute of Information and Communications Technology (NICT), promotes research and development in fundamental technologies in the fields of networks, including wireless communication, universal communication, advanced ICT, and electromagnetic sensing. Through these technologies, we aim to contribute to improving and resolving various challenges that society faces.

In particular, NICT positions big data of a public nature that helps to contribute to society as "Social Big Data." We focus on R&D of such Social Big Data, with the goal of having it used throughout society as social infrastructure, and ensuring that the knowledge and information gained from it is further disseminated. Additionally, efforts leading to the Internet of Things (IoT) and Internet of Everything (IoE), where all things and all data become connected, are advancing, and NICT is actively contributing to the IoT Acceleration Consortium, which represents Japan's efforts in this area, and its technology development working group, the Smart 'IoT Acceleration Forum'. Furthermore, learning from the response to the Great East Japan Earthquake that devastated Japan in March 2011, we are also engaging in research and development to swiftly deploy a wireless telecommunications network in the aftermath of a disaster.

For this symposium, NICT has set up a Wi-SUN workshop, 5G workshop, and Resilient Wireless Network Technologies workshop as themes related to such areas of research and development at this symposium. Currently, data gathering through networks using wireless technology is being conducted in various fields and industries across the globe. At the same time, the diversification of ICT had made wireless communications technology increasingly available to people. Given this situation, I believe that holding

this ICT workshop here in India will be extremely effective and holds great significance.

Lastly, I sincerely hope that WPMC'15 will be a significant forum that promotes extensive collaborations and interchanges among those engaged in the R&D of wireless communications, towards the realization of a society where people can live with a sense of security and comfort.

Masao Sakauchi,

President, National Institute of Information and Communications Technology, Japan

On behalf of YRP R&D Promotion Committee, one of the co-organizers of the 18th International Symposium on Wireless Personal Multimedia Communications (WPMC 2015), it is my great pleasure to welcome you in Hyderabad, India.

Since the first WPMC was held in our Yokosuka Research Park (YRP), Japan, in 1998, this symposium had been held in various cities in the world every year providing researchers of wireless communications with opportunities to gain new knowledge and information and also to exchange with each other. We are excited that this year the WPMC is held in India for the second time after the WPMC 2007 held in Jaipur owing to the great cooperation of Global ICT Standardization Forum in India (GISFI), Indian Institute of Technology Bhubaneswar and Kharagpur, Jawaharlal Nehru Technological University Hyderabad, and other Indian colleagues, and we truly appreciate hard work and great efforts of all people concerned. YRP has developed as an international R&D hub for radio and telecommunications technologies since its establishment in 1997. Currently, about 58 organizations with 5,200 researchers and engineers gather in YRP, and the member of our Committee, one of the promoting bodies of YRP, has reached to around 150. We have also concluded memorandums of understanding for research exchange with research parks and ICT institutions, totaling 51 organizations in 15 countries and one region.

Now, in YRP, in addition to the R&D of the 4th generation mobile communication systems, discussions and studies on the 5th generation mobile communication systems that are to be introduced in 2020 are under way. In Broadband Wireless Forum, which was established in our Committee in 2009, discussions on practical application of wireless power transmission technologies are going on, and last year in May, we also established a new Committee to promote application of Wireless Smart Utility Network, Wi-SUN. YRP intends to use the fruits of these activities as a foothold to lead the world's R&D in ICT and further enhance YRP's function. We also would like to further strengthen wide-ranging international collaboration encompassing Europe, America, Asia and Oceania, and other regions, and we expect WPMC to be the very important platform for international exchange.

I hope that this WPMC2015 will be fruitful and enjoyable to all participants.

Mitsutoshi Hatori,

Chairman, YRP R&D Promotion Committee, Japan

At the outset, as the Executive Chairman of the Technical Program Committee (TPC) of the third Global Wireless Summit (GWS-2015), it gives me an immense pleasure to heartily welcome you to this Summit being held in the City of Hyderabad, India during December 13-16, 2015.

The Global Wireless Summit (GWS) has been conceptualized in bringing together wireless media communication/personal communication, etc. The First GWS was successfully held in Princeton (USA), in 2013, followed by the Second one in Aalborg (Denmark), in 2014. Under the theme "Democratizing Communications", the GWS-15 brings together academia, industry and standardization bodies working on green and secure communication. The conference will explore activities, trends and future challenges towards ICT globalization including energy and security issues in existing and future wireless technologies.

Global Wireless Summit 2015 is hosting 18th International Symposium on Wireless Personal Multimedia Communications (WPMC); 5th International Conference on Wireless Communications, Vehicular Technology, Information Theory Aerospace & Electronics Systems (WirelessVITAE) 2015, IC5 and World Wide Security & Mobility Conference (WWSMC). The WPMC-15 and WirelessVITAE 2015 are the major events and both are held second time in India. The 1st International Symposium on WPMC was held in 1998, and since then it is held every year with an objective of providing a 'global platform' for discussions on the latest trends in the wireless multimedia communications. In the year 2007, this event was held in Jaipur (India). Wireless VITAE is the only international conference broadly addressing the wireless developments in the world by merging the communities from four different IEEE societies. The 1st Conference was held in 2009 in Aalborg (Denmark) followed by 2nd in 2011 in Chennai (India).

The Global Wireless Summit-15 presented high-level technical sessions; tutorials, and special sessions on advance topics; workshops; and panel discussions. All the submitted contributions received for technical and special sessions have been thoroughly reviewed by the TPC including other leading experts and only the best quality of papers have been accepted for presentations. It may be mentioned that each paper was reviewed by at least three experts. TPC of GWS-15 has 15 Co-chairs and over 70 members, from a wide variety of academic, industrial, and research organizations around the globe.

As has been the tradition for this Summit, it continues to feature a high-quality technical program across a wide range of research in the wireless communications and related areas.

I would like to take this opportunity to profoundly thanks the TPC Co-chairs; TPC members; Chairpersons of Special Sessions, Workshops; reviewers; and authors.

I request you all to take the advantage of this grand Summit and have thought provoking 4 days in the City of Hyderabad.

Ashok Chandra

Technical Program Committee (TPC) Executive Chair, WPMC 2015 and GWS 2015

Former Wireless Adviser to the Government of India

Welcome to Hyderabad, India to join WPMC2015.

On behalf of the Steering Board of WPMC, I would like to express my deep gratitude to all the delegates for coming from all over the world, and expect you will be having exciting experiences at WPMC2015 in Hyderabad.

The WPMC2015 is the 18th WPMC held for the second time in India, one of the most fantastic and attractive countries in the world.

The WPMC was inaugurated in 1998 to establish a global platform for mutual cooperation and discussions in the field of wireless multimedia communications with a strong financial supports by National Institute of Information and Communications Technology (NICT). The first WPMC was held at Yokosuka Research Park (YRP) in Japan in honor of the opening of YRP in 1997.

Since the first WPMC in YRP, seventeenth WPMCs were held through the world in Asia, Europe, North and South Americas.

With the continued and close support by numerous organizations and human relationships, the WPMC has grown into an international symposium widely recognized by industries and academic societies.

I wish to take this opportunity to thank all supporting committee members and staffs of WPMC2015, especially for General Chair, Prof. R.V Rajakumar, Director IIT Bhubaneswar, India, and TPC Chair, Dr. Ashok Chandra, Former Wireless Advisor, to the Government of India.

Shingo Ohmori

Co-chair of WPMC Steering Board

President, YRP International Alliance Institute, Japan

Vice President, YRP R&D Promotion Committee, Japan

08:30-19:00	Registration	
	Morning Tutorial Session	
09:00-13:30 Coffee Break 11:00-11:30	**WPMC Tutorial Session on "TV White Space for Affordable Broadband Access "** **Kentaro Ishizu**, *National Institute of Information and Communications Technology*, **Japan; Abhay Karandikar,** *Indian Institute of Technology Bombay*, **India; Takeshi Matsumura,** *National Institute of Information and Communications Technology*, **Japan**	**MR 2.01**
	WPMC Tutorial Session on "Optimal Filtering and Parameter Estimation Techniques for Statistical Models" **Laxminarayana Pillutla,** *Dhirubhai Ambani Institute of Information and Communication Technology*, **India**	**MR 2.02**
	WPMC Tutorial Session on " Antennas for Millimeter-wave Wireless Communications" **T Rama Rao,** *SRM University*, **India**	**MR 2.03**
	WVITAE Tutorial Session on "IoT and Low Voltage Analog Design for Wireless Applications" **Sudhanshu S. Jamuar,** *University Malaysia Perlis*, **Malaysia**	**MR 2.04**
	WVITAE Tutorial Session on "Energy-Spectral Efficiency in Cooperative Cognitive Radio Network with Challenges in Security" **Santi Prasad Maity,** *Indian Institute of Engineering Science and Technology, Shibpur*, **India**	**MR 2.05**
13:30-14:30	**LUNCH**	
	Afternoon Tutorial Session	
14:30-18:30 Coffee Break 16:30-17:00	**WPMC Tutorial Session on "Road to 5G Wireless Systems: Challenges Ahead vis-à-vis Progress Made "** **Amitava Mukherjee,** *IBM Pvt. Limited*, **India; Debashis Saha,** *Indian Institute of Management Calcutta*, **India**	**MR 2.01**
	WPMC Tutorial Session on "Wireless Channel Impairments Removal Techniques" **Sanjay Kumar,** *Birla Institute of Technology*, MESRA , **India**	**MR 2.02**
	WVITAE Tutorial Session on "Transmission Technologies for 5G" **Suvra Sekhar Das,** *Indian Institute of Technology, Kharagpur*, **India**	**MR 2.03**
	WVITAE Tutorial Session on "Visible Light Communication for Road Safety in the Intelligent Transportation Systems" **Navin Kumar,** *Amrita University & School of Engineering*, **India**	**MR 2.04**
	WVITAE Tutorial Session on "ICT for Health Care" **Vishwanath Sinha,** *M. N. National Institute of Technology, Jaipur,* **India**	**MR 2.05**
19:00-20:00	Welcome Reception in Foyer/ Pool Side Lawns	

Monday, December 14 Day 2

"Workshops, Special Sessions, Contributed Papers"

Time Slot	Day2: Monday, December 14 | Grand Opening Program		
08:30-19:00	**Registration**		
09:00-10:00	**GRAND OPENING**		**HALL 1**
	Ceremony	**Lighting of the Lamp Ceremony: Presided by B.N. Bhandari, Local Organizing Chair, WPMC/ GWS 2015**	
	Welcome Speech	**Ratnam Varada Rajakumar**, *General Chair*, WPMC/GWS 2015	
	Inaugural Speech	**Ramjee Prasad**, *Steering Board Chair/Co-Chair of WPMC, GWS and Wireless VITAE; Founder Chair, GISFI*	
	Introduction Speech	**Ashok Chandra, TPC Executive Chair, WPMC/ GWS 2015**	
	Opening Speech-1	**Fumihiko Tomita**, Vice President, *NICT*, **Japan**	
	Opening Speech-2	**Mitsutoshi Hatori**, Chairman, *YRP*, **Japan**,	
	Opening Speech-3	**Smriti Dagar**, *President, IETE*, **India**	
	Round Table Discussions: "India Knowledge Economy- Transformation through Digitization and Innovation"		
10:00-11:00	**Discussion**	Moderator:-**Sudhir Dixit**, WWRF, **USA**, **Anand R. Prasad**, NEC Corporation **Japan,** **Dina Simunic,** *University of Zagreb***, Croatia** **Ashok Chandra,** *TPC Executive Chair, WPMC/ GWS 2015*, **India** **Kiritkumar Lathia, GISFI/CTIF, Denmark,**	
	Vote of Thanks	**Sandip Inamdar**, Finance Chair, **WPMC/ GWS 2015**	
11:00-11:30	**Coffee Break**		
11:30-19:00		**Technical Sessions**	
19:30-22:30	END of DAY 2 || Cultural Program (Mridangam and Kuchipudi Group Dance Recital), GALA DINNER & Best Paper Award: HALL1		

Time Slot	Day2: Monday, December 14 || HALL 1.1 Activities || Workshops & Special Sessions (I-A)		
08:30-19:00	Registration		
09:00-11:00	**GRAND OPENING**		**HALL 1**
11:00-11:30	**COFFEE BREAK**		
11:30-13:30	**WPMC Special Session on "Mobile applications for Management of the Digital Business, Implications for the Infrastructures and Organisations"** **Session Organizer and Chair: Zoran Veljovic,** *University of Montenegro,* **Montenegro**		HALL 1.1
	Invited Talk	Manufacturing and Standardization in India**, Arun Golas**, *former DDG, Ministry of Communications, Government of India, New Delhi,* **India**	
	1570231052	Dynamic Pathloss Model for Future Mobile Communication Networks; **Ambuj Kumar, Albena Mihovska, Ramjee Prasad**; *CTIF, Aalborg University,* **Denmark**	
	1570228076	Challenges and Opportunities for Enhancing User Privacy and User Empowerment; **Prashant Dhotre, Samant Khajuria , Henning Olesen**; *Center for Communication, Media and Information Technologies (CMI),Aalborg University Copenhagen,* **Denmark (***)**	
	1570228069	Sensitive Association Rules Hiding Methods: A Survey; **Geeta Navale, Suresh Mali**; *Sinhgad Institute of Technology and Science, Pune,* **India**	
13:30-14:30	LUNCH		
14:30-16:30	**WPMC Workshop on "Vision and research activities toward the Fifth Generation Mobile Systems (5G)"** **Workshop Organizer and Chair: Kentaro Ishizu,** *Association of Radio Industries and Businesses (ARIB) & National Institute of Information and Communications Technology (NICT),* **Japan**		HALL 1.1
	Activities on 5th Generation Mobile Communications System in Japan ;**Kohei Sato;** *Association of Radio Industries and Businesses (ARIB),* **Japan**		
	5G Prospects in India; **VikramTiwathia**; *The Cellular Operators Association India (COAI),* **India**		
	5G research activities and key enabling technologies ;**Haesik Kim**; *VTT,* **Finland**		
	Small-cell Structured Wireless Networks for 5G: Centralized vs Decentralized Architecture ;**Fumiyuki Adachi**, *Tohoku University,* **Japan**		
	The Unified 5G Platform; **J. VinoshBabu James**, *Qualcomm,* **India**		
16:30-17:00	COFFEE BREAK		
17:00-19:00	**WPMC Special Session on "Combedded Systems"** **Session Organizer and Chair: Abhay Gandhi,** *Viswesarayya National Institute of Technology, Nagpur,* **India**		HALL 1.1
	1570227356	Artificial intelligence auto-mobility in material handling & fork-lift manufacturing; **Ajinkya Vasant Nichit①, Kedar S. Joshi①, Sachin B. Rao ②, Sushant S. Gaidhani ①, Shrinivas Vasantrao Shinde③**; ①*Sandip Institute Of Engg, & Management, Nashik,* ②*G.H. Sapat College Of Engg., Nashik,* ③*Jawahar Institute Of Technology, Nashik;* **India**	
	1570227801	Interference Analysis and Mitigation Techniques in Wireless Body Area Network; **Subhojit Moitra, P.H.Ghare, A.G. Kothari**; *VNIT, Nagpur,* **India**	
	1570227808	Implementation of Low Cost IoT Based Smart Home using Open Source Platform; **Varun Tiwari, Avinash Keskar** □; *Visvesvaraya National Institute of Technology, Nagpur,* **India**	
	1570227846	Performance Comparison of DCT based Entropy Coding Techniques; **Samruddhi Y. Kahu, Kishor M. Bhurchandi**; *Visvesvaraya National Institute of Technology, Nagpur,* **India**	
	1570227857	UWB Sensing antenna, Reconfigurable transceiver and antenna based Cognitive Radio Test bed; **S. Manoj, Sumin. D. Joseph**□, **Chetan. Waghmare, Nandakumar. K., Ashwin Kothari**; *Department of Electronics VNIT, Nagpur,* **India**	
	1570227987	Methods of Frequency Offset Estimation in OFDM Based System; **A. P. Rathkanthiwar①, A.S.Gandhi②**; ①*Priyadarshini College of Engineering Nagpur,* ②*Visvesvaraya National Institute of Technology, Nagpur* , **India**	
19:30-22:30	END of DAY 2 || Cultural Program (Mridangam and Kuchipudi Group Dance Recital), GALA DINNER & Best Paper Award: HALL1		

Time Slot	Day2: Monday, December 14 || HALL 1.2 Activities || Workshops & Special Sessions (I-B)		
08:30-19:00	Registration		
09:00-11:00	**GRAND OPENING**		**HALL 1**
11:00-11:30	**COFFEE BREAK**		
11:30-13:30	**WVITAE Special Session on " mHealth and Medical Informatics"** **Session Organizer and Chair: Albena Mihovska, Aalborg University, Denmark**		HALL 1.2
	Opening Talk	**Shyam Chakrabortty,** *Oy Trinnect Ltd.,* **Finland**	
	Invited Talk	Role of ICT for the Advancement of Dentistry **, Gianpaolo Sannino,** *University of Rome, Tor Vergata,* **Italy**	
	Invited Talk	Patient centered learning and Early clinical exposure of medical students to 'Diabetes and Metabolic syndrome**, Yogesh Sharma①, Ankur Joshi②, Dept of Medicine③, Rakesh Biswas;** *①LNMCH,②dept of Medicine, GMC,③dept of Medicine, LNMCH;* *Bhopal Madhya Pradesh*, **India**	
	Invited Talk	Review of telemedicine technologies in India**, Sumit Gautam***①***, Shyam Chakraborty②;** *① IIIT Hyderabad, India;* ***②****Trinnect Ltd.,* **Finland**	
13:30-14:30	LUNCH		
14:30-16:30	**WPMC Workshop on "Resilient Wireless Network Technologies" (I)** **Workshop Organizer and Chair: Ryu Miura,** *National Institute of Information and Communications Technology (NICT)*, **Japan**		HALL 1.2
	1570213366	On-going Field Experiment of NerveNet in Shirahama Town for Resilient Town Network; **Masugi Inoue, Yasunori Owada , Kiyoshi Hamaguchi** *; Resilient ICT Research Center,* *National Institute of Information and Communications Technology (NICT)*☐, **Japan**	
	1570213263	Pilot testing and demonstration of self-management network and applications by NerveNet; **Yasunori Owada , Kiyoshi Hamaguchi, Masugi Inoue;** *Resilient ICT Research Center,* *National Institute of Information and Communications Technology (NICT)*☐, **Japan**	
	1570213055	Development and Field Experiment of Distributed Peer Aware Communication Networks; **Lin Shan, Huan-Bang Li, Takashi Matsuda, Ryu Miura**; *Wireless Network Research Institute, National Institute of Information and Communications Technology (NICT)*☐, **Japan**	
	1570213332	A hybrid multi-hop network by small-unmanned aircraft and satellite telecommunication systems; **Fumie Ono①**; **Byeong-pyo Jeong②, Yasunori Owada②, Shan Lin ①, Ryu Miura①**; *①Wireless Network Research Institute,* ***②****Resilient ICT Research Center, National Institute of Information and Communications Technology (NICT)*☐; **Japan**	
16:30-17:00	COFFEE BREAK		

16:30-17:00	(Continued: Hall 1.2 Activities) COFFEE BREAK		
17:00-19:00	**WPMC Workshop on "Resilient Wireless Network Technologies" (II)** **Workshop Organizer and Chair: Ryu Miura,** *National Institute of Information and Communications Technology (NICT)***, Japan**		HALL 1.2
	1570213462	QZSS SS-CDMA Location and Short Message Communication System; **Noriharu Suematsu, Suguru Kameda, Yuji Miyake, Tomohide Takahashi , Akinori Taira, Tadashi Takagi, Kazuo Tsubouchi**; *Research Institute of Electrical Communication, Tohoku University*, **Japan**	
	1570213016	Disaster Countermeasure Experiments using WINDS; **Takashi Takahashi①, Kazuyoshi Kawasaki①, Akira Akaishi①, Toshio Asai①, Maki Akioka①, Tomoshige Kan①, Morio Toyoshima①, Byongpyo Jeong②, Hajime Susukita②, Shuji Murakami②**; ①*Wireless Network Research Institute,* ②*Resilient ICT Research Center; NICT,* **Japan**	
	1570195491	A Path Ordering and Reference Selection Method for the Differential Delay Tomography; **Takehiro Otsuka① , Shinsuke Hara①②, Takahiro Matsuda③②, Kenichi Takizawa③, Fumie Ono‡ , Ryu Miura‡**; ①*Graduate School of Engineering,* ②*Osaka City University,* ③ *Graduate School of Engineering, Osaka University*; **Japan**	
	1570205987	Experimental Evaluation on Wireless Tomography with Compressed Sensing in a Three-Dimensional Space**; Kengo Yokota; Kengo Yokota① , Shinsuke Hara① , Takahiro Matsuda②, Masaki Mukamoto②, Yuki Uemura②, Kenichi Takizawa③, Fumie Ono④, Ryu Miura④** □; ①*Graduate School of Engineering, Osaka City University ,Sugimoto, Sumiyoshi-ku, Osaka,* ②*Graduate School of Engineering, Osaka University 2-1 Yamadaoka, Suita, Osaka,* ③*Strategic Planning Office, National Institute of Information and Communications, Koganei, Tokyo ,* ④*Wireless Network Research Institute, National Institute of Information and Communications Technology ,Kanagawa*; **Japan**	
19:30-22:30	END of DAY 2 || Cultural Program (Mridangam and Kuchipudi Group Dance Recital), GALA DINNER & Best Paper Award: HALL1		

Time Slot	Day2: Monday, December 14 || MRG .01 Activities || Contributed Papers: Cognitive Radio Networks and Spectrum Management (I)		
08:30-19:00	Registration		
09:00-11:00	**GRAND OPENING**		**HALL 1**
11:00-11:30	COFFEE BREAK		
11:30-13:30	**Cognitive Radio Networks and Spectrum Sensing & Management (I-A) | CRN, Relay and Routing : WVITAE & WPMC || *Session Chair: K.T.V. Reddy, TPC Chair, IETE, India***		MRG .01
	1570213275	C2R2M: Cluster-based Cognitive Radio Routing Mechanism; **Shriram Kulkarni, Shriram Markande**; *University of Pune*, **India**	
	1570209919	Adaptive Cooperative Spectrum Sensing and Access in Cognitive Radio Networks; **Kayalvizhi G;** *SSN College of Engineering*, **India**	
	1570212756	Evaluation of Channel Assembling Strategies with Single-Class Users in Cognitive Radio Networks; **Ebenezer Esenogho, Tom Walingo**; *University of KwaZulu-Natal*, **South Africa**	
	1570188607	Evaluating the Effect of Selfishness on Flooding Based DTN Routing Algorithms; **C Sobin**, **Vaskar Raychoudhury**; *IIT Roorkee*, **India**	
	1570213104	**WPMC:** Throughput of Secondary User in Underlay Cognitive Relay Network with Energy Harvesting; **Binod Prasad, Sanjay Dhar Roy, Sumit Kundu**; *National Institute of Technology, Durgapur*, **India**	
	1570207535	**WPMC:** Quality of Service Enforcing Centrally Optimized Routing for Delay Tolerant Networks; **Abhishek Thakur, Chittaranjan Hota**; *BITS Pilani, Hyderabad Campus* , **India**	
13:30-14:30	LUNCH		
14:30-16:30	**Cognitive Radio Networks and Spectrum Sensing & Management (I-B): WPMC || *Session Chair: Masahiro Umehira, Ibaraki University, Japan***		MRG .01
	1570193943	A Compressive Sensing-based Channel Estimation via GAMP in FBMC/OQAM System; **Meng Lin, Yunzhou Li, Limin Xiao, Yan Zhang, Xibin Xu, Jing Wang**; *Tsinghua University*, **China**	
	1570206001	New Pricing Model for Dynamic Dual-operator Spectrum Sharing in GSM; **Meghan Saitwal, Yuva Kumar, Brij Mohan Baveja, Mohammed Zafar Ali Khan, Uday B Desai;** *Indian Institute of Technology, Hyderabad*, **India**	
	1570192957	Improved p-norm Energy Detector with Soft Combining in AWGN Channel for Spectrum Sensing; **Vaibhav Kumar, Deep Kandpal, Ranjan Gangopadhyay, Soumitra Debnath;** *L.N.Mittal Institute of Information Technology, Jaipur*, **India**	
	1570213925	Selective Sensing Framework for Opportunistic Mobile Phone Sensing Networks; **Thejaswini M, Pachamuthu Rajalakshmi, Uday B Desai**; *Indian Institute of Technology, Hyderabad*, **India**	
	1570193867	Investigation on Listen-Before-Talk Mechanism of Licensed-Assisted Access to Unlicensed Spectrum; **Yu Jiang①, Hiroki Harada②, Liu Liu①, Huiling Jiang① ,Satoshi Nagata††**; ① *DOCOMO Beijing Communications Laboratories Co., Ltd*, **China**, ② *NTT DOCOMO, INC*, **Japan**	
	1570213278	CDF Based Spectrum Occupancy Rate Measurement Using Least Square Estimation of Gaussian Noise Period; **Shota Rachi, Akira Saito, Masahiro Umehira, Shigeki Takeda;** *Ibaraki University*, **Japan**	
16:30-17:00	COFFEE BREAK		

16:30-17:00	(Continued: MRG .01 Activities) COFFEE BREAK		
17:00-19:00	**Cognitive Radio Networks and Spectrum Sensing & Management (I-C): WPMC** ***||Session Chair: Sumit Kondu, NIT DurgapurA Leti, France***		MRG .01
	1570208599	Detection Performance of Soft Data Fusion in Rician Fading Channel for Cognitive Radio Network; **Srinivas Nallagonda[1][2], V Chandra Sekhar[1], Aniruddha Chandra[3][4], Sanjay Dhar Roy[4], Sumit Kundu[4];** *[1]M V S R Engineering College ,[2]Osmania University,[3]Brno University of Technology, [4]National Institute of Technology, Durgapur, WB*;**[1][2][4]India, [3]Czech Republic**	
	1570213378	Evaluation of permutation entropy detection for cognitive radio networks; **Srinu Sesham, Amit Kumar Mishra**; *University of Cape Town, Cape Town*, **South Africa**	
	1570208853	Optimization of Cooperative Spectrum Sensing in Cognitive Radio over Erroneous Reporting Channel; **Narasimha Rao Banavathu, Mohammed Zafar Ali Khan**; *Indian Institute of Technology, Hyderabad*, **India**	
	1570213111	Distributed Token Based MAC for Multi-Channel Multi-Interface Cognitive Radio WMN; **Mohammed A R Quadri, Ramesh Babu Battula, Manoj Singh Gaur, Dinesh Gopalani, Meenakshi Tripathi**; *Malaviya National Institute of Technology Jaipur*, **India**	
	1570209789	Path and Load Aware Routing Algorithm for Cognitive Radio Wireless Mesh Network**; Ramesh Babu Battula, Manoj Singh Gaur, Dinesh Gopalani, Emmanuel Shubhakar Pilli**; *Malaviya National Institute of Technology, Jaipur*, **India**	
	1570213374	Fractal dimension of spectral estimates for spectrum sensing under noise variance uncertainty; **Srinu Sesham[1], Amit Kumar Mishra[1], Siba Kumar Udgata [2], Samrat Sabat[2]**; *[1]University of Cape Town, Cape Town* ,**South Africa,** *[2]University of Hyderabad, Hyderabad*, **India**	
19:30-22:30	END of DAY 2 || Cultural Program (Mridangam and Kuchipudi Group Dance Recital), GALA DINNER & Best Paper Award: HALL1		

Time Slot	Day2: Monday, December 14 || MRG .02 Activities || Contributed Papers: Next Generation Networks & Internet of Things (I)		
08:30-19:00	Registration		
09:00-11:00	**GRAND OPENING**		**HALL 1**
11:00-11:30	COFFEE BREAK		
11:30-13:30	**Next Generation Networks (I-A) | 5G and Device to Device Communications: WPMC || *Session Chair: Sri Ganesh Rao, Tata Consultancy Services, Bangalore, India***		MRG .02
	1570194953	The impact of Network Neutrality on the OTT Service of 5G WISDOM; **Yapeng Wang, Ramjee Prasad**; *Center of TeleInFrastrukur, Aalborg University,Aalborg*, **Denmark**	
	1570206855	Efficient Device-to-Device (D2D) Offloading Mechanism in LTE Networks; **Bighnaraj Panigrahi, Rashmi Ramamohan, Hemant Kumar Rath, Anantha Simha**; *Tata Consultancy Services*, **India**	
	1570208181	Survey of Device-to-Device Communications Infrastructure-less in IEEE 802.15.8 Task Group; **Marco Hernandez, Ryu Miura**; *NICT*, **Japan**	
	1570208909	Link Adaptation Strategies for Cellular Downlink with low-fixed-rate D2D Underlay; **Afonso Eduardo, Ivo Sousa, António J. Rodrigues**; *Instituto de Telecomunicações (IT) Instituto Superior Técnico (IST), Universidade de Lisboa Lisbon*, **Portugal**	
	1570210057	A Pattern Division Multiple Access Scheme for 5G wireless communication systems; **Zhang Kai, Jin Xu**; *Beijing University of Posts and Telecommunications*, **China**	
	1570213212	Coexistence of Systems with Different Multicarrier Waveforms in LSA Communications; **Mirza Golam Kibria, Gabriel Porto Villardi, Kentaro Ishizu , Fumihide Kojima**; *Wireless Network Research Institute, National Institute of Information and Communications Technology*, **Japan**	
13:30-14:30	LUNCH		
14:30-16:30	**Next Generation Networks (I -B) | Spectrum Issues and Intelligent Approach: WVITAE || *Session Chair: S.K. Agarwal, Former Director, DIETY, Government of India, India***		MRG .02
	1570213573	Spectrum Scarcity at the Extensive and Intensive Edges: From White Space to 5G; **Benoît Pierre Freyens**; *University of Canberra*, **Australia**	
	1570210051	Real Time Evaluation of Energy Detection and Covariance based Spectrum Sensing Algorithms; **Sunil Devanahalli, Samrat Sabat**; *University of Hyderabad*, **India**	
	1570213985	Self Configurable Intelligent Distributed Antenna System; **Ambuj Kumar, Albena Mihovska, Ramjee Prasad**; CTIF, *Aalborg University*, **Denmark**	
	1570209885	Distributed Forward-Backward Pursuit Algorithm for Distributed Compressive Sensing; **Suchithra Sudhakaran, Neelakantan PC**; *Adi Shankara College of Engineering and Technology*, **India**	
	1570210103	Spectrum for 5G Services; **Purnendu Shekhar Mani Tripathi①②, Ramjee Prasad②**; ①*Ministry of Communications* & IT, **India**, ②*Centre for TeleInFrastructure(CTiF),Aalborg University, Aalborg*, **Denmark**	
	1570209977	On Performance of Eigenvalue based Detectors for Spectrum Sensing under Different Fading Conditions; **Ashwini Deshmukh①, Madhukar Deshmukh②, Flemming Bjerge Frederiksen②, Ramjee Prasad②③**; ①*Trinity College of Engineering Research Pune*, **India**, ②*RATE, Department of Electronic Systems,* ③*CTIF; Aalborg University*, **Denmark**	
16:30-17:00	COFFEE BREAK		

16:30-17:00	(Continued: MRG .02 Activities) COFFEE BREAK		
17:00-19:00	**Next Generation Networks (I- C) | Future Vision and IoT: WVITAE & WPMC ||*Session Chair: Raja Rajeswari, IETE, India***		MRG .02
	1570213430	Access for Internet of Things using Smartphone as a Gateway utilizing LTE and WiFi; **Prateek Mathur[1], Rasmus Hjorth Nielsen[2], Neeli Rashmi Prasad[3], Ramjee Prasad[1]**; *[2]Cisco Systems* , **USA,** *[3]Center for TeleInFrastructure (CTIF)*, **USA**, *[1]Center for TeleInFrastructure (CTIF), Aalborg University*, **Denmark**	
	1570213454	Cognitive framework for flexible queuing strategy in Next Generation Networks; **Hanuma Chitti[1], Neeli Rashmi Prasad[2], Knut Ovsthus[3], Ramjee Prasad[1]**; *[2]Center for TeleInFrastructure (CTIF)*, **USA**, *[3]Bergen University College*, **Norway**, *[1]Center for TeleInFrastructure (CTIF), Aalborg University*, **Denmark**	
	1570215979	Service Interaction through Gateways for Inter-Cloud Collaboration within the Arrowhead Framework; **Pál Varga[1], Csaba Hegedus[2]**; *[1]Budapest University of Technology and Economics, [2] AITIA International Inc.*; **Hungary**	
	1570191635	Single Thing Sign On Identity Management for Internet of Things; **Vanya Zdravkova, Mihail Mihaylov, Albena Mihovska, Ramjee Prasad**; *Department of Electronic Systems, Center for TeleInfrastruktur, Aalborg University*, **Denmark**	
	1570191687	**WPMC:** Towards Internet of Services - SDN-enabled IMS Architecture for IoT Integration; **Anton Katov[1], Bayu Anggorojati[1], Sofoklis Kyriazakos[1], Albena Mihovska[1], Neeli Rashmi Prasad[2]**; *[1]Center for TeleInFrastructure (CTIF), Aalborg University*, **Denmark,** *[2]Center for TeleInFrastructure (CTIF), Aalborg University*, **USA**	
	1570195595	**WPMC:** Packet Scheduling Scheme to Guarantee QoS in Internet of Things; **Reema Sharma[1], Navin Kumar[2], Namratha Gowda[1,3], Srinivas Talabattula[4];** *[1]The Oxford College Of Engineering, [2]Amrita University & School of Engineering, [3]Visvesvaraya Technological University, Karanataka, [4]Indian Institute of Science, Bangalore*; **India**	
19:30-22:30	END of DAY 2 || Cultural Program (Mridangam and Kuchipudi Group Dance Recital), GALA DINNER & Best Paper Award: HALL1		

Time Slot	Day2: Monday, December 14 || MRG .03 Activities || Contributed Papers: Vehicular & Mobile Ad-hoc Networks (I)		
08:30-19:00	Registration		
09:00-11:00	GRAND OPENING		HALL 1
11:00-11:30	COFFEE BREAK		
11:30-13:30	**Vehicular & Mobile Ad-hoc Networks (I-A)| Aerial and Sensor Ad-Hoc Networks: WVITAE|| *Session Chair: Sanjay Kumar, Birla Institute of Technology, Ranchi, India***		MRG .03
	1570214001	Embedded Video Processing and Data Acquisition for Unmanned Aerial Vehicle; **Vrunal Mhatre, Akshay Patil, Siddhesh Chavan, Ashish Chittimilla, Aaron Samuel;** *Fr. Conceicao Rodrigues College of Engineering*, **India**	
	1570194189	HANET: Millimeter wave based intelligent radio architecture for serving place time capacity issue; **Purnima Lala Mehta[①②③④], Troels B. Sørensen[①③], Ramjee Prasad[①②③]**; *[②]Center for TeleInFrastructure (CTIF),* **Denmark**; *[③]Department of Electronic Systems, [①]Aalborg University,* **Denmark**; *[④]HMRITM, New Delhi,* **India**	
	1570195421	GSHMAC: Green and Secure Hybrid Medium Access Control for Wireless Sensor Network; **Pranav Pawar[①], Rasmus Hjorth Nielsen[②], Neeli Rashmi Prasad[③], Ramjee Prasad[①]**; [②]Cisco Systems , **USA**; [③]Center for TeleInFrastructure (CTIF), **USA**; [①]Center for TeleInFrastruktur, Aalborg University, Aalborg, **Denmark**	
	1570214751	Automatic Household Power Measurement & Control System based on Wireless Sensor Networks; **Jameel Ahamed;** *Aligarh Muslim University, Aligarh,* **India**	
	1570213872	Conducted EMI Analysis of Vehicle Positioning System and Strategies to Reduce Conducted EMI; **Shreenivas Ramesh Jog, Nidhi Chaturvedi**; *D. Y. Patil Institute of Engineering & Tech.*, **India**	
	1570213870	Study of Radiated Emission from Wireless Positioning System and the strategies to minimize it; **Shreenivas Ramesh Jog, Suvidha Chitnis**; *D. Y. Patil Institute of Engineering & Tech.*, **India**	
13:30-14:30	LUNCH		
14:30-16:30	**Vehicular & Mobile Ad-hoc Networks (I-B) |Wireless Sensor Networks: WPMC || *Session Chair: Vishwanath Sinha, M N National Institute of Technology, Jaipur, India***		MRG .03
	1570210123	An Interdependent Source-Channel Coding for Energy Efficient Communication in WSNs**; Resmi N C, Sonali Chouhan**; *Indian Institute of Technology Guwahati,* **India**	
	1570194199	Impact of Network Coding on Distributed Indoor Target Tracking using Wireless Sensor Networks; **Laxminarayana Pillutla, Shourya Gupta, Dushyant Singh**; *Dhirubhai Ambani Institute of Information and Communication Technology (DA-IICT)*, **India**	
	1570195119	Mobility-aware Hybrid Synchronization for Wireless Sensor Network; **Dnyaneshwar Mantri, Neeli Rashmi Prasad, Ramjee Prasad**; *Center for TeleInFrastructure (CTIF), Aalborg*, **Denmark**	
	1570195013	Characterization for Reporting Rate of Adaptive Sectoring Scheme to Improve Reliability in WSN; **Manohar S. Chaudhari [①], Vivek Shankar Deshpande[②], Ramjee Prasad[③]**; *[①]Sinhgad Institute of Technology, Pune University,* **India**; *[②]University of Poona & MIT College of Engineering,* **India**; *[③]Center for TeleInFrastructure (CTIF), Aalborg University,* **Denmark**

19:30-22:30	END of DAY 2 || Cultural Program (Mridangam and Kuchipudi Group Dance Recital), GALA DINNER & Best Paper Award: HALL1		

Time Slot	Day2: Monday, December 14 || MRG .04 Activities || Contributed Papers: Technology Applications (I)		
08:30-19:00	Registration		
09:00-11:00	**GRAND OPENING**		**HALL 1**
11:00-11:30	COFFEE BREAK		
11:30-13:30	**Technology Applications (I-A) | Human Applications : WVITAE & WPMC || *Session Chair: Vladamir Poulkov, Technical University of Sofia, Bulgaria***		MRG .04
	1570213423	Behavior State Feature Extraction through Single Channel EEG Device for Medical Application; **Sravanth Kumar Ramakuri, Vivek Kumar, Bharat Gupta**; *Birla Institute of Technology Mesra, Ranchi*, **India**	
	1570206439	Real-time Detection of EEG Electrode Displacement for Brain-Computer Interface Applications; **Giulia Cisotto, Silvano Pupolin**; *University of Padua*, **Italy**	
	1570213165	Remote Heart Rate Evaluation by Variational Mode Decomposition**; Bogdan Gavriloaia[1], Octavian Fratu[1], Simona Halunga[1], Gheorghe Gavriloaia[2], Constantin Mara[2], Radu Vizireanu[1]**; [1]University Politehnica of Bucharest, [2]University of Pitesti; **Romania**	
	1570210205	Speech Feature Analysis and Selection for Emotion Classification; **Angel Manolov, Ognian Boumbarov, Agata Manolova, Vladimir K. Poulkov, Krasimir Tonchev**; *Technical University of Sofia*, **Bulgaria**	
	1570213386	Public Auditing and Data Dynamics in Cloud with Performance Assessment on Third Party Auditor; **Snehal Sawant[1,2], Aaradhana Arvind Deshmukh[1,2], Albena Mihovska[1], Ramjee Prasad[1];** [1]*CTIF, Aalborg University*, **Denmark,** [2]*Smt.Kashibai Navle College of Engineering, Vadgoan BK, Pune*, **India**	
	1570195309	**WPMC:** Non Audio-Video gesture recognition system; **Razvan Craciunescu[1,2], Cristian Ionut Dita[1], Albena Mihovska[1], Octavian Fratu[2], Sofoklis Kyriazakos[1], Ramjee Prasad[1]**; [1]*CTIF, Aalborg University*, **Denmark**, [2]*University Politehnica of Bucharest*, **Romania**	
13:30-14:30	LUNCH		
14:30-16:30	**Technology Applications (I-B) | Human Applications : WPMC || *Session Chair: fred Harris, San Diego State University, USA***		MRG .04
	1570207155	Fuzzy Logic based Human Detection in Video; **Manojkumar M Gawali, Dipti R. Pawar**; *Sinhgad College of Engineering, Pune*, **India**	
	1570207563	Improving Segmentation Accuracy for Motion Detection using Bidirectional Video Processing**; Abhishek Thakur, Ankesh Kumar**; *BITS Pilani , Hyderabad Campus*, **India**	
	1570194919	Automatic Speaker Detection and Recognition in a multi classroom E-Learning System; **Amitha Vijayan, Balaji Hariharan**; *AMRITA Vishwa Vidyapeetham Amritapuri, Kollam*, **India**	
	1570213262	Real-time EEG Monitoring and Transmission over Low Bandwidth Wireless Networks; **Kaushik Lahiri[1], Amitava Mukherjee[1], Mrinal Kanti Naskar[2]**; [1]*IBM India Pvt Ltd;* [2]*Jadavpur University*; **India**	
	1570194425	Adaptive priority based network bandwidth throttling for a Virtual Classroom System**; Jobina Varghese, Balaji Hariharan**; *AMRITA Vishwa Vidyapeetham Amritapuri, Kollam*, **India**	
	1570213445	Minimal Error IEEE 802.15.4 Communication Module for Heart Monitoring Data Transmission in IoT; **Subrahmanyam Vuddagiri, Mohammed Abdullah Zubair, Ajay Yadav, Pachamuthu Rajalakshmi**; *Indian Institute of Technology Hyderabad*, **India**	
16:30-17:00	COFFEE BREAK		

16:30-17:00	(Continued MRG .04 Activities) COFFEE BREAK		
17:00-19:00	**Technology Applications (I-C) | Multiple Areas: WVITAE || *Session Chair: Hiroshi Harada, Kyoto University, Kyoto, ICT, Koganei,* Japan**		MRG .04
	1570207041	Design of Amateur Radio Wireless Transceiver to Reduce the Impact of Natural Calamities; **Ashwini Shingate[1], Rushikesh Borse[2], Shubham Tiwari[3], Arvind Jawale[4]**; [1][2]*Savitribai Phule Pune University*, [2]*Savitribai Phule Pune University*, [2]*Shubhra Energy*, [4]*Scout Satara*; **India**	
	1570210199	Deep Sea Exploration Recovery and Transport [DESERT] Vehicle and its Modes of Communication; **Aileen Sengupta[1], Pavel Sengupta[2]**; [1]*Techno India College of Technology, Rajarhat,* [2]*Dr. Sudhir Chandra Sur Degree Engineering College, Dum Dum, Kolkata* □; **India**	
	1570208685	Energy Efficient Lighting System for Indoor Parking with Ubiquitous Communication; **Mahesh Jha[1], Navin Kumar[2]**; [1]CMRIT, VTU, [2]Amrita University & School of Engineering; **India**	
	1570210063	Recent Progress in Radioclimatological Modeling in Equatorial and Tropical Africa; **Thomas Afullo, Akintunde Alonge**; University of Kwazulu-Natal, Durban, **South Aftrica**	
	1570210261	Digital door lock using fingerprint, webcam and GSM - a novel approach for smart homes; **Ashish Patwari, Karuna Yepuganti, Arpit Omar, Shekhar Thakur, Kaushik Kumar**; *VIT University, Vellore*, **India**	
	1570209921	Marine Vessel Detection Comparing GPRS and Satellite Images for Security Applications; **Sajan Ambadiyil[1], Dintu Thomas[2], V P Mahadevan Pillai[3]**; [1]*Optical Image Processing Division, C-DIT,* [2]*SCMS School of Engineering and Technology,* [3]*University of Kerala, Thiruvanthapuram, Kerala*; **India**	
19:30-22:30	END of DAY 2 || Cultural Program (Mridangam and Kuchipudi Group Dance Recital), GALA DINNER & Best Paper Award: HALL1		

Time Slot	Day2: Monday, December 14 || MRG .05 Activities || Special Sessions on WWRF & GISFI and; Contributed Papers: Physical and Fundamentals (I)		
08:30-19:00	Registration		
09:00-11:00	**GRAND OPENING**		**HALL 1**
11:00-11:30	COFFEE BREAK		
11:30-13:30	**WPMC Special Session on "Selected Topics"** **Session Organizer and Chair: Shinsuke Hara,** *Osaka City University*, **Japan**		MRG .05
	Invited Talk	"Home neuro- rehabilitation: an ICT near Future Service", **Silvano Pupolin**, *University of Padua*, **Italy**	
	Invited Talk	" **Lakhshmi Mukunkutla**, *USA/Aalborg University*, **Denmark**	
	Invited Talk	"Convergence Techniques for Future Communications", **M. Jankiraman**, *Larsen & Toubro Ltd. (L&T), Bangalore*, **India**	
	Invited Talk	" Making a Safe and Secure 4 G World", **Debu Nayak**, *Huawei Telecommunications India Pvt. Ltd*, **India**	
13:30-14:30	LUNCH		
14:30-16:30	**Physical and Fundamentals (I-A) | LTE and Multiple Access Techniques (OFDMA/OFDM/SC-FDMA, MIMO, SISO): WPMC & WVIATE || *Session Chair:* ", M. Jankiraman, *Larsen & Toubro Ltd. (L&T), Bangalore, India***		MRG .05
	1570196365	Joint Transceiver Design for QoS-Constrained MIMO Two-Way Non-Regenerative Relaying; **Rohit Budhiraja, Bhaskar Ramamurthi**; *Department of Electrical Engineering, IIT Madras*, **India**	
	1570190883	New virtual 8x1 MISO scheme with QOSTBC; **Ugljesa Urosevic, Zoran Veljovic, Milica Pejanovic-Djurisic**; University of Montenegro, Podgorica, **Montenegro**	
	1570212700	Limited Feedback Scheduling For MIMO-OFDM Broadcast Network; **Prabina Pattanayak, Preetam Kumar;** *Indian Institute of Technology, Patna*, **India**	
	1570193823	An Efficient Deterministic Scheme for Blind CFO Estimation in SC-FDMA; **Vinay Kumar Trivedi, Vidya Sagar, Preetam Kumar**; *Indian Institute of Technology, Patna*, **India**	
	1570209997	**WVIATE:** Capacity Analysis of MIMO BC Channels in Presence of Spatial Correlation; **Ashok Panda①, Swadhin Kumar Mishra②, Ajit Kumar panda②**; ①IIIT Bhubaneswar,② *NIST Berhampur*; **India**	
	1570212704	**WVITAE:** Error Rate Performance for Multiuser scheduling in MIMO downlink system with imperfect CSI; **Prabina Pattanayak, Diwakar Pandey, Preetam Kumar;** *Indian Institute of Technology, Patna*, **India**	
16:30-17:00	COFFEE BREAK		
17:00-19:00	**WVITAE Special Session: Wireless World Research Forum (WWRF):** **Knud Erik Skouby,** Aalborg University **, Denmark and Sudhir Dixit,** WWRF**, USA**		MRG .05
	Theme : **Mobile History of India**		
	Opening Speech	**Knud Erik Skouby,** *Aalborg University* **, Denmark**	
	Keynote Speech	**Sudhir Dixit,** *WWRF*, **USA**	
	Invited Talk	**Krishna Sirohi,** *NIKSUN*, **India**	
19:30-22:30	END of DAY 2 || Cultural Program (Mridangam and Kuchipudi Group Dance Recital), GALA DINNER & Best Paper Award: HALL1		

Time Slot	Day2: Monday, December 14 || MRG .06 Activities || Second International Workshop on Innovation and Entrepreneurship(IWIE) (I)			
08:30-19:00	Registration			
09:00-11:00	**GRAND OPENING**			**HALL 1**
11:00-11:30	COFFEE BREAK			
11:30-13:30	**Second International Workshop on Innovation and Entrepreneurship(IWIE) :(I-A) || Entrepreneurship Contest** Second International Workshop on Innovation and Entrepreneurship(IWIE) | (I –A) Organizer and Chair: Sofoklis Kyriazakos, CTIF, Aalborg University, Denmark **Introduction to the Workshop and Entrepreneurship Contest**			MRG .06
	Mayank Kumar Mittal, **SaleYourBooks.com** Mayank Semwal , **Genralsorts** Shilpa Chaudhary, **Car security Systems** Meenakshi Gupta, **MNY PRO** Jafar Mapara, **Identity Management System** Akskay Radke, **Smart Indian railways**	Mayank Semwal, **App for professional Help** Deepak Sharma, **Instant Presentation and Converter** Mukesh Wadile, **SecureChip** Heramb Pawar, **Clear Vision** Naman Vashishth, **Find ME!!!!** Darshan Vyas, **CLOTH TESTER using IMAGE PROCESSING** Shashank Roy, **Electronic Refigerator**	Adarsh Mishra, **Virtual PPM-1** Utkarsh Trivedi, **Service Providers Support** Irram Patharwat, **Methane Extraction Digester** Manoj Radadiya, **Gesture and Voice based Television Control System** Nikhil Prabhu, **Smart Electric Car using AMR7** Jafar Mapara, **Connected Homes** Madhukesh Heggannavar, **Design and Development of Magnetron Power Source**	
13:30-14:30	LUNCH			
14:30-16:30	**Second International Workshop on Innovation and Entrepreneurship(IWIE) :(I-B) || Entrepreneurship Contest** Second International Workshop on Innovation and Entrepreneurship(IWIE) | (I –B) Organizer and Chair: Sofoklis Kyriazakos, CTIF, Aalborg University, Denmark IWIE Activities			MRG .06
16:30-17:00	COFFEE BREAK			
17:00-19:00	**Second International Workshop on Innovation and Entrepreneurship(IWIE) :(I-C) || Entrepreneurship Contest** Second International Workshop on Innovation and Entrepreneurship(IWIE) | (I –C) Organizer and Chair: Sofoklis Kyriazakos, CTIF, Aalborg University, Denmark **Results and Discussion of Entrepreneurship Contest of the IWIE Workshop Day -1**			MRG .06
19:30-22:30	END of DAY 2 || Cultural Program (Mridangam and Kuchipudi Group Dance Recital), GALA DINNER & Best Paper Award: HALL1			

Tuesday, December 15

Day 3

"Workshops, Special Sessions, Contributed Papers"

Time Slot	Day3: Tuesday, December 15 || HALL 1.1 & 1.2 Activities || Workshops & Special Sessions (II-A)			
08:30-19:00	Registration			
09:00-11:00	**Keynote Speech || Chair: Ashok Chandra, TPC Executive Chair, WPMC/ GWS-2015** **Lars Kiekegaard**, Teracom, **Denmark** **Ramesh Rao**, University of California, San Diego, **USA**			**HALL 1**
11:00-11:30	**COFFEE BREAK**			
11:30-13:30	**WPMC Special Session on "Smart Village 'Rural Model': Basic Unit for a Digital India" || Session Organizer and Chair: Mayur Dave,** *IETE*, **INDIA**			HALL 1.1
	1570227716	Demonstrating SWiFiIC - Sustainable WiFi for Rural Communication; **Abhishek Thakur, Aarthi J, Amit Chawla, Chittaranjan Hota**; *BITS Pilani, Hyderabad Campus,Hyderabad*, **India**		
	1570234273	"IoT" based Smart Village: An Indigenous step towards 'Digital India'; **Madhukant Patel①, Piyush Yadav②**; *①MD, Reve Automation LLP, ②Green Cloud iSoft P. Ltd., Dehradun*, **India**		
	1570234316	Rurbanisation of India; **Bipin Pradeep Kumar**, *Gaia Smart Cities*, **India**		
	WVITAE Special Session on "Persuasive Multi Business Model Innovation in a World of Persuasive Technologies" **Session Organizer and Chair: Peter Lindgren,** *Multi Business Model Innovation and Technology, Aarhus University*, **Denmark ||Session Co-organizers: Troels Christian, K. Andersen, Torben Bjerrum, Annabeth Aagaard, Ole Horn Rasmussen, Morten Karnøe Søndergaard** *Aarhus University*, **Denmark; Theodoor van Dongen,** *VDMBee, Veenendaal*, **The Netherlands**			HALL 1.2
	1570228216	Persuasive Technology and Business Models; **Morten Karnøe Søndergaard, Peter Lindgren, Niels Einar Veirum;** *Stanford Peace Innovation Lab, Department of Business Development and Technology, Aarhus University*, **Denmark**		
	1570228627	Service and Big Data business model in a world of persuasive technologies; **Troels Christian K. Andersen, Torben Cæsar Bisgaard Bjerrum**; *Aarhus University, Herning*, **Denmark**		
	1570228634	Secure Persuasive Business Models and Business Model Innovation in a World of 5G; **Peter Lindgren, Katharina Wuropulos**; *Aarhus University*, **Denmark (###)**		
13:30-14:30	LUNCH			
14:30-16:30	**WPMC Workshop on " Advanced Technologies and Promotion Strategies for Wi-SUN and the Wireless Grid Systems" || Workshop Organizer and Chair:** *Fumihide Kojima*, **Japan**			HALL 1.1
	Wi-SUN Alliance -Promoting open interoperable industry standards for smart utility networks; **Hiroshi Harada**, NICT, Japan		NICT's R&D, Standardization and Promotion Avtivities on Wi-SUN and the wireless grid systems; **Fumihide Kojima**, NICT, Japan	
	Wi-SUN RLMM Profile for Sensor Network Application; **Ryota Yamada**, Omron, Japan		Wi-SUN Alliance Activity in India; **Amarjeet Kumar**, Wi-SUN Alliance, India	
	WVITAE Workshop on "Wearable and Nearable Internet of Things (WaNIOT 2015)"|| Workshop Organizer and Chair: Balamuralidhar P, *Tata Consultancy Services (TCS)*, **Bangalore, India**			HALL 1.2
	Introduction by the workshop chair: Dr. Balamuralidhar P., TCS Innovation Lab, Bengaluru Wearables for Newborns": Prof. Bharadwaj Amrutur, Indian Institute of Science, Bengaluru Wearables for Safety: Mr. Ganesh Suryanarayanan, GTIO, Tata Group, Bengaluru		Data-driven Healthcare using Affordable Sensing", Dr. Arpan Pal, TCS Innovation Lab, Kolkata RF based Sensing of Cardiopulmonary Vital Signs": Mr. R.P.Pinto, SAMEER, Mumbai IoT in healthcare: Applications to neurology: Dr. Jayavardhana Gubbi, TCS Innovation Labs, Bengaluru	
16:30-17:00	COFFEE BREAK			

16:30-17:00	(Continued Hall 1.1 and 1.2 Activities) BREAK				
17:00-19:00	**Matchmaking session – Indian industry meets Global Industry || Organizer and Chair: Krishnal Sirohi,** *GISFI*, **India**				HALL 1.1
	Lars Kierkegaard, *Teracom*, **Denmark**	**Srinivasa Gutta, INVECAS,** *Hyderabad,* **India**	**Sivabalan Arumugam,** *NEC* **, Japan**	**Kiritkumar Lathia, GISFI/CTIF, Denmark**	
	Sandip Inamdar, *WISDOM Pvt. LTD.*, **India**	**Balaji Kanigicherla,** *Ineda Systems, Hyderabad,* **India**	**Gangadhar Gude, SoCtronics,** *Hyderabad,* **India**	**Subbarangaiah,** *VEDA IIT, Hyderabad*, **India**	
	WVITAE Special Session on " Fiber-Wireless Convergence for broadband Connectivity in 5G perspective" || **Session Organizer and Chair: Jayashree Ratnam,** International Institute of Information Technology, *Hyderabad*, **India**				HALL 1.2
	Invited Talk	Journey to World Wide Wireless and its Deployment Challenges**, D.S. Rao**, Tata Communications Ltd, Hyderabad, India			
	1570228022	Participation of Optical Backbone Network in Successful Advancement of Wireless Network; **Rajarshi Mahapatra**; *CVR College of Engineering*, **India**			
	1570228026	On 5G Cellular Backhaul Networks; **Mahima Mehta**, *Intel Mobile Communications India Pvt. Ltd., Bangalore*, **India**			
	1570228029	Telecom Regulatory Issues in Converged Era; **G. Muralidhar , Robert Ravi**; *Telecom Regulatory Authority of India*, India **(***)**			
19:30-22:30	END of DAY 3 || NETWORKING DINNER: FOYER				

Time Slot	Day3: Tuesday, December 15 || MRG .01 Activities || Workshops & Special Sessions (II-B)		
08:30-19:00	Registration		
09:00-11:00	**Keynote Speech**		HALL 1
11:00-11:30	COFFEE BREAK		
11:30-13:30	**WVITAE Special Session on" Internet of Things (IoT)"** **Session Organizers: Birger Andersen①, Knud Erik Skouby②, ② Samant Khajuria,** ①*Technical University of Denmark, Copenhagen*, ②*Aalborg University, Copenhagen*, **Denmark** **Session Chair: Birger Andersen,** *Technical University of Denmark, Copenhagen*, **Denmark**		MR G.01
	Keynote Talk	IoT in Theory and Practice**, Birger Andersen,** *Technical University of Denmark, Copenhagen*, **Denmark**	
	1570227404	Heuristic Trust in IoT; **Bipjeet Kaur①, Henrik Tange②;** ①*Denmark Technical University* , ②*Wireless Center CTIF Copenhagen*; **Denmark (###)**	
	1570228109	Cyber security for M2M Smart Grid; **Sarmistha De Dutta①, Prof. Ramjee Prasad②**; ①*NIKSUN, Inc.*, **USA** ②*Center For TeleInFrastruktur , Aalborg University*, **Denmark**	
	1570228247	GET IoT- Green Computing and Energy Harvesting technology in Internet of Things (IoT); **Jetendra Joshi, Anshumali Singh, Lakshya Gourav Moitra , Manash Jyoti Deka**; *NIIT University, Neemrana, Alwar, Rajasthan*, **India**	
	1570228361	An Energy Efficient Adaptive Wireless Link for Farms based on IoT technologies**; T. Blaszczyk①, P. Lynggaard②**; ①*Technical University of Denmark,* ②*CMI, Aalborg University Copenhagen*; **Denmark**	
	1570231008	Implementation Of Internet Of Things Using Near Field Communication For Parking Automation; **Aishwarya Sanjay Ikhe, Sagar Jayant More, Priyanka Sanjay Suranglikar, Prashant S Dhotre;** *Sinhgad Institute of Technology and Science, Pune*, **India**	
13:30-14:30	LUNCH		
14:30-16:30	**WVIATE Special Session on "Spectrum Management and Networking for Multi-link Satellite and Terrestrial Communication Systems"** **Session Organizers and Chairs: Preetam Kumar, Vinay Kumar Trivedi, Akash Agarwal;** *Indian Institute of Technology Patna*, **India**		MR G.01
	Invited Talk	Vimal Bhatia, *Associate Professor, IIT Indore*, **India**	
	Invited Talk	Preetam Kumar, *Assistant professor, IIT Patna*, **India**	
	1570221151	Cancellation of Inter-Cell Interference in Downlink with No Backhaul Information Exchange; **Shuvabrata Bandopadhaya①, Jibendu Sekhar Roy②**; ①*Silicon Institute of Technology, Bhubaneswar, Odisha,* ②*School of Electronics Engineering, KIIT University, Bhubaneswar, Odisha*.; **India**	
	1570226980	Performance Analysis Of Interference Cancellation In MIMO-FBMC; **V.Padmapriya , N.Venkateswaran**; *SSN College of Engineering, Chennai*,**India**	
	1570227724	Measurement and Identification of White Space using Low Cost SDR for Rural Wireless Broadband; **Vinit Sharswat, Pradeep Godara, Abhijeet Bishnu, Vimal Bhatia;** *Indian Institute of Technology Indore*, **India**	
16:30-17:00	COFFEE BREAK		

16:30-17:00	(Continued MRG .01 Activities) COFFEE BREAK		
17:00-19:00	**WVITAE Special Session on " eWALL"** **Session Organizer and Chair: Sofoklis Kyriazakos, CTIF,** *Aalborg University***,** *Aalborg,* **Denmark**		MR G.01
	1570224200	Improving the Trustworthiness of Ambient Assisted Living Applications; **Elias Z. Tragos①, Pavlos Charalampidis①, Alexandros Fragkiadakis①, George Lambropoulos②, Sofoklis Kyriazakos②;** ①FORTH-ICS,② Converge SA**; Greece**	
	1570224206	Requirements and Challenges in Evaluation of Systems for Independent Living of Senior Citizens; **Antun Kerner, Antonija Marinčić, Ana Koren, Dina Šimunić ,Ramjee Prasad**; *Faculty of Electrical Engineering and Computing, University of Zagreb,* **Croatia**	
	1570224166	Virtual sensing environment for care at home; **Aristodemos Pnevmatikakis;** *Athens Information Technology, IRIS Laboratory, Athens,* **Greece**	
	1570224167	Expression recognition using graph based feature selection; **Krasimir Tonchev, Nikolay Neshov, Agata Manolova ,Vladimir Poulkov**; Technical University of Sofia, **Bulgaria**	
	1570213206	Participatory Heuristic Evaluation of the First Iteration of the eWALL Interface Application**; Clara Schaarup①, Louise Bilenberg Pape-Haugaard①, Stine Veje Hangaard①, Albena Mihovska② ,Ole Hejlesen①; ①Department of Health Science and Technology, ②Center for TeleInfrastruktur □;** *Aalborg University, Aalborg,* **Denmark**	
	1570195309	Non Audio-Video gesture recognition system; **Razvan Craciunescu, A. Mihovska ; Center for TeleInfrastruktur □;** *Aalborg University, Aalborg,* **Denmark**	
19:30-22:30	END of DAY 3 || NETWORKING DINNER: FOYER		

Time Slot	Day3: Tuesday, December 15 || MRG .02 Activities || Workshops & Special Sessions (II-C)		
08:30-19:00	Registration		
09:00-11:00	**Keynote Speech**		HALL 1
11:00-11:30	COFFEE BREAK		
11:30-13:30	**WPMC Special Session on "Manufacturing Engineering"** **Session Organizer and Chair: Dnyandeo Dattatray Shinde,** *Sandip Foundation, Sandip Institute of Engineering & Management, Nashik, Maharashtra*, **India**		MR G.02
	Invited Talk	Total Productive Maintenance (TPM) an overview; **Rajendra G. Tated**; *Sandip Foundations, Sandip Institute of Engineering and Management, Nashik*, **India**	
	Invited Talk	Application of KK pillar of TPM – An Industrial Case study; **J. P Yavalkar;** *TPM-Learning center, Bajaj auto ltd. Waluj Aurangabad*, **India**	
	Invited Talk	Lean Six Sigma - Success Story of Kavach; **Jadhav Ganesh A.;** *Gabriel India Ltd. Pune*, **India**	
13:30-14:30	LUNCH		
14:30-16:30	**WPMC Special Session on "Manufacturing Engineering" (Contd.)** **Session Organizer and Chair: Dnyandeo Dattatray Shinde,** *Sandip Foundation, Sandip Institute of Engineering & Management, Nashik, Maharashtra*, **India**		MR G.02
	1570226974	Identifying Root Causes for Students Problems in Technical Education using Fishbone Diagram; **Dnyandeo Dattatraya Shinde①, Shwetambari Sanjay Ahirrao①, Prachi Dilip Shinde①, Rajendra G. Tated①, Morten Falch②**; ①*Sandip Foundations, SIEM, Nashik, India,* ②*Center for Communication, Media and Information Technologies (CMI), Aalborg University Copenhagen*, **Denmark**	
	1570226994	Effect of Newly Designed Burnishing Tool on Surface Micro hardness of AA6351; A. S. Maheshwari①, Dr. R. R. Gawande②; ①*Sandip Institute of Technology & Research Centre, Nashik. (Maharashtra),* ②*Bapurao Deshmukh College of Engineering, Wardha (Maharashtra)*; **India**	
	1570228066	Application of Principal Component Analysis to Magnetic Abrasive Finishing**; Sandip B. Gunjal, P. J. Pawar**; *K.K.W.I.E.E. & R, Nasik*, **India**	
	1570227495	Metric Based Efficiency Analysis Of Educational ERP System Usability - Using Fuzzy Model; **Anil Kumar, Reza Tadayoni, Lene Tolstrup Sorensen**; *Department of Electronic Systems, Aalborg University*, **Denmark**	
	1570227534	A Brief Review on Process Parameter Optimization of GMAW Process and Grey-based Taguchi Method; **U. V. Patil, G. R. Naik**; *KIT's College of Engineering, Shivaji University, Kolhapur*, **India**	
	1570227977	Vehicle Monitoring and controlling system using CAN protocol; Mosam Sangole□, **Vicky Chaudhary, Vishakha Nighute, Priyanka Satpute;** *Sandip Foundation Nashik, Maharashtra*,**India**	
16:30-17:00	COFFEE BREAK		

16:30-17:00	(Continued MRG .02 Activities) COFFEE BREAK		
17:00-19:00	**WPMC Special Session on "Manufacturing Engineering" (Contd.)** **Session Organizer and Chair: Dnyandeo Dattatray Shinde,** *Sandip Foundation Sandip Institute of Engineering & Management, Nashik, Maharashtra,* **India**		MR G.02
	1570227004	Application of Real Coded Genetic Algorithm to Dynamic Layout Benchmark Problem; **Kailas V. Chandratre, P.J. Pawar**; *, K.K.W.I.E.E. & R, Nasik*, **India**	
	1570227011	Model Development for Preventive Maintenance and Replacement Policy; **Anand S. Relkar, Keshav N. Nandurkar**; *S. I.T.R.C., Nashik, K.K.W.I.E.E.R, Nashik*; **India**	
	1570227290	Vacuum Gripper Design For An Industrial Handling System; **Ajinkya Vasant Nichit, Suraj Ramesh Jadhav, Anirudh Arun Desai, Vishal Eknath Patil,Vishal Sonowane**; *Sandip Institute Of Engg. & Mangt. Nashik*, **India**	
	1570228555	Automatic Ration Distribution System-A Review; **Swapnil R. Kurkute, Dipak P. Patil, Chetan Medhe, Ashwini Kshirsagar, Ashlesha Revgade** □; *SIEM Nasik*, **India**	
	1570227469	Self -Balancing Platform for Personal Transport; **Yogesh Risodkar , Ganesh Shirsath, Monali Holkar, Mayur Amle**; *SIEM, Sandip Fondation, Nashik*, **India**	
	1570228052	Decommissioning of Nuclear Facilities and Dose Rate Calculations for Nuclear Power Plant Staff; **Pushkar Prashant Lachake, Dnyandeo Dattatraya Shinde**; *Sandip Institute of Engineering and Management, Nashik*, **India**	
19:30-22:30	END of DAY 3 || NETWORKING DINNER: FOYER		

Time Slot	Day3: Tuesday, December 15 || MRG .03 Activities || Contributed Papers: Physical and Fundamentals (II-A)		
08:30-19:00	Registration		
09:00-11:00	**Keynote Speech**		**HALL 1**
11:00-11:30	COFFEE BREAK		
11:30-13:30	**Physical and Fundamentals (II-A-1) | Antenna & Circuit Design, Analysis and Investigation: WPMC || *Session Chair: Laxminarayana Pillutla; Dhirubhai Ambani Institute of Information and Communication Technology, India*** 1570213114	Design Optimization and SAR Evaluation of SS-UWB Patch Antenna for WBAN; **Vivek Kumar, Sravanth Kumar Ramakuri**; **Bharat Gupta**; *Birla Institute of Technology Mesra, Ranchi,* **India**	MRG .03
	1570210207	Radar Range and Range Resolution Enhancements; **Uma S Jha, Erik Chowdhury**; *Space & Airborne Systems, Raytheon Co, El Segundo, California,* **USA**	
	1570209793	SIW based Antipodal Linear Tapered Slot Antenna for Inter-Satellite Communication Links at 60 GHz; **Nishesh Tiwari, T Rama Rao, Purva Shrivastava**; *SRM University,Chennai,* **India**	
	1570192429	SAR and Thermal effects of a Body Wearable Microstrip Antenna at UHF and UWB frequencies; **Varshini Karthik, T Rama Rao**; *SRM University,Chennai,* **India**	
	1570213460	Antenna Radiation Pattern Based 3D Localization Technique; **Amarlingam Madapu[1], Pachamuthu Rajalakshmi[1], Vinod Kumar Netad[1], Masaya Yoshida[2], Kiyohito Yoshihara**; [1]Indian Institute of Technology Hyderabad, Hyderabad, **India,** [2]*KDDI R&D Laboratories Inc., Green and M2M Application Laboratory Iidabashi,* **Japan**	
13:30-14:30	LUNCH		
14:30-16:30	**Physical and Fundamentals (II-A-2) | LTE & Multiple Access Techniques (OFDMA/OFDM/SC-FDMA, MIMO, SISO): WPMC || *Session Chair: Uma S. Jha, Raytheon Co., California, USA*** 1570213429	Distributed Spatial Modulation-OFDM in Uplink Relay-assisted Cellular Network; **Kunal Sankhe, Rama Garimella**; *International Institute of Information Technology, Hyderabad,* **India (***)**	MRG .03
	1570213444	Simultaneous Transmission of Information and Energy in OFDM Systems; **Sumit Gautam, P. Ubaidulla**; *International Institute of Information Technology-Hyderabad,* **India**	
	1570210151	Blind Channel Length Estimation for OFDM Systems using Cumulant Features; **Ajay Kambhampati, Udit Satija, Baratram Ramkumar, M Sabarimalai Manikandan**; *IIT-Bhubaneswar,* **India**	
	1570213302	A Feasibility Analysis of LTE-CommSense; **Amit K. Mishra[1], Mohammed Zafar Ali Khan[2], Santu Sardar[3]**; [1]*Department of Electrical Engineering, University of Cape Town,* **South Africa**, [2]*Department of Electrical Engineering, IIT Hyderabad,* **India,** [3] *ANURAG, Defence Research & Development Organization*, **India**	
	1570167111	An Efficient Resource Block Allocation Algorithm in LTE-Based Systems with User Rate Constraints; **Vijay Gutta, AmruthMuddana, T K Ramesh**; *Amrita VishwaVidyapeetham,* **India**	
	1570213529	LTE-Advanced Radio and Network Optimization: Basic Coverage and Interference Constraints; **Fernando J. Velez, Sofia Sousa, Jessica Acevedo ,Daniel Robalo**; *Instituto das Telecomunicações - DEM Universidade da Beira Interior,Faculdade de Engenharia, Covilhã,* **Portugal**	
16:30-17:00	COFFEE BREAK		

16:30-17:00	(Continued MRG .03 Activities) COFFEE BREAK		
17:00-19:00	**WPMC Special Session on " Selected Topics in Physical & Fundamentals-1"** **Session Organizer and Chair** : **T Rama Rao,** SRM University, **India**		MRG .03
	1570160791	Performance of MIMO Detection Techniques with Spatial Multiplexing**; Soma Umamaheshwar①, Tipparti Anil Kumar②, K Srinivas Rao③**; ①*SR Engineering College,* ②*SVS Group of Institutions,* ③*TRR College of Engineering, Telangana*, **India (###)**	
	1570213390	Reducing memory consumption with a lossless image compression algorithm based on predictive coding; **Rupali S. Vairagade**; *Sinhgad Institute of Technology and Science, Pune*, **India (***)**	
	1570209839	Enhancement in Spectral Efficiency using Circular Convolution in MIMO FBMC towards Wireless Network 5G; **Payal P. Tayade, Vandana M. Rohokale**, *SKNSITS, Lonavala*, **India (###)**	
	1570209843	Performance Analysis of Group based Cooperative Sensing Schemes; **K Jyostana①, N. Vandana②, Swathi Roja②, B. N. Bhandari②**; ①*VNR Vigana Jyothi Institute of Engineering and Technology,* ②*Jawaharlal Nehru Technological University*; Hyderabad, **India (###)**	
	1570238199	A Comparative Study of Channel Estimation for MIMO-OFDM system; **G Surendher**, Sree Chaitanya *Institute of Technological Sciences, Karimnagar,* **India (###)**	
19:30-22:30	END of DAY 3 || NETWORKING DINNER: FOYER		

Time Slot	Day3: Tuesday, December 15 || MRG .04 Activities || Contributed Papers: Physical and Fundamentals (II-B)		
08:30-19:00	Registration		
09:00-11:00	**Keynote Speech**		**HALL 1**
11:00-11:30	COFFEE BREAK		
11:30-13:30	**Physical and Fundamentals (II-B-1) | Channel Fading and Selection :WVIATE || *Session Chair-Ernesthina Cianca, University of Rome, Tor Vergata, Italy***		MRG .04
	1570208291	Joint Channel Estimation and CCI Cancellation for STBC-OFDM System in Fast Fading Channel; **Jyoti P Patra, Prasanta Kumar Pradhan,, Poonam Singh, Sarat Kumar Patra**; *National Institute of Technology Rourkela*, **India**	
	1570210195	Rate Independent Multicarrier Variable Rate Scheme over Frequency Selective Channel; **Akash Agarwal**, **Vijay Mukati**, **Preetam Kumar**; *Indian Institute of Technology, Patna*, **India**	
	1570210219	Performance of Amplify-and-Forward Cooperative Diversity under Ricean Fading; **Maja Delibasic, Milica Pejanovic-Djurisic, Zoran Veljovic**; *University of Montenegro*, **Montenegro**	
	1570213163	Performance of a space-time coded MC-CDMA system in a Rayleigh fading channel; **Olanrewaju B Wojuola**, **Stanley H. Mneney**, **Viranjay M Srivastava**; *University of KwaZul-Natal*, **South Africa**	
	1570194569	A new shaping code for PAPR Reduction in Single-Carrier Modulation; **Yonathan Tate, Dan Raphaeli;** *Tel Aviv University*, **Israel**	
	1570207637	PAPR Reduction Comparison of the MC-CDMA System with Various Companding Techniques; **Sarala Beeram①, Bhagya sree Vonguru②, BN Bhandari③, Dronam Raju Venketeswarlu③**; *①M V S R Engineering College, Hyderabad & Osmania University*; *②B E & Osmania University, Hyderabad*; *③JNT University Hyderabad;* **India**	
13:30-14:30	LUNCH		
14:30-16:30	**Physical and Fundamentals (II-B-2) | Physical Channel: WPMC || *Session Chair-Thomas J. O. Afullo, University of KwaZullu-Natal, South Africa***		MRG .04
	1570213381	On Detection Improvement in MC-CDMA Image Watermarking on Fading Channel; **Santi Prasad Maity①, Seba Maity②**; ①Indian Institute of Engineering Science and Technology, Shibpur, ②CEMK, Kolaghat, **India**	
	1570213387	On the Backhaul Reduction in Joint Transmission Network with Channel Uncertainty; **Zhangxing Liu, Hui Tian, Cheng Qin** ; *Beijing University of Posts and Telecommunications*, **China**	
	1570212327	Variable Encoding and Sequencing Pattern Driven Multiple Image Bit Watermarking for Wireless Domain; Soumit Chowdhury①, Nabin Ghoshal ②; ①Govt. College of Engineering & Ceramic Technology, Kolkata, ② University of Kalyani, India	
	1570177831	Improving Performance of Impulsive Noise Canceller Under Class A Impulsive PLC Channel; **Hirotomo Yasui, Akira Nakamura, Makoto Itami**; *Tokyo University of Science*, **Japan**	
	1570211271	A Generic and Compatible Implementation for 2D and 3D Geometry-based Stochastic Channel Models; **Zhenzi Liu, Tian Lei, Yuming Bi, Pan Tang, Wei Chen, Jianhua Zhang**; *Beijing University of Posts and Telecommunications*, **China**	
	1570209407	Low Rate Common Control Channels with Distributed Cross-Layer Optimization via Genetic Algorithm; **Pranoti Balki, Kishor P. Patil**; *Sinhgad Academy of Engineering, Pune*, **India**	
16:30-17:00	COFFEE BREAK		

16:30-17:00	(Continued MRG .04 Activities) COFFEE BREAK		
17:00-19:00	**Physical and Fundamentals (II-B-3) Performance, Analysis and Ranking: WPMC || *Session Chair- Mqhele Dlodlo, University of Cape Town, South Africa***		MRG .04
	1570194241	Analysis of Data Transmission Management through Software Defined POX Controller; **Vaishnavi Moorthy, Revathi Venkatraman**; *SRM University, Chennai*, **India**	
	1570193591	Design and Performance Analysis of a Penta-band Spiral Antenna for Vehicular Communications; **Ramya R, T Rama Rao;** *SRM University, Chennai*, India	
	1570194537	Performance Analysis of Energy Detector in Correlated Log-normal Fading Channels for IR-UWB Systems; **S. Josephine, Anil Mahanta, P. R. Sahu**; *IIT Guwahati*, **India**	
	1570208727	Performance Comparision of Various Detection Methods for QO-STBC over Time Selective Channel; **Jyoti Patra, Poonam Singh**; *National Institute of Technology Rourkela*, **India**	
	1570211595	Design and Data Analysis of a Signal Measurement System Based on Variable Signature Sequences; **Ji-Hyun Moon, Jeong-Ho Kim, Na-Hyung Kim, and Bing Yuan Chen**; *Ewha Womans University*, **Republic of Korea**	
	1570191499	Ranking of Total Productive Maintenence pillars using Analytical Hierarchy Process; **Dnyandeo Shinde[1][2][3], Morten Falch[2], Rajendra Tated[3], Ramjee Prasad[4];** [1]*Center for Communication, Media and Information Technologies (CMI), Aalborg University Copenhagen,* **Denmark**, [2]*Aalborg University Copenhagen,* **Denmark,** [3] *Sandip Foundations, Nashik***, India,** [4]*CTIF, Aalborg University*, **Denmark**	
19:30-22:30	END of DAY 3 || NETWORKING DINNER: FOYER		

Time Slot	Day3: Tuesday, December 15 || MRG .05 Activities || Contributed Papers: Efficient Wireless Communications		
08:30-19:00	Registration		
09:00-11:00	**Keynote Speech**		**HALL 1**
11:00-11:30	COFFEE BREAK		
11:30-13:30	**Efficient Wireless Communications (A) | Energy Harvesting: WPMC || *Session Chair- Sudhanshu S. Jamuar, University of Malaysia Perlis*, Malaysia**		MRG .05
	1570213231	Energy-Efficient Resource Allocation for Hybrid Services with QoS Requirements in Cellular Network*;* **Yuhao Zhang, Ning Wang, Baoling Liu***; Beijing University of Posts and Telecommunications*, **China**	
	1570192925	DEAR: An Energy-centric Adaptive Region of Interest Mechanism for Wireless Mobile Devices; **Hrishikesh Venkataraman①, Ting Bi②, Ting Wu②, Gabriel-Miro Muntean②;** ①*Center for Smart Cities, Indian Institute of Information Technology (IIIT), Chittoor, Sricity, AP,* **India,** ②*Performance Engineering Laboratory, Dublin City University (DCU), Glasnevin, Dublin 9,* **Ireland**	
	1570192965	EDAS- Energy-Efficient Device-based Adaptive Cross-Layer Scheme for Wireless Multimedia Transmission; **Hrishikesh Venkataraman①, Shen Wang②, Gabriel-Miro Muntean②;** ①*Center for Smart Cities, Indian Institute of Information Technology (IIIT), Chittoor, Sricity, AP,* **India,** ②*Performance Engineering Laboratory, Dublin City University (DCU), Glasnevin, Dublin 9,* **Ireland**	
	1570194465	Energy Efficient Scheduling Algorithm for the Real-time Multicast and Unicast Services; **Min Wang①, Qiaoyun Sun①, Shuguang Zhang①, Yinlong Liu②, Yu Zhang②;** ①*Information School, Beijing City University;* ②*Institute of Information Engineering Chinese Academy of Sciences, Beijing;* **China**	
	1570213117	Secrecy Outage of a Cognitive Relay Network with Energy Harvesting and Imperfect CSI; **Pranabesh Maji, Binod Prasad, Sanjay Dhar Roy, Sumit Kundu;** National Institute of Technology, Durgapur, **India**	
	1570213446	Analytical Model of Relay Node Integrating IEEE 802.15.4 MAC and Energy Conserving State Behaviour; **Rajavaraprasad Yerra, Malyala Pavana Ravi Sai Kiran, Pachamuthu Rajalakshmi**; Indian Institute of Technology Hyderabad, **India**	
13:30-14:30	LUNCH		
14:30-16:30	**Efficient Wireless Communications (B) | Security, Trust, Privacy and Authentication: WPMC || *Session Chair- Vandana Rohokale , SIT, Lonavala, India***		MRG .05
	1570194123	Elliptic Curve Cryptography based Key Management for the M2M Local Cloud Platform; **Bayu Anggorojati①, Neeli Rashmi Prasad②, Ramjee Prasad①;** ①*Center For TeleInFrastruktur , Aalborg University*, **Denmark**; ②*Center For TeleInFrastruktur*, **USA (***)**	
	1570210161	Privacy-Preserving Friend Matching Protocol approach for Pre-match in Social Networks; **Shubhangi S.Ople①, Aaradhana A. Deshmukh②, Albena Mihovska②, Ramjee Prasad②;** *Savitribai Phule Pune University*, **India,** ②*CTIF, Department of Electronics Systems Aalborg University, Aalborg*, **Denmark**	
	1570195039	A certificate-driven Approach to Access Control in Future Internet; **Nancy Ambritta①, Poonam Railkar②, Parikshit Narendra Mahalle①;** ①*Sinhgad Institute of Technology and Sciences & Smt. Kashibai Navale College of Engineering,* ②*Smt. Kashibai Navale College of Engineering of Engineerin, Pune University*; **India (***)**	
	1570195141	A Modified RFID Authentication Protocol Using Elliptic Curve Cryptography; **Rajesh Dochania, Nirmal Roberts, Karm V Arya***; ABV-Indian Institute of Information Technology and Management, Gwalior*, **India**	
	1570213335	Secure and Privacy Enabled Anonymous Computing for Heterogeneous (SPEACH) IoT; **Meena Singh, Rajan M A, Shivraj Vl , P. Balamuralidhar**; *Tata Consultancy Sevices Limited*, **India**	
16:30-17:00	COFFEE BREAK		

16:30-17:00	COFFEE BREAK		
17:00-19:00	**Efficient Wireless Communications (C)	Security, Trust, Privacy and Authentication: WVITAE || *Session Chair-K.V. Arya, AVIIITM, Gwalior, India***		MR5 .05
	1570213434	Architectural Integration for Security in Advanced Metering Infrastructure; **Priyanka D.Halle[1], Vandana Rohokale[1], Ramjee Prasad[2]**; [1]E&TC SKNSITS, Lonavala, **India** [2] *Center For TeleInFrastruktur , Aalborg University*, **Denmark**	
	1570194669	Trustbook: A Trust-based access control in Online Social Networks; **Vedashree Takalkar, Parikshit Narendra Mahalle**; Savitribai Phule Pune University, STES, Pune, **India**	
	1570210113	Daubechies Wavelet based Effective Data Authentication in Wireless Domain; **Anirban Goswami[1], Nabin Ghoshal[2]**; [1]*Techno India*, [2]*University of Kalyani*; **India**	
	1570211897	Mesh IP Video Surveillance Systems Model Design and Performance Evaluation; **Smart Lubobya[1], Mqhele E. Dlodlo[1], De Jager Gerhard[1], Ackim Zulu[2]**; [1]*University of Cape Town*, **South Africa**; [2]*University of Zambia*, **Zambia**	
	1570210201	Secret Transmission through Audio Signal with Reduced Distortion for Wireless Communication (STASRD); **Dipnkar Pal[1], Nabin Ghoshal[2]**; [1]*Techno India*, [2]*University of Kalyani*; **India**	
	1570209931	Secure E- Voting System with integration of NFC, Biometrics and Cloud Computing; **Amol Potgantwar[1], Tejas Upasani[2]**; [1] *Sandip Foundation*, [2]*Savitribai Phule*,[1][2]*Pune University*; **India**	
19:30-22:30	END of DAY 3 || NETWORKING DINNER: FOYER		

Time Slot	Day3: Tuesday, December 15 || MRG .06 Activities || 23rd GISFI Standardization Series Meeting Meeting on Security and Privacy/ WWSMC	
08:30-19:00	Registration	
09:00-10:30	**23rd GISFI Standardisation Meeting on Security and Privacy/ WWSMC:** *Session Chair:* ***Anand R. Prasad****, NEC Corporation* ***Japan****; Session Organiser:* ***Anand R. Prasad,*** *NEC Corporation* ***Japan****;* ***Krishna Sirohi****, NIKSUN,* ***USA;*** ***Sivabalan Arumugam,*** *NEC Mobile Network Excellence Centre(NMEC), NEC India Pvt Ltd,* ***India*** Opening by Co-Chairs: **Anand R. Prasad**, Chief Advanced Technologist, Executive Specialist, NEC Corporation ; **Krishna Sirohi**, Senior Advisor, Niksun **Session 1: Cyber Security ||** Moderator**: Krishna Sirohi**, NIKSUN Topic: Cyber Security**, Ramamurthy Gemini,** *Chairman , Cyber security & privacy foundation***, India** **Session 2: IoT Security ||** Moderator: **Krishna Sirohi**, NIKSUN Topic: Internet of Things – Security**; Sivabalan Arumugam,** NEC Mobile Network Excellence Centre(NMEC), NEC India Pvt Ltd	MRG .06
10:30-11:00	COFFEE BREAK	
11:00-13:00	**GISFI Special Session on Security and Privacy/ WWSMC-1** **Session 3: Communication System Security ||** Moderator: Anand R. Prasad, NEC Corporation Topic: Telecom Security **; Vijay Madan,** Chief Mentor - IT & Technology, Network Operation, Tata Teleservices Limited Topic: Telecom Security **; Alf Zugenmaier,** Professor, Munich University of Applied Sciences Topic: Mobile PKI , **Zia Saquib**, Scientist, CDAC, Hyderabad Topic: Wired & Wireless Security **G.K. Satyanarana;** Head, Telecom, ECIL, Hyderabad	MRG .06
13:00-14:00	LUNCH	
14:00-16:00	**GISFI Special Session on Security and Privacy/ WWSMC-1** **Session 4: Cloud & Platform Security ||** Moderator: Sivabalan Arumugam, NEC India Pvt Ltd Topic: Information Security - Cloud Environment ; **Gopala Rao Jammi**, Professor , MEC (A Group of TechM), Hyderabad Topic: Personal Safety: Next Frontier in Mobile Security ; **Kulkarni Dattatraya**, Intel Security Group, Bangalore Topic: NFV Security**; Prabhu T**, NEC India, Chennai, **India** Topic: Monitoring Aspects**; Krishna Sirohi,** Senior Advisor, NIKSUN	MRG .06
16:00-16:15	COFFEE BREAK	
16:15-17:15	**GISFI Special Session on Security and Privacy/ WWSMC-2** **Session 5: Panel Discussion "What are the pains? What is needed?" ||** Moderator: **Anand R. Prasad**, NEC Corporation, **Japan** **Vijay Madan,** Chief Mentor - IT & Technology, Network Operation, Tata Teleservices Limited **G.K. Satyanarana,** Head, Telecom, ECIL, Hyderabad **Krishna Sirohi,** Senior Advisor, NIKSUN **Alf Zugenmaier,** Professor, Munich University of Applied Sciences	MRG .06
19:30-22:30	END of DAY 3 || NETWORKING DINNER: FOYER	

Wednesday, December 16

Day 4

"Workshops, Special Sessions, Contributed Papers"

Time Slot	Day4: Wednesday, December 16 || HALL 1.1 & 1.2 Activities || Workshops & Special Sessions (III-A)		
08:30-19:00	Registration		
09:00-11:00	**Keynote Speech || Session Chair : Ramjee Prasad, Center for TeleInFrastructure , Aalborg University, Denmark** **fred Harris**, San Diego State University, **USA** **Harish Mysore**, *IEEE*, **India** **Dinesh Chand Sharma,** *SESEI*, **India**		HALL 1
11:00-11:30	COFFEE BREAK		
11:30-13:30	**Second International Workshop on Innovation and Entrepreneurship(IWIE)- III** **Workshop Organizer and Chair: Sofoklis Kyriazakos,** CTIF, Aalborg University, **Denmark**		HALL 1.1
	WVITAE Special Session on "Communication, Navigation, Sensing and Services (CONASENSE)" - I **Session Organizers and Chairs: *Leo Ligthart, Tu-Delft, the Netherlands; Ernestina Cianca, University of Rome Tor Vergata, Italy***		HALL 1.2
	1570227732	Modified RAR and PLSR-based artifact removal for stroke detection in UWB radar imaging; **E. Ricci, A. Colucciello, S. Di Domenico, E. Cianca, T. Rossi**; University of Rome "Tor Vergata",Rome, **Italy**	
	1570228263	Communication Framework for Tele-rehabilitation Systems with QoS Guarantee; Plamen Semov, **Nikolay Dandanov, Georgi Balabanov, Krasimir Tonchev and Vladimir Poulkov**; *Technical University of Sofia*, **Bulgaria**	
	1570230189	vNet Zero Energy for Radio Base Stations- Balearic Scenario①; Pere Sabater Frau①, Albena Mihovska①, Ramjee Prasad①, Andreu Moia Pol② ,Angel Igelmo Ganzo②, Xavier Canals Solé③, Jaume Ochogavia Colom④; *Center for TeleInFrastruktur (CTIF) Aalborg University, **Denmark**; ②Universitat Illes Balears (UIB), ③Telefonica España S.A., ④Balearic Islands Government*, **Spain**	
	1570236132	Reliable Frame Selection for Speaker Identification under Voice Disguise Scenario; **Swati Prasad, Ramjee Prasad**; *Centre for TeleInfrastruktur (CTIF), Aalborg University, Aalborg*, **Denmark**	
	1570228151	Performance Analysis of SOFDM Transmission Scheme over Integrated Satellite/Terrestrial Network; **Akash Agarwal□①, B. M. Bhaveja②, Preetam Kumar①**; ①*Indian Institute of Technology Patna□*, ②*Department of Electronics & Information Technology (DeitY) New Delhi*, **India (***)**	
13:30-14:30	LUNCH		
14:30-16:30	**Second International Workshop on Innovation and Entrepreneurship(IWIE)- III (Contd)** **Workshop Organizer and Chair: Sofoklis Kyriazakos,** CTIF, Aalborg University, **Denmark**		HALL 1.1
	WVITAE Special Session on "Communication, Navigation, Sensing and Services (CONASENSE)" -II **Session Organizers and Chairs: *Leo Ligthart, Tu-Delft, the Netherlands; Ernestina Cianca,** University of Rome Tor Vergata, **Italy***		HALL 1.2
	1570226963	Efficient Filtering Technique for Chronic Wound Image Processing under Tele-Wound Network; **Chinmay Chakraborty, Bharat Gupta**; *Birla Institute of Technology Jharkhand*, **India**	
	1570227100	End-to-End Delay Analysis of IEEE 802.15.6 Standard for WBAN Medical Paradigm; **Vivek Kumar, Bharat Gupta**; *Birla Institute of Technology Jharkhand*, **India**	
	1570227212	Relevance of signal processing of the voice in diagnosing human tuberculosis; **Giovanni Saggio①, Santosh Bothe②**; ①University of Rome "Tor Vergata",Rome, **Italy, ②***Bharati Vidyapeeth University , Pune*, **India**	
	1570227247	A P2P architecture for Mobile Assisted Logistic Operations; **Pierpaolo Loreti* , Lorenzo Bracciale* , Francesco Zampognaro* , Massimo Povia† , Gianluca Gargiulo‡;** **NITEL - University of Rome Tor Vergata, †Technosky Via del Casale Cavallari, §NAIS Via Andrea Noale; Rome*, **Italy**	
	1570238200	GeoLocation Aware Dynamic Spectrum Sensing in Cognitive Radio Networks; **Usha Kurumaddali,** *GGS Indraprastha University*, **India**	
17:30	END OF WPMC-2015 & GWS-2015		

Time Slot	Day 4: Wednesday, December 16 || MRG .01 Activities || Contributed Papers: Wireless Communications		
08:30-19:00	Registration		
09:00-11:00	**Keynote Speech**		**HALL 1**
11:00-11:30	COFFEE BREAK		
11:30-13:30	**Wireless Communications (A) | Spectrum for Future Radio Networks: WPMC || *Session Chair: Albena Mihovska, CTIF, Aalborg University, Denmark***		MRG .01
	1570235616	Preliminary performance evaluation of the FBMC based future IEEE 1900.7 Standard; **D. Noguet, J.-B. Doré and B. Miscopein**; *Minatec Campus CEA Leti 17, rue des Martyrs – 38054 Grenoble Cedex 9*, **France**	
	1570213121	Long-haul Communication Trial in London TV White-space with IEEE 802.11af-based High Power Prototype; **Takeshi Matsumura[1] , Kentaro Ishizu[1] , Keiichi Mizutani[2], Tran Ha Nguyen[1], Homare Murakami[1][3], Fumihide Kojima[1][3], Hiroshi Harada[2][3]**; *[1]NICT, Yokosuka, [2]Kyoto University, [3]Kyoto, ICT, Koganei*, **Japan**	
	1570192849	Outage Analysis of Cellular Two-Way Relaying with Spectrum Sharing in Nakagami-m Fading; **Ronshee Chawla, M. Mounika Reddy, Prabhat Kumar Upadhyay**; *IIT Indore*, **India**	
	1570213448	Field Experiments for Broadband Mesh Network Operating in TV White Space; **Kentaro Ishizu, Fumihide Kojima**; *National Institute of Information and Communications Technology*, **Japan**	
	1570210145	TVWS Regulations and the first IEEE 802.11af indoor experiments in Singapore; Dien Vinh Hoang[1], Takeshi Matsumura[2], Kentaro Ishizu[2], Homare Murakami[2], Fumihide Kojima[2]; [1]*Singapore Smart Wireless Lab, National Institute of Information and Communications Technology* (NICT), **Singapore**, [2]*NICT*, **Japan**	
	1570194697	Novel Closed form Expression for Multi Cell Cooperation using MHCP to Reduce Interference; **Suman Yadav, S Pratap Singh**; *Galgotia College of Engineering and Techolongy*, **India**	
13:30-14:30	LUNCH		
14:30-16:30	**Wireless Communications (B) | Algorithms and Innovative Approach: WVITAE || *Session Chair: Sri Chandrasekaran, IETE, India***		MRG .01
	1570210211	Classification Based Automatic Assessment for Web Based Learning; Wacharawan Intayoad, Punnarumol Temdee; Mae Fah Luang University, **Thailand**	
	1570188921	Comparative analysis of load balancing algorithms for LTE/LTE-A Hetnets; **Diego Castro-Hernandez**, **Raman Paranjape**; *University of Regina*, **Canada**	
	1570208745	Fuzzy based Moving Object Detection and Classification in Video; **Manojkumar M Gawali**, *Sinhgad College of Engineering*, Pune, **India**	
	1570213914	Swarm Optimization Based on Genetic Algorithm & Relevance Feedback Technique for Data Clustering; **Gandamalla Malini, M.Seetha, K.V.N.Sunitha**; *GNITS, Hyderabad*, **India**	
	1570212950	Downlink Joint Processing for Non Orthogonal Multiple Access; **Islam Atef, Essam Sourour;** *Alexandria University, Alexandria*, **Egypt**	
	1570197177	The Studies of Millimeter Waves at the frequencies of 60 GHz in Outdoor Environments- A Survey; **Hitesh Singh**; *HMRITM, Delhi*, **India**	
16:30-17:00	COFFEE BREAK		
	Networking		
	END OF WPMC-2015 & GWS-2015		

Time Slot	Day 4: Wednesday, December 16 || MRG .02 Activities || Contributed Papers: Physical and Fundamentals (III)		
08:30-19:00	Registration		
09:00-11:00	**Keynote Speech**		**HALL 1**
11:00-11:30	COFFEE BREAK		
11:30-13:30	**Physical and Fundamentals (III–A) | Signal Processing-1: WPMC & WVITAE || *Session Chair: Navin Kumar, Amrita University, Bangalore, India***		**MRG .02**
	1570194245	Blind Image Quality Assessment Based on Phase Congruency and Spatial-spectral Entropies; **Maozheng Zhao, Yanping Lu, Cuiwei Li, Ran Gao, Qin Tu, Bo Yang, Aidong Men**; *Beijing University of Posts and Telecommunications*, **China**	
	1570195699	Opinion-unaware blind image quality assessment based on sparse representation; **Maozheng Zhao[1], Xiaoqiang Guo[2], Ran Gao[1], Bo Yang[1], Aidong Men[1]**; [1]*Beijing University of Posts and Telecommunications*, [2]*Academy of Broadcasting Science*, **China**	
	1570208027	QoE Based Pseudo Heartbeat Message Compression Mechanism for Wireless Networks; **Zhiqun Hu, Xiangming Wen, Zhaoming Lu, Zhaoxing Li**; *Beijing University of Posts and Telecommunications*, **China**	
	1570213506	**WVITAE**: On CS Reconstruction Images using LDPC code over Radio Mobile channel; **Ankita Pramanik, Santi Prasad Maity**; *Indian Institute of Engineering Science and Technology, Shibpur*, **India**	
	1570210061	Modeling of Modified Erlang-k Distribution for Raindrop Size Distribution over South Africa; **Akintunde Alonge, Thomas Afullo**; *University of KwaZulu-Natal, Durban*, **South Africa**	
	1570192393	Enhanced Turbo Equalizer Using 2 Dimensional Iterative Soft Decision Interference Cancellation; **Doron Shinbox, Dan Raphaeli**; *Tel-Aviv University*, **Israel**	
13:30-14:30	LUNCH		
14:30-16:30	**Physical and Fundamentals (III –B) | Design and Development: WPMC & WVITAE || *Session Chair: Venkatapathy Prithviraj, Rajalakshmi Institute of Technology, Chennai, India***		**MRG .02**
	1570209863	Modeling & Simulation for complex System of systems design, test, and verification; **Uma Jha, Jon Wada**; *Space & Airborne Systems, Raytheon CoEl Segundo, California* , **USA**	
	1570213885	Design Of Low Voltage Bandgap Reference Circuit Using Subthreshold MOSFET; Sushma Sangolli, Rohini Hongal; *B.V.B College of Engineering and Technology, Hubli*, **India**	
	1570194201	Eight-Path Harmonic Rejection Mixer for Full Band Mobile TV; **Kiran B, Roy P Paily**; *Indian Institute of Technology Guwahati*, **India**	
	1570209947	Database Assisted Automatic Modulation Classification Using Sequential Minimal Optimization; **K. Pavan Kumar Reddy, Lakhan Shiva, Kadiri Abhilash, Yoganandam Yeleswarapu**; *Birla Institute of Technology and Science, Hyderabad Campus*, **India**	
	1570212671	Design and Development of a Mobile Wireless Video Streaming Mote; **Bhuvanesh D, Manjunath Hegde, Manikandan J**; *PES Institute of Technology*, **India**	
	1570213484	Design of BiCMOS based low temperature coefficient bandgap reference; **Deepa Talewad, Anilkumar Nandi, Ramesh Karmungi**; *B.V.B College of Engineering and Technology, Hubli*, **India**	
16:30-17:00	COFFEE BREAK		
	Networking		
	END OF WPMC-2015 & GWS-2015		

Time Slot	Day 4: Wednesday, December 16 || MRG .03 Activities || Contributed Papers: Wireless Networks		
08:30-19:00	Registration		
09:00-11:00	**Keynote Speech**		**HALL 1**
11:00-11:30	COFFEE BREAK		
11:30-13:30	**Wireless Networks | WPMC & WVITAE || *Session Chair: G S Tomar, MIR Labs, Gwalior, India***		MRG .03
	1570184143	A Fine Grained Position for Modular Core NoC; B. **Naresh Kumar Reddy, M.H.Vasantha, Y.B.Nithin Kumar, Dheeraj Sharma**; *National Institute of Technology, Goa*, India **(***)**
	1570191965	Analytical Evaluation of Frequency Reuse For Hybrid Full-/Half-Duplex Cellular System; Wenping Bi, Limin Xiao, Xin Su, Shidong Zhou; *Tsinghua University*, **China**
	1570192715	A New Approach for Crossed Sector Detection in Live Mobile Networks based on Radio Measurements; David Duarte①②, Pedro Vieira①②, António J. Rodrigues③, André Martins, Nuno Silva③; ①*Instituto Superior de Engenharia de Lisboa (ISEL),* ②*Instituto de Telecomunicac¸˜oes (IT), Lisbon,* ③*Instituto Superior T´ecnico (IST), Lisbon,* **Portugal**
	1570213280	A Revolutionary Rural Agricultural Participatory Sensing Approach Using Delay Tolerant Networks; **Prateek Gupta, Bhushan Gurmukhdas Jagyasi, Bighnaraj Panigrahi, Hemant Kumar Rath, Srinivasu Pappula, Anantha Simha**; *Tata Consultancy Services*, **India**
	1570213277	**WVITAE:** Performance Analysis of EPC with IMS Network Architecture; **A Bagubali①, Prithiviraj Venkatapathy②, Pathak Mallik①**; ①*VIT University, Vellore,* ②*Rajalakshmi Institute of Technology , Chennai,India,* **India**
	Invited Talk	Role of Cyber Security for Digital Business; **T. R. Dua**, *GISFI*, **India**
13:30-14:30	LUNCH		
14:30-16:30	**Wireless Networks | WPMC || *Session Chair: Hrishikesh Vankataraman, Indian Institute of Information Technology, Chittoor, India***		MRG .03
	1570213596	IEEE802.15.4g based Wide Area and Mobile Wi-SUN Communication Systems; **Hiroshi Harada, Keiichi Mizutani, Kentaro Mochizuki, Kentaro Obata**; *Kyoto University*, **Japan**
	1570207517	Hierarchical Mesh Based Energy Efficient Multicast Routing on IEEE 802.15.4 based networks; **Verotiana Rabarijaona①, Fumihide Kojima①, Hiroshi Harada②**; ①*National Institute of Information and Communication Technology,* ②*Kyoto University & Graduate School of Informatics,* **Japan**
	1570192635	Efficient Visibility Modeling for Free-Space Optical Systems Design; **Ivo Sousa①③, António J. Rodrigues②, Maria Paula Queluz②**, ①*Instituto de Telecomunicac¸˜oes (IT), Lisbon,* ②*Instituto Superior T´ecnico (IST), Lisbon,* **Portugal**
	1570187749	Reliable Link Layer Packet Reconstruction for Rotating Polarization Based Radio Communication; **Ritesh Kumar Kalle**, *HITACHI*, **India**
	1570213414	SUN-RAN Orchestrating Resource Management using Superframe Division Data Aggregation Technology; **Fumihide Kojima, Chang-Woo Pyo, Masayuki Oodo**; *National Institute of Information and Communications Technology(NICT),* **Japan**
	1570176791	Green Indoor Network In A Passive Way; Yu Liu, *Jiangsu Automation Research Institute*, **China**
16:30-17:00	COFFEE BREAK		
	Networking		
	END OF WPMC-2015 & GWS-2015		

Time Slot	Day 4: Wednesday, December 16 || MRG .04 Activities || Workshops & Special Sessions (III-B); IC5		
08:30-19:00	Registration		
09:00-11:00	**Keynote Speech**		**HALL 1**
11:00-11:30	COFFEE BREAK		
11:30-13:30	23rd GISFI Standardization Meeting- 5 G Innovation in India **Session Chair: Ashutosh Dutt**		
	Presentation1	5G Framework for a Personalised Network; **Nitish Mittal**, *5G Company, Vishawaniketan*, **India**	
	Presentation2	5G Model in WISDOM; **Sounak Moulik**, *5G Company, Vishawaniketan*, **India**	
	Presentation3	Security Challenges in a 5G Network; **Nidhi** , *5G Company, Vishawaniketan*, **India**	
	Presentation4	5G Concept; **Sandeep Mukherjee**, *,5G Company, Vishawaniketan*, **India**	
13:30-14:30	LUNCH		
14:30-16:30	**IC5: Third International Conference on Communications, Connectivity, Convergence, Content and Cooperation** **Session Chair: Swrana Ravindra Babu, IETE, India**		MRG .04
	1570213308	Survey on Service Discovery Mechanisms; **Gitanjali Shinde Henning Olesen**; *Center for Communication, Media and Information Technologies (CMI) Aalborg University Copenhagen*, **Denmark**	
	1570191301	Multislotted Microstrip Patch Antenna for Dual Band and UWB Applications; **Shailendra Kumar Dhakad, Dr. Neeraj Kumar, Keshav Kumar, Swapnil Mengade, Rohit Gupta**; *Birla Institute Of Technology and Science Pilani, Goa*, **India (***)**	
	1570194207	An application of Internet of Things in Transportation System; **Ganesh Balaraman, Harisudha Kuresan**; *SRM University*, **India (***)**	
	1570195047	Analysis of Audio Watermarking Techniques for Cyber Security in Copyright Infringement; **Sushma Ambekar① □, Vandana Rohokale①, Ramjee Prasad②;** ①SKNSITS, Lonavala, **India**, ②CTIF, Aalborg University, **Denmark**	
	1570208707	30-Second Integration Time Power Law Conversion Model for Rainfall Attenuation in South Africa; **Mary N. Ahuna,, Thomas J. Afullo, , Akintunde A. Alonge**; *University of KwaZulu Natal Durban*, **South Africa**	
	1570209327	Illumination, Indoor Localization and Very High Speed Data Communication using VLC; **Anusha Addanki, Navin Kumar**; *Amrita Vishwa Vidyapeetham (University) Bangalore*, India	
16:30-17:00	COFFEE BREAK		
	Networking		
	END OF WPMC-2015 & GWS-2015		

Time Slot	Day 4: Wednesday, December 16 || MRG .05 Activities || Workshops & Special Sessions (III-C)		
08:30-19:00	Registration		
09:00-11:00	**Keynote Speech**		**HALL 1**
11:00-11:30	COFFEE BREAK		
11:30-13:30	**WVITAE Special Session on " Wireless Communications"** **Session Organizer and Chair** : *Mqhele Dlodlo, University of Cape Town, South Africa*		MRG .05
	1570227491	Hard-combined Cooperative spectrum sensing using Time-frequency method; **S M Hiremath①, Sarat Kumar Patra①, Amit Kumar Mishra②;** ①*National Institute of Technology Rourkela, Odisha,* **Indiadlodlo,** ②*University of Cape Town*, **South Africa**	
	1570228229	The Implementation of the Modified AODV Routing Protocol in Mobile Ad-Hoc Networks; **Vekani Reviet Baloyi, Lesiba Kola**; *University of Limpopo*; **South Africa (###)**	
	1570228530	Enlarged QR-LRL Based Massive MIMO Detector for Soft Output Generation; **Sukriti Garg, Krati Mittal, Divyang Rawal**; *LNM Institute of Information Technology, Jaipur*, **India**	
	1570230967	Interference Management in Heterogeneous and Small Cell NetwPerorks; **M. Bala Krishna, Puneet Bansal**; *Guru Gobind Singh Indraprastha University , New Delhi,* **India**	
	1570233114	Mesh IP Video Surveillance System - A System Perspective and Performance Evaluation; **M .E. Dlodlo, C. S. Lubobya, S Lubobya, O Osanaiye, E Okumu, H Ohize,** *University of Cape Town*, **South Africa**	
13:30-14:30	LUNCH		
14:30-16:30	**WPMC Special Session on " Selected Topics in Physical & Fundamentals -2"** **Session Organizer and Chair** : ***Bharat Gupta, Birla Institute of Technology, Ranchi, India***		MRG .05
	1570210153	An ingenious framework for solving cold start problem in recommender system; **Pankaj Chaudhary① , A. A. Deshmukh②**; ①*Smt. Kashibai Navale College of Engineering, Pune* **India**, ②*Department of Electronics Systems, Aalborg University*, **Denmark (***)**	
		Area-Power Analysis of Carry Selected Adder using Transmission Gates; **Ch. Rajendra Prasad①, T. Anil Kumar②**; ①*SVS Institute of Technology*, ②*SR Engineering College*; Warangal, **India (###)**	
		Privacy Preserving Friend Matching Protocol for Pre match in Social Networks; **Shubhangi Ople, Aradhna Deshmukh**; *Smt. Kashibai Navale College of Engineering, Pune* **India (###)**	
		Self-Programmable Variable Digital Filter (VDF) Design Based of FPGA; **T. Anil Kumar;** *SR Engineering College,* Warangal, **India (###)**	
		Design of High Performance Phase Locked Loop for Clock Synchronization; A. Rajesh①, B.L. Raju①, K. Chenna Kesava Reddy②; ①ACE, Engineering College, ②*Jawaharlal Nehru Technological University College of Engineering*; Hyderabad, **India** (###)	
	1570237867	Object Detection, Passive tracking and Active Tracking; **Shreeya Shevade**, *Government College of Engineering, Aurangabad, Maharashtra,* **India (***)**	
16:30-17:00	COFFEE BREAK		
	Networking		
	END OF WPMC-2015 & GWS-2015		

Time Slot	Day 4: Wednesday, December 16 || MRG .06 Activities || Workshops & Special Sessions (III-C)	
08:30-19:00	Registration	
09:00-11:00	**Keynote Speech**	**HALL 1**
11:00-11:30	COFFEE BREAK	
11:30-13:30	**Networking Meeting**	MRG .06
13:30-14:30	LUNCH	
14:30-16:30	**GISFI Future Strategy Meeting**	MRG .06
16:30-17:00	COFFEE BREAK	
	Networking	
	END OF WPMC-2015 & GWS-2015

Index of Papers
WPMC-2015

INDEX OF PAPERS SUBMITTED IN WPMC 2015

Conference	Paper #	Title	Page #
WPMC 2015	1570167111	An Efficient Resource Block Allocation Algorithm in LTE-Based Systems with User Rate Constraints	66
WPMC 2015	1570176791	Green Indoor Network In A Passive Way	70
WPMC 2015	1570177831	Improving Performance of Impulsive Noise Canceller Under Class A Impulsive PLC Channel	75
WPMC 2015	1570187749	Reliable Link Layer Packet Reconstruction for Rotating Polarization Based Radio Communication	80
WPMC 2015	1570188641	Transmission Capacity Analysis for Linear Vehicular Ad Hoc Networks	85
WPMC 2015	1570190883	New virtual 8x1 MISO scheme with QOSTBC	90
WPMC 2015	1570191499	Ranking of Total Productive Maintenance pillars using Analytical Hierarchy Process	95
WPMC 2015	1570191687	Towards Internet of Services - SDN-enabled IMS Architecture for IoT Integration	100
WPMC 2015	1570191965	Analytical Evaluation of Frequency Reuse For Hybrid Full-/Half-Duplex Cellular System	105
WPMC 2015	1570192429	SAR and Thermal effects of a Body Wearable Microstrip Antenna at UHF and UWB frequencies	110
WPMC 2015	1570192635	Efficient Visibility Modeling for Free-Space Optical Systems Design	115
WPMC 2015	1570192715	A New Approach for Crossed Sector Detection in Live Mobile Networks based on Radio Measurements	120
WPMC 2015	1570192849	Outage Analysis of Cellular Two-Way Relaying with Spectrum Sharing in Nakagami-m Fading	125
WPMC 2015	1570192925	DEAR: An Energy-centric Adaptive Region of Interest Mechanism for Wireless Mobile Devices	130
WPMC 2015	1570192957	Improved p-norm Energy Detector with Soft Combining in AWGN Channel for Spectrum Sensing	135
WPMC 2015	1570192965	EDAS- Energy-Efficient Device-based Adaptive Cross-Layer Scheme for Wireless Multimedia Transmission	140
WPMC 2015	1570193591	Design and Performance Analysis of a Penta-band Spiral Antenna for Vehicular Communications	145
WPMC 2015	1570193823	An Efficient Deterministic Scheme for Blind CFO Estimation in SC-FDMA	150
WPMC 2015	1570193867	Investigation on Listen-Before-Talk Mechanism of Licensed-Assisted Access to Unlicensed Spectrum	155
WPMC 2015	1570193943	A Compressive Sensing-based Channel Estimation via GAMP in FBMC/OQAM System	160
WPMC 2015	1570194199	Impact of Network Coding on Distributed Indoor Target Tracking using Wireless Sensor Networks	165
WPMC 2015	1570194201	Eight-Path Harmonic Rejection Mixer for Full Band Mobile TV	170
WPMC 2015	1570194241	Analysis of Data Transmission Management through Software Defined POX Controller	175
WPMC 2015	1570194245	Blind Image Quality Assessment Based on Phase Congruency and Spatial-spectral Entropies	180
WPMC 2015	1570194425	Adaptive priority based network bandwidth throttling for a Virtual Classroom System	185
WPMC 2015	1570194465	Energy Efficient Scheduling Algorithm for the Real-time Multicast and Unicast Services	190
WPMC 2015	1570194537	Performance Analysis of Energy Detector in Correlated Log-normal Fading Channels for IR-UWB Systems	195
WPMC 2015	1570194567	On Supporting Integrated Multimedia Traffic in TDMA based Mobile Ad hoc Networks	200
WPMC 2015	1570194697	Novel Closed form Expression for Multi Cell Cooperation using MHCP to Reduce Interference	205

WPMC 2015	1570194813	Intrusion Detection System Against Colluding Misbehaviour in MANETs	210
WPMC 2015	1570194919	Automatic Speaker Detection and Recognition in a multi classroom E-Learning System	215
WPMC 2015	1570194953	The impact of Network Neutrality on the OTT Service of 5G WISDOM	220
WPMC 2015	1570195013	Characterization for Reporting Rate of Adaptive Sectoring Scheme to Improve Reliability in WSN	224
WPMC 2015	1570195063	Q-MOHRA: QoS Assured Multi-Objective Hybrid Routing Algorithm for Heterogeneous WSN	229
WPMC 2015	1570195073	Two-Party Key Agreement Protocol for MANETs based on Verifiable Secret Sharing Scheme	234
WPMC 2015	1570195119	Mobility-aware Hybrid Synchronization for Wireless Sensor Network	239
WPMC 2015	1570195141	A Modified RFID Authentication Protocol Using Elliptic Curve Cryptography	244
WPMC 2015	1570195309	Non Audio-Video gesture recognition system	248
WPMC 2015	1570195491	A Path Ordering and Reference Selection Method for the Differential Delay Tomography	253
WPMC 2015	1570195595	Packet Scheduling Scheme to Guarantee QoS in Internet of Things	258
WPMC 2015	1570195699	Opinion-unaware blind image quality assessment based on sparse representation	263
WPMC 2015	1570196365	Joint Transceiver Design for QoS-Constrained MIMO Two-Way Non-Regenerative Relaying	268
WPMC 2015	1570199753	Trust based Detection and Elimination of Packet Drop Attack in the Mobile Ad-hoc Networks	273
WPMC 2015	1570199757	The Behavioral Based Gray Hole Attack Detection in Mobile Ad-hoc Network (MANET)	277
WPMC 2015	1570205987	Experimental Evaluation on Wireless Tomography with Compressed Sensing in a Three-Dimensional Space	282
WPMC 2015	1570206001	New Pricing Model for Dynamic Dual-operator Spectrum Sharing in GSM	287
WPMC 2015	1570206855	Efficient Device-to-Device (D2D) Offloading Mechanism in LTE Networks	292
WPMC 2015	1570207155	Fuzzy Logic based Human Detection in Video	297
WPMC 2015	1570207517	Hierarchical Mesh Based Energy Efficient Multicast Routing on IEEE 802.15.4 based networks	302
WPMC 2015	1570207535	Quality of Service Enforcing Centrally Optimized Routing for Delay Tolerant Networks	307
WPMC 2015	1570207563	Improving Segmentation Accuracy for Motion Detection using Bidirectional Video Processing	312
WPMC 2015	1570208027	QoE Based Pseudo Heartbeat Message Compression Mechanism for Wireless Networks	317
WPMC 2015	1570208181	Survey of Device-to-Device Communications Infrastructure-less in IEEE 802.15.8 Task Group	322
WPMC 2015	1570208599	Detection Performance of Soft Data Fusion in Rician Fading Channel for Cognitive Radio Network	327
WPMC 2015	1570208727	Performance Comparision of Various Detection Methods for QO-STBC over Time Selective Channel	332
WPMC 2015	1570208853	Optimization of Cooperative Spectrum Sensing in Cognitive Radio over Erroneous Reporting Channel	337
WPMC 2015	1570208909	Link Adaptation Strategies for Cellular Downlink with low-fixed-rate D2D Underlay	342
WPMC 2015	1570209407	Low Rate Common Control Channels with Distributed Cross-Layer Optimization via Genetic Algorithm	347
WPMC 2015	1570209789	Path and Load Aware Routing Algorithm for Cognitive Radio Wireless Mesh Network	352
WPMC 2015	1570209793	SIW based Antipodal Linear Tapered Slot Antenna for Inter-Satellite Communication Links at 60 GHz	357
WPMC 2015	1570209863	Modeling & Simulation for complex System of systems design, test, and verification	362

WPMC 2015	1570209947	Database Assisted Automatic Modulation Classification Using Sequential Minimal Optimization	367
WPMC 2015	1570210057	A Pattern Division Multiple Access Scheme for 5G wireless communication systems	372
WPMC 2015	1570210123	An Interdependent Source-Channel Coding for Energy Efficient Communication in WSNs	377
WPMC 2015	1570210145	TVWS Regulations and the first IEEE 802.11af indoor experiments in Singapore	382
WPMC 2015	1570210151	Blind Channel Length Estimation for OFDM Systems using Cumulant Features	387
WPMC 2015	1570210161	Privacy-Preserving Friend Matching Protocol approach for Pre-match in Social Networks	391
WPMC 2015	1570210207	Radar Range and Range Resolution Enhancements	395
WPMC 2015	1570211271	A Generic and Compatible Implementation for 2D and 3D Geometry-based Stochastic Channel Models	400
WPMC 2015	1570211595	Design and Data Analysis of a Signal Measurement System Based on Variable Signature Sequences	405
WPMC 2015	1570212700	Limited Feedback Scheduling For MIMO-OFDM Broadcast Network	409
WPMC 2015	1570213016	Disaster Countermeasure Experiments using WINDS	414
WPMC 2015	1570213055	Development and Field Experiment of Distributed Peer Aware Communication Networks	419
WPMC 2015	1570213104	Throughput of Secondary User in Underlay Cognitive Relay Network with Energy Harvesting	424
WPMC 2015	1570213111	Distributed Token Based MAC for Multi-Channel Multi-Interface Cognitive Radio WMN	429
WPMC 2015	1570213114	Design Optimization and SAR Evaluation of SS-UWB Patch Antenna for WBAN	434
WPMC 2015	1570213117	Secrecy Outage of a Cognitive Relay Network with Energy Harvesting and Imperfect CSI	439
WPMC 2015	1570213121	Long-haul Communication Trial in London TV White-space with IEEE 802.11af-based High Power Prototype	444
WPMC 2015	1570213206	Participatory Heuristic Evaluation of the First Iteration of the eWALL Interface Application	449
WPMC 2015	1570213212	Coexistence of Systems with Different Multicarrier Waveforms in LSA Communications	454
WPMC 2015	1570213231	Energy-Efficient Resource Allocation for Hybrid Services with QoS Requirements in Cellular Network	459
WPMC 2015	1570213262	Real-time EEG Monitoring and Transmission over Low Bandwidth Wireless Networks	464
WPMC 2015	1570213263	Pilot testing and demonstration of self-management network and applications using NerveNet	470
WPMC 2015	1570213278	CDF Based Spectrum Occupancy Rate Measurement Using Least Square Estimation of Gaussian Noise Period	475
WPMC 2015	1570213280	A Revolutionary Rural Agricultural Participatory Sensing Approach Using Delay Tolerant Networks	480
WPMC 2015	1570213289	Performance Analysis of Total Power Consumption in Linear Multi-hop Networks	485
WPMC 2015	1570213302	A Feasibility Analysis of LTE-CommSense	490
WPMC 2015	1570213332	Hybrid multi-hop network by small-unmanned aircraft and satellite telecommunication systems	494
WPMC 2015	1570213335	Secure and Privacy Enabled Anonymous Computing for Heterogeneous (SPEACH) IoT	498
WPMC 2015	1570213366	On-going Field Experiment of NerveNet in Shirahama Town for Resilient Town Network	503
WPMC 2015	1570213374	Fractal dimension of spectral estimates for spectrum sensing under noise variance uncertainty	508
WPMC 2015	1570213378	Evaluation of permutation entropy detection for cognitive radio networks	513
WPMC 2015	1570213381	On Detection Improvement in MC-CDMA Image Watermarking on Fading Channel	518

***Abstract*— In this paper we proposed an Efficient Resource Block Allocation Algorithm (ERBAA). The Base Station will allocate resource blocks to users in LTE-Based systems. Resource block establishes the communication channel between base station and corresponding user. The selection and allocation of this resource block is critical in all LTE Based systems with respect to Quality of Service, in order to increase the QoS ERBAA uses an efficient algorithm in selection process i.e., it use the Channel State Information (CSI) which describes the quality and fading details of the channel. CSI will be computed among all the possible users and available resource blocks. Once it computes complete CSI matrix, algorithm find out which resource block needs to be allocated for which user. The selection is based on both user to resource block and resource block to user CSI values. By using this process, ERBAA will have better QoS across all the various network dynamic scenarios and also our simulation results shows, ERBAA has improved average CSI of the network in comparison with Greedy Based Sub-channel Processing (GBSP).**

Index Terms*— *Long Term Evaluation, 4G, MIMO-OFDMA, Resource Allocation, Resource Block (RB)

I. INTRODUCTION

In recent years the excessive growth of user requirements on ubiquitous access and high data rate multimedia traffic, QoS is becoming difficult to be maintained in LTE Based systems of wireless communication industry.

The radio transmissions in LTE are based on the Orthogonal Frequency Division Multiplexing (OFDM) modulation scheme. In particular, the Single Carrier Frequency Division Multiple Access (SC-FDMA) and the OFDM Access (OFDMA) are used in uplink and downlink transmissions, respectively. Differently from basic OFDM, they allow multiple access by assigning sets of sub-carriers to each individual users [3].

To develop an efficient resource allocation scheme applicable for LTE systems, some important factors have to be considered. First, an RB to be full considered for sub-channel assignment. The basic unit for sub-channel assignment is stipulated as the RB, which consists of a set of subcarriers that need to be identically allocated, in LTE systems. This indicates that the sub-channel assignment by individual subcarrier as in [5], [6], [9] is not allowed, and each RB should be assigned according to the aggregate channel state information (CSI) of all the subcarriers it includes rather than that of some individual subcarriers. Second, as the basic structure of LTE systems, MIMO-OFDMA should be jointly considered when carrying out resource allocation. Since multiple spatial wireless channels can be provided by MIMO transmission to achieve spatial multiplexing gain, the CSI of these spatial links should also be aggregately considered as the sub-carriers within one RB in frequency. Therefore, this work integrates these two important factors and develops an energy-efficient resource allocation algorithm that is more applicable in LTE systems. Specifically, with both RBs and MIMO-OFDMA being considered, the proposed algorithm may optimize the energy efficiency effectively, as well as fully satisfy user's rate requirements. Moreover, it is equipped with polynomial complexity and is thus favorable for practical application. With all these advantages, this work may function as a more promising candidate for the energy-efficient design of LTE systems, compared with most of the existing related works [4].

To maintain the Quality of Service we have considered scheduling process, which plays a very important role in the resource allocation to user according to a request in LTE Based systems. Resource allocation plays a very important role where resource blocks allotted to users according to their need and the priority and to increase the system performance and the throughput of the system. Scheduling takes place as follows to a particular user which is having best channel conditions for a given

time-frequency resource block should be allotted for transmission [5].

Round Robin (RR), Proportional Fair (PF) and Best Channel State Information are various types of scheduling algorithms. Some users are never been scheduled for transmission because of their degraded channel quality in comparisons with others. Because of this the QoS can be affected [10]. Here in our paper we considered Best CSI algorithm which results in the better throughput and it totally ignore the fairness.

To perform scheduling, the terminal sends channel state information to base station. Better channel condition means best CSI value. Resource blocks will be allotted to users with best channel quality.

II. RELATED WORKS

Xiao, Xiaoming Tao and Jianhua Lu proposed an algorithm GBSP (Greedy Based Channel Preprocessing) where they first considered to calculate the channel state information as follows. When there are m (1, 2, 3…..m) number of users and n (1, 2, 3, 4….n) number of resource blocks considering always m < n. The channel state information is calculated for user1 with respect to each and every resource block and the resource block which provides best CSI value is assigned to that user and remove that allocated RB from consideration. For next user again the CSI is calculated with respect to resource blocks left and the resource block which provides next best CSI is assigned, this process will continue till each user is assigned with one resource block. Here in case of last few users there might be an issue which leads to a scenario where they will be left with resource blocks which might even not suitable for channel allocation which leads to service outage but they might show some better CSI for the users which were allotted before . This point is considered in our paper and we made an algorithm which reschedules the resource block by consider each and every resource block to each and every user till every user is left with one resource block assigned [4].

Will Jeng-Ji Huang, Wei-Keng Lin and Hung-Hsiang Ko has proposed an algorithm by assigning scheduling blocks (SBs) to the UEs based on channel information. Here instead of assigning two resource Blocks (one SB) to each user, our proposed algorithm will assign one resource block to each user initially and thereafter depending on the user requirement remaining resource blocks will be assigned which improves spectral efficiency [3]. In this paper we have considered CSI matrix values in the allocation process of resource blocks, along with this in order to improve the QoS considered the need of a particular resource block to user and users demand for a particular resource block.

In our work to improve transmission rate, for each sub-channel we mainly considered the point to point MIMO transmission, for complete utilization of spatial multiplexing gain of MIMO. Thus, a specific user will be allotted with a sub-channel considering Single User (SU) MIMO transmission, and in frequency domain multiple access is realized by OFDMA.

III. CSI CALCULATION

CSI matrix between the BS and user m on subcarrier $k(n)$ at each resource allocation time is $H_{\boldsymbol{m,k(n)}} \in C_{A_{\boldsymbol{m}}*\boldsymbol{A}}$ where $A_{\boldsymbol{m}}$ represents the antennas at the mobile station and the base station has A antennas. $S_{\boldsymbol{m,k(n)}} \in C_{\boldsymbol{A,1}}$ is the input vector emitted from the multiple antennas of the BS, and $n_{\boldsymbol{m,k(n)}} \in C_{A_{\boldsymbol{m}}*\boldsymbol{1}}$ is the complex Gaussian noise vector with zero mean. We considered a block fading model and a static channel is assumed within the duration of each RB. Then the output vector $\boldsymbol{y}_{\boldsymbol{m,k(n)}} \in C_{A_{\boldsymbol{m}}*\boldsymbol{A}}$ received by user m from $H_{\boldsymbol{m,k(n)}}$ can be expressed as

$$\boldsymbol{y}_{\boldsymbol{m,k(n)}} = H_{\boldsymbol{m,k(n)}} \boldsymbol{s}_{\boldsymbol{m,k(n)}} + \boldsymbol{m}_{\boldsymbol{m,k(n)}} \quad (1)$$

Via singular value decomposition,

$$H_{\boldsymbol{m,k(n)}} = U_{\boldsymbol{m,k(n)}} \Lambda_{\boldsymbol{m,k(n)}} V^{*}_{\boldsymbol{m,k(n)}} \quad (2)$$

Where $U_{\boldsymbol{m,k(n)}} \in C_{A_{\boldsymbol{m}}*A_{\boldsymbol{m}}}$ and $V^{*}_{\boldsymbol{m,k(n)}} \in C_{\boldsymbol{A,A}}$ are both unitary matrices and $\Lambda_{\boldsymbol{m,k(n)}} \in C_{A_{\boldsymbol{m}}*\boldsymbol{A}}$ is a rectangular matrix whose diagonal elements are non-negative real numbers and whose off-diagonal elements are zero. The diagonal elements $\boldsymbol{\lambda}^{(\boldsymbol{1})}_{\boldsymbol{m,k(n)}} \geq \boldsymbol{\lambda}^{(\boldsymbol{2})}_{\boldsymbol{m,k(n)}}) \geq, \ldots, \boldsymbol{\lambda}^{(\boldsymbol{J_m})}_{\boldsymbol{m,k(n)}}$ are the ordered singular values of the matrix, where $\boldsymbol{J}_{\boldsymbol{m}} = \min \{A, A_{\boldsymbol{m}}\}$[4].

IV. EFFICIENT RESOURCE BLOCK ALLOCATION ALGORITHM (ERBAA)

Our proposed algorithm allocates the resource block to the users with maximum and suitable CSI values. We considered both user to resource block and resource block to user demand, by using this we can

improve the average CSI value in the entire network through which overall quality of service of the network can be improved.

Step 1: Base station gets the information of newly requested users (M) and available resource blocks (N) information.
User Matrix M = {1,2,3,4……..…M}
Resource Block Matrix N = {1,2,3,4…….N}

Step 2: For MIMO transmission, average CSI of all KJ_m channels is formulated below

$$h_{m,n} = (1/KJ_m) \sum_{k=1}^{K} \sum_{a=1}^{Jm} \left| \lambda_{m,k(n)}^{(a)} \right|^2$$

$$m^* \in M, n^* \in N$$

Step 3: Get the resource block number {n*} for user {m*} where the CSI (m*, n*) value is maximum.

Step 4: If the resource block is not allocated to any user then go to Step 10.

Step 5: If the resource block is allotted for some other user then compute the CSI difference between current user and previously allotted user.

Step6: If the difference is lesser than 10% of its value, then compute the next non allocated resource block where CSI value is maximum, update the resource block number and go to Step 10.

Step 7: If the difference is higher than 10% then get the next maximum CSI (m*, n*) value of non-allocated resource block for both the users. Compute the difference of current resource block and next maximum resource block for both the users.

Step 8: If the difference value of already allotted user is higher than current user then update the next maximum resource block to current resource block and go to Step 10.

Step 9: If the difference of current user value is higher, then re-allocate the next maximum resource block for the already allotted user and go to Step 10.

Step 10: Allot the resource block for the current user and update the user and resource block information table.

Step 11: Repeat Step 3 to 10 till all the users gets one dedicated resource block.
Step 12: Remaining resource blocks will be allocated as per user requirement by repeating Step 3 to Step 10.

V. SIMULATION RESULTS

We have studied the performance of our proposed algorithm an Efficient Resource Block Allocation Algorithm (ERBAA) and compared its performance with GBSP (Greedy Based Channel Pre-processing) by using MATLAB (R2013a) simulation software.

Table I: Simulation parameters

Simulation parameter	Value
Users	20-50
Resource Blocks	50-80
Sub-carriers	12
Antennas	4X4

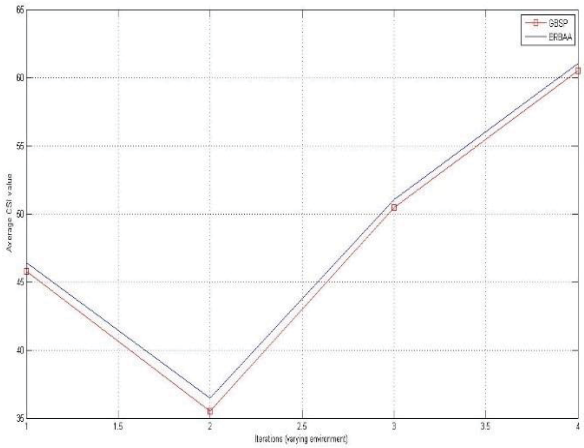

Fig.1: Average CSI value for ERBAA Vs. GBSP

For study and analysis purpose we considered a network model where the number of users and number of available resource blocks will be changed in each iteration or observation. In each instance first we allotted RB's to users based on GBSP and computed its Average CSI value across the network and in the same instance allotted RB's to users by using ERBAA and computed average CSI value. In all conditions/scenarios our experiment showed that ERBAA average CSI value is better that GBSP as shown in fig.1. Various simulation parameters are as mentioned in Table I. Improved average CSI shows that the Quality of Service in the network is improved by using ERBAA in comparison with GBSP. Because CSI value is computed based on the communication channel performance between user and base station which shows that lower CSI value means poor channel communication and which has more fading.

VI. CONCLUSION

In this paper we have proposed An Efficient Resource Block Allocation Algorithm (ERBAA) by using the concept of Channel State Information. CSI will be computed among all the possible users and available resource blocks. CSI matrix will be updated dynamically at regular events, whenever a user needs a resource block it will be allocated as per the CSI based resource block allocation algorithm. In this resource block to user requirement and users to resource block demand are taken into consideration. By using this our MATLAB simulated results shows that our proposed algorithm has improved performance in average CSI value of the LTE-Based systems network in various dynamic scenarios. This Average CSI represents the quality of the user communication channel and fading information, we have improved the quality of channel and reduced fading by using best and suitable CSI technique which leads to the improved Quality of Service.

Green Indoor Network In A Passive Way

Yu Liu
Jiangsu Automation Research Institute, Lianyungang 222061 P. R. China
Email: {liuyu@jari.cn

***Abstract*—With the explosive growth in the number of wireless users and the data traffic needs, how to improve coverage and provide ubiquitous broadband access causes a great challenge for operators. This paper presents a green wireless channel concept for the indoor coverage enhancement. The whole system is composed of the donor antenna, the service antenna and the coaxial cable. These antenna prototypes have good features of minimization, high gain etc. To verify its real applications, we have demonstrated the coverage enhancement under the real commercial 3G WCDMA network through multi-antenna passive energy harvesting and forwarding without any additional power consumption. When users are in the poor coverage, over 20 dB receiving power improvement can be achieved by employing the proposed passive antenna system. Finally, we proposed an interference cancellation algorithm which can further improve the receiving SINR.**

I. Introduction

A wireless cellular network is made up of a number of radio cells, each served by at least one fixed-location transceiver known as a cell site or base station. [1] Hundreds of cell sites are deployed in a typical large city to create a coverage in 95% or more of the targeted areas, so that a variable number of portable transceivers can be used in any cell and moved through more than one cell during transmission.

Coverage hole is an area within the radio coverage footprint of a wireless system in which the Radio Frequency (RF) signal level is below the designed threshold, which is usually caused by physical obstructions such as buildings, foliage, hills etc. It also occurs in places where there are no nearby base stations. In these areas, service quality can drop off sharply, resulting in slow data rates and poor voice quality. Improvements on the quality of service are always pursued by wireless service providers for competitive reasons, so a solution which offers uninterrupted access to wireless services can be very compelling. On the other hand, the poor indoor wireless coverage is now recognized globally as one of the biggest communication obstacles for mobile subscribers today. This is particularly prominent with data service and with LTE licenses being issued in frequencies as high as 2.6 GHz with a promise of 100 Mbps download and 50 Mbps upload speeds per cell. [2]

Although power boosting [3] at base station could extend coverage range of its cell, it is cost-ineffective for operator and will cause strong interference to neighboring cells. More importantly, power-inefficient solutions can not meet the operators demands in terms of cost reduction and environmental impact targets. Therefore, more power-efficient and cost-effective solution is desired to deliver better coverage and larger capacity to these hard-to-reach places.

Relay stations [4], [5] are introduced in IEEE 802.16 and 3GPP LTE-A, and other solutions such as picocell and femto cell can also be deployed in the existing network for coverage extension and throughput enhancement. However, the adoption of those solutions means more power consumption due to new active components introduced into the network, which also results in a complicated network topology, a great deal of signalling exchange and higher requirement for backhaul link etc.

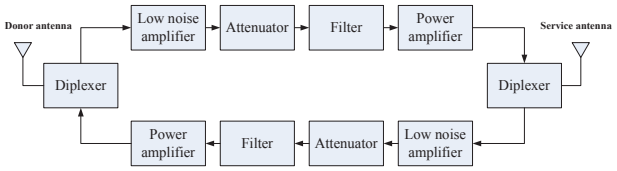

Fig. 1. Typical structure of a repeater.

Another traditional solution to coverage problems is the repeater [6]. As illustrated in Fig. 1, a repeater is typically a combination of a radio receiver and a radio transmitter that receives a weak or low-level signal and retransmits it at a higher level or higher power, so that the signal can reach a longer distance or fill in coverage holes without degradation. Although simpler and lower cost compared to the above solutions, unfortunately it has the following drawbacks:

- Power consumption by low noise amplifier and power amplifier
- Amplifying and forwarding the heat noise
- Restricted to electric power supply

Green wireless communications has recently attracted a lot of attention by researchers and engineers. [7] In radio access networks, most of the green related research focuses on the transmitter and receiver with hardware or procedure optimization for energy saving. Actually, for signal radiation, we have found that a great deal of energy is wasted during the propagation. Our research is trying to make wireless channel more energy-efficient through changing or optimizing radio propagation. The remaining part of this paper is organized as follows. The concept of green wireless channel is introduced in Section II. An implementation case with a demonstration system in the real 3G WCDMA communication network is presented in Sections III. Finally, concluding remarks are offered in Section IV.

II. Concept of green wireless channel

Green wireless channel takes good advantage of electromagnetic characteristics of radio signal for indoor or blind spot coverage, through special metal/non-metal material usage, building surface or structure optimization, or introduction of passive devices / antennas, etc.

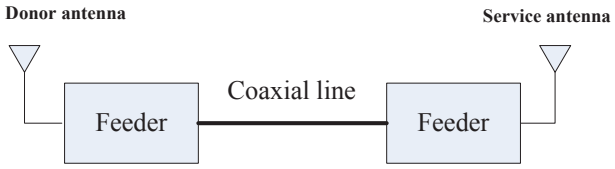

Fig. 2. Structure of passive relay system (DL).

For the purpose of further reduction of energy consumption and deployment cost, a kind of passive relay technique is employed for the coverage enhancement.

The proposed structure is described in Fig. 2. It is basically made up of a pair of donor antenna and service antenna, a basic antenna feed system and a coaxial cable to connect the receiving and the transmitting parts.

Considering the case of downlink, the donor antenna is deployed in a favorable position to harvest radio energy from donor eNode B and forward it through coaxial cable to the service antenna. The transferred energy is served as the excitation to drive the service antenna. The service antenna is typically deployed to make up the coverage hole or cover buildings for indoor coverage enhancement.

The prominent feature is that all the components are passive devices and no any power supply is required, so it is very energy efficient and suitable for power supply limited scenarios such as remote places or emergency communications.

Here, we actually proposed an implementation example of a passive relay technique. Considering a scenario of the urban wireless communication, line-of-sight (LOS) signals from donor eNB are easily blocked or attenuated by high buildings, the penetration loss of transmit signals after going through the buildings may result in a sharp degradation of receiving signal strength at mobile users.

To deal with this kind of coverage hole, we can firstly choose a favorable position for deploying donor antenna, such as the top of high building, so that LOS or near LOS path from eNB can be available. Generally, a highly-directional antenna is used with its main lobe pointed to the donor eNode B to guarantee a strong power reception. As a matter of fact, in the dense urban areas, most of eNBs are invisible to the terminal users, because there may be buildings or other obstacles (i.e. there is no direct wave) between them. In this case, the donor antenna needs to have a high gain and a relatively wide beam in order that the electromagnetic waves can be harvested from multiple directions. To ensure an effective energy receiving and conversion via antenna, a matched antenna feed system is also required.

Again, we consider the downlink (DL) communication. The energy harvested by donor antenna will be transferred to the antenna feed system of service antenna via the coaxial cable, which is used as an excitation to drive service antenna. The service antenna is normally with an omni-directional radiation pattern. It is useful for a good coverage of the indoor environment as most of WiFi access points do nowadays. The service antenna can be typically a directional antenna, and the antenna gain and beam width can be carefully designed according to the distance and size of the coverage hole.

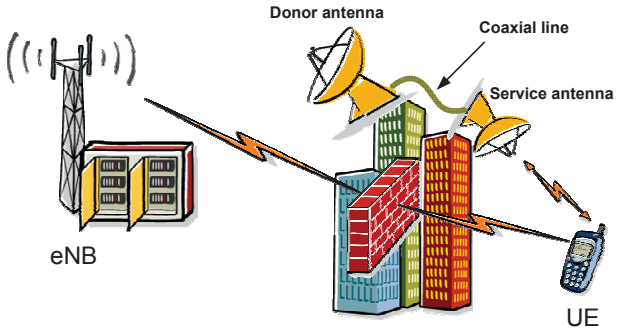

Fig. 3. Reception enhancement of UE behind tall buildings that block LOS path (DL).

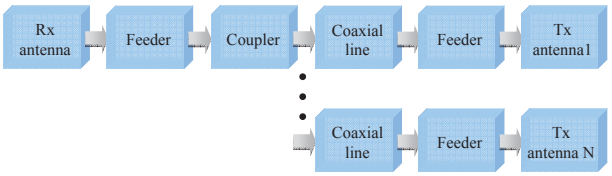

Fig. 4. Structure of downlink with multiple service antennas.

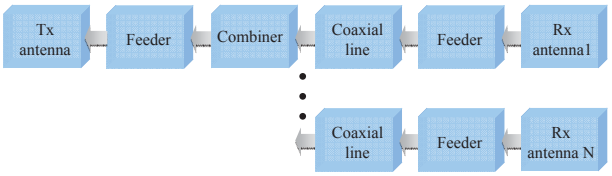

Fig. 5. Structure of uplink with multiple service antennas.

If only one service antenna exists, as shown in Fig. 3, the receiving energy at donor antenna will be transferred totally to service antenna. In real environment, there may simultaneously exist several coverage holes around buildings, so a low-cost and power efficient solution is to deploy several service antennas each covering one coverage hole, while only one donor antenna is deployed. As shown in Fig. 4, the total energy received at donor antenna will be divided equally or unequally into several portions by a coupler, each used to excite one service antenna. Correspondingly, when it works on the uplink, energy from different service antennas is combined via a combiner and then transmitted through the donor antenna (illustrated in Fig. 5).

III. An Implementation Case

We have demonstrated the green indoor coverage by employing a passive relay system.

A. Demo setup

The demonstration is composed of a monitoring module, a console module and an emulation module as shown in Fig. 6. A box covered with semi-shielding net to attenuate part of electromagnetic waves, is used to emulate the indoor environment. In such emulated indoor environment, there is a common smart phone with Andorid operation system which is connected to live WCDMA base station provided by China Unicom Co., Ltd. For a better observation, we display the

Fig. 6. The configuration of demo setup.

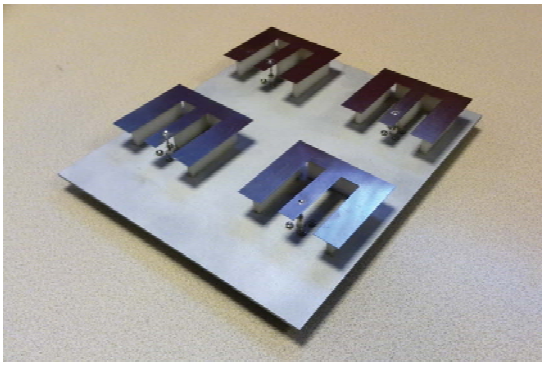

Fig. 7. E-shaped antenna array as donor antenna deployed outside of buildings.

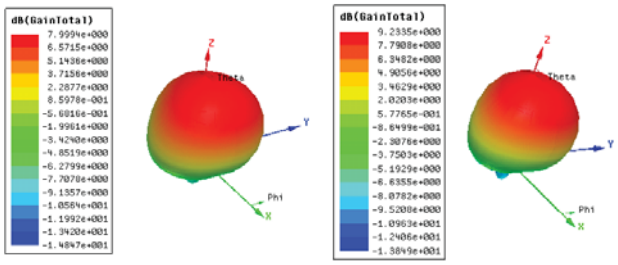

(a) 1940MHz (b) 2130MHz

Fig. 8. Normalized radiation patterns at the center frequency.

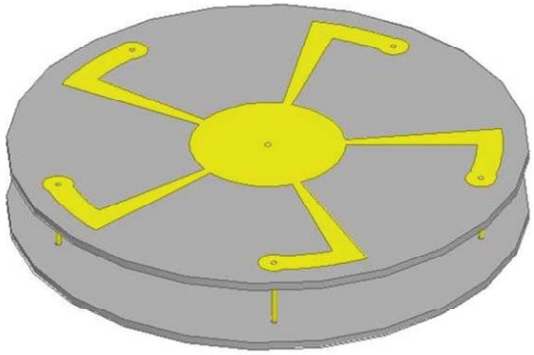

Fig. 9. Circularly polarized antenna as service antenna deployed inside of buildings.

contents of mobile phone onto a high definition monitor via a HDMI cable and control the mobile phone by a laptop via a USB cable outside of the box.

1) E-shaped antenna: For the outdoor deployment, we have designed an E-shaped antenna array which is given in Fig. 7. It has a large gain in order to convert more power from the outside to the inside building. It has a relatively wide frequency band to support both uplink and downlink transmission at least, and it also needs to be adaptive to multi-standards in order to support different operators. It has a wide beam to better harvest the wireless signal from various directions, because in the dense urban area there may be a lot of obstacles between the base stations and the user terminals. The -10 dB operational frequency bands can cover China Unicom 3G ($1940-1955$, $2130-2145$ MHz) bands. The simulated radiation patterns of the proposed antenna at 1940 MHz and 2130 MHz are illustrated in Fig.8. The simulated results are obtained using the Ansoft HFSS (High Frequency Structure Simulator) version 13 [9], and similar results of the simulation and measurement are obtained.

2) Circularly polarized antenna: The overall structure shown in Fig. 9 mainly consists of two layers of printed spoke-like metal strips on two planar substrates, respectively. The center of the upper strip is connected to the elongated inner conductor of the feeding coaxial cable; and the center of the lower strip is connected to the outer conductor. Several metal vias around the circumference connect the ends of the upper and lower strips. The current flows from the inner conductor of the feeding coaxial cable, then through the elongated inner conductor, upper strip, via and lower strip, and returns to the outer conductor of the feeding coaxial cable. The currents on them are some in phase due to half wave resonance.

All axial parts of the spoke-like metal strips, together, act as a loop with in-phase current; while the radial parts work as transmission lines for the axial parts, since the currents on each pair of them are same in amplitude and reversed in phase. A far-field similar to that generated by a small loop can thus be obtained. Elongated inner conductor of the feeding coaxial cable works as a short dipole; meanwhile, it, together with the radial parts of the metal strips, also works as the feeding structure for the axial parts of the strips.

A prototype working at 2 GHz has been designed. The goal of the design is to maintain a low axis ratio in the azimuthal plane, simultaneously, maximize the impedance and axis ratio bandwidths. The axis ratio in elevation and azimuthal planes at the center frequency, normalized radiation patterns at the center frequency is given in Figs. 10 to 11, respectively. As can been seen, (1) -10 dB impedance bandwidth is 12.2% and the 3dB axis ratio bandwidth is 95%, hence the overlapped bandwidth is only determined by the impedance bandwidth; (2) the radiation pattern is omni directional and donut shaped. The radiation is right-handed circularly polarization (RHCP); (3) the axis ratio is around -2dB within the whole space at the center frequency. The gain is 1.2 dBi at the center frequency in the elevation plane.

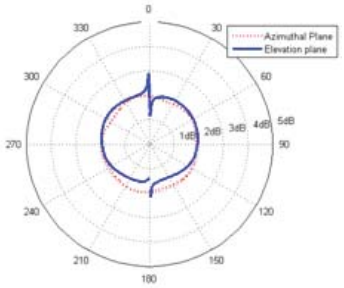

Fig. 10. Axis ratio in azimuthal and elevation planes at the center frequency.

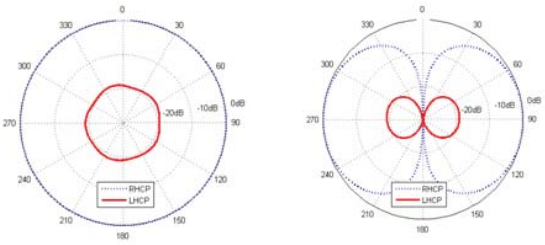

(a) Azimuth Plane (b) Elevation Plane

Fig. 11. Normalized radiation patterns at the center frequency.

Fig. 12. Performance enhancement after employing the proposed passive system.

B. Demo procedures

Firstly, the smart phone is put in the poor coverage box and is inserted a 3G WCDMA (provided by China Unicom [8]) SIM card. Without any other measures aided, the receiving signal strength on the mobile phone is very weak and if we open some online videos, the video quality is not fluent at all. After connecting the designed donor and service antennas, the signal strength is significantly improved by more than 20 dB. And if we open the online video again, it is observed that the videos can be played very fluently and clearly as shown in Fig. 12.

C. Discussion

This demonstration shows that when users are in the poor coverage, over 20 dB receiving power improvement can be achieved by employing the proposed passive antenna system. Naturally, we must raise a question: will it achieve more receiving gain if we employ higher gain antennas? To a certain extent, it is right because higher gain antennas can naturally deliver more power. As a matter of fact, the achieved 20 dB

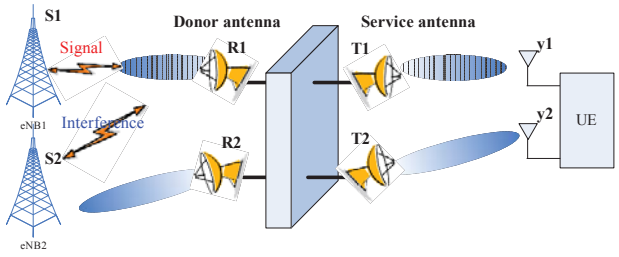

Fig. 13. Interference cancellation with two passive relays.

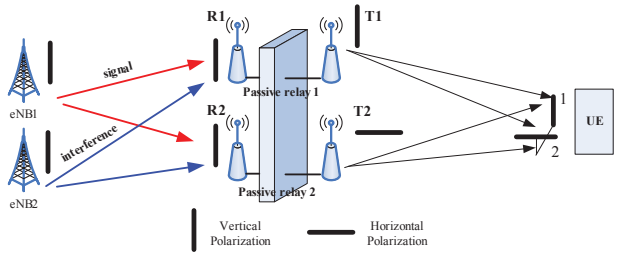

Fig. 14. Multi-polarization passive relays.

in this example is highly determined by the penetration loss of the buildings/obstacles. In other words, the more loss caused by the building, the more receive gain is capable to be obtained by the mobile terminals.

IV. Green Channel with Interference Cancellation

Assuming that there is a strong interference eNB2, one of passive relays (R1-T1 in Fig. 13) is mainly used to transfer signal to UE, and the other passive relay (R2-T2 in Fig. 13) is used to deliberately collect as much interference as possible and transfer it to the antenna 2 of UE. In the meanwhile, T2 dose not introduce more interference to antenna 1 of UE. The collected interference signal at antenna 2 of UE is used to cancel the interference received at antenna 1 of UE.

In order to improve the performance of interference cancellation, we can further utilize the polarization characteristics of antennas. In Fig. 14, horizontal polarization is used at T2 of passive relay 2 and antenna 2 of UE to let much interference and little signal reach at antenna 2 of UE, and in the meanwhile, avoid extra interference arriving at UE antenna 1. In order to describe the interference cancellation algorithm, the received signals at y_1 and y_2 are

$$y_1 = \alpha_1 \cdot s_1 + \beta_1 \cdot s_2 + n_1; \quad (1)$$

$$y_2 = \alpha_2 \cdot s_1 + \beta_2 \cdot s_2 + n_2, \quad (2)$$

and the interference cancellation is as bellow,

$$\begin{aligned} y &= y_1 - \gamma y_2 \\ &= (\alpha_1 - \gamma\alpha_2)S_1 + (\beta_1 - \gamma\beta_2)S_2 + (n_1 - \gamma n_2). \quad (3) \end{aligned}$$

Here γ is obtained by making $\beta_1 - \gamma\beta_2 = 0$ for cancellation of the interference in y_1. The parameters α, β can be obtained through channel estimation at UE. Because β_2 is much larger than β_1, γ is far less than 1, there is little impact on S_1 in y_1.

We have tested the function of the above interference cancellation algorithm in our demo platform through video communication. We first create a NLOS (LOS path is blocked) scenario that a reliable communication only can be ensured with help of passive relay. Secondly, we add a new transmitter as interference to test our interference cancellation algorithm. In the demo, it can be observed that with help of passive relay and interference cancellation algorithm, the video quality can be improved greatly at receiver and the SINR can be increased by about 20 dB.

V. CONCLUSION

From the above sections, the proposed concept of green wireless channel is a promising means to make up the coverage hole or enhance the poor indoor coverage without any external power supply. We also provide an algorithm of interference cancellation in green wireless channel for further SINR improvement.

The optimization of wireless channel for power saving probably leads to new RF structure design in eNB or UE, new signal transmission or reception mode, even new channel coding technique. These may have significant impact on green communication in various emerging mobile wireless standards and technologies, and enable a new paradigm in green networking design.

With possible introduction of new artificial passive devices into the existing system, the original network deployment and optimization may be changed accordingly. Even building material and architecture design may be reconsidered after green wireless channel research.

***Abstract*—OFDM (Orthogonal Frequency Division Multiplexing) is a technique used for many modern applications. However, in using OFDM transmission system such as PLC (power line communication), the performance is strongly influenced by the impulsive noise with very large magnitude and short time duration. Therefore, many schemes have been proposed to reduce the influence of the impulsive noise in OFDM systems. In this paper, the algorithm for impulsive noise suppression in OFDM receivers improving time sample replacement scheme is proposed and investigated. Simulation results are provided to show the improvement in bit error rate.**

Keywords—OFDM; Impulsive Noise; PLC; Class A Noise;

I. INTRODUCTION

The OFDM (Orthogonal Frequency Division Multiplexing) is the modulation scheme that the sub-carriers are orthogonally arranged and multiple data symbols are transmitted simultaneously. The frequency band can be used effectively in OFDM system because the shape of the spectrum is nearly rectangle. Therefore high-speed communication is possible in limited frequency band [1], [2]. In addition, the addition of a GI (Guard Interval) can reduce the interference between OFDM symbols under multi-path channel as long as the maximum delay spread of the channel is shorter than the guard interval length. The OFDM system is widely studied and applied to high speed data transmission systems such as digital television broadcasting, wireless LAN, PLC (power line communication), and so on.

In PLC system that operates in the high frequency band, the multi-path by the reflected waves generated at the multiple branches and ends of power line exists. Moreover, the impulsive noise is frequently generated in the power line channels by switching operations of the appliances connected to the power line and ON-OFF noise of the power source. Impulsive noise has short time duration and very high magnitude. The performance of the OFDM system is degraded by the impulsive noise, because it has very wide frequency band width and data symbols on many OFDM sub-carriers may be severely influenced as shown in Fig. 1 [3]-[7]. Therefore, it is necessary to reduce the influence of the impulsive noise under multi-path channels.

Many schemes such as clipping and nulling scheme [8], [9], time sample replacement scheme [10], [18] and frequency domain noise reduction scheme [11] have been proposed to reduce the influence of the impulsive noise in OFDM systems.

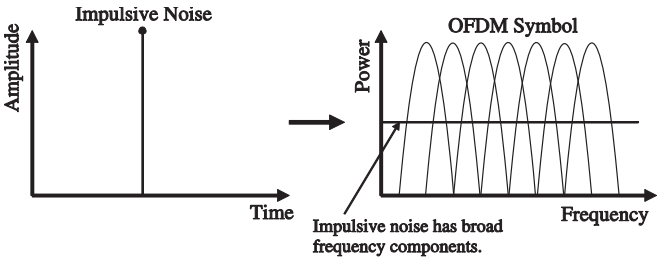

Fig. 1. The influence of the impulsive noise

In this paper, time sample replacement scheme is improved. This method is high quality in the case of low modulation scheme such as QPSK and 16QAM. However, in high density modulation scheme such as 64QAM, performance is degradation. In this paper, improving the time sample replacement scheme is shown. The performance of the proposed scheme is evaluated under the class A noise environment by using computer simulation.

This paper consists of the following sections. In section 2, OFDM transmission and the influence of the impulsive noise on OFDM signal are briefly described. In section 3, the impulsive noise mitigation schemes are described. The results of simulation are shown in section 4. Finally, this paper is concluded in section 5.

II. SYSTEM MODEL

In this section, the system model is explained. Fig. 2 shows the block diagram of the OFDM transmission system that is considered in this paper. In Fig. 2, transmitted signal at time t, $s(t)$, is expressed as

$$s(t) = \frac{1}{\sqrt{N}} \sum_{n=0}^{N-1} S_n e^{j2\pi(f_c + nf_0)t}, \qquad (1)$$

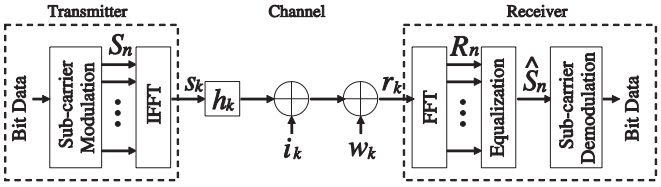

Fig. 2. System Model

where N denotes the number of sub-carriers and S_n denotes the complex data symbol transmitted on the n-th sub-carrier. Lowest sub-carrier frequency and sub-carrier spacing are denoted by f_c and f_0 respectively. If it is assumed that s_k is generated by sampling $s(t)$ with the sampling frequency of $1/(Nf_0)$, received OFDM sample, r_k, which is affected by the multipath channel and additive noises is expressed as

$$r_k = h_k \otimes s_k + w_k + i_k \qquad (k = 0,1,\dots,N-1), \quad (2)$$

where h_k denotes the impulse response of the transmission channel, $\otimes$ denotes convolution operation. In this paper, it is assumed that delay spread of the transmission channel is shorter than the guard interval length. w_k denotes the additive white Gaussian noise and it is the random variable that follows the Gaussian distribution. i_k denotes the additive impulsive noise that is added to the specific samples randomly. Generally, i_k has a high magnitude and a random phase.

In the receiver, by applying the fast Fourier transform (FFT) to r_k, the symbol transmitted on the n-th sub-carrier, R_n, is obtained by the following formula.

$$R_n = \frac{1}{\sqrt{N}} \sum_{k=0}^{N-1} r_k \left(e^{-j\frac{2\pi}{N}}\right)^{kn} = H_n S_n + W_n + I_n, \quad (3)$$

where H_n denotes the channel transfer function corresponding to the n-th sub-carrier, W_n denotes the complex Gaussian noise obtained by applying FFT to w_k, I_n denotes the complex impulsive noise obtained by applying FFT to i_k.

In order to equalize R_n in (3) and Fig. 2, zero forcing equalization is performed by dividing received OFDM symbol, R_n, by the channel transfer function, H_n, as

$$\hat{S}_n = \frac{R_n}{H_n} = S_n + \frac{W_n}{H_n} + \frac{I_n}{H_n}, \quad (4)$$

where $\hat{S}_n$ denotes the estimation of transmitted data symbol that contains the influence of the additive Gaussian noise and impulsive noise. In (4), first term, S_n, denotes actual complex data symbol transmitted on the n-th sub-carrier and the second term and later contain influence of additive noise. In (4), influence of additive impulsive noise appears on whole symbol because the additive impulsive noise consists of broad frequency components as shown in Fig. 1. We propose a method which reduces the influence of the impulsive noise as represented by 3rd term in (4). In the next section, impulsive noise mitigation schemes under multi-path channel are described.

III. Impulsive Noise Reduction Schemes

In this section, conventional impulsive noise reduction schemes and proposed scheme are explained. Conventionally "clipping and nulling scheme" and "time sample replacement scheme" have been proposed. In the following sub-sections, these schemes are explained.

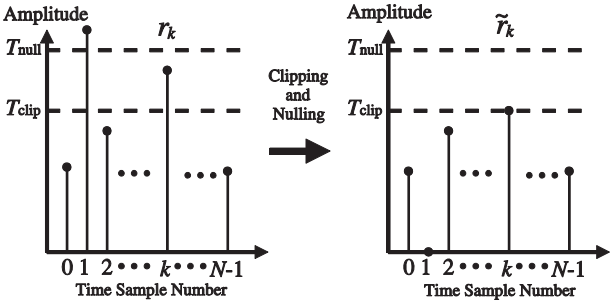

Fig. 3. Clipping and Nulling Scheme

A. Clipping and Nulling Scheme

Clipping and nulling is the scheme which combines clipping scheme and nulling scheme [8]. Clipping and nulling can be applied to the received signal, r_k, to reduce the influence of the impulsive noise by limiting and zeroing the amplitude of the signal exceeding the threshold as shown in Fig. 3. Against the received signal, r_k, received signal after impulsive noise reduction, $\tilde{r}_k$, are given as

$$\tilde{r}_k = \begin{cases} r_k, & \text{if } |r_k| \le T_{\text{clip}} \\ T_{\text{clip}} e^{j\arg r_k}, & \text{if } T_{\text{clip}} < |r_k| \le T_{\text{null}}, \\ 0, & \text{if } |r_k| > T_{\text{null}} \end{cases} \quad (5)$$

where T_{clip} and T_{null} denote the clipping threshold and nulling threshold that are defined by $T_{\text{clip}} = 2.2\sigma_s$ and $T_{\text{null}} = 3.08\sigma_s$, respectively [8]. σ_s denotes the standard deviation of OFDM signal. Conventional OFDM demodulation is performed against $\tilde{r}_k$.

B. Time Sample Replacement Scheme

In this sub-section, conventional time sample replacement scheme is described [10]. The purpose of this method is to replace the sample influenced by impulsive noise with sample that impulsive noise is reduced by re-generated. The block diagram of this scheme is shown in Fig. 4.

At first by applying the FFT to r_k in (2), the symbol transmitted on the n-th sub-carrier, R_n, is obtained in (3). After that, zero forcing equalization is performed by dividing received OFDM symbol, R_n, by the channel transfer function, H_n, in (4). After that, $\hat{S}_n$ in (4) is remapped to nearest positions in constellation plot as shown in Fig. 5. Re-modulated signal $\tilde{s}_k$ is generated by the IFFT (Inverse FFT) to $H_n\tilde{S}_n$ as

$$\tilde{s}_k = \frac{1}{\sqrt{N}} \sum_{n=0}^{N-1} H_n \tilde{S}_n \left(e^{-j\frac{2\pi}{N}}\right)^{-kn}. \quad (6)$$

If the influence of noise is small enough, $\tilde{s}_k$ is assumed to be approximately equivalent to the transmitted symbol, s_k. Therefore, in the difference signal, $D = |r_k - \tilde{s}_k|^2$, between the received signal, r_k, and the re-generated time domain signal, $\tilde{s}_k$, the influence of additive noise appears especially if there is an

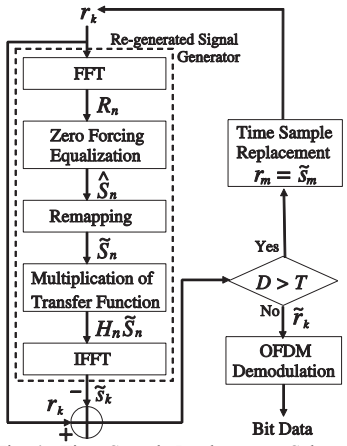

Fig. 4. Time Sample Replacement Scheme

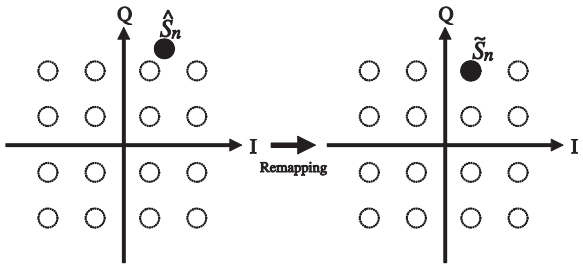

Fig. 5. Remapping

impulsive noise in r_k. By analyzing the difference signal, it is possible to detect additive impulsive noise. In this scheme, the additive impulsive noise is searched from the magnitude of the difference signal based on the pre-defined threshold value, T. In this research, the threshold value is defined as [12]

$$T = 0.01\Gamma \cdot \sigma^2, \tag{7}$$

where σ^2 denotes the average power of the additive noise, where Γ denotes impulse to Gaussian noise ratio. If the impulsive noise is detected by the threshold value, r_m is replaced by $\tilde{s}_m$ as shown in Fig. 6. m denotes the time sample number where the largest peak was detected in the difference signal.

The same procedure is repeated against replaced r_k to reduce the influence of the next largest impulsive noise until no impulsive noise is detected. If no impulsive noise is detected, conventional OFDM demodulation is performed.

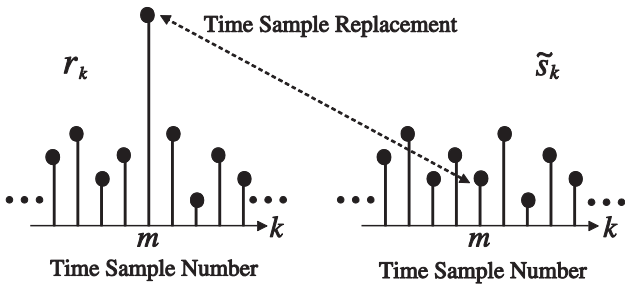

Fig. 6. Time Sample Replacement

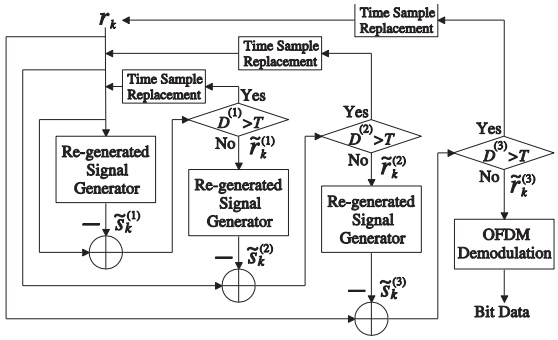

Fig. 7. Proposed Impulsive Noise Mitigation Scheme

C. Proposed Scheme

This scheme is method improved time sample replacement scheme. The BER (bit error rate) of the time sample replacement scheme is better than the clipping and nulling scheme in the low constellation modulation such as QPSK or 16QAM. However, in the high constellation modulation such as 64QAM, decision error occurred continually in the remapping process as shown in Fig. 5 because the number of signal points grows dense. Therefore, BER of the time sample replacement scheme is degraded in the high constellation modulation such as 64QAM.

In proposed scheme, BER characteristics are improved by reducing the decision error of the remapping process in the case of high order modulation scheme. The block diagram of the proposed scheme is shown as Fig. 7. In the problem of the time sample replacement scheme, decision error occurs continually in the remapping process as shown in Fig. 5 because remapping process is performed by using signal, r_k, including the influence of the impulsive noise. In the proposed scheme, in accordance with time sample replacement scheme, $\tilde{r}_k^{(1)}$ is generated as shown in Fig. 7. Against $\tilde{r}_k^{(1)}$, Re-generated signal process is performed again. Consequently, decision error is reduced by using signal that impulsive noise is mitigated, $\tilde{r}_k^{(1)}$. On the basis of this concept, it is considered that reception characteristic is improved by repeating the above process such as $\tilde{r}_k^{(2)}$ or $\tilde{r}_k^{(3)}$ as shown in Fig. 7.

IV. Results of Simulation

In this section, BER characteristics of the proposed scheme are evaluated by using the computer simulation. It is assumed that channel characteristics are time-invariant.

A. Impulsive Noise Model

In this paper, Middleton's class A impulsive noise model [13] is used to evaluate BER characteristics by using the computer simulations. This is a model which represents the Gaussian noise and impulsive noise simultaneously. It is known that class A noise well expresses the noise generated in the actual PLC systems [14]-[16], [18]. Probability density function of Middleton's class A noise model is shown as

$$p(x) = \sum_{u=0}^{\infty} \frac{e^{-A}A^u}{u!} \cdot \frac{1}{\sqrt{2\pi}\sigma_u} \exp\left(-\frac{|x|^2}{2\sigma_u^2}\right)$$
$$= \sum_{u=0}^{\infty} P_{P,A}(u) \cdot p_{G,0,\sigma_u^2}(x), \quad (8)$$

where A denotes the probability where the impulsive noise is added to each sample, $P_{P,A}(u) = \frac{e^{-A}A^u}{u!}$ denotes the probability density function of the Poisson distribution whose average value is A. $p_{G,0,\sigma_u^2}(x) = \frac{1}{\sqrt{2\pi}\sigma_u} \exp\left(-\frac{|x|^2}{2\sigma_u^2}\right)$ denotes the probability density function of the Gaussian distribution whose average value and variance are 0 and σ_u^2 respectively. If it is assumed that the number of impulsive noise sources is denoted by u, σ_u^2 is expressed as

$$\sigma_u^2 = \frac{\sigma^2\left(\frac{u}{A} + \Gamma\right)}{1+\Gamma} = u \cdot \frac{\sigma_I^2}{A} + \sigma_W^2, \quad (9)$$

$\Gamma = \sigma_W^2/\sigma_I^2$ denotes the ratio of the power of the Gaussian noise, σ_W^2, against the average power of the impulsive noise, σ_I^2. Total noise, σ^2, is defined by $\sigma_I^2+\sigma_W^2$.

B. Bit Error Rate Characteristics

In this section, the reception characteristics of the proposed scheme are compared to those of conventional schemes. Parameters used in the simulation for BER characteristics are shown in Table 1. In this paper, the values of A and Γ that are introduced in the previous researches [14]-[17] are used.

Fig. 8~10 show the BER characteristics against CNR (Carrier to Noise Ratio) under three different class A noise parameters. As shown in the figures, "w/o Impulsive Noise" denotes additive noise is only Gaussian noise without impulsive noise. In the following legends, class A noise is used for the computer simulation. "No Reduction" denotes the reduction of impulsive noise is not performed. "Clipping and Nulling" and "Time Sample Replacement" denote clipping and nulling scheme and time sample replacement scheme are respectively performed to the reduction of the additive impulsive noise. "Proposed Scheme (2)" denotes proposed scheme in the case of using $\tilde{r}_k^{(2)}$ as shown in Fig. 7. "Proposed Scheme (3)" and "Proposed Scheme (4)" are also the same as above. As shown in the figures, it is possible to much improve the performance with an increase in repeat count. As shown in the above results, the proposed impulsive noise mitigation scheme can achieve more BER performance than the conventional schemes under different class A noise parameters.

V. Conclution

In this paper, the impulsive noise reduction scheme under the impulsive PLC channel was proposed. The performance of the proposed scheme is compared to the conventional impulsive noise mitigation schemes using the clipping and nulling and time sample replacement scheme under the Middleton's class A noise environment. As the result of simulations, the BER performances against data symbols were compared and it was confirmed that the proposed scheme can achieve better performance in the high constellation modulation such as 64QAM. In the further researches, complexity reduction and theoretical optimization of the proposed scheme are studied.

TABLE I. Simulation Parameters

Reliable Link Layer Packet Reconstruction for Rotating Polarization Based Radio Communication

Ritesh Kumar Kalle, *Member IEEE*
Hitachi India Pvt. Ltd., Bangalore, India
ritesh@hitachi.co.in

***Abstract*— Rotating polarization wave based radio has been proposed for enhanced wireless communication using optimum polarization(s) to transmit and receive data in multiple reflection prone environments. The transmitter expands data by orthogonal codes that divide the polarization angle space into well-distinguished regions. However, harsh radio environments to which the waves are subjected to, result in erroneous bits at the receiver. Techniques proposed in this paper provide reliable communication through link layer combination of packets received over independent polarization angles. Analytical result shows that the proposed mechanism provides higher reliability.**

Keywords*— *M2M, wireless network, rotating polarization, orthogonal code, packet combination, error correction

I. INTRODUCTION

Social infrastructure systems require periodic maintenance, failure prediction, and remote diagnosis that need reliable communication network. Due to the very nature of these systems (generation, distribution and consumption of electric power, water etc.) and the backbones of urban societies (petroleum, steel, transportation etc.), the communication network that integrates these elements should be robust, secure, and simple to deploy as well as manage. Wireless communication technologies that provide machine to machine (M2M) services in industrial scenario are viewed as the most suitable candidates for such application. However radio technologies in unlicensed band based on the existing Wireless Personal Area network (WPAN) standards perform poorly in the presence of large number of metallic reflectors which are characteristic of social infrastructure deployments.

In this context, a novel radio technology has been proposed in [1] that uses polarization angle diversity to mitigate the effects of multiple reflections. In this method, the receiver determines an optimum transmit polarization that maximizes the sum power of the received waves. The transmitter expands data by orthogonal codes that divide the polarization angle space into well-distinguished regions [2]. Further digital signal processing techniques are applied to combine the received signals and decode the information. These wireless communication systems are expected to provide better resilience against multiple reflections in industrial environments especially when operated in sub-GHz frequencies. It may be noted that the transmitted information signal may still be affected by radio interference noise due to other sources such as co-channel interference by other similar devices in vicinity, electro-magnetic (EM) emissions from high-power sources such as electric power transformer partial discharges etc. Under such circumstances, erroneous bits may be received, leading to failure of communication.

It is important to note that M2M services deployed to monitor or control social infrastructure may have varying degrees of tolerance towards erroneous received data or latency of communication. In certain cases, the application may impose strict reliability and latency requirements. In other cases, the requirements may be adequately met through higher layer protocols for error correction through retransmission and data approximation. The performance cost (space, energy, redundancy) of introducing an error control code to the original information signal can be traded off with latency of retransmissions. In order to reduce the number of packet retransmissions and for reliable reception, several packet combination techniques [4-9] have been proposed in literature. These techniques have been designed to work with multiple received packet copies through means such as antenna diversity, time diversity or code diversity reception etc. In this paper, a novel link layer packet combination scheme for rotating polarization wave (RPW) based communication system is proposed that provides reliable communication along with lower overhead. Not only is the proposed scheme feasible to be implemented on low complexity wireless devices, but also applicable to transmit-only sensors that periodically transmit sensed information and are gathered at remote nodes.

The proposed method can achieve highly reliable link layer packet reconstruction without explicit retransmission requests in case of erroneous packets. Additionally this technique can be applied without support of any explicit automatic repeat request (ARQ) and forward error correction code (FEC) and is suitable for RPW based communication system. Furthermore, it can be applied to receivers that are unable to combine signals received over the multitude of polarization angles and time instants for coherent demodulation. From the numerical result, it can be observed that the proposed technique provides up to 13% gain in packet reconstruction probability without retransmissions at BER of 10^{-3} for packet sizes varying from 10 to 100 bits used in M2M networks.

This paper is organized as follows. Section II provides a detailed overview of RPW communication system. Section III describes existing protocols for packet combination in M2M networks and key challenges faced. Section IV provides details of the proposed algorithm for packet combination and analytical results. Finally, Section VI provides key conclusions.

II. ROTATING POLARIZATION WAVE COMMUNICATION

A. *Generation, Propagation and Reception of RPW*

In [1], the proposed RPW radio transmits signal with a rotating frequency lower than those of the two carrier frequencies composing the wave using two spatially perpendicular antennas. The transmitter expands very low rate information signal by orthogonal codes at high chip rate that divide the polarization angle space into well-distinguished regions. The receiver radio can potentially use the optimum combination of transmitting and receiving polarizations to enhance communication quality. Fig. 1 depicts an example of the generation, propagation and reception of RPW radio signal.

1) Generation:

The RPW consists of two distinct narrowly spaced carrier frequencies that rotate at a frequency equal to half of the difference between the two frequencies. The occupied bandwidth is equal to the product of the frequency of the polarization-rotation and the number of bits in the chip code. Mathematically the output of the above arrangement would be,

$$Y_v(t) = x(t)\left[\cos(2\pi f_1 t) - \cos(2\pi f_2 t)\right]$$

$$= 2x(t)\left[\sin\left(2\pi\frac{\delta_1}{2}t\right).\sin\left(2\pi\frac{\delta_2}{2}t\right)\right] \quad (1)$$

$$Y_h(t) = x(t)\left[\sin(2\pi f_1 t) + \sin(2\pi f_2 t)\right]$$

$$= 2x(t)\left[\sin\left(2\pi\frac{\delta_1}{2}t\right).\cos\left(2\pi\frac{\delta_2}{2}t\right)\right] \quad (2)$$

Where, $Y_v(t)$ and $Y_h(t)$ are the outputs of the vertical and horizontal antennas respectively and the frequencies $\delta_1/2$ and $\delta_2/2$ correspond to the carrier frequency and the polarization rotating frequency respectively. $x(t)$ is the chip sequence.

2) Propagation:

The RPW changes the direction of its polarization-rotation when it is reflected from a reflector surface. The sum of waves arriving at a receiver consists of right and left handed RPWs as these waves experience reflections of odd or even numbers. The differentiation of polarization is achieved by the use of (semi-) orthogonal codes both at the transmitter and receiver.

3) Reception:

To obtain a receiving wave on an arbitrary polarization, the receiver has two spatially perpendicular antennas. The outputs from the two antennas are amplified and down-converted using the local carrier frequency (difference between the averages of two carriers) and the intermediate frequency. This signal is later decoded by block codes to recover the information.

There are several advantageous effects of using the polarization diversity for transmission and reception of information in industrial environments with multiple reflectors. This includes greater control in exploiting the path diversity using the phase angle approach, avoiding situations where receivers are permanently in deep fade condition etc. However, challenges exist with respect to achieving accurate frame synchronization, stable operational BER (< 10^{-5}) conditions etc. Also, the practical data rates achieved in conventional channels are less than 100 kbps. This motivates the design of low overhead, high reliability link layer protocols.

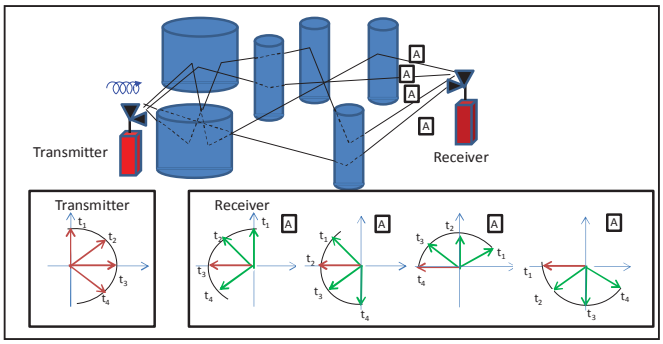

Fig. 1. RPW propagation in well defined polarization regions

III. RELIABILITY IN M2M COMMUNICATION

As described in previous sections, link layer protocol to supplement the RPW communication holds the potential to achieve higher reliability. In practice, the RPW prototype can achieve BER of 10^{-5} in the ideal scenario, but this may deteriorate in non-ideal channel conditions. Conventional methods to achieve higher reliability are compared below:

i. Forward Error Correction (FEC):

The tradeoff between the achieved coding gain due to FEC codes and energy consumed is significant for M2M applications. However, FEC codes are not suitable for low rate communication since the protection offered is proportional to the redundancy of information encoded. Also, it is essential to distinguish between bit-flips and bit-erasures in the wireless channel, FEC being suitable for the former error condition.

ii. Automatic Repeat Request (ARQ):

ARQ schemes using positive, negative acknowledgements (ACKs) and its variants with timeouts have been successfully used in low rate wireless networks for reliable transfer of information at the cost of increased latency. Variants of ARQ that weigh all the received copies of information signal before additional retransmission can be suitable for M2M application.

iii. Diversity techniques:

Packet-level diversity complements the use of radio diversity techniques. In case of wireless local area networks, packet-level diversity gain achieved by combining the received information from adjacent access-points is shown in [9]. More complex diversity techniques exploiting space, time and code space can be overwhelming for simple M2M devices.

Packet combining techniques proposed in multi-hop networks and for wireless local area networks enhances the BER performance when applied in conjunction with modified ARQ and FEC codes. However, in case of RPW, FEC and ARQ may not be best suited due to their higher overhead. A survey of packet combination methods proposed in research literature is provided in the following sub-section:

A. *Survey of techniques proposed in literature*

1) Diversity packet combining extended ARQ (EARQ) [3]: In the EARQ protocol, erroneous copies of the same packet are combined using bitwise logical XORs to locate errors in a combined copy. A brute force search method with a cyclic redundancy check (CRC) at every step is used to recover the correct copy. EARQ does not require coherent detection. Even if all the blocks received over the diversity branches are corrupt, they may be combined to retrieve the correct packet. However, the latency is high due to retransmissions and extensive CRC evaluation.

2) Simple packet combining(SPaC) [4]*:* The *SPaC* method exploits the broadcast medium and spatial diversity of a multi-hop wireless network by using overheard packets at any node, in addition to the next-hop destination of the packet. If these corrupt copies correspond to identical transmissions of the same packet, then combining them corresponds to decoding a repetition code. In a multi-hop low rate wireless network, overheard packets can be combined either having the same original information or in other cases with additional redundancy to improve the error recovery.

3) Packet merging [5]*:* For packet merging, the destination accepts two packets of the same type and creates a merged error mask also known as "Ambiguity Vector, VA". Once VA is obtained, it is then used with one of the packets, and the Frame Check Sequence (FCS) to obtain the original packet. This is achieved by modifying each bit position where there is a potential error (as indicated by V_A), and checking whether the resulting packet matches the FCS. Method to select the packet and the algorithm to search through bit combinations has been proposed to match the FCS.

4) Destination packet combining (DPC) [7]*:*

In DPC scheme, the receivers store successive received corrupted packets and use a majority voting strategy on these packets to reconstruct the original packet. The value of each bit of the determined packet depends on the values of the corresponding bit in all the corrupted packets. It was originally proposed for under water sensor networks with possibility of multipath transport or routing.

B. *Key challenges*

The retrieval process described in literature fails if there is at least one bit position where both copies have an error (hidden error). The probability of occurrence of hidden error increases with the increase of BER, thereby causing a downgrade in recovery speed. However, none of the above schemes address the issue of hidden errors and potentially led to inconclusive execution of algorithm. Furthermore, none of the schemes have been designed for the polarization diversity transmission applicable to the RPW communication. In the next section, a novel packet combination scheme for RPW is proposed that enhances the reliability of packet reconstruction.

IV. PROPOSED RPW PACKET RECONSTRUCTION TECHNIQUE

On point-to-point links, packet combining is treated equivalent to a class of coding techniques known as Hybrid ARQ (HARQ). However, the proposed scheme does not necessarily require an FEC code to protect the packet; and may be extended to support such supplementary code. Also, unlike the previously described schemes, this method does not use explicit notification to request retransmission on receipt of packets with bit errors. However, multiple packet copies with the same information content are received at the receiver node.

A. *Overview of the packet reconstruction scheme for RPW*

As depicted in Fig. 1, the transmitter encodes the same information (marked as A) with partially orthogonal periodic codes and transmits at different time points (t_1, t_2, t_3 and t_4). This scheme not only exploits the polarization diversity, but also the time diversity due to the staggered transmission that traverses different radio path owing to the nature of reflectors in the vicinity. At the receiver, therefore multiple (at least four) copies of the transmitted information (A) is received. In the hardware implementation, the FCS sequence of each packet can be checked at receiver. The packet reconstruction scheme follows only if all the copies fail to satisfy the FCS.

In Fig. 2, a six step procedure has been outlined to reliably reconstruct the transmitted packet at the receiver without explicit request for retransmissions. It may be noted that implementation specific details of the algorithm and the receiver architecture are not included due to lack of space.

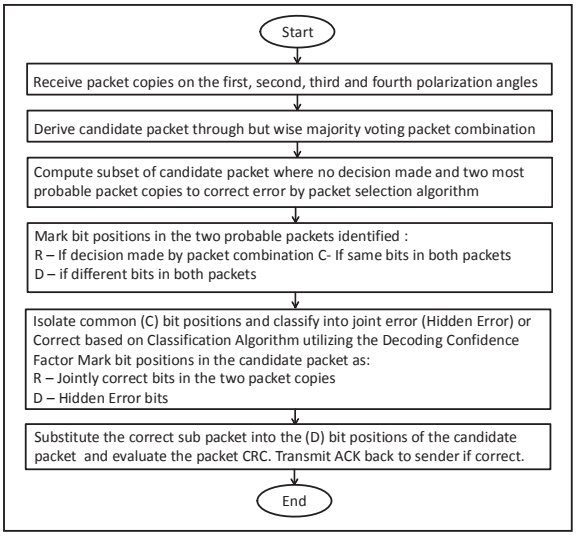

Fig. 2. Overview of steps for the proposed packet reconstruction algorithm

Step 1 describes the first stage in which the four packet copies are received over the four distinct polarization angles and passed on to the Link Layer packet processor. Note that the use of four packet copies is for illustration only and the scheme described in this paper may be applied to lower or higher polarization angles too. The packet reconstruction is only required when none of the multiple copies of packets received are deemed to be correct.

In Step 2, a candidate packet is derived through bit wise majority voting based packet combining technique. The candidate packet is stored in an appropriate structure such as the packet buffer, which may be later utilized by the packet correction unit of the packet processor. The candidate packet

is a temporary structure that holds the estimate of the final packet derived through majority vote mechanism. This mechanism (majority voting) for even number of packet copies is inconclusive when equal number of 0s and 1s are found at the same position in the packets to be combined or the number of error bits is more than the correct bits at the same position. Such errors are recovered in the Step 5.

Step 3 computes the subset of candidate packet where no decision could be made. It also selects two most probable packets amongst the multiple copies by packet selection algorithm described in Fig. 3. This algorithm first computes the pairwise Hamming distance (h_{ab}) for each of the packet copies. It also computes the pairwise function (e_{ab}) of the received packet's energy profile. This can be based on the Received Signal Strength Indicator (RSSI) signal profile (correlation characteristics, weighted average etc.). By maximizing the utility function ($\max\left(e_{ab}/h_{ab}\right)$), a pair of packets that are nearest to each other and having the highest received energy can be selected for further processing.

In Step 4, bit positions in the two probable packets are marked as: (i) Recovered (R) if decision made and assigned to candidate packet, (ii) Common (C) if bits match amongst the packets, (iii) Different (D) if bits don't match. Both (C) and (D) positions indicate the possibility of hidden error.

Step 5 isolates Common (C) positions and classifies into jointly correct or error bits (hidden errors that cannot be identified in both packets) based on classification algorithm described in Fig. 3 utilizing the Decoding Confidence metric. Decoding confidence metric is fed to the packet processor as cross layer information from the physical layer. The bit position with High decoding confidence is marked as '1' and the position with Low decoding confidence is marked as '0'. Positions where the one or both of the packets has low decoding confidence, a decision is not made and the bit position is marked 'D'. Decision is made at (C) marked positions with high decoding confidence in both copies and corresponding bits substituted in candidate packet. The packet candidate with highest number of high decoding confidence bits is utilized for the next step.

In a hard decision block decoder, such as that used for RPW system, the recovered codeword is mapped to nearest valid codeword. A threshold based classification (as High or Low) of the Hamming distance between the two can serve as one of the decoding confidence metric. In case of soft decoding, an analogous metric may be computed based on correlation between the received samples (Y) and each codeword (C_i).

$$C(Y, C_i) = \sum_{j=1}^{n} y_j c_{ij} \quad (3)$$

In Step 6, bit combinations of the selected packet (or sub-packet) are successively evaluated to satisfy the FCS. The packet is decoded to be the right packet if the FCS check is satisfied and an ACK is transmitted back to the sender. The packet candidates are evaluated in the order of increasing Hamming distance from the initial candidate packet. Also, the order of bit evaluation is dependent on pool of bit positions having low decoding confidence vector first and later with high decoding confidence vector. In case the FCS is satisfied by one of the combinations, the evaluation is terminated. Once the packet FCS is satisfied, the receiver transmits the ACK.

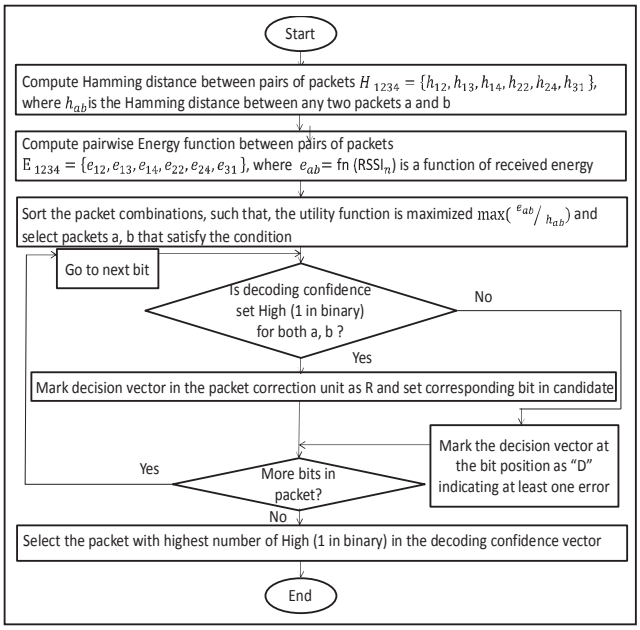

Fig. 3. Packet selection and error classification algorithm

In the worst case, if decisions could not be made at any of the n bit positions, the cost of evaluation of all possible packet candidates is prohibitively large (2^n). But in practice for RPW communication system, for small packet sizes (10 – 100 bits) and moderate BER (10^{-5} to 10^{-3}), the proportion of error bits is reasonably small and can be easily recovered by the above proposed algorithm. In the following subsection, a simple analytical model to compare the probability of decoding success is proposed.

B. Analysis and numerical results

Let p_e denote the operating BER of the wireless link. The Packet Error Rate (PER) can therefore be expressed as $B(p) = 1-(1-p_e)^n$ where n is the packet size. Consider the combination of at least two erroneous packets to generate a candidate packet without our proposed algorithm. The procedure would fail, when at least one position in which both copies have error – hidden error scenario. Further, this procedure would fail as long as additional copies of packets also contain one or more hidden errors. The probability of success in at the reception of L^{th} packet copy would be:

$$P(L) = \left[1 - \sum_{r=1}^{L-1} P(r)\right].\left[(1-p_e)^n + (1-(1-p_e)^n)(1-\alpha_d(L))\right] \quad (4)$$

where, $\alpha_d(L)$ is the probability of hidden error with all preceding L-1 copies in the packet buffer. It can be shown from [3] that,

$$\alpha_d(L) = \frac{\sum_{K_1=1}^{n} \cdots \sum_{K_L=1}^{n} P(K_1 \ldots K_L) \prod_{1 \le i,j \le L, i<j} P_{i,j}}{(1-(1-p_e)^n)^L \prod_{l=2}^{L-1} \alpha_d(l)} \quad (5)$$

where, based on assumption independent occurrence of errors

$$P(K_1 \ldots K_L) = P(K_1).P(K_2) \ldots P(K_L) \quad (6)$$

is the joint probability of the L copies having $K_1 \ldots K_L$ errors respectively. $P(K_i) = \binom{n}{K_i} p_e^{K_i} (1-p_e)^{n-K_i}$ being the probability of a copy having K_i error.

Further, $P_{i,j}$ is the probability that two copies with K_i and K_j errors, have a hidden error:

$$P_{i,j} = 1 - \frac{(n-K_i)!(n-K_j)!}{n!(n-K_i-K_j)!} \quad (7)$$

It can be considered that, the proposed algorithm in this paper eliminates the probability of occurrence of hidden error ($\alpha_d(L) \to 0$). Therefore from Eq. (3),

$$P_{proposed}(L) = \left[1 - \sum_{r=1}^{L-1} P(r)\right] \quad (8)$$

The relative benefit in terms of decoding success probability can therefore be expressed in percentage as

$$\left(P_{proposed}(L) - P(L)\right) * 100 / P_{proposed}(L) \quad (9)$$

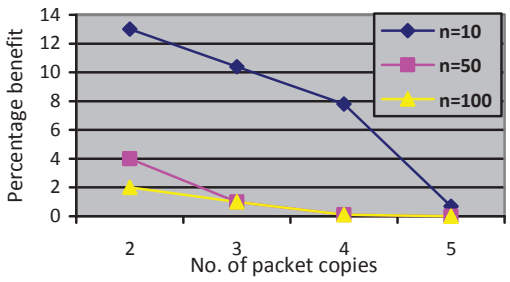

Fig. 4. Relative benefit in decoding success for varying packet sizes (n= 10, 50, 100) expressed in percentage at BER of 10^{-3}

This measures the advantage of the proposed algorithm w.r.t schemes using ARQ for packet combination such as [3], [5]. Fig. 4 depicts the numerical result of relative benefit in decoding probability w.r.t number of packet copies combined for varying packet sizes. It may be noted that the relative benefit reduces from a peak of 13% with the increasing number of packet copies through retransmissions. This however adds an additional latency proportional to the round trip time of the wireless link. Also, the proposed mechanism is most suitable for small packets on low rate wireless networks such as RPW system, where FEC and EARQ are infeasible.

There is still a small probability of false positive in which case, the packet reconstruction algorithm results in an incorrect packet that satisfies the FCS checksum. The probability of false positives is never zero, because a checksum cannot detect every possible error pattern. For a packet size of 320 bits, experimental observations in [5] indicate 0.06% of false positive for a 16-bit CRC polynomial in bad channel state. The elimination of hidden errors from the packet candidate in the proposed packet reconstruction algorithm minimizes the false positives. In RPW system, packet size of up to 100 bits is considered for packet reconstruction based link layer protocol as the probability of false positive reduces with lower packet size for any given FCS polynomial.

V. CONCLUSIONS AND FUTURE WORK

In this paper, a novel link layer mechanism to reliably combine multiple copies of the packet received at distinct polarization angles of the RPW communication system has been described. Analysis and numerical result indicates that the proposed cross layer method provides distinct feature of negating the effect of hidden errors, thereby enhancing the probability of success in packet reconstruction and minimizing the false positives. In future, it is proposed to evaluate the performance of the algorithm along with the hardware prototype of RPW communication system in field conditions.

***Abstract*—In this paper, the transmission capacity of highway vehicular ad-hoc networks (VANET) is analysed based on a one-dimensional line model in topology and CSMA/CA protocol in MAC, which is described from the perspective of geometric relationship between simultaneous transmitters. The desired channel and interfering channels are assumed experience the same amount of path-loss and Rayleigh fading. Based on the proposed model, we analyse the attempted transmission probability of each active transmitter and the maximum intensity of active transmitters, followed by their theoretical values. After the outage probability is obtained, we derive the upper bound of transmission capacity of VANET, which is defined as the average spatial density of successful transmissions in the networks. Finally simulation results validate that the theoretical value offers a good bound of the network capacity.**

Keywords—VANET; Transmission Capacity; Line model; CSMA/CA

I. INTRODUCTION

Vehicular Ad Hoc Networks (VANETs) have recently become an intense research topic in the field of Intelligent Transportation Systems. VANETs assume that all or a subset of all vehicles is equipped with radio devices, treating driving vehicles as moving wireless nodes and moving routers, and forming a wide range of wireless mobile networks that take advantage of brief communication between vehicles. IEEE802.11p [1] (also referred to Wireless Access in Vehicular Environments, WAVE) was standardised to support these communications. This standard inherits many properties of IEEE 802.11, but defines enhancements to 802.11 in order to adapt to the vehicular environment.

Typically, VANET applications are categorised into safety, transport efficiency, and information/entertainment applications. Safety applications are the most important applications. Periodic messages, such as location, speed, traffic, or alert messages (accident signals), may be exchanged in VANET to help drivers navigate and adjust their vehicle to avoid dangerous situations[2-4]. Transport efficiency and information/entertainment applications are directly used by the users, such as enabling voice or communications between vehicles, analysing exemplarily enhanced route guidance and navigation, green light optimal speed advisory, and so forth. As soon as an emergency occurred, a lot of vehicles are jammed suddenly. Hence, the more frequencies for communication or entertainment is increasing. However, network capacity is limited, and not all messages can be transported effectively. Therefore, research on improving VANET capacity is crucial.

Gupta and Kumar [5] conduct a large-scale study on the asymptotic capacity of wireless ad hoc networks and prove that the per-node throughput capacity of $O\left(1/\sqrt{n}\right)$ is feasible. When the network contains n nodes, a capacity of $\Omega\left(1/\sqrt{n\log n}\right)$ is feasible. In [6], S. Weber and J.G. Andrews develop this theory and deduced the expression of transmission capacity. Numerous works [7–9] improve this bound in different scenarios and environments; however, all of these works do not prove the precise estimates, and only ALOHA protocol is used in these papers. Furthermore, the topology of networks and behaviors of nodes in these works are always described as a Poisson process in a 2-dimiensional (2D) plane, which cannot be directly applied in VAENT.

Because the vehicles are limited along the street roads or highways, and the radio range in 802.11p is much longer than the road width, the 1-demiensional (1D) lines or grids are appropriate for modelling VANET topologies. Some capacity results have been achieved based on those models [10-14]. In [10-11], the authors model the area of urban vehicular networks as a scalable grid and only intuitively analysed the asymptotic capacity performance by utilizing the protocol model without detailed theoretical results or simulation analysis. In [12-13], the authors propose an asymptotic bound of transmission capacity in linear networks. However, their model is unrealistic because the impact of interference and outage probability are ignored. In [14], the VANET capacity is estimated with interference in a straight long road. However, the model of MAC mechanism does not exactly mimic the impacts of CSMA/CA, and the interference is considered only from the two neighbor nodes. Meanwhile, only path-loss is considered while small-scale fading is ignored, and the outage probability has not been considered. Therefore the estimation of VANET capacity is not valid enough. In this paper, a 1D line model and CSMA/CA protocol are used to discuss the capacity of a linear VANET. Furthermore, all

interferences among all simultaneous transmitters are taken into account. After intuitively describe the CSMA/CA, we analyse the attempted transmission probability of each active transmitter and the maximum intensity of active transmitters, followed by their theoretical values. Then, we derive the outage probability and upper bound of transmission capacity of the networks under Rayleigh fading. Finally, we use the Matlab simulator to perform the model and validated our theoretical results.

This paper is organised as follows. Section II introduces the system model. Section III analyses the upper bound of network transmission capacity. Section IV presents the simulations and analytical results. Finally, we conclude the paper in Section V.

II. System Model

A. Proposed Model

Our model is built on the basis of a highway scenario with sufficiently great length L $(L \to \infty)$ in Fig.1. All transmitting vehicles share a same transmitting data-rate R and a same transmitting power P . Each transmitter is equipped with a dedicated receiver within its transmission range. In IEEE 802.11p standard, the transmission range D of a vehicle is about 500 to 1000 meters, which is much longer than the highway width. Therefore, we simplify the 2D strip-shaped network area into a 1D straight line.

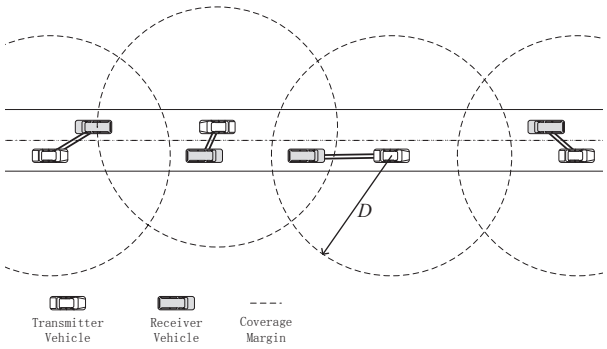

Fig.1. Basic highway scenario

As represented in Fig. 2, the line road is divided into G equal segments of length $r(d \le r < D)$, that is, $L = Gr$ where d is the average effective distance between each transmission group. We assume that a pair of vehicles can communicate only when they are on the same road segment at the same time slot. With all vehicles equipped with only one single-channel transceiver, a maximum of one transmission can occur on each road segment at each time slot. In this scenario, all the vehicles move independently along the straight line. We consider unicast flows to exist concurrently in the network, and the source and destination vehicles of each unicast flow are spatially close to each other.

The MAC protocol in this study follows the typical CSMA/CA, and it distinguishes the priorities of different businesses by setting distinct parameters. In the CSMA/CA protocol, a candidate node will sense the channel before sending the messages. In [15], whether the channel is busy or not is determined by a sensing power threshold θ , which can be translated to an exclusive region (ER) with radius R_s centered at the reference transmitter T , and $R_s = (\theta / P)^{-1/\alpha}$, where α is the path-loss exponent. With the postpone working procedure, there is no other simultaneous active transmitters in the ER. In spite of certain collisions are avoided, not every transmission is successful due to the noise and interference. Thus another interest is the outage probability, which is introduced as followed.

B. Definitions of Outage Probability and Transmission Capacity

Definition 1: The outage probability q is the probability the SIR experienced by the reference receiver at the origin is below the threshold [6]

$$q = \Pr\left(\frac{P_r}{I} < \beta\right) \tag{1}$$

where P_r is the received signal power at reference receiver, I is the total measured interference at reference receiver, the ambient noise is neglected in this interference-limited environment.

Definition 2: The transmission capacity C_T is defined as the average spatial density of successful transmissions in the networks [6]

$$C_T = \lambda(1-q)R \tag{2}$$

where λ is the maximum intensity of active transmitters, and R is transmission data rate.

III. Network Transmission Capacity Analysis

In this section, we first propose a transmission scheme mimics the CSMA/CA, and derive the attempted transmission probability of each road segment and the maximum intensity of active transmitters. After that, we obtain the outage probability and transmission capacity of the network.

As shown in Fig. 2, we partition the line into equal-sized sub-areas. Each sub-area contains M road segments, and each road segment is assumed to have a probability to transmit at a time slot. The average length of R_s around each active transmitter is about Mr , and we have

$$M = R_s / r = \left\lceil (\theta / P)^{-1/\alpha} / r \right\rceil. \tag{3}$$

The highlighted green segments in each sub-area comprise one active transmission group, that is, the measured interference on the active transmitter is no more than the predefined threshold θ . As each one sub-area contains M road segments, there are M transmission groups over the line collectively. With transmitting iteratively, each group becomes active every $1/p = M$ time slots, which means that a vehicle on one specific road segment can have an opportunity to transmit with probability p at a random time slot.

Corollary 1: The maximum density of simultaneous active transmitters over the line is given by

$$\lambda = Gp/L = p/r = 1/r\left\lceil (\theta/P)^{-1/\alpha}/r \right\rceil. \tag{4}$$

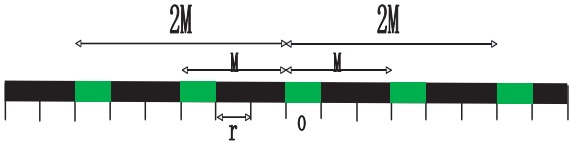

Fig.2. A line-like highway layout

In this work we treat the road as infinite and ignore the endpoints' impacts. As shown in Fig. 2, we assume the reference transmission group is on segment O. As the length of the line is sufficiently great, it can be supposed that there are both K ($K \to \infty$) simultaneous active transmitters on each side of the reference node on highlighted green segments. According to the physical model in [5], the total measured interference I at reference receiver R_0 can be defined as

$$I = 2\sum_{i=1}^{K} \frac{PH_{io}}{(iMr)^{\alpha}}. \tag{5}$$

According to definition 1, the outage probability q is the probability the SIR experienced by the reference receiver at the origin is below the threshold β. We have

$$q = \Pr\left\{ \frac{PH_{oo} r^{-\alpha}}{2\sum_{i=1}^{K} PH_{io} (iMr)^{-\alpha}} < \beta \right\}$$
$$= \Pr\left\{ H_{oo} < \beta r^{-\alpha} I \right\} \tag{6}$$

where H_{io} is the channel power gain of the interfering link from the interference vehicle to the reference receiver, and H_{oo} is the channel power gain of the desired link. All the channels are subject to Rayleigh fading and thus the channel power gain H is exponentially distributed, that is $f_H(x) = \tau \exp(-\tau x)$. Hence, formula (6) can be converted as

$$q = E\left[\int_0^{\beta r^{\alpha} I} \tau \exp(-\tau x) dx \right]$$
$$= 1 - E\left[\exp\left(-\tau \beta r^{\alpha} I\right) \right]$$
$$= 1 - L_I\left(\tau \beta r^{\alpha}\right). \tag{7}$$

Corollary 2: Under Rayleigh fading of both desired signal and interfering signals, an lower bound on the outage probability is given by

$$q_{lb} = = 1 - \left(\frac{1}{2\beta r^{\alpha} (L/4)^{-\alpha} + 1} \right)^{L/4r\left\lceil (\theta/P)^{-1/\alpha}/r \right\rceil}. \tag{8}$$

proof: Under Rayleigh fading of both desired signal and interfering signals, the Laplace transform of aggregate interference I is derived as

$$L_I(s) = E\left[\exp\left(-2s \sum_{i=1}^{K} H_{io} (iMr)^{-\alpha} \right) \right]$$
$$\le \left\{ E\left[\exp\left(-2(Mr)^{-\alpha} s H_{io} \left(\frac{K}{2}\right)^{-\alpha} \right) \right] \right\}^{\frac{K}{2}}$$
$$\underline{\underline{(a)}} \left\{ \int_{x=0}^{\infty} \tau \exp(-\tau x) \exp\left(-2s \left(\frac{MrK}{2} \right)^{-\alpha} x \right) dx \right\}^{\frac{K}{2}}$$
$$= \left\{ \int_{x=0}^{\infty} \tau \exp\left(-\left(2s \left(\frac{MrK}{2} \right)^{-\alpha} + \tau \right) x \right) dx \right\}^{\frac{K}{2}}$$
$$= \left\{ \frac{\tau}{2s \left(\frac{MrK}{2} \right)^{-\alpha} + \tau} \right\}^{\frac{K}{2}}$$
$$\underline{\underline{(b)}} \left\{ \frac{\tau}{2s \left(\frac{L}{4} \right)^{-\alpha} + \tau} \right\}^{\frac{L}{4Mr}} \tag{9}$$

where (a) follows by $f_H(x) = \tau \exp(-\tau x)$, (b) follows by $K = L/2Mr$. Therefore, we have $L_{I_{ub}}(s) = \left\{ \tau / \left(2s \left(\frac{L}{4} \right)^{-\alpha} + \tau \right) \right\}^{\frac{L}{4Mr}}$, and this upper bound can be used to obtain a low bound on the outage probability by substituting (9)and(3) into (7) as follow

$$q_{lb} = 1 - L_I\left(\tau \beta r^{\alpha}\right) = 1 - \left(\frac{1}{2\beta r^{\alpha} (L/4)^{-\alpha} + 1} \right)^{L/4r\left\lceil (\theta/P)^{-1/\alpha}/r \right\rceil}.$$

Corollary 3: Under Rayleigh fading of both desired signal and interfering signals, an upper bound on the transmission capacity is given by

$$C_{T_{ub}} = \lambda(1 - q_{lb}) R$$
$$= \frac{R}{r\left\lceil (\theta/P)^{-1/\alpha}/r \right\rceil} \left(\frac{1}{2\beta r^{\alpha} (L/4)^{-\alpha} + 1} \right)^{L/4r\left\lceil (\theta/P)^{-1/\alpha}/r \right\rceil} \tag{10}$$

where q_{lb} is obtained in corollary 2 and λ is obtained in (4). This upper bound limits the maximal possible value of transmission capacity for the linear VANET.

IV. SIMULATION RESULTS

In this section, in order to validate the upper bound of network transmission capacity, we used the simulator Matlab to build a highway environment where the highway is modeled as a line with distance of 4km, and vehicles' distribution and data transmission mechanisms were simulated in 802.11p. All vehicles in these simulations transmit frames to a neighbor with a constant bit rate, and the moving pattern of all potential transmitting vehicles is described as the classic Car-Following Model [16], which claims that the mean distance X between any two neighbor vehicles on a linear road follows a log-normal distribution parameterized by μ and σ :

$$D_X(x) = \frac{1}{\sqrt{2\pi}\sigma x}\exp\left(\frac{-(Inx-\mu)^2}{2\sigma^2}\right). \qquad (11)$$

This Car-Following Model is mainly used to simulate more realistic behaviors of vehicles in VANET. The instantaneous distribution of all transmitters in any timeslot is obtained from the model. The capacity is computed as the average spatial density of successful transmissions in the networks, and the intensity of transmitters is computed as the total number of simultaneous transmitters at a given time during the simulation. All the channels experience the same amount of path-loss and Rayleigh fading, and the value of path-loss exponent is 2. All parameters set in our simulation are shown in TABLE I.

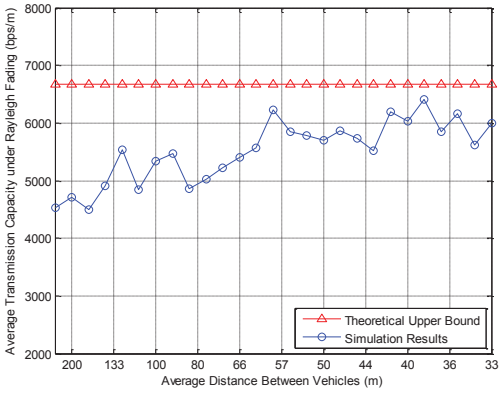

Fig. 3. Average transmission capacity and upper bound under Rayleigh fading.

Fig.3 shows the simulation results of average transmission capacity over the 2km-long central part of the road and its upper bounds. The circle-dotted curve depicts the relation between distance of neighbor vehicles and average transmission capacity under Rayleigh fading. In this paper, we set and , and the upper bound of transmission capacity equals 6583.03bps/m by solving equation (10) with parameters aforementioned in TABLE I. This upper bound is plotted as the triangle-dotted line and it constrains simulation results tight enough. Fig.4 illustrates the simulation results of successful simultaneous transmitters' average density (circle-dotted curve), and the upper bound (triangle-dotted line) is calculated by solving equation (10) without considering transmission data rate .Our result still performs well.

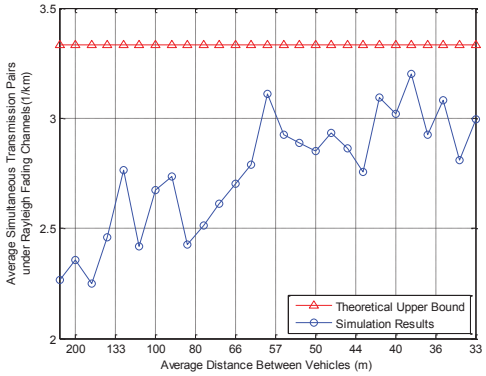

Fig.4. Average density of simultaneous transmitters and maximal density under Rayleigh fading .

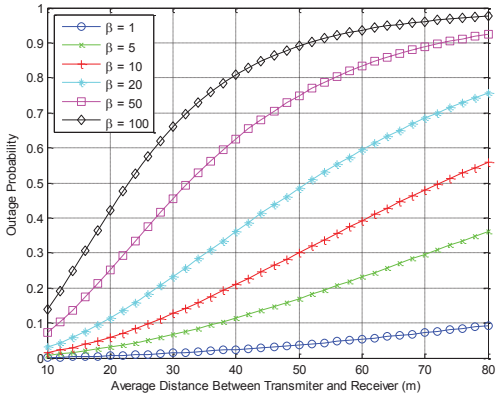

Fig.5. Outage probability vs. average distance between each transmission group under Rayleigh fading. Different colours represent different threshold β .

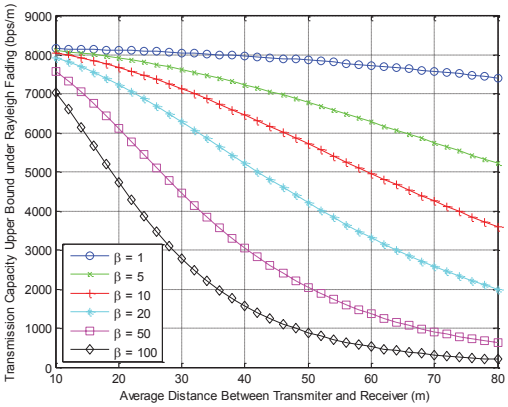

Fig.6. Transmission capacity upper bound vs. average distance between each transmission group under Rayleigh fading. Different colours represent different threshold β .

We also present numerical results based on the above analysis and give some interpretations. In fig.5, the outage probability vs. distance between each transmission group under Rayleigh fading is illustrated with different threshold β . Generally, when the distance between transmitter and receiver r is increased, the outage probability is also increased. This could be explained as that, as other parameters are fixed, the increased signal transmission distance will decrease the received signal power, which represented as the declined SIR comprehensively. It is also clear that, the outage probability is increased with the increasing of β . Fig.6 illustrates opposite change trend of Fig.5, the transmission capacity upper bound is decreased with the increasing of distance between transmitter and receiver. It is clear that larger distance will increase the outage probability, thus the transmission capacity is decreased.

TABLE I. SIMULATION PARAMETERS

Simulation Parameter	**Numerical Value**
IEEE 802.11std	802.11p
CCA mode	CCA mode 1
Carrier Wavelength	0.051 m
Packet Length	7680 byte
DCF Inter-frame Space (DIFS)	50 μs
Short Inter-frame Space (SIFS)	1 μs
Transmission Power P_t	33 dBm
Transmission Gain G_t	34 dBm
Receiving Gain G_r	33 dBm
Threshold θ	-50 dBm
Path-loss exponent α	2
Transmission Data-rate R	2 Mbps
Transmission Radium D	500m
Road Length L	4km
Duration of Simulation t_s	3 seconds

I. CONCLUSION

In this paper, we built our model on the basis of a highway scenario, and the proposed model mimics the CSMA/CA used in IEEE802.11p from the perspective of geometric relationship between simultaneous transmitters. After intuitive describe the CCA mechanism, we derive the upper bound on network capacity of VANET. Finally, we use the network simulator Matlab to perform our model and validated that the theoretical result offers a well bound on the network capacity.

***Abstract*— In this paper, we propose new scheme for creating virtual 8x1 multiple input-single output (MISO) channel with quasi orthogonal space time block coding (QOSTBC). This scheme includes one base station (BS), two relay stations (RS), and one mobile station (MS). BS and RSs are equipped with two antennas, while MS is equipped with one antenna. In our previous work we have proposed schemes for virtual 4x1 MISO channel with QOSTBC or OSTBC. Here we assumed more antennas per each RS, so the new coding procedure was necessary. The simulation results show SNR gains obtained with the new proposed virtual QOSTBC scheme.**

Keywords*— *BER; MISO, Relay; QOSTBC

I. INTRODUCTION

High data rates followed by appropriate quality of service (QoS) are becoming one of the major features in the future wireless communication systems regarding increasing demands for multimedia services and web-related content and applications. Creating reliable wireless connections in all possible environment types, where plethora of new applications will be realized, is the most challenging task in design of communicational part of future wireless networks. Among the many solutions proposed for addressing impairments introduced by wireless fading channels, special place belongs to relaying and multiple-input-multiple-output (MIMO) systems. These techniques improve the reliability of wireless communications, enhance the capacity and extend the coverage area of different wireless networks.

Relaying assumes resource sharing among the cooperative nodes which behaves as RS in information transmission from source to destination terminal. In this way, long wireless links can be separated into two, or more, shorter ones for performance improvement and coverage extension of wireless network, or RSs can cooperatively transmit the toward destination in order to achieve diversity gain, i.e. to realize a sort of distributed (virtual) MIMO system.

Traditional MIMO concept, also known as collocated MIMO, assumes implementation of multiple antennas at transmitter and/or receiver in order to attain spatial diversity gain. MIMO architectures are effective in improving bit error rate (BER), system capacity, spectrum efficiency, etc., of wireless communication systems, [1]-[3]. Benefits of collocated MIMO may be combined with advantages brought by relaying systems, if the RSs may implement multiple transmit and/or receive antennas, [4]-[9]. However, in some situations it is not easily feasible to implement multiple antennas on nodes, with enough separation among them in order to provide uncorrelated diversity branches. Thus, the concept of distributed, or virtual MIMO system, has gained significant research attention in recent period.

In this paper we propose new distributed QOSTBC scheme for creating virtual 8x1 MISO channel. The proposed scheme assumes one BS, two RSs, and one MS. BS and RSs are equipped with two antennas, while MS is equipped with one antenna. In this 2-hop scheme, the procedure at the RS is reduced due to omitting the decoding process. There is no need for detection and space-time decoding at RS. The procedure at RS is just permutation and forwarding of the signal sequences. This new coding procedure is extension of our previous proposed virtual QOSTBC schemes, [10]-[12]. The simulation results show the SNR gains obtained with the proposed scheme, i.e. the BER performance improvements by adding one more antennas per each RS. This paper is composed in the following order. After describing the virtual QOSTBC for creating 4x1 MISO channel and the proposed scheme for creating 8x1 MISO channel in Sect. II and III the simulation results are presented in Sect. IV. Finally, conclusions are drawn in Sect. V.

II. VIRTUAL QOSTBC FOR CREATING 4X1 MISO CHANNEL

QOSTBC for system with four transmit antennas is defined with next relation, [13]-[15]:

$$\mathbf{QOSTBC}_4 = \frac{1}{\sqrt{4}}\begin{bmatrix} a_1 & -a_2^* & -a_3^* & a_4 \\ a_2 & a_1^* & -a_4^* & -a_3 \\ a_3 & -a_4^* & a_1^* & -a_2 \\ a_4 & a_3^* & a_2^* & a_1 \end{bmatrix} \quad (1)$$

Here, a_i, i=1,…,4, are input symbols in QOSTB encoder. Average power spent per data symbol is fixed with scaling factor of $\frac{1}{\sqrt{4}}$. As it can be seen, for every four input symbols there are four output symbols at every antenna, i.e. the code rate is 1.

This code can be virtually realized [10]-[12]. The system model for the cooperative relaying with virtual QOSTBC, defined with (1) is presented in Fig. 1. The system includes one BS, two RSs and one MS. BS is equipped with two antennas, while the RS and MS are equipped with one antenna. BS transmits symbol sequences and the MS receives symbol sequences via two RSs.

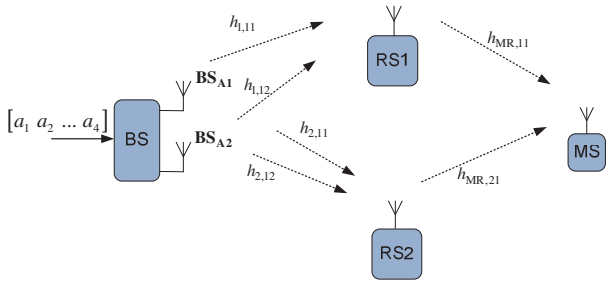

Fig. 1. Cooperative relaying scheme for virtual QOSTBC$_4$

For every four data symbols a_i, i=1,…,4, BS generates two symbol sequences:

$$\mathbf{BS_{A1_QOSTBC4}} = \frac{1}{\sqrt{2}}\left[a_1 \quad -a_2^* \quad -a_3^* \quad a_4\right]$$
$$\mathbf{BS_{A2_QOSTBC4}} = \frac{1}{\sqrt{2}}\left[a_2 \quad a_1^* \quad -a_4^* \quad -a_3\right] \tag{2}$$

Transmitted symbol sequences consist of four symbols while the average power spent per data symbol is fixed with scaling factor of $\frac{1}{\sqrt{2}}$. It is assumed that all the symbols in a single sequence suffer from same fading condition.

The channel coefficient between the i-th RS and the j-th antenna at BS is $h_{i,1j}$, i=1,2; j=1,2.

Received symbol sequence at i-th RS is:

$$\mathbf{RS_{Ai_in_QOSTBC4}} = \sum_{j=1}^{2} \mathbf{BS_{Ai_QOSTBC4}} \cdot h_{i,1j} + \mathbf{N_{Ri_QOSTBC4}} \tag{3}$$

$\mathbf{N_{Ri_QOSTBC4}}$ is additive white Gaussian noise (AWGN) matrix at i-th RS:

$$\mathbf{N_{Ri_QOSTBC4}} = [n_{Ri1_QOSTBC4} \quad n_{Ri2_QOSTBC4} \quad n_{Ri3_QOSTBC4} \quad n_{Ri8_QOSTBC4}] \tag{4}$$

Here, $n_{Ris_QOSTBC4}$, j=1,…,4 represents AWGN at i-th RS at s-th time slot.

RS1 generates the symbol sequence:

$$\mathbf{RS_{A1_out_QOSTBC4}} = \frac{1}{\sqrt{2}}\mathbf{RS_{A1_in_QOSTBC4}} \tag{5}$$

RS2 permutes the received symbol sequence, and generates output symbol sequence:

$$\mathbf{RS_{A2_out_QOSTBC4}} = \frac{1}{\sqrt{2}}\left[-\mathbf{RS}^*_{\mathbf{A2_in_QOSTBC4}}(3) \quad -\mathbf{RS}^*_{\mathbf{A2_in_QOSTBC4}}(4) \quad \mathbf{RS}^*_{\mathbf{A2_in_QOSTBC4}}(1) \quad \mathbf{RS}^*_{\mathbf{A2_in_QOSTBC4}}(2)\right] \tag{6}$$

Average power spent per data symbol is fixed with scaling factor of $\frac{1}{\sqrt{2}}$.

The channel coefficient between the i-th RS and MS is $h_{\mathrm{MR},i1}$. The received symbol sequence at MS is:

$$\mathbf{MS_{in_QOSTBC4}} = \sum_{i=1}^{2} \mathbf{RS_{Ai_out_QOSTBC4}} \cdot h_{MR,i1} + \mathbf{N_{MS_QOSTBC4}} \tag{7}$$

$\mathbf{N_{MS_QOSTBC4}}$ is AWGN matrixes at MS:

$$\mathbf{N_{MS_QOSTBC4}} = [n_{MS1_QOSTBC4} \quad n_{MS2_QOSTBC4} \quad n_{MS3_QOSTBC4} \quad n_{MS4_QOSTBC4}] \tag{8}$$

With this relaying virtual 4x1 MISO channel is created between BS and MS, i.e.:

$$\mathbf{MS}^T_{\mathbf{in_QOSTBC4}} = \frac{1}{\sqrt{4}}\begin{bmatrix} a_1 & -a_2^* & -a_3^* & a_4 \\ a_2 & a_1^* & -a_4^* & -a_3 \\ a_3 & -a_4^* & a_1^* & -a_2 \\ a_4 & a_3^* & a_2^* & a_1 \end{bmatrix}^T \begin{bmatrix} H_{1_QOSTBC4} \\ H_{2_QOSTBC4} \\ H_{3_QOSTBC4} \\ H_{4_QOSTBC4} \end{bmatrix} + \mathbf{N}^T_{\mathbf{QOSTBC4}} \tag{9}$$

where:

$$\begin{aligned} H_{1_QOSTBC4} &= h_{1,11} h_{MR,11} \\ H_{2_QOSTBC4} &= h_{1,12} h_{MR,11} \\ H_{3_QOSTBC4} &= h^*_{2,11} h_{MR,21} \\ H_{4_QOSTBC4} &= h^*_{2,12} h_{MR,21} \end{aligned} \tag{10}$$

and:

$$\mathbf{N_{_QOSTBC4}} = \mathbf{N_{MS_QOSTBC4}} + \frac{1}{\sqrt{2}}\mathbf{N_{R1_QOSTBC4}} \cdot h_{MR,11} + \frac{1}{\sqrt{2}}\left[-n^*_{R23_QOSTBC4} \quad -n^*_{R24_QOSTBC4} \quad n^*_{R21_QOSTBC4} \quad n^*_{R22_QOSTBC4}\right] \cdot h_{MR,21} \tag{11}$$

III. Proposed virtual QOSTBC scheme for creating 8x1 MISO channel

QOSTBC for system with eight transmit antennas is defined with [13]-[15]:

$$\mathbf{QOSTBC}_8 = \frac{1}{\sqrt{8}}\begin{bmatrix} a_1 & -a_2^* & -a_3^* & a_4 & -a_5^* & a_6 & a_7 & -a_8^* \\ a_2 & a_1^* & -a_4^* & -a_3 & -a_6^* & -a_5 & a_8 & a_7^* \\ a_3 & -a_4^* & a_1^* & -a_2 & -a_7^* & a_8 & -a_5 & a_6^* \\ a_4 & a_3^* & a_2^* & a_1 & -a_8^* & -a_7 & -a_6 & -a_5^* \\ a_5 & -a_6^* & -a_7^* & a_8 & a_1^* & -a_2 & -a_3 & a_4^* \\ a_6 & a_5^* & -a_8^* & -a_7 & a_2^* & a_1 & -a_4 & -a_3^* \\ a_7 & -a_8^* & a_5^* & -a_6 & a_3^* & -a_4 & a_1 & -a_2^* \\ a_8 & a_7^* & a_6^* & a_5 & a_4^* & a_3 & a_2 & a_1^* \end{bmatrix} \quad (12)$$

Here, a_i, i=1,…,8, are input symbols in QOSTB encoder. Average power spent per data symbol is fixed with scaling factor of $\frac{1}{\sqrt{8}}$. As it can be seen the code rate is 1, as in Sect. II.

Here we proposed new cooperative relaying scheme for creating virtual 8x1 MISO channel. The system model includes one BS, two RSs and one MS. BS and RSs are equipped with two antennas, while the MS is equipped with one antenna. BS transmits symbol sequences and the MS receives symbol sequences via two RSs. The system model is presented in Fig. 2.

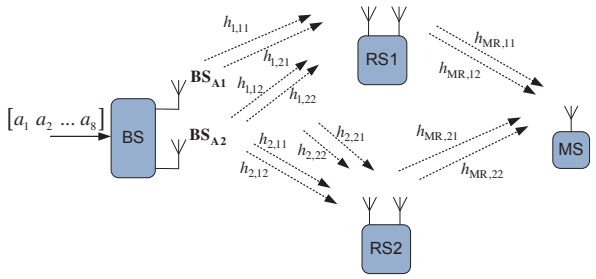

Fig. 2. The first proposed cooperative relaying scheme for virtual QOSTBC_8

We proposed that for every eight data symbols a_i, i=1,…,8, BS generates two symbol sequences:

$$\mathbf{BS_{A1}} = \frac{1}{\sqrt{2}}\begin{bmatrix} a_1 & -a_2^* & -a_3^* & a_4 & -a_5^* & a_6 & a_7 & -a_8^* \end{bmatrix}$$
$$\mathbf{BS_{A2}} = \frac{1}{\sqrt{2}}\begin{bmatrix} a_2 & a_1^* & -a_4^* & -a_3 & -a_6^* & -a_5 & a_7 & a_8^* \end{bmatrix} \quad (13)$$

Transmitted symbol sequences consist of eight symbols while the average power spent per data symbol is fixed with scaling factor of $\frac{1}{\sqrt{2}}$. It is assumed that all the symbols in a single sequence suffer from same fading condition.

The channel coefficient between the i-th, i=1,2, antenna at k-th RS, k=1,2, and the j-th, j=1,2, antenna at BS is $h_{k,ij}$.

Received symbol sequence at i-th antenna at k-th RS is:

$$\mathbf{RS}k_{\mathbf{A}i_\mathbf{in}} = \sum_{j=1}^{2} \mathbf{BS}_{\mathbf{A}j} \cdot h_{k,ij} + \mathbf{N}_{\mathbf{R}k,i} \quad (14)$$

$\mathbf{N_{Rk,}}_i$ is AWGN matrix at i-th antenna at k-th RS:

$$\mathbf{N}_{\mathbf{R}k,i} = [n_{Rk,i1}\ \ n_{Rk,i2}\ \ \ldots\ \ n_{Rk,i8}] \quad (15)$$

Here, $n_{Rk,is}$, s=1,…,8 represents AWGN at i-th antenna at k-th RS at s-th time slot.

At the first antenna RS1 generates the symbol sequence:

$$\mathbf{RS}1_{\mathbf{A}1_\mathbf{out}} = \frac{1}{\sqrt{4}}\mathbf{RS}1_{\mathbf{A}1_\mathbf{in}} \quad (16)$$

At the second antenna RS1 permutes the received symbol sequence, and generates output symbol sequence:

$$\mathbf{RS}1_{\mathbf{A}2_\mathbf{out}} = \frac{1}{\sqrt{4}}\Big[-\mathbf{RS}1^*_{\mathbf{A}2_\mathbf{in}}(3)\ \ -\mathbf{RS}1^*_{\mathbf{A}2_\mathbf{in}}(4)\ \ \mathbf{RS}1^*_{\mathbf{A}2_\mathbf{in}}(1)$$
$$\mathbf{RS}1^*_{\mathbf{A}2_\mathbf{in}}(2)\ \ -\mathbf{RS}1^*_{\mathbf{A}2_\mathbf{in}}(7)\ \ -\mathbf{RS}1^*_{\mathbf{A}2_\mathbf{in}}(8)\ \ \mathbf{RS}1^*_{\mathbf{A}2_\mathbf{in}}(5)\ \ \mathbf{RS}1^*_{\mathbf{A}2_\mathbf{in}}(6)\Big] \quad (17)$$

At the first and second antenna RS2 generates the symbol sequences:

$$\mathbf{RS}2_{\mathbf{A}1_\mathbf{out}} = \frac{1}{\sqrt{4}}\Big[-\mathbf{RS}2^*_{\mathbf{A}1_\mathbf{in}}(3)\ \ -\mathbf{RS}2^*_{\mathbf{A}1_\mathbf{in}}(4)\ \ -\mathbf{RS}2^*_{\mathbf{A}1_\mathbf{in}}(1)$$
$$-\mathbf{RS}2^*_{\mathbf{A}1_\mathbf{in}}(2)\ \ \mathbf{RS}2^*_{\mathbf{A}1_\mathbf{in}}(7)\ \ \mathbf{RS}2^*_{\mathbf{A}1_\mathbf{in}}(8)\ \ \mathbf{RS}2^*_{\mathbf{A}1_\mathbf{in}}(5)\ \ \mathbf{RS}2^*_{\mathbf{A}1_\mathbf{in}}(6)\Big] \quad (18)$$

$$\mathbf{RS}2_{\mathbf{A}2_\mathbf{out}} = \frac{1}{\sqrt{4}}\Big[\mathbf{RS}2_{\mathbf{A}2_\mathbf{in}}(3)\ \ \mathbf{RS}2_{\mathbf{A}2_\mathbf{in}}(4)\ \ -\mathbf{RS}2_{\mathbf{A}2_\mathbf{in}}(1)$$
$$-\mathbf{RS}2_{\mathbf{A}2_\mathbf{in}}(2)\ \ -\mathbf{RS}2_{\mathbf{A}2_\mathbf{in}}(7)\ \ -\mathbf{RS}2_{\mathbf{A}2_\mathbf{in}}(8)\ \ \mathbf{RS}2_{\mathbf{A}2_\mathbf{in}}(5)\ \ \mathbf{RS}2_{\mathbf{A}2_\mathbf{in}}(6)\Big] \quad (19)$$

Average power spent per data symbol is fixed with scaling factor of $\frac{1}{\sqrt{4}}$.

The channel coefficient between the i-th antenna at k-th RS and MS is $h_{\mathrm{MR},ki}$. The received symbol sequence at MS is:

$$\mathbf{MS}_{\mathbf{in}} = \sum_{k=1}^{2}\sum_{i=1}^{2} \mathbf{RS}k_{\mathbf{A}i_\mathbf{out}} \cdot h_{\mathrm{MR},ki} + \mathbf{N}_{\mathbf{MS}} \quad (20)$$

$\mathbf{N_{MS}}$ **is** AWGN matrixes at MS:

$$\mathbf{N}_{\mathbf{MS}} = [n_{MS1}\ \ n_{MS2}\ \ \ldots\ \ n_{MS8}] \quad (21)$$

With this relaying virtual 8x1 MISO channel is created between BS and MS, i.e.:

$$\mathbf{MS}_{\mathbf{in}}^{T}=\frac{1}{\sqrt{8}}\begin{bmatrix} a_1 & -a_2^* & -a_3^* & a_4 & -a_5^* & a_6 & a_7 & -a_8^* \\ a_2 & a_1^* & -a_4^* & -a_3 & -a_6^* & -a_5 & a_8 & a_7^* \\ a_3 & -a_4^* & a_1^* & -a_2 & -a_7^* & a_8 & -a_5 & a_6^* \\ a_4 & a_3^* & a_2^* & a_1 & -a_8^* & -a_7 & -a_6 & -a_5^* \\ a_5 & -a_6^* & -a_7^* & a_8 & a_1^* & -a_2 & -a_3 & a_4^* \\ a_6 & a_5^* & -a_8^* & -a_7 & a_2^* & a_1 & -a_4 & -a_3^* \\ a_7 & -a_8^* & a_5^* & -a_6 & a_3^* & -a_4 & a_1 & -a_2^* \\ a_8 & a_7^* & a_6^* & a_5 & a_4^* & a_3 & a_2 & a_1^* \end{bmatrix}^{T}\begin{bmatrix} H_1 \\ H_2 \\ H_3 \\ H_4 \\ H_5 \\ H_6 \\ H_7 \\ H_8 \end{bmatrix}+\mathbf{N}^{T} \tag{22}$$

where:

$$\begin{aligned} H_1 &= h_{1,11}h_{\mathrm{MR},11} \\ H_2 &= h_{1,12}h_{\mathrm{MR},11} \\ H_3 &= h_{1,21}^{*}h_{\mathrm{MR},12} \\ H_4 &= h_{1,22}^{*}h_{\mathrm{MR},12} \\ H_5 &= h_{2,11}^{*}h_{\mathrm{MR},21} \\ H_6 &= h_{2,12}^{*}h_{\mathrm{MR},21} \\ H_7 &= h_{2,21}h_{\mathrm{MR},22} \\ H_8 &= h_{2,22}h_{\mathrm{MR},22} \end{aligned} \tag{23}$$

and:

$$\begin{aligned} &\mathbf{N}=\mathbf{N}_{\mathbf{MS}}+\frac{1}{\sqrt{4}}\mathbf{N}_{\mathbf{R1,1}}\cdot h_{\mathrm{MR},11}+ \\ &\frac{1}{\sqrt{4}}\left[-n_{R1,23}^{*}\ -n_{R1,24}^{*}\ n_{R1,21}^{*}\ n_{R1,22}^{*}\ -n_{R1,27}^{*}\ -n_{R1,28}^{*}\ n_{R1,25}^{*}\ n_{R1,26}^{*}\right]\cdot h_{\mathrm{MR},12}+ \\ &\frac{1}{\sqrt{4}}\left[-n_{R2,13}^{*}\ -n_{R2,14}^{*}\ -n_{R2,11}^{*}\ -n_{R2,12}^{*}\ n_{R2,17}^{*}\ n_{R2,18}^{*}\ n_{R2,15}^{*}\ n_{R2,16}^{*}\right]\cdot h_{\mathrm{MR},21}+ \\ &\frac{1}{\sqrt{4}}\left[-n_{R2,23}\ -n_{R2,24}\ -n_{R2,21}\ -n_{R2,22}\ n_{R2,27}\ n_{R2,28}\ n_{R2,25}\ n_{R2,26}\right]\cdot h_{\mathrm{MR},22} \end{aligned} \tag{24}$$

IV. SIMULATION RESULTS

In this section the proposed scheme for creating virtual 8x1 MISO channel (QOSTBC$_8$) and the scheme for creating virtual 4x1 MISO channel (QOSTBC$_4$) are compared, regarding BER performance. The simulation results are presented under assumption that the propagation conditions are defined with Rayleigh fading statistics. Also, perfect estimation of channel coefficients and no direct link between BS and MS are assumed.

For the QPSK, 16QAM and 64QAM modulations BER performance in function of signal to noise ratio (SNR) per bit, of the proposed scheme and of the scheme with virtual QOSTBC$_4$ are presented in Fig. 3, 4 and 5, respectively. As it was expected it can be seen that the proposed scheme outperform scheme with QOSTBC$_4$, regarding BER performance.

For example, in the case of QPSK modulation and BER value of 10^{-5} we can see from Fig. 3 that for the proposed scheme the required SNR is smaller for 4.7dB in comparison with scheme with virtual QOSTBC$_4$. In the case of 16QAM modulation and BER value of 10^{-4} we can see from Fig. 4 that for the first proposed scheme the required SNR gain equals 3.8dB. In the case of 64QAM modulation and BER value of 10^{-3} we can see from Fig. 5 that for the first proposed scheme the required SNR is smaller for 2.4dB in comparison with scheme with virtual QOSTBC$_4$.

Obtained SNR gains are results of adding one more antenna per each RS in comparison with virtual QOSTBC$_4$.

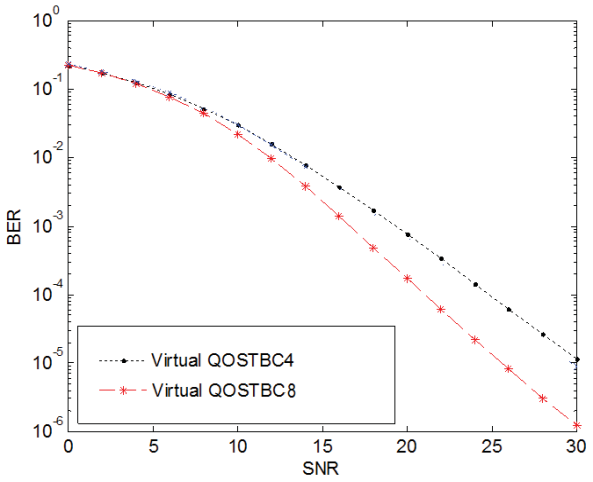

Fig. 3. BER performance of the proposed virtual QOSTBC$_8$ and virtual QOSTBC$_4$, QPSK modulation

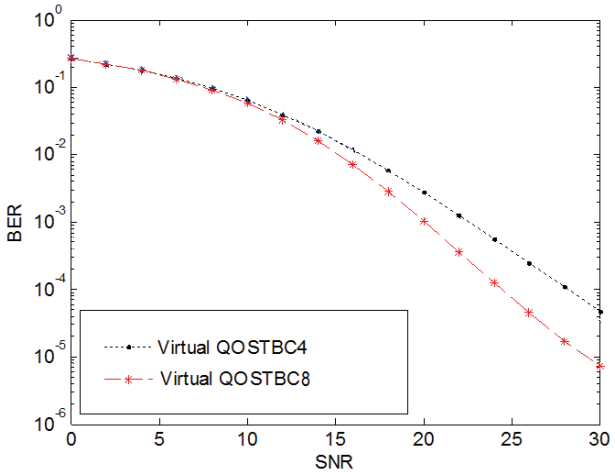

Fig. 4. BER performance of the proposed virtual QOSTBC$_8$ and virtual QOSTBC$_4$, 16QAM modulation

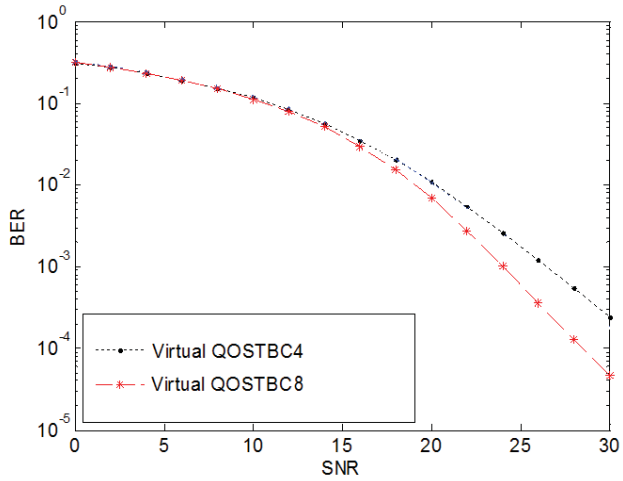

Fig. 5. BER performance of the proposed virtual QOSTBC$_8$ and virtual QOSTBC4 scheme, 64QAM modulation

V. CONCLUSIONS

In this paper we propose new distributed QOSTBC scheme for creating virtual 8x1 MISO channel. The proposed scheme assumes one BS, two RSs, and one MS. BS and RSs are equipped with two antennas, while MS is equipped with one antenna. The procedure at the RS is reduced due to omitting the decoding process. There is no need for detection and space-time decoding at RS. The procedure at RS is just permutation and forwarding of the signal sequences. There is no need for detection and space-time decoding at RS. The proposed scheme and the scheme for creating virtual 4x1 MISO channel are compared, regarding BER performance. It is assumed that the propagation conditions are defined with Rayleigh fading statistics. The simulation results show obtained BER performance improvements, i.e. SNR gains provided by proposed scheme.

ACKNOWLEDGMENT

The results presented in this paper are part of the "Improving the concept of MIMO communications in cellular networks of the next generations" research project, funded by Montenegrin Ministry of Science. Also, work is funded by European Union project Fore-Mont as a part of Seventh Framework Programme (Grant Agreement No. 315970 FP7-REGPOT-CT-2013) http://www.foremont.ac.me. Also, this work has been supported by the Ministry of Science of Montenegro and the HERIC project through the BIO-ICT Centre of Excellence (Contract No. 01-1001).

***Abstract*— Total Productive Maintenance (TPM) is widely being used in industries for manufacturing excellence. TPM is based on eight pillars. Successful Implementation of TPM depends on in-depth knowledge of these pillars. The purpose of the paper is to understand the importance of these pillars mutually in terms of Quality, Cost, Delivery in time and Productivity (QCDP). In this work, ranking of TPM pillars is done by a questionnaire-based review by using Analytic Hierarchy Process (AHP), a multiple criteria decision-making (MCDM) methodology. A pairwise comparison of TPM pillars is done by survey considering a case of automotive industries in India. Ranking of TPM pillars is proposed to guide the management to decide the weightage of each pillar in terms of major factors to improve Overall Equipment Efficiency (OEE). This in terms will guide them to give proper preference and allocate fund at proper time to proper pillar. The ranking suggested suites for automotive sector and assembly lines. By varying the judgemental rating according to type of industrial sector the new ranking can be obtained from the suggested guidelines on similar basis.**

Keywords— Analytical hierarchy process (AHP); Total productive maintenance(TPM); TPM pillars

I. INTRODUCTION

In today's competitive world, it is a great challenge for industries to achieve World class excellence. To cope up with the globalized economy, manufacturers are facing stiff competition. It is a tedious task to produce maximum with minimal resources and finances available, with eminent quality and timely deliverance. Proper production planning and timely maintenance with zero defects can cause the system pull through. Proper implementation of Total Productive Maintenance (TPM) will lead the industries towards manufacturing excellence.

TPM is based on eight pillars with the foundation of 5S (Sort, Set in order, Shine, Standardize, and Sustain)[1]. It is not an easy task to understand and implement TPM, as if a set of standard procedures which, when implemented will give the results[2]. TPM is widely used to improve effective use of equipment's and to obtain world class manufacturing system in terms of Quality and Cost[3]. Successful implementation of the TPM is a team work in which individuals from each and every department should work together, it is employee focused. Due to experience and expertise operator knows more about his machine and process. In most of the case studies, barriers in implementing TPM are discussed[4][5]. It is reflected that successful implementation of TPM is difficult without the support of top management. Financial constraints are more important as per the management is concerned. If management is convinced properly, then the major hurdle in the TPM implementation will be taken away. To merge the gap it is needed to present the analytical approach, to formulate a quantitative analysis of the TPM process to focus on the most important pillar. Top management can lead discussions as per budgetary provision or can allot extra fund for TPM implementation. Detailed review of the Industries shows that only some of the areas are being focused. Survey in Indian industries reflects the limitations of TPM implementation[6]. It is mainly due to lack of knowledge and fear of investments in terms of returns.

Considering all these factors, it is important to identify the priority of the TPM pillar analytically so that the management is convinced to implement the changes step by step and monitor the returns and see the improvement in OEE to make the industry to achieve world class excellence[7].

This paper thus proposes ranking of the eight TPM pillars, as per their significance in terms of four major parameters Quality, Cost, Delivery in time and Productivity (QCDP). A pairwise comparison is done showing their hierarchy, by using Analytic hierarchy process (AHP). AHP makes it possible to assess the criteria's based on the experience [8]. Based on the survey conducted in Indian industries, the ranking of pillars is made in hierarchical order. This makes it easy to focus on the particular task of comparatively higher priority and the judgmental forecast can be done with saving plans. As per hierarchy of pillars, priority can be given to the critical maintenance activities, with optimum use of the resources, which will increase Overall Equipment Efficiency (OEE).

II. LITERATURE REVIEW

TPM plays vital role in making the industry world class, measured by Overall Equipment Efficiency (OEE). TPM kick-off takes place in many industries but very few are able to successfully implement it. To the best of author's knowledge, most of the literature discusses the failures due to improper implementations of the TPM. Review of TPM implementation in the Indian Service sector shows a tendency of people react to

implement new things, approach of top management to curb down the budget for several activities, problem of purchase and replacement of material, visionary approach and management support, are some of the factors bearing on effective implementation of TPM in Indian industries[7].

Significant review of TPM implementation in Indian industries is addressed by Ahuja & Khamba[1][9], Gupta and Vardhan[10]. TPM initiatives in steel plant, highlights how TPM implementation improved the production facilities in terms of four major criteria's – QCDP. In typical Indian industry, holistic approach for TPM needs to be implemented successfully. Team work, motivation and continuous improvement are necessary factors for positive results.

It is discerned that Indian industries are facing challenges because of many reasons like – sluggish response to change with the current market scenarios, traditional organizational structure, low quality and productivity, lacking in employee skill, education, motivation and safety, low automation, more wastage, failure to delivery in time, costumer complaints, taxes and infrastructural lacunas. According to Attri[5] et al. barriers to implementation of TPM in Indian industry can be classified as : Behavioral, Technical, Human and Cultural, Strategic and operational. Whereas Ahuja[4] has classified the barriers as : i) Organization – inability to change managerial & cultural approach, inability to convince unions, wrong focus on TPM, improper communication from top to bottom, ii) Cultural – resistance to change traditional approach, lack of consistency, iii) Behavioral - resistance from employees to adopt new changes, iv) Technological – little effort to improve design, reliability, lack of training and skills, v) Operational – acceptance of high rejection, lack of implementing standard procedures, absence of planned maintenance, vi) Financial – additional fund required in beginning to implement TPM, financial constraints from top management. vii) Departmental – poor team work.

For successful implementation of TPM it is important to find proper hierarchy of TPM pillars with respect to QCDP.

This can be done through pairwise comparison by Multi Criteria Decision Method (MCDM). Martin et al.[11] summarized various MCDM methods with its application. AHP suits for ranking the pillars, as pairwise comparison between the pillars with respect to the criteria's can be easily done. Lot of improvements are been done through TPM in Indian industries by using AHP. But only the importance of TPM verses Traditional maintenance system (TMS) is analyzed[12]. Similar attempts are being made by other researchers to justify TQM by using AHP[13]. Proper application of AHP or any other analytical method for hierarchy of TPM pillar is missing.

Use of AHP is found in various Production/manufacturing applications, N. Buyurgan presented a framework in advanced manufacturing[14], Madu implemented it for improving maintenance float system[2]. Ishizaka and Labib described its use for process ordering method[15]. This technique is applied in many areas social, personal, education, engineering, manufacturing, banking, sports, government[16] and many more fields and showed good results. No attempt has been made to use it for TPM. Attempt has been made to rank the TPM pillars by using AHP.

III. BACKGROUND

Brief regarding the TPM pillars and AHP process is given herewith:

A. TPM Pillars: Abbrivations used

TPM pillars and abbreviations used are shown in Fig. 1

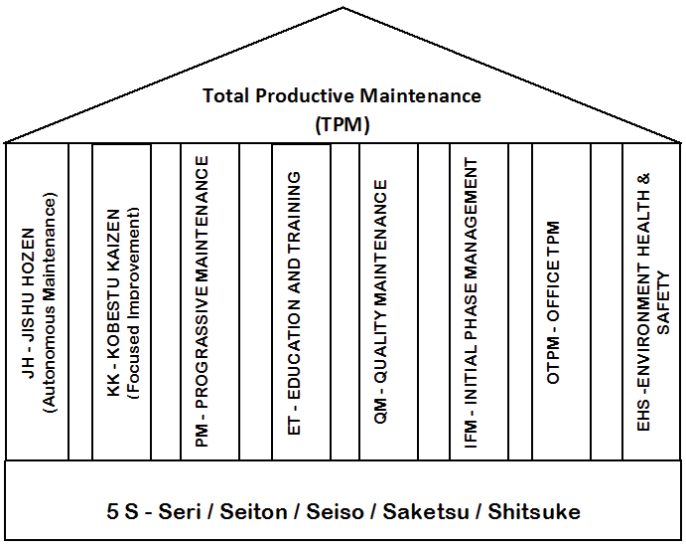

Fig. 1. TPM Pillars

TPM is based on eight pillars with a base of 5S. The goal of 5S is to create a clean and well-organized work environment.

Pillar 1: JH is mother pillar. It brings the ownership approach in the operator. Cleaning and maintenance is taken care by the the operator himself.

Pillar 2: KK aims to identify and minimize waste, quality and manufacturing losses. Elimination of losses helps improving OEE.

Pillar 3: PM pillar deals with Preventive break down (Time Base Maintenance). It establish Preventative and Predictive Maintenance systems for equipment and tooling. Effectiveness of maintenance department is increased to the point where 8 big losses are not generated.

Pillar 4: ET boost the moral and expertise of the operators and persons involved by to providing soft skill training and technical training.

Pillar 5: QM pillar monitors the factors affecting variability in product quality. It focus to accomplish zero quality defects.

Pillar 6: IFC establish systems to shorten new product or equipment development prototyping lead time. Achieve stable commissioning of new product and equipment vertical start up.

Pillar 7: OTPM goal is to achieve zero functional losses, create highly efficient offices and provide effective service and support to other departments. Administrative and support departments can be seen as process plants whose principal tasks are to collect, process, and distribute information. Process analysis should be applied to streamline information flow

Pillar 8: SHE Assures safety and prevents adverse environmental impacts which are important priorities in any

TPM effort. EHS achieve and sustain zero accidents, creates healthy, rewarding and pleasant workplace.

B. *Analytic Hierarchy Process*

Analytic Hierarchy Process (AHP) was developed by Thomas L. Saaty in 1970's[8]. It is used for multi criteria decision making in which the factors are arranged in a hierarchic structure. An advantage of the AHP over other MCDM methods is that AHP is designed to incorporate tangible as well as intangible factors, especially where the subjective judgments of different individuals constitute an important part of the decision process.

A pairwise comparison method is used to calculate relative values between each TPM pillar with respect to each other for four criteria's QCDP. A scale of judgments ranging from 1 to 9 (equal to extreme) is used for rating.

The methodology of AHP consists of following steps[17]:

Step 1: Statement of Problem having Attributes and Criteria.

Step 2: Represent problem in form of tree.

Step 3: Pairwise comparison of alternatives

Step 4 Formation of square matrix of above comparison.

Step 5: Normalization matrix is formed from eigenvalues and eigenvectors (weights)

Step 6: Check Consistency of the matrix by calculating the Consistency Index, CI. The value of CI should be less than 0.1 as recommended by Saaty.

Step 7: Obtain local & global ratings.

Step 8: Priorities or overall goal.

IV. OBJECTIVE

The objective of the research paper is to rank TPM pillars in terms of their importance in contributing to the factors QCDP of Industrial excellence using AHP developed by Thomas L. Saaty[8] for the excellence of Indian industries. Pairwise comparison of each pillar considering each criteria is done. Influence of Moral and Safety is equal with respect to each pillars, there contribution is not significant as compared to other criteria's. So analysis is carried out by considering QCDP criteria's only.

This research is based on providing the best possible solution with an analytical approach to the present theoretical concept of TPM. The study focuses on Indian industries where the TPM is not effectively implemented. During the survey for ranking of the pillars, it was clear that the TPM kick off takes place, but it is not implemented properly and over a period of time it stops. Failure occurs due to one or more constraints and barriers as discussed. The main reason is involvement of management and availability of fund for implementing the things at right time in right place. If the management is convinced by proper grading of the pillars it will be easy to allocate the fund at proper time. Ranking will give the proper focus and set the priorities for the budget. This will help in successful implementation of TPM, in terms increase in OEE.

V. METHODOLOGY

A survey was conducted based on the questioner using 9 point rating scale of Saaty for AHP[8]. Companies from Automobile and assembly sectors were considered for the survey. Following points were considered while selecting the company for survey:

a) The industry should have 5S culture, ensuring environmental cleanliness, safety and comfort. Thus the role of the criteria's Safety and Moral shall not be reckoned in determining hierarchy based on QCPD.
b) This will be more rational if the Industry happens to be an engineering Industry of Assembly type instead of a Process plant where dust and contamination of air, water etc. is dominant.

A. *Collection of Data*

Analysis is based on the data collected from Indian industries. As a part of research methodology the paired comparison data is collected in consultation with the management representatives of some companies or other persons responsible for TPM implementation. The management representatives have overall responsibility of TPM planning and implementation and they are appointed by the CEO of the company. Apart from them, consult of various pillar heads of the industry are taken to make the data more authentic. Each of these pillar heads is an experienced senior manager aware of all the pillars and their impact on QCDP. A questioner is designed based on 9 point rating scale for AHP.

B. *Ranking of TPM Pillars*

Analytical Approach: A study of literature on TPM reveals that most of reported information describes the eight pillars in a QUALITATIVE manner without resorting to utilize mathematical modelling. Most of the literature available gives an account of how a certain industry applied TPM and achieved increased productivity, quality, etc. at reduced cost. It is almost a monotonous repetition of the eight pillars. There is a need to make a proper attempt to rank the pillars in a QUANTITATIVE way so as to be a helpful guideline for research into Total Productive Maintenance.

Analysis is carried out by using paired comparison of each of the eight pillars with the objectives: Quality, Cost, Productivity and Delivery on time. The paired comparison helps in calculating the relative score of each of the TPM pillars on the four criteria. Next the four criteria are compared with each other through paired comparison to find the weightage of each of the criteria. Finally, on multiplying the scores of the eight TPM pillars, the summed, weighted score of these pillars is calculated. This helps in identifying the most important pillar on the overall ranking.

C. *AHP for Ranking of the pillars*

For the objective to rank eight pillars of TPM with respect to their importance towards QCPD, AHP process is used to find the hierarchy of the pillars as follows:

1. *Criteria and Attributes*

For ranking of the TPM pillars, its eight pillars are criteria's and Quality, Cost, Delivery in time and Productivity (QCDP) are considered as attributes.

2. *Hierarchy of Decision*

The hierarchy of the attributes and criteria are shown in Fig. 2.

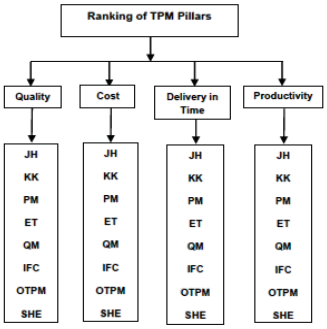

Fig. 2. Hierarchy of Decision

3. *Pairwise comparison scale*

Scale for AHP: Standard 9 point rating scale proposed by T.L. Saaty[18] is used for rating the pillars.

4. *Pairwise comparison matrix*

A questioner was generated to rate the pillars with respect to each other, sample shown in Table I. Nine point Linkert scale is used for rating the pillars with respect to each other.

TABLE I. SAMPLE VALUES FROM QUESTIONEER

Factor	Factor weighting Score - Quality																Factor
	More important than								Equal	Less important than							
JH	9	8	7	6	5	4	3	2	1	2	3	4	5	6	7	8	9	PM
JH	9	8	7	6	5	4	3	2	1	2	3	4	5	6	7	8	9	OTPM

Based on the ratings given a pairwise comparison matrix is prepared for each criteria. Table II shows rating of various pillars considering Cost as the criteria.

TABLE II. CRITERIA QUALITY: PAIRWISE COMPARISON

	JH	KK	PM	ET	QM	IFC	OTPM	SHE
JH	1.00	6.00	1.00	4.00	1.00	6.00	8.00	8.00
KK	0.17	1.00	0.50	0.50	0.50	1.00	6.00	8.00
PM	1.00	2.00	1.00	4.00	0.50	6.00	8.00	8.00
ET	0.25	2.00	0.25	1.00	0.50	6.00	8.00	8.00
QM	1.00	2.00	2.00	2.00	1.00	8.00	8.00	8.00
IFC	0.17	1.00	0.17	0.17	0.13	1.00	1.00	4.00
OTPM	0.13	0.17	0.13	0.13	0.13	1.00	1.00	4.00
SHE	0.13	0.13	0.13	0.13	0.13	0.25	0.25	1.00

Similarly, based on the data from questionner, matrix are obtained for other criteria. Table III, IV and V shows rating for Cost, Delivery in time and Productivity respectively.

TABLE III. CRITERIA COST: PAIRWISE COMPARISON

	JH	KK	PM	ET	QM	IFC	OTPM	SHE
JH	1.00	1.00	1.00	4.00	1.00	4.00	0.50	4.00

IFC	0.13	0.13	0.13	0.17	0.13	1.00	0.50	0.50
OTPM	0.17	0.17	0.17	0.25	0.17	2.00	1.00	4.00
SHE	0.25	0.17	0.17	0.25	0.17	2.00	0.25	1.00

5. *Normalization*

Table VI gives the calculations for normalization matrix for various pillars with respect to Quality as a criteria.

TABLE VI. CRITERIA QUALITY: NORMALIZATION MATRIX

	JH	KK	PM	ET	QM	IFC	OTPM	SHE
JH	0.261	0.420	0.194	0.336	0.258	0.205	0.199	0.163
KK	0.043	0.070	0.097	0.042	0.129	0.034	0.149	0.163
PM	0.261	0.140	0.194	0.336	0.129	0.205	0.199	0.163
ET	0.065	0.140	0.048	0.084	0.129	0.205	0.199	0.163
QM	0.261	0.140	0.387	0.168	0.258	0.274	0.199	0.163
IFC	0.043	0.070	0.032	0.014	0.032	0.034	0.025	0.082
OTPM	0.033	0.012	0.024	0.010	0.032	0.034	0.025	0.082
SHE	0.033	0.009	0.024	0.010	0.032	0.009	0.006	0.020

Normalization matrix for other criteria can be obtained similarly.

6. *Consistency Check*

Saaty[18] proposed that the consistency index should be less than 10%, if not the priorities does not make any sense and the judgements may need to be revised for various pillars with respect to Quality as a criteria. Consistency check is conducted after normalization matrix.

Table VII shows the Consistency check for the above normalization results.

TABLE VII. CRITERIA QUALITY: CONSISTANCY CHECK

	Weights	Products	Ratio
JH	0.2544	2.3963	9.4196
KK	0.0910	0.7891	8.6750
PM	0.2033	1.9168	9.4296
ET	0.1292	1.1859	9.1787
QM	0.2312	2.0604	8.9131
IFC	0.0416	0.3625	8.7180
OTPM	0.0315	0.2622	8.3282
SHE	0.0179	0.1498	8.3547
		CI =	0.1253
		CI / RI =	0.09

As consistency ratio CR is less than 10% the matrix can be considered as having an acceptable consistency.

Similarly weightage are found for cost, delivery in time and productivity.

7. Ratings

After comparing all the pillars with respect to different criteria's, the criteria's are also compared with respect to each as per the priority. Weightage for QCDP are tabulated below. The comparison matrix for QCDP is in Table VIII.

TABLE VIII. PAIRWISE COMPARISM OF QCDP

	Q	C	D	P
Q	1.00	4.00	2.00	1.00
C	0.25	1.00	0.50	0.17
D	0.50	2.00	1.00	0.50
P	1.00	6.0	2.00	1.00

8. Overall Goal

Finally the percentage weightage are calculated in Table: IX. The graphical representation of the hierarchy obtained by AHP is shown in Fig. 3.

TABLE IX. SCORE OF THE PILLARS

Pillar	% Weightage				
	Q	C	D	P	Overall %
JH	25.44	15.18	11.44	21.43	**20.581**
KK	9.10	19.15	22.29	28.73	**19.903**
PM	20.33	19.15	19.31	16.92	**18.722**
ET	12.92	5.71	10.50	8.14	**10.048**

VI. RESULTS AND DISCUSSION

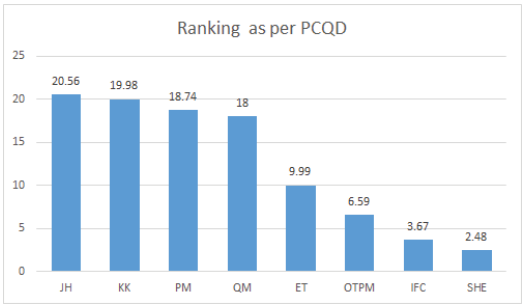

Fig. 3. Ranking of TPM pillars as per contribution towards criterias PCQD

In case of TPM implemented industries it can be seen that out of eight pillars JH and KK are used more number of times than other six. JH & KK pillars has the maximum weightage, with marginable difference. JH focus on improvement of Quality which enhances productivity whereas KK has high impact on Productivity by reducing various losses, increased production rate maintaining prompt delivery schedule followed by reduction in manufacturing cost. It is recommended to start implementing TPM with JH pillar followed by KK. After that the focus on PM & QM pillars. Once all these are in action, it will be enhanced with ET & OTPM pillar activities. IFC and SHE can be followed thereafter.

VII. CONCLUSION AND FUTURE SCOPE

The results obtained helps to categorize the pillars according to priority as: top priority (JH and KK), medium (PM and QM) and low priority (ET, OTPM, IFC and SHE). It will be easy for the managers to convince the top management and attract attention on the pillars with top most priority. However the results obtained will work for particular set of companies, it should not be treated as universal. The survey results are for automobile components manufacturing industries. According to the type of industries the rating can be varied and the new hierarchy can be obtained easily. For chemical industry top priority may go to pillar SHE, whereas for service industries it may be OTPM.

***Abstract*—The Internet of Things (IoT) paradigm is gaining tremendous popularity and the number of connected devices, or "things", is continuously growing, aiming to transform our everyday life. In order to address the real needs of the end user, the capabilities of the individual "things" have to be combined and offered as "services". The use of a local cloud of gateways that aggregate and analyze the data of different heterogeneous IoT devices and expose unified service oriented interfaces in support of machine-to-machine (M2M) applications has been presented in earlier works. This paper proposes a novel software-defined networking (SDN)-enabled IP Multimedia Subsystem (IMS) architecture that aims to facilitate the provision of IoT-based services over an all-IP telecom service provider's network. The architecture combines the advantages of reduced network complexity and improved efficiency of network utilization that SDN brings with the standardized approach of service deployment and management over all-IP networks, offered by IMS.**

Keywords—IoT, SDN, IMS, fog computing, BETaaS

I. INTRODUCTION

The concept of Internet of Things (IoT) incorporates the vision of ubiquitous virtual connectivity of billions of physical objects or "things" through a global network infrastructure with interoperable, self-configuring and scalable capabilities. "Things" might be part of various application domains and therefore are represented by different types of devices that have heterogeneous technical parameters and communication capabilities. This imposes various technical challenges in terms of adaptation, context awareness, device discovery and management, scalability, managing a large data volumes, privacy, and security.

The "Building the Environment for Things as a Service" (BETaaS) paradigm is the outcome of a successful research initiative [1] that leverages the concept of fog computing, and introduces the novel concept of 'Things as a Service' (TaaS) in support of machine-to-machine (M2M) applications. Fog computing [2] was introduced as a concept to cut down the amount of data that needs to be transported to the cloud and, thus, to reduce the processing burden of cloud systems, by implementing data processing, storage, analytics and networking closer to the network edge. BETaaS extended the fog computing paradigm by introducing a local cloud of M2M gateways that aggregate and analyze the data of different heterogeneous IoT devices and expose unified service oriented interfaces that can be used to access the things connected to the local cloud, thus introducing the concept of TaaS. This approach offers distinct benefits such as reduced network complexity, reduced amount of transported data, generated by the things and homogeneous service oriented interfaces that can provide access to different types of devices that have heterogeneous technical parameters and communication capabilities. In order to fully exploit the benefits of the exposed IoT services, however, an efficient mechanism for service deployment, management and delivery to the end users is needed.

The current paper addresses the main challenges for IoT integration and proposes a novel Software Defined Networking (SDN)-enabled IP Multimedia Subsystem (IMS) architecture that aims to offer a possible solution. IMS is a technology that manages session establishment, management and termination via SIP (Session Initiation Protocol) protocol in order to enable service deployment over all-IP networks. IMS provides common IP interface that simplifies signaling and application development and facilitates handling of multiple sessions that might be used by different applications. Furthermore, IMS enables access control and billing handling, which allows consistent management of the different applications on the network [3, 4]. The benefits of introducing IMS to the IoT domain have already been examined by several research teams. In [5] a generic IMS framework for integration of IoT networks and cloud computing networks is described and the implementation issues of such integration are examined. A cloud-based implementation of the generic framework is later described in [6], where the core IMS components are virtualized into a resource pool and provided as Infrastructure as a Service (IaaS). The framework concept is further extended in [7], where a mechanism for object management and naming, based on IMS uniform resource identifiers (URI) is proposed. The paper introduced a naming delivery agent that utilized SIP 'MESSAGE' messages to assign specific URIs to the 'things'. In [8] the integration of IoT devices into a SIP-IMS platform is considered in context of WLAN-3GPP networks. Different SIP message flows are designed to provide different IoT functions, such as registration, transmission of streaming data and notifications, based on query/report messages. Finally, in [9] a carrier class IoT service-oriented architecture that integrates IMS with wireless sensor networks (WSN) is prototyped. The architecture utilizes sensor web enablement (SWE) framework to tackle the heterogeneity of IoT devices, by introducing two main components – an enabler that introduces IoT services to the telecom operation platform, and a gateway that interconnects the enabler and the WSN. As a proof of concept the proposed design was implemented in an application scenario with 20 WSN nodes and the network load

was evaluated, showing that the introduction of the M2M gateway effectively reduces the generated data traffic.

The current paper proposes an architecture for the provision of IoT-based services over an all-IP telecom service provider's networks, while facilitating the development and implementation of innovative networking solutions. We take the IoT IMS integration a step further by introducing SDN-based virtualization of the IMS core elements as a solution to meet the challenges of increased traffic and network complexity. SDN is defined by the Open Network Foundation as a technology where "network control is decoupled from forwarding and is directly programmable".

Previously related work, proposed an implementation of various software modules that can exert dynamic control on the network functions, for support of the network expansion and innovation and for more efficient utilization of network resources [10]. One of the main advantages of SDN is believed to be its capability to route efficiently the traffic flows, thus facilitating the support of quality of service (QoS) differentiation. In [11], an SDN and IMS converged infrastructure is presented, which incorporates an OpenFlow controller that communicates with IMS application servers via RESTful application programmable interfaces (APIs). This allows application-based QoS classification and data flow routing. OpenFlow integration within IMS is also proposed in [12], where a research SDN IMS testbed is designed.

The rest of the paper is organized as follows: Section II summarizes the challenges for IoT integration within the existing network infrastructures and outlines how the novel design tackles these issues. Section III gives a short overview of the enabling functionalities for the exposure of IoT-based services. Furthermore, a deeper inside on the mechanisms for SDN IMS convergence is proposed. Section IV describes the component and features of the proposed architecture. Finally, Section V concludes the paper and outlines the direction of the future research.

II. CHALLENGES FOR IOT INTEGRATION

ITU define IoT as "a global infrastructure for the information society enabling advanced services by interconnecting (physical and virtual) things based on existing and evolving, interoperable information and communication technologies." In order for this futuristic vision to become reality, however, a range of technological challenges are yet to be overcome. Some of the main enabling technologies and the corresponding research issues have been discussed in [13] and [14] and briefly summarized below. The proposed technologies to address these issues are also outlined.

Architecture – an open architecture that will enable interoperability and of a large number of heterogeneous devices and distributes resources is needed. Moving the intelligence at the edge of the network is identified as a possible approach to address these issues. The current paper proposes an architecture that combines two novel technologies, SDN and IMS, which offer access to an agnostic environment for the creation, deployment and management of converged telecommunications services. Furthermore, the design integrates the M2M development and execution platform – BETaaS – which tackles the heterogeneity of IoT devices and leverages the concept of fog computing to bring some of the intelligence to the edge of the network.

Identification - creating a digital identity of the 'things', defined by a digital name and the relationships between things in the digital domain is vital for realizing the IoT vision. The identities should be globally unique, offer significant consistency and enclose the multiple existing identifiers, such as identifiers, assigned by the manufacturer and network IPv6 addresses. A possible solution, proposed in [7] and adopted in the current design, is the utilization of IMS/SIP uniform resource identifiers (URI).

Communication Technologies – the utilized communication technologies should allow efficient communication between things, between things and human users, between things and the Internet. Furthermore, access to distributed units for data collection, data mining and information processing should be provided. In the proposed architecture, the powerful capabilities for session management of IMS, combined with the SDN techniques for flow control provide an efficient communication environment for the creation and deployment of IoT services.

Network Technologies – should provide ubiquity of access of almost anything, anywhere, offering scalability and reliable identification and tracking of the various objects in the IoT domain. The implementation of IPv6 over SDN, combined with IMS URIs, can bring the required scalability and consistency of identification of the expected huge number of interconnected IoT objects.

Service Discovery – automated discovery and mapping mechanisms will be essential for the efficient network and communication management and the utilization of the IoT resources. The discovery mechanisms need to be dynamically adaptable and continuously evolving to accommodate changing topologies or changing user needs. The IMS service discovery mechanisms, integrated by the Service Capability Interaction Manager (SCIM), might offer an efficient solution for service composition and service interaction.

Data and Signal Processing – the expected massive number of interconnected devices will generate huge amounts of data traffic. In order to utilize efficiently these resources, different mechanisms for edge processing, filtering and aggregation, semantic interoperability, data sharing and collaboration, QoS and streaming processing are needed. The concept of fog computing, realized by BETaaS local cloud, offers implementation of such capabilities closer to the network edge.

Network Management – the huge number of devices and the increasing complexity of communication networks predetermine the need of improved resource allocation techniques, which incorporate traffic and congestion management and resource reservation for time-critical and life-critical data flows. SDN concentrates the network intelligence in software-based central controllers, provides more efficient control, customizability and adaptability.

Security, Trust and Privacy – the high penetration of the interconnected devices that will expose even more information about our environment, habits and needs will pose new security and privacy problems in terms of confidentiality, authenticity and integrity of data. Efficient mechanisms that

prevent unauthorized identification and tracking will be of primary importance. The BETaaS platform implements security mechanisms that monitor the environment and retrieve and impose security policies in order to prevent malicious behavior or unauthorized access. Additionally, the IMS framework provides the means for user authentication and IPsec association with the IMS terminal.

Standardization – in order to ensure high degree of interoperability between a large number of heterogeneous devices and systems the definition and use of standard interfaces and data models is needed. IMS technology specifications are defined by 3GPP's Services and System Aspects group. Regarding SDN, the Open Networking Foundation is responsible for the technology's promotion, adoption and open standards development.

III. Enablers of IoT-Based Services

A. M2M development and execution platform: BETaaS

BETaaS is an M2M development and execution platform based on a distributed runtime environment made of a so-called local cloud of nodes that allows accessing things connected to the platform regardless of their access technology and location. It creates a horizontal runtime platform. Its distributed architecture also allows for the computation (i.e. M2M application) to run in close proximity to the physical thing, which is a crucial enabler for the M2M applications that require fresh information from the physical thing [1].

The BETaaS high level architecture consists of three main layers: Adaptation, TaaS (Things as a Service), and Service, which is shown in the left hand side of Fig. 1. This structure guarantees the proper level of abstraction to the applications at the top and the flexibility in integrating different M2M systems at the bottom. At the bottom layer, BETaaS integrates heterogeneous M2M systems at the physical layer into a unified M2M system thanks to the Adaptation layer. The adaptation layer allows plugins to be dynamically added and deployed into the platform to accommodate different M2M systems, e.g. ETSI M2M, CoAP, and even some proprietary systems, within the platform. The plugins provide interfaces to the higher layer components and convert the request from the later into their respective M2M systems. On top of the adaptation layer, the TaaS layer provides an abstract and uniform description of the underlying M2M systems regardless of the technology, communication protocol, and physical location. The TaaS paradigm defines a service for each thing connected to the platform; a thing service is created to represent the basic service(s) that can be exposed to the applications in a content-centric manner. the TaaS layer is implemented in a distributed fashion to cooperatively share resources among gateways. This approach allows for the application to transparently access thing services irrespective of the gateway that provides the physical thing connection. On top of the TaaS layer, the Service layer is designed to define the platform interface to the external applications. In general, the Service layer exposes all of the available thing services in the platform as basic services allowing the applications to interact with the things connected to the platform. In addition to the basic services, this layer also allows for the dynamic deployment of a so-called extended service, from a third party

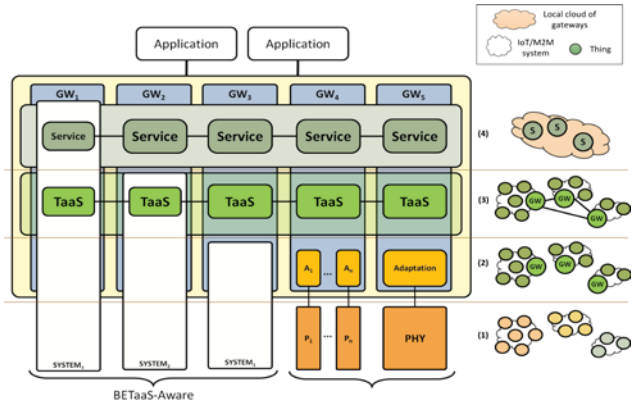

Fig. 1. BETaaS high level architecture

[1], which opens the opportunity to establish a marketplace of extended services that can be installed on demand by users [18].

B. SDN-based IMS implementation

IMS is identified in [4] as the enabling technology for the creationof a service environment over disparate all-IP networks and a step towards the Service Oriented Architecture (SOA). It provides a mechanism for session management of services, such as video conferencing and voice over IP, and open APIs for third-party access and web services integration. Furthermore, it aims to ensure relevant QoS parameters for different classes of services and to enforce the service level agreements (SLAs). In these aspects, the SDN-enabled implementation of the IMS core can be particularly beneficial, because of the powerful capabilities of adapting the network flow to the bandwidth and traffic changes and the management of virtualized resources. Such implementation will provide a synergic environment for the development and the deployment of innovative services.

Several open source implementations of the IMS core have been proposed. Two of the notable examples include the OpenIMS [15] and the Project Clearwater [16]. Project Clearwater proposes a cloud-oriented design that claims to be extremely suitable for deployment in network functions virtualization (NFV) environments. It is based entirely on open source components and supports all standardized interfaces related to the IMS core. The OpenIMS, on the other hand, offers an open source implementation IMS Call Session Control Functions (CSCFs) and a lightweight Home Subscriber Server (HSS). It does not target carrier grade deployments, but rather aims to accelerate the IMS development and adoption. It has served as the basis of the SDN-based OSIMS open source IMS experimentation platform [11].

IV. Proposed Architecture

The proposed architecture leverages the TaaS concept, defined by the BETaaS paradigm, in order to facilitate the provision of IoT-based services over an all-IP telecom service provider's network. The main purpose of the design, described in the current paper, is to offer not only an open environment for the development and deployment of innovative user-centered services, but also an architecture that targets provider

related issues, such as improved resource utilization, simplified network management, billing and access approval for the provided services. In order to address the aforementioned requirements and to tackle the various IoT-related technological challenges, described in Section II, the proposed design combines the advantages of two novel technologies - SDN and IMS - which both focus on making the network infrastructure horizontal and on the service exposure to third parties. The architecture design, shown in Fig.2, follows a layered approach distinguishing between an access layer, a transport layer, a control layer and an application layer. The current paper focuses mainly on the SDN and IMS integration, service creation, deployment and management and therefore the access and transport layers' functionalities will only be briefly mentioned.

A. Access Layer

IMS provides a standardized framework for service creation and deployment over all-IP networks, independent of the access technology, supporting mobile, wireless and wireline telecommunication environments. From the IoT device perspective, the BETaaS Adaptation Layer (described in Section III) integrates heterogeneous M2M systems at the physical layer into a unified M2M system, thus addressing the challenge of interoperability between the existing IoT technologies.

B. Transport Layer

SDN decouples the control plane and the data plane and concentrates the data forwarding decisions into a centralized software controller. A common standardized protocol that defines the communication between the control and the data forwarding plane is the OpenFlow. In the current architecture, the transport layer directly corresponds to the SDN's data forwarding plane, which consists of OpenFlow switches. Each OpenFlow switch contains one or more flow tables and an abstraction layer that communicates with the controller.

C. Control Layer

In the SDN scenario the data forwarding decisions and higher level control functions are performed by a logically centralized software controller. The network configuration is performed on a simplified network abstraction and the data flow configurations are communicated to the data forwarding devices via the OpenFlow protocol. The control plane is implemented using the SDN Network Operating System (NOS) and a set of software modules that perform the various network control functions. The NOS exposes the open APIs (northbound APIs) to allow for the development of various applications that can interact with the network and provide an improved network management. In such a scenario, the IMS core elements can be implemented as software modules that communicate with the NOS via the northbound open APIs. Several possible open source IMS solutions were mentioned in Section III. The core IMS components functions are described below.

The IMS Call Session Control Function (CSCF) server – provides the registration of the endpoints, routing of the SIP signaling messages and QoS. We distinguish the following:

- *Serving CSCF* – this is the central session control entity for the endpoint devices; it maintains the session state; stores the public user identity and the contact address of each subscriber of the network and retrieves the user profiles from the Home Subscribe Server.
- *Proxy CSCF* – this is the IMS entry point for the devices; it forwards the SIP messages to the user's home S-CSCF; provides the user authentication, the device control interworking security; and provides the QoS management, based on policy rules. The policy-based QoS control mechanism is implemented by two main entities – the Policy Decision Point (PDP) and the Policy Enforcement Point (PEP) [17]. The PDP is the logical entity that stores and retrieves the predefined policy rules and performs policy decisions, based on static or dynamic information from the network. In the current architecture, the PDP is implemented by the policy and charging rule function (PCRF) IMS component. PEP is responsible for enforcing the policies by communicating with the corresponding network elements. In the current scenario, the PEP entity is implemented by the policy and charging enforcement function (PCEF) that communicates with the SDN controller's NOS via the exposed northbound APIs.
- *Interrogating CSCF* – it maintains the session state; forwards the SIP request to the correct S-CSCF; retrieves the information regarding the correct S-CSCF from the HSS or assigns an S-CSCF if information is not available.

The Home Subscribe Server (HSS) - manages the subscriber database for the home network; grants or restricts access to the users, based on their subscriber information; and communicates with the S-CSCF.

D. Application Layer

The IMS control layer utilizes several interfaces to communicate with the service layer, which offer the capability of providing applications implemented by heterogeneous resources and application servers (AS). The ASs are the entities that host and execute the services provided by the IMS. These communicate with the S-CSCF using SIP in order to realize service the session control. These also communicate with the HSS via DIAMETER in order to retrieve or update the subscriber's profile information. The SIP ASs are the most common type of application servers used in IMS scenarios. They support SIP-based applications and respond to requests with SIP messages in order to enable the further processing of the user requests at the S-CSPF. The SIP applications might include the presence service or sessions involving multimedia elements such as voice, video, chat, gaming, etc. The proposed here architecture focuses on enabling the integration with third-party services, and particularly web services and the IoT-based services exposed by BETaaS local clouds. Such integration is enabled by the Open Service Access Gateway (OSA-GW) and the Open Service Access/Parlay Application Server (OSA/Parlay AS) components. The main purpose of these components is to allow for the integration of the underlying network assets with the third party services. This would allow for the network providers to employ a superior service access control and the QoS differentiation, which will result in an

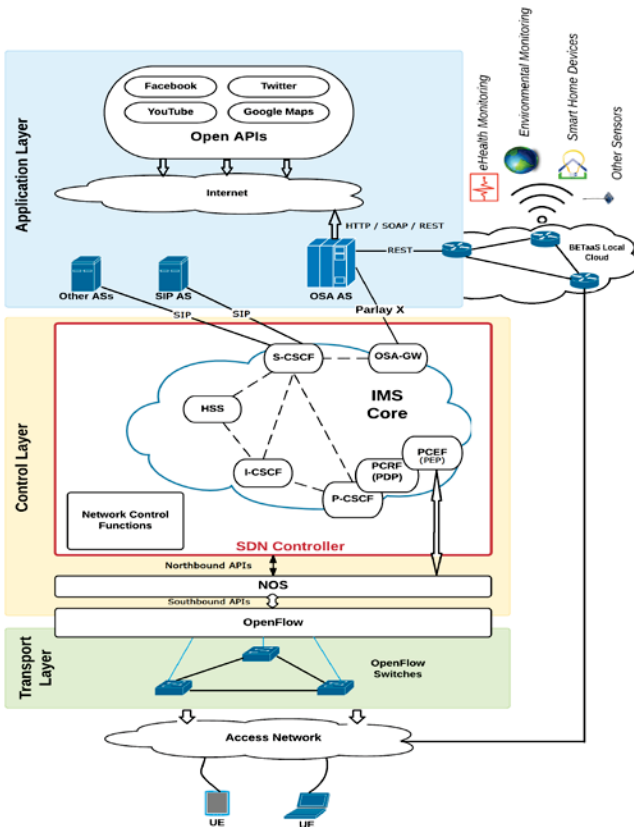

Fig. 2. SDN-based IMS architecture for IoT integration.

enhanced security and reliability of the provided services and improved quality of experience for the end-user. A set of standard web service APIs – Parlay – has been developed by The Parlay Group in collaboration with ETSI and 3GPP to allow such interoperability. The OSA/Parlay AS main purpose is to host a variety of applications that can access standard web services (via HTTP/SOAP/REST) and IoT-based services exposed by BETaaS (via REST APIs) and can communicate with the underlying network assets (via Parlay X interfaces). The OSA-GW is the session mediation gateway that defines the control flow of the established service sessions and implements the Parlay APIs and SIP protocol mapping mechanism.

V. CONCLUSION

The paper proposed a conceptual design that integrates the BETaaS M2M development and execution platform and an SDN-based IMS architecture in order to provide an open environment for the development and the provisioning of IoT services. The required technologies and the corresponding challenges for the service deployment in such a scenario were outlined and the main functional components to address these issues are described. The proposed architecture is the foundation for the planned future research on inter-cloud communication mechanisms and QoS classification and management in SOAs.

Analytical Evaluation Of Frequency Reuse For Hybrid Full-/Half-Duplex Cellular System

Wenping Bi, Limin Xiao, Xin Su, Shidong Zhou
Tsinghua National Laboratory for Information Science and Technology
Department of Electronic Engineering, Tsinghua University, Beijing, China

***Abstract*—Full-duplex (FD) communication has drawn more and more attention due to the potential to double the spectral efficiency. Dense cellular network is one of the possible application scenarios. However, the severe inter-cell interference may largely degrade the system performance, especially for the cell-edge users. In this paper, we focus on the hybrid full-/half-duplex (HFHD) cellular network, which is composed of a mixture of base-stations (BS) working either in half-duplex (HD) or FD mode. Frequency reuse (FR) is introduced into HFHD cellular system to deal with the serious inter-cell interference. The considered FR schemes include the traditional full FR and two main categories of Fractional Frequency Reuse (FFR) named Strict FFR and Soft FFR. Instead of assuming the base-stations are placed based on deterministic grid, we utilize stochastic geometry approach to model the base-station locations. Through the analytical results, we observe that FR is more effective used in FD system than HD network. We also study the relationship between the system spectrum efficiency and the proportion of FD BSs under different residual self-interference (SI). The simulation result shows that if the residual SI is not very large, operating all the BSs in FD mode can achieve the best performance, otherwise, it is better to operate all the BSs in HD mode.**

I. Introduction

Full-duplex (FD) communication is one of the most promising solutions to enhance the spectral efficiency (SE) in the 5th generation (5G) wireless communication system. Compared with traditional half-duplex (HD) transceiver operating either in frequency division duplex (FDD) mode or time division duplex (TDD) mode, FD radios can simultaneously transmit and receive signals over the same frequency, offering the potential to double the spectral efficiency. However, the self-interference (SI) caused by the transmitted signal at the receiver may overwhelm the desired signal and is a main obstacle to build a FD transceiver. Advanced and effective SI cancellation technologies [1] have been proposed to make the FD radios feasible. FD radios have been applied to several fields [1], including FD cognitive radio system , FD relay, FD bi-direction communication system and FD cellular system. Among all the applications, FD cellular system is an important research issue, especially in the small cells, where the transmission power is low and the distance between the base-station (BS) and user equipment (UE) is short.

(a) HD Cellular Network (b) FD Cellular Network

Fig. 1. An Exemplary Interference Scenario Of HD/FD Cellular Network

In this paper, we focus on Orthogonal Frequency Division Multiple Access (OFDMA) based cellular network with hybrid duplex BSs and HD UEs. In other words, FD and HD BSs co-exist in the network. In FD cells, a FD BS simultaneously serves two HD UEs with one in downlink and the other in uplink direction over one sub-band. Unfortunately, extra inter-cell and intra-cell interference may largely degrade the system performance.

As illustrated in Fig. 1, for simplicity, we take two neighboring cells as an example. As shown in Fig. 1(a), in HD network, the BS in cell 1 only suffers the interference from the transmission of the uplink UE in neighbor cell. In the same way, the downlink UE in cell 1 only gets interference from the downlink signal of neighbor BS. While, as to FD cells in Fig. 1(b), besides the interference discussed in HD cells, the BS receives two extra interference: the SI and the downlink transmission of the neighbor BS. The downlink UE in FD cells also suffers two extra interference: the inter-cell and intra-cell inter-user interference.

With the cellular network becoming denser, the inter-cell interference will be more destructive, especially for the cell-edge UEs. In this paper, frequency reuse (FR) methods are applied to deal with the inter-cell interference. The focused FR schemes include the traditional full FR and Fractional Frequency Reuse (FFR) [2].

We analyze the hybrid duplex system with stochastic geometry approach, in which the BS locations are distributed based on a spatial Poisson Point Process (PPP). The authors in [3] evaluated the performance of the one tier FD network with perfect SI cancellation using stochastic geometry method. The performance of heterogeneous networks with FD bi-directional transceivers was studied in [4]. However, none of

them considers interference suppression technologies, which is impractical in the interference limited FD cellular system.

The contributions of this paper are as follows. Firstly, the primary contribution of our work is the analytical evaluation of the hybrid duplex cellular system with FR. Secondly, we analyze the impact of the proportion of FD BSs on the system spectrum efficiency (SE) under different residual SI. The results show that FR is more effective in FD system and the more FD BSs we deploy, the higher SE we can achieve, if the SI is cancelled properly.

The rest of the paper is organized as follows. In section II, we introduce the system model and the adopted FR technologies. In section III, the coverage probability is derived for different FR schemes. Simulations are conducted in section IV. Section V is the conclusion of the paper.

II. System model and relevant technologies

A. System Model And Assumptions

In this paper, we consider an OFDMA-based cellular network with hybrid duplex BSs and legacy HD UEs. The BSs are distributed in the space based on a homogeneous spatial PPP with density λ. The proportions of FD BSs and HD BSs working in the uplink and downlink direction are p_f, p_{hu} and p_{hd} , respectively. Obviously, $p_f + p_{hd} + p_{hu} = 1$. Therefore the locations of FD BSs and HD BSs working in the uplink and downlink direction are also distributed based on independent spatial PPP with density λp_f, λp_{hu} and λp_{hd}, respectively. UEs are assumed to communicate with their closest BSs, which follows the association principle of maximum average received power. The UEs uniformly distribute in each Voronoi cell formed by the BSs and we randomly select only one UE to work in one specific transmission direction over one sub-band. Based on the assumptions above, the density of active UEs is the same as their serving BSs'. We should note that the locations of the active UEs no longer follow the spatial PPP [5]. However, as confirmed in [5], the actual distribution of the active UEs' locations is almost the same as the spatial PPP. Therefore, in this paper, the locations of the active UEs are also assumed to be based on the spatial PPP. Then, the probability density function (pdf) of the distance r between the BS and its serving UE can be derived as [6]:

$$f_r(r) = 2\pi\lambda r e^{-\lambda\pi r^2} \tag{1}$$

The residual SI I_s after interference cancellation is assumed to be a gaussian random variable with zero mean and variance depending on the transmission power of the BS P_b . Then I_s can be written as:

$$I_s \sim \mathcal{N}(0, {\sigma_I}^2), \quad {\sigma_I}^2 = P_b |h_I|^2 \tag{2}$$

Where $|h_I|^2$ reflects the capability of SI cancellation.

In FD cells, the transmission of uplink UE will cause interference to the downlink UE working in the same sub-band. A bin-and-cancel (BC) strategy was proposed in [7] to mitigate the intra cell inter-user interference (IUI) and the results showed that the IUI was effectively removed. Therefore, in this paper, the IUI is ignored. Then the received signal-to-interference-plus-noise-radio (SINR) at the BS and UE can be uniformly derived as follows:

$$SINR_m = \frac{P_t G_m {r_m}^{-\alpha}}{\sigma^2 + I_m + \delta_{fb} I_s} \tag{3}$$

Where the subscript $m \in \{b, u\}$ denotes the type of receiver. b and u represent the receivers of BS and UE, respectively. G_m and r_m denote the small scale fading and distance between the focused receiver and its transmitter, respectively. We assume the small scale fading of all the channels to be Rayleigh fading, i.e. $G_m \sim \exp(1)$. $\alpha > 2$ is the path loss exponent and we assume the path loss exponents for all the channels are the same. P_t represents transmission power and it is P_u in the uplink and P_b in the downlink transmission direction. δ_{fb} is 1 only when the FD BS receiver is considered, otherwise δ_{fb} is 0. I_m denotes the received inter-cell interference. Inter-cell interference will generate from all the cells that use the same sub-band. Then the received inter-cell interference I_m can be formulated as follows:

$$\begin{aligned} I_m = &\sum_{z_b \in \mathcal{Z}_f} P_b G_{z_b,m} D_{z_b,m}^{-\alpha} + \sum_{z_u \in \mathcal{Z}_f} P_u G_{z_u,m} D_{z_u,m}^{-\alpha} \\ &+ \sum_{z_{hb} \in \mathcal{Z}_{hd}} P_b G_{z_{hb},m} D_{z_{hb},m}^{-\alpha} + \sum_{z_{hu} \in \mathcal{Z}_{hu}} P_u G_{z_{hu},m} D_{z_{hu},m}^{-\alpha} \end{aligned} \tag{4}$$

Where $\mathcal{Z}_f$, $\mathcal{Z}_{hu}$ and $\mathcal{Z}_{hd}$ denote the interfering cell sets working in FD-mode, HD-mode in the uplink and downlink direction, respectively. z_k and z_{hk} ($k \in \{b, u\}$) represent the interfering nodes in FD and HD cells. b and u denote the interfering nodes are BS and UE, respectively. $G_{z_k,m}$(or $G_{z_{hk},m}$) $\sim \exp(1)$ is the small scale fading between the interfering node z_k (or z_{hk}) and the interested receiver $m \in \{b, u\}$. $D_{z_k,m}$ (or $D_{z_{hk},m}$) denotes the distance between interested receiver m and interfering node z_k (or z_{hk}).

In a FD interfering cell, both the BS and the uplink UE will generate interference to the interested receiver. According to the association principle, the interfering UE is located in the Voronoi cell formed by the FD BS. Therefore these two interfering distance $D_{z_b,m}$ and $D_{z_u,m}$ are correlated together. Fortunately, authors in [4] demonstrated that, in dense cellular system, these two distances are almost the same. That is to say:

$$D_{z_b,m} \approx D_{z_u,m} \tag{5}$$

Here, we also adopt this approximation. Then the inter-cell interference can be re-presented as follows:

$$\begin{aligned} I_m = &\sum_{z \in \mathcal{Z}_f} G_{fz} D_{z,m}^{-\alpha} + \sum_{z_{hb} \in \mathcal{Z}_{hd}} P_b G_{z_{hb},m} D_{z_{hb},m}^{-\alpha} \\ &+ \sum_{z_{hu} \in \mathcal{Z}_{hu}} P_u G_{z_{hu},m} D_{z_{hu},m}^{-\alpha} \end{aligned} \tag{6}$$

Where $G_{fz} = P_b G_{z_b,m} + P_u G_{z_u,m}$.

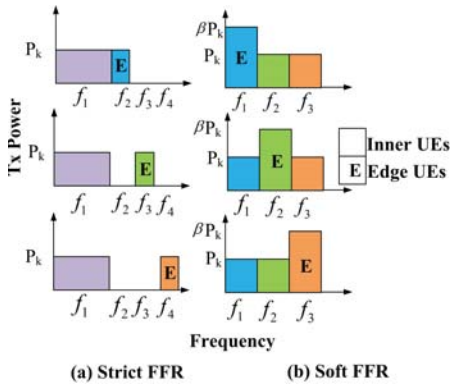

Fig. 2. Strict FFR and Soft FFR With frequency reuse factor $\Delta = 3$ for cell-edge UEs

B. Frequency Reuse

It is well known that, traditional full FR scheme is to allocate $\frac{1}{\Delta}$ of the total sub-bands to each cell randomly. By utilizing traditional full FR, inter-cell interference is well managed, but the spectrum efficiency is very low.

The adopted FFR [2] schemes will be introduced. As shown in Fig. 2, it is an example of Strict FFR (StFFR) and Soft FFR (SoFFR) with reuse factor $\Delta = 3$. The basic idea of StFFR is that, the frequency allocated to the cell-inner UEs is shared by all the inner-UEs overall the network, while the sub-bands reserved for the cell-edge UEs are reused with factor Δ.

SoFFR uses a different frequency partition scheme. All the sub-bands can be used by each cell, while the sub-bands partitioned to the cell-edge UEs are still reused according to the reuse factor Δ. The transmission power of cell-edge UEs boosts by factor β and the typical value of β is 2-20.

In order to apply StFFR and SoFFR, we should first define the cell-edge UE and cell-inner UE. We pre-define a SINR threshold value T_{FR} and the UE whose SINR is larger than the threshold is classified into cell-inner UEs, otherwise the UE is regarded as cell-edge UEs.

III. Coverage Probability and Rate

In this section, the coverage probabilities for both uplink and downlink UEs are derived. The coverage probability is defined as the probability that the received SINR of a receiver is larger than the threshold T:

$$\bar{F}(T) = \mathbb{P}(SINR > T) \tag{7}$$

It is the complementary cumulative distribution function (CCDF) of the SINR equivalently. We can also observe that $F = 1 - \bar{F}$ gives the outage probability.

A. Coverage Probability For Full FR With Reuse Factor Δ

In this section, the coverage probability of the cellular system applying traditional full FR with reuse factor Δ is studied. Based on the assumptions above, the coverage probabilities of the uplink and downlink UEs in the same cell can be solved independently and the uniform results can be given. Since each cell is assigned one of Δ sub-bands, the interference is generated from $\frac{1}{\Delta}$ of all the cells. Then we can derive the coverage probability as follows.

Theorem 3.1: When the BSs are distributed based on the spatial PPP with density λ, the coverage probability of a typical UE employing traditional full FR with reuse factor Δ can be derived as:

$$\begin{aligned}&\bar{F}_{\Delta,m}(\Delta, T, \lambda, P_t, P_b, P_u)\\ &= \pi\lambda \int_{v=0}^{\infty} \left(e^{-2\pi\lambda v \frac{1}{\Delta}\left(\sum_q p_q \psi_{s,q,m}\right) - \frac{T v^{\frac{\alpha}{2}} (\sigma^2 + \delta_{fb} I_s)}{P_t}} \right) dv\end{aligned} \tag{8}$$

Where p_q $(q \in \{f, hu, hd\})$ represents the proportion of q interfering cell set defined in section II. $\psi_{s,q,m}$ is defined as:

$$\begin{aligned}&\psi_{s,q,m}(T, P_t, P_b, P_u) =\\ &\mathbb{E}_{G_{qm}}\left(-\frac{1}{\alpha}\left(\frac{T}{P_t}G_{qm}\right)^{\frac{2}{\alpha}}\Gamma\left(-\frac{2}{\alpha}\right) + \frac{1}{\alpha}\left(\frac{T}{P_t}G_{qm}\right)^{\frac{2}{\alpha}}\Gamma\left(-\frac{2}{\alpha}, \frac{TG_{qm}}{P_t}\right)\right)\end{aligned} \tag{9}$$

Where $\Gamma(x, a) = \int_x^{\infty} t^{a-1}e^{-t}dt$ and $\Gamma(a) = \int_0^{\infty} t^{a-1}e^{-t}dt$ denote incomplete gamma function and standard gamma function, respectively. G_{qm} is defined as:

$$G_{qm} = \begin{cases} P_b G_{z_b,m} + P_u G_{z_u,m} & \text{if } q = f \\ P_u G_{z_{hu},m} & \text{if } q = hu \\ P_b G_{z_{hb},m} & \text{if } q = hd \end{cases} \tag{10}$$

Proof: Starting from the definition of the coverage probability and based on the property of expectation we have,

$$\begin{aligned}\bar{F}_{\Delta,m}(T, \lambda, P_t, P_b, P_u) &= \mathbb{P}\left(\frac{P_t G_m {r_m}^{-\alpha}}{\sigma^2 + \delta_{fb} I_s + I_m} > T\right)\\ &= \mathbb{E}_{r_m, I_m}\left(\mathbb{P}\left(\frac{P_t G_m {r_m}^{-\alpha}}{\sigma^2 + \delta_{fb} I_s + I_m} > T | r_m, I_m\right)\right)\\ &\overset{(a)}{=} 2\pi\lambda \int_{r=0}^{\infty} \left(r e^{-\frac{T r^{\alpha}(\sigma^2 + \delta_{fb} I_s)}{P_t} - \pi\lambda r^2} L_{I_m}\left(\frac{T r^{\alpha}}{P_t}\right)\right) dr\end{aligned} \tag{11}$$

(a) follows the fact that $G_m \sim \exp(1)$. $\mathcal{L}_{I_m}(s)$ is the Laplace transform of the received inter-cell interference I_m and based on the definition of the Laplace transform we can get:

$$\begin{aligned}L_{I_m}(s) &= \mathbb{E}(e^{-sI_m}) \overset{(b)}{=} \prod_q \mathbb{E}\left(\exp\left(-s\sum_{z \in \mathcal{Z}_q} G_{z,m} D_{z,m}^{-\alpha}\right)\right)\\ &\overset{(c)}{=} \prod_q \exp\left(-2\pi\lambda_q \frac{1}{\Delta}\int_r^{\infty} \mathbb{E}_{G_{qm}}\left(1 - e^{\left(-sG_{qm}D^{-\alpha}\right)}\right) D dD\right)\\ &= \prod_q \exp\Big\{ -2\pi\lambda_q \frac{1}{\Delta}\mathbb{E}_{G_{qm}}\Big[-\frac{1}{\alpha}(sG_{qm})^{\frac{2}{\alpha}}\Gamma\left(-\frac{2}{\alpha}\right) - \frac{1}{2}r^2\\ &\quad + \frac{1}{\alpha}(sG_{qm})^{\frac{2}{\alpha}}\Gamma\left(-\frac{2}{\alpha}, \frac{sG_{qm}}{r^{\alpha}}\right)\Big]\Big\}\end{aligned} \tag{12}$$

Where (b) follows from the fact that the BSs working in different mode are distributed independently. (c) follows from

the probability generating functional of PPP. Substitute Eq. (12) into Eq. (11) and we can get Theorem 3.1. ■

B. Coverage Probability For Strict FFR

We first focus on the cell-edge UEs when using StFFR. The cell-edge UEs, whose SINR is less than a pre-defined threshold T_{FR} when using the frequency shared by all the cells, are assigned a reserved sub-band that is reused according to a reuse factor Δ. Then the cell-edge UE experiences new channel fading $\tilde{G}_m$ and inter-cell interference $\tilde{I}_m$. As discussed above, $\tilde{I}_m$ is generated from $\frac{1}{\Delta}$ of all the other cells. Then the coverage probability of the system with StFFR can be derived as follows.

Theorem 3.2: When using StFFR scheme, the coverage probability of a cell-edge UE is defined as follows:

$$\begin{aligned}&\bar{F}_{strict,e,m}(T,T_{FR},\Delta,\lambda,P_t,P_b,P_u)\\&=\frac{\bar{F}_{\Delta,m}(\Delta,T,\lambda,P_t,P_b,P_u)}{1-\bar{F}_{\Delta,m}(1,T,\lambda,P_t,P_b,P_u)}\\&\quad-\frac{\pi\lambda\int_{v=0}^{\infty}\left(e^{-2\pi\lambda v(\sum_q p_q\psi_{j,q,m})-\frac{(T_{FR}+T)v^{\frac{\alpha}{2}}(\sigma^2+\delta_{fb}I_s)}{P_t}}\right)dv}{1-\bar{F}_{\Delta,m}(1,T,\lambda,P_t,P_b,P_u)}\end{aligned} \tag{13}$$

Where

$$\begin{aligned}&\psi_{j,q,m}(\Delta,T_{FR},T,P_t,P_b,P_u)\\&=\frac{\Delta-1}{\Delta}\psi_{s,q,m}(T_{FR},P_t,P_b,P_u)\\&\quad-E_{\Omega_{qm}}\left(\frac{(\Omega_{qm})^{\frac{2}{\alpha}}}{\Delta\alpha}\left(\Gamma(-\frac{2}{\alpha})-\Gamma(-\frac{2}{\alpha},\Omega_{qm})\right)\right)\end{aligned} \tag{14}$$

Where $\Omega_{qm}=\frac{T_{FR}}{P_t}G_{qm}+\frac{T}{P_t}\tilde{G}_{qm}$. $\psi_{s,q,m}$ is defined by Eq. (9). G_{qm} and $\tilde{G}_{qm}$ are defined by Eq. (10) and denote the small scale fading of the interfering channel before and after assigned the reserved sub-band, respectively.

Proof: Starting from the definition, we can get:

$$\begin{aligned}&\bar{F}_{strict,e,m}(T,T_{FR},\Delta,\lambda,P_t,P_b,P_u)\\&=\mathbb{P}(\frac{P_t\tilde{G}_m{r_m}^{-\alpha}}{\sigma^2+\tilde{I}_m+\delta_{fb}I_s}>T|\frac{P_tG_m{r_m}^{-\alpha}}{\sigma^2+I_m+\delta_{fb}I_s}<T_{FR})\\&=\frac{\mathbb{E}\left(\mathbb{P}(\frac{P_t\tilde{G}_m{r_m}^{-\alpha}}{\sigma^2+\tilde{I}_m+\delta_{fb}I_s}>T,\frac{P_tG_m{r_m}^{-\alpha}}{\sigma^2+I_m+\delta_{fb}I_s}<T_{FR}|r,\tilde{I}_m,I_m)\right)}{\mathbb{E}_{r,I_m}(\mathbb{P}(\frac{P_tG_m{r_m}^{-\alpha}}{\sigma^2+I_m+\delta_{fb}I_s}<T_{FR}|r,I_m))}\end{aligned} \tag{15}$$

Then following the steps of the proof in Theorem 3.1, we can get Theorem 3.2. ■

Now, we pay our attention to the cell-inner UEs when StFFR is used.

Theorem 3.3: The coverage probability of a cell-inner UE with StFFR is given by:

$$\begin{aligned}&\bar{F}_{strict,i,m}(T,T_{FR},\lambda,P_t,P_b,P_u)\\&=\mathbb{P}(\frac{P_tG_m{r_m}^{-\alpha}}{\sigma^2+\delta_{fb}I_s+I_m}>T|\frac{P_tG_m{r_m}^{-\alpha}}{\sigma^2+\delta_{fb}I_s+I_m}>T_{FR})\\&=\frac{\bar{F}_{\Delta,m}\left(1,\max(T,T_{FR}),\lambda,P_t,P_b,P_u\right)}{\bar{F}_{\Delta,m}(1,T_{FR},\lambda,P_t,P_b,P_u)}\end{aligned} \tag{16}$$

Proof: Its proof is similar with that of Theorem 3.2. ■

C. Coverage probability for Soft FFR

In the case of SoFFR, each cell can reuse all the sub-bands and $\frac{1}{\Delta}$ of the whole sub-bands are allocated to the cell-edge UEs. The cell-edge UEs transmit signals with power βP_t. Then in each interfering cell, $\frac{\Delta-1}{\Delta}$ of all the sub-bands apply power P_t and the rest sub-bands use power βP_t. Therefore, the effective inter-cell interference can be denoted as ηI_m, where $\eta=\frac{\Delta-1+\beta}{\Delta}$ and I_m is defined by Eq. (6) . Now we also first consider the cell-edge UEs with SoFFR.

Theorem 3.4: The coverage probability of a cell-edge UE with SoFFR is given as follows.

$$\begin{aligned}&\bar{F}_{soft,e,m}(T,T_{FR},\eta,\lambda,\beta,P_t,P_b,P_u)\\&=\bar{F}_{strict,e,m}(\frac{T}{\beta},T_{FR},1,\lambda,P_t,\eta P_b,\eta P_u)\end{aligned} \tag{17}$$

Where the $\bar{F}_{strict,e,m}$ is defined by Eq. (13).

Proof: Please refer to the proof of Theorem 3.2. ■

Then, in the same way as StFFR, we can get the coverage probability of a cell-inner UE with SoFFR.

Theorem 3.5: The coverage probability of a cell-inner UE with SoFFR can be given as follows.

$$\begin{aligned}&\bar{F}_{soft,i,m}(T,T_{FR},\eta,\lambda,\beta,P_t,P_b,P_u)\\&=\bar{F}_{strict,i,m}(T,T_{FR},1,\lambda,P_t,\eta P_b,\eta P_u)\end{aligned} \tag{18}$$

Where $\bar{F}_{strict,i,m}$ is given by Eq. (16).

Proof: Please refer to the proof of Theorem 3.2. ■

D. Average User Rate

In order to evaluate the spectrum efficiency of the network, we define the average user rate as follows:

$$R=\mathbb{E}\left(\ln(1+SINR)\right)=\int_{t>0}\bar{F}\left(e^t-1\right)dt \tag{19}$$

Then, according to Eq. (19) and the coverage probability we have already solved, we can get the average user rates of the cellular systems utilizing different FR methods.

IV. Performance Evaluation

In this section, we apply the analytical results derived in Section III to evaluate the system performance. Unless otherwise specified, the parameters used in the simulations are presented in Table I.

Firstly, the coverage probabilities of cell-edge UEs utilizing different FR methods are compared. Without loss of generality, we just focus on the downlink transmission. As shown in Fig. 3, we can observe that the analytical results match the simulation results perfectly, which identifies the effectiveness of the analytical results presented in Section III. We can also observe that, FFR can largely improve the performance of cell-edge UEs and the StFFR outperforms other schemes from the point of cell-edge UE coverage probability as expected.

Next, we evaluate the sum throughput with respect to the sub-bands allocated to the cell-edge UEs. As shown in Fig. 4, the sum throughput has been normalized according to the sum throughput of the system using full FR with reuse factor

TABLE I
SIMULATION PARAMETERS

α	Band width	Thermal noise	P_b	P_u
3	10MHz	-174dBm/Hz	0.2W	0.2W
Δ	λ	T_{FR}	$\|h_I\|^2$	β
3	$10^{-3}/m^2$	0dB	$-90dB$	2

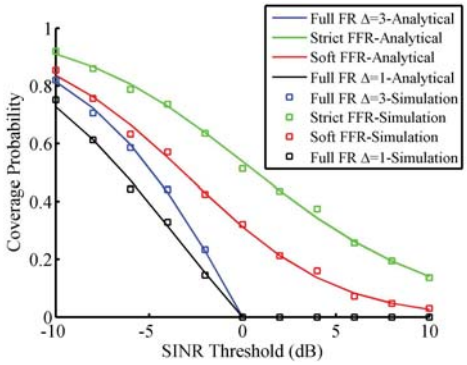

Fig. 3. Cell-Edge UE Coverage Probability. Here, $p_f = 1$.

$\Delta = 1$. We can observe that the SoFFR always outperforms other schemes at the expense of booting the cell-edge UEs' transmission power by β. Under the same assumption parameters, we also compare the relative sum throughput in FD and HD cellular system in Table II. The sub-bands allocated to the cell-edge UEs are 6. We can observe that the FR technologies are more effective in FD system.

At last, we analyze how the sum SE of uplink and downlink transmission varies along the proportion of FD radios. In the simulation, full FR with reuse factor $\Delta = 1$ is applied. As shown in Fig. 4, SE is a monotonic function with respect to the proportion of FD BSs. We can observe that there is a critical point of the SI cancelation capability. When the SI cancellation capability is larger than the critical point, the more FD BSs is deployed, the higher SE is achieved, otherwise, operating all the BSs in HD mode is better. So this point can guide the deployment of the FD BSs in the future.

V. CONCLUSION

In this paper, the analytical evaluation of the hybrid duplex system with different FR methods is conducted. The results are based on the stochastic geometry approach. Tractable expressions of coverage probability for different FR schemes are given. We also compare the system performance when utilizing different kinds of FR methods. The results show that, from the point of cell-edge UEs' coverage probability, StFFR is the best, while, SoFFR outperforms others when considering the SE. In addition, FR technologies are more effective in FD cellular network. At last, we analyze the relationship between SE and the proportion of FD BSs under different residual SI. Simulation results show that when residual SI is not very strong, operating all the BSs in FD mode is better, otherwise, it is better to operate all the BSs in HD mode.

TABLE II
RELATIVE SUM THROUGHPUT

	Full FR $\Delta = 1$	Full FR $\Delta = 3$	StFFR	SoFFR
FD	1	0.61	1.44	1.90
HD	1	0.56	1.15	1.49

***Abstract*—Microstrip based Multiband Antenna for Body Wearable Wireless Devices (BWWD) is proposed and investigations on the thermal effects caused by the interaction of the antenna with human tissues are done in this research work. Ultra high frequency (UHF) and Ultra wide band (UWB) spectrum effectively meet power, size and distance considerations for Wearable Wireless Communication Networks (WWCN) utilizing BWWDs. The antenna designed works at quad-bands, resonating at 1.8 GHz, 2.4 GHz, 5.0 GHz and 8.9 GHz when placed on human body. The electromagnetic (EM) effects in terms of Specific Absorption Rate (SAR) and thermal effects of the antenna when placed on different sites on the body are analyzed analytically and experimentally using Infra-red thermography (IRT). A simplified, human body tissue layer model that is frequency dependent in its properties is used for simulations. Simulated and experimental results are compared and are found to be in good agreement. The rise in temperature is found to be compliant with international safety regulations, favoring the use of the antenna for wearable wireless devices.**

I. INTRODUCTION

The aim of wearable technology is to create convenient, portable access to information in real time and use of this Body Wearable Wireless Devices (BWWD) finds wide-ranging applications in health care, fitness, augmented reality, ambient assisted living setups, smart entertainment and many more in all walks of life via Wearable Wireless Communication Networks (WWCN). Antennas connecting these wearable devices at UHF and UWB frequencies offer high performance, ultra-low power and safe operations on human body complementing other longer range radio technologies. The human body is inhomogeneous with high loss and permittivity that are frequency dependent and which affect the properties of an antenna. The site of an antenna on the body has major control on the size and shape of the antenna being used, therefore constraining the designer. The power usage, heating effects on the body should be taken into account in BWWD antenna design. A good antenna design is essential for limited Specific Absorption Rate (SAR) values as the SAR depends on directivity, orientation and gain of the antenna [1].

In recent years, the electromagnetic (EM) effect of antennas on the human body has been an area of great interest [2]. With an extensive use of wearable wireless devices at greater proximity to the body, the concern about biological effects due to the interaction of human tissues with the RF waves is of pronounced importance. The amount of exposure of the human tissues to EM radiations is indexed in terms of SAR that gives the amount of energy absorbed by tissues when exposed to EM signals. The biological manifestation of SAR is the temperature rise. It is observed from literature that an increase of temperature greater than 1˚C would be hazardous [3]. In this context, a temperature-based technique for the evaluation of safety compliance when millimeter wave devices are used very close to the body has been proposed by [4].

In this work, a quad-band based microstrip antenna operating at UHF (30 – 3000 MHz) and UWB (3.1-10.6 GHz) frequencies is proposed for wearable wireless applications. The SAR and thermal effects of the proposed antenna when used at different places on the body is analyzed analytically and experimentally using infrared thermography (IRT) to find out the suitability of the antenna to be used as a wearable one despite its descent gain and efficiency values using 3D EM tools of HFSS and Sim4Life. Sim4Life is used for on-body simulations for the designed antenna at various body sites utilizing its high-fidelity computable human phantoms with advanced tissue models and HFSS (based on FEM) used for antenna design and fabrication

II. MODELING HUMAN TISSUES AND ANTENNA DESIGN

A. *Phantom model of human tissues*

A three layered rectangular biological tissue model made up of skin, fat and muscle is chosen as it represents the outermost body tissues. The designed antenna is proposed to be placed over the stacked tissues with an average thickness of 2 mm, 3.5 mm and 10 mm for skin, fat and muscle layer respectively as shown in Fig.1. The electrical properties of the tissues at UWB frequencies of the antenna designed are referred from [5].

Fig. 1. Layered model of human tissue with antenna

B. *Microstrip antenna design*

It is critical that the antenna has a compact design for use on the human body. The antenna design requirements differ from that of a conventional antenna that is designed for free space because of the tissue environment. Fig.2 shows the simulation model of the proposed staircase microstrip antenna. Microstrip model design equation [6] was used to design the antenna. The antenna has dimension of 35 x 32 x1.57mm^3 and is made of Rogers RT/Duroid 5880 substrate with relative permittivity of 2.2 and loss tangent of 9x10^{-3}. The selection of the substrate is due to its low electric loss along with low moisture absorption. An optimized design of the antenna with a partial ground plane and staircase rectangular patch is used. The step size of 1mm followed by 1.5mm from both the top and bottom edges is used for the staircase pattern. Horizontal slots each measuring 6 mm in length and 0.5 mm in width are used on the right and left sides of the radiating patch. A 50Ω microstrip line feeds the radiating patch. Good impedance matching is achieved by a tapered microstrip line.

Strips of conducting material at top and bottom provide a partial ground plane. The design is optimized to make the antenna work at four bands with return loss less than -10 dB at all the bands. A quad-band operation is chosen to offer better EM compatibility with existing unlicensed wireless communication technologies, such as GSM, Wi-Fi, and unlicensed UWB spectrum at low and high data rate wireless applications.

III. Simulations and Measured Results

A. *Antenna simulations, measurements in free space and on-body*

The antenna is simulated as well measured for its performance in free space and on-body. Measurements of return loss were made for the prototyped antenna shown in Fig.3.using RS-ZVL Vector Network Analyzer of frequency range 9 KHz-13.6 GHz. Placement of the antenna in direct contact with the body decreases the gain and radiation efficiency with due effects on the impedance matching due to the dielectric loading provided by the lossy human tissues. A frequency shift in the resonating frequency of 100 MHz from 1.8 to 1.9 GHz, 80 MHz from 2.4 to 2.48 GHz, 140 MHz from 5.0-5.14 GHz, 100 MHz from 8.9 to 8.8 GHz was observed between simulated and measured results in the four bands respectively. The designed antenna is kept on the human body with cotton padding of 5 mm between them. The performance of the antenna on body is enhanced due to the bio and electromagnetic compatibility nature of the chosen fabric which makes it realizable for real time use when compared to the few mm of air gap used in previous designs.

A good agreement between the simulated and measured results is seen as observed from Fig.4. Quasi-omnidirectional radiation pattern of the antenna considering the thickness of the layers of skin, subcutaneous fat and muscle as 2, 3.5, 10 mm respectively at the four bands are shown in Fig.5 for theta at 90^0. The performance of the quad bands is studied and tabulated in Table I. It is seen from table that the upper band performs well when compared to lower band. This is important while considering the EM waves (thus also antennas) interaction with body [7]. Major reflections occur due to the wave impedance mismatch between low (fat) and high water content (skin, muscle) tissues. This effect can cause an increased specific absorption rate (SAR) [8].

B. SAR and thermal effectts at different body sites

SAR is a good dosimetric quantity that measures the rate of energy absorption by human body when exposed to radio frequency EM field. SAR is calculated as:

$$SAR = \frac{\sigma.|E|^2}{\rho_m} \qquad (1)$$

Here, E is the RMS value of induced field in (V/m), σ is the conductivity of tissue in (S/m), ρ_m is the mass density of tissue in kg/m^3.The antenna is analyzed for its SAR on body through simulations for the four bands for the various tissues at five different anatomical sites on the body and are shown in Fig.6 and are tabulated in Table II. In order to obtain the relation between rise in temperature and time, in the case of long time exposures, the Pennes Bio Heat equation has been used [2]. Simplifying the Bio heat differential equation yields (2) that gives the Maximum temperature rise over a long period of time in the order of minutes [9]. In the equation, S is average SAR in W/kg, ρ is the mass density of tissue in kg/m^3, K is thermal conductivity of the tissue, ρ_b is mass density of blood, c_b is the heat capacity of blood and w is blood perfusion rate in ml/g/min, λ is the wavelength of the EM wave in m. The maximum temperature rise for the different tissues at all the four bands is tabulated using (2) in Table III.

$$Tmax = \frac{q}{\lambda'}[1 - (\sqrt{\lambda'}\,A + 1)e^{-\sqrt{\lambda' A}}\,] \qquad (2)$$

where, $q = \frac{\rho S}{K}$; $\lambda' = \frac{w\,c_b}{K}$; $A = \frac{\lambda}{4}$

Transient analysis of the temperature rise in the time domain is the most interesting part. There are two different approaches depending on whether the distance (radius) of the tissue at a body region is smaller or greater than the wavelength considered. When the equation above is plotted, considering the different body tissues and the different parameters, the evolution time of the rise of temperature for long time exposure is obtained. To take a closer look at the long term thermal effect of the designed antenna, the transient analysis is done for a scenario when the antenna is placed on the forearm and excited at 1.8 GHz with an input power of 1 mW. The rise in temperature with time is plotted using Matlab tool using (3) from [9], which is the second approach of the transient case where distance is greater than quarter wavelength. The graphs for skin, fat and muscle are shown in Fig.7 and Fig.8.

$$T(t) = \frac{q}{2\lambda'}\frac{\rho}{r}\left\{\frac{e^{(r-\rho)}}{2}\left(1+\frac{1}{\rho}\right).erfc\left(\frac{r-\rho}{2\sqrt{\pi}}\right) + \frac{e^{-(r-\rho)}}{2}\left(1-\frac{1}{\rho}\right).erfc\left(\frac{r-\rho}{2\sqrt{\pi}} - \sqrt{\pi}\right) + \frac{e^{(r+\rho)}}{2}\left(1-\frac{1}{\rho}\right).erfc\left(\frac{r+\rho}{2\sqrt{\pi}} + \sqrt{\pi}\right) - \frac{e^{-(r+\rho)}}{2}\left(1+\frac{1}{\rho}\right).erfc\left(\frac{r+\rho}{2\sqrt{\pi}} - \sqrt{\pi}\right) + \frac{r}{\rho}e^{-\tau}\left[erfc\left(\frac{r+\rho}{2\sqrt{\pi}}\right) - erfc\left(\frac{r-\rho}{2\sqrt{\pi}}\right) + \frac{2}{\rho}\sqrt{\frac{\tau}{\pi}}\left(exp - \frac{(r-\rho)^2}{4\tau} - exp - \frac{(r+\rho)^2}{4\tau}\right)\right]\right\} \qquad (3)$$

Where,

$\rho = \sqrt{\lambda'}\,A$; $\tau = \frac{\lambda'}{\mu}$ t; $r = \sqrt{\lambda'}\,R$;erfc(x)=1-$\frac{2}{\sqrt{\pi}}\int_0^x e^{-t^2}\,dt$

C. Experimental validation of the on- body thermal effect of the antenna

Infrared Thermography (IRT) is an imaging modality using which the variations in temperature in human beings can be measured. An experimental setup to validate the safe thermal effects of the designed antenna was made with comfortable subjects with the region of interest at a distance of 1m from the IR camera. Thermograms were taken against a dark non-reflecting background using FLIR A305SC series IR camera and analyzed using FLIR R&D research IR software tool. The images were captured and analyzed under normal body condition of the subject with no special regards to hormonal, metabolic, digestive and drug effects. Thermograms were taken for the marked area of interest on the forearm giving skin temperature before placing the antenna and exciting it. The antenna was excited at 1.8, 2.4 and 5 GHz at 1.0 mW power level by Agilent's N5182A MXG vector signal generator. Images were obtained after duration of 10, 20, and 30 minutes emission from the antenna placed on body and a sample of the thermograms is shown in Fig.9. Temperature rise in degree Celsius was analyzed on skin as it is the tissue that has maximum temperature rise as found out from Table III and using the relevant software to process thermograms it is tabulated in Table IV. It is observed that the maximum temperature rise is only a fraction of a Celsius and is within safe limits of 1°C.

		10 minutes	*20 minutes*	*30 minutes*
Skin	1.8 GHz	0.2	0.6	0.6
	2.4 GHz	0.1	0.4	0.4
	5.0 GHz	0.1	0.3	0.3

IV. DISCUSSION AND CONCLUSION

The performance of a human tissue model based quad-band microstrip patch antenna for BWWDs was investigated in free space and on body. The antenna's return loss satisfies S_{11}< -10 dB in free space and on body simulations at all the four bands. Less value of gain at lower bands is due to the more omnidirectional radiation pattern at these bands. The performance was also studied in terms of SAR and thermal effects for different sites on the human body at all quad-bands. It is observed from Table II that the SAR at the various body sites considered was more in lower band than the upper band. This is due to the decrease in permittivity as frequency increases, leading to better reflections away from the body, lesser SAR and decreased thermal effects, improving the performance of the antenna. It is analytically analyzed that the highest temperature rise was found on skin, the outermost tissue, irrespective of the body sites. The temperature increase was found to be indeed less of about fractions of a degree Celsius for all bands at all body sites. The time evolution of temperature for the three tissues obtained show that after an initial increase in temperature, there is saturation in the graph owing to the physiological aspects of the thermoregulation of the body. Thermograms taken for several minutes of exposure also showed that the maximum temperature rise was well within limits making the antenna compliant with international safety regulations, favoring the use of the antenna for wearable devices for variety of wireless applications.

***Abstract*—Free-Space Optical (FSO) systems are greatly affected by fog conditions, which cause very high attenuation over considerable amounts of time. Therefore, some models have been adopted by the designers of FSO links, which take into account visibility values in order to compute the attenuation due to fog. However, the visibility distribution for an FSO link site may not be available. In this paper we propose a simple but reliable framework that estimates the visibility distribution and has a single statistical input: the number of foggy hours per year. The proposed tool is evaluated using real visibility data from a large variety of sites within the Portuguese territory. The results show that the predicted visibility distributions considerably agree with the real data for all sites, proving that the simple metric proposed herein is an easy-to-use and valid tool to take into account when designing FSO systems.**

Keywords*—Free-Space Optical (FSO) Communications; Visibility Modeling; Wireless Links Design.

I. INTRODUCTION

Over the last two decades, Free-Space Optical (FSO) links have become an attractive solution to be taken into account when designing high bandwidth wireless communication links [1]. Historically, this technology started being used in satellite communications as well as by military forces, due to a number of interesting characteristics [2]: fast installation, operation in the infrared spectrum (780–1550 nm, which is unlicensed), high data rates and high immunity to electromagnetic interference. Moreover, FSO links ensure high security of the transmitted data due to the low diffraction of the optical beam generated by a laser equipment, i.e., an interceptor would need to have its receiver perfectly aligned with the transmitted optical beam in order to receive the signal. FSO systems can also be used as an alternative to microwave links, e.g., they can be used in the mobile backhaul last-mile in order to connect base stations to the core network and provide broadband internet access to rural areas. Some of other possible applications are video teleconferencing, real-time medical imaging transfer, enterprise networking, work-sharing capabilities and high speed interplanetary internet links [3].

Nevertheless, the use of optical signals raises some challenges that must be taken into account when adopting FSO systems. Since the propagating channel for wireless optical communication is the atmosphere, factors like rain, snow, clouds, smoke, fog and mist have a negative impact on the system performance, as these atmospheric attenuators not only absorb but also cause scattering of optical beams [4]. In addition, scintillation, caused by atmospheric turbulence, also gives rise to fluctuations in the received signal power (e.g., the twinkling of the stars). Scintillation effects can be mitigated using several techniques proposed in the literature [5]. However, the major concern of terrestrial FSO links is fog, since it causes very high attenuation over considerable amounts of time [4].

Some statistical models for fog have been proposed [6], [7], [8], which yield a better understanding of the attenuation caused by fog, namely the continental fog. On the other hand, International Telecommunications Union (ITU) issued recommendations for the design of terrestrial FSO links [9], [10], in which the attenuation coefficient due to fog is easily computed by taking into account the visibility – the technical definition of visibility is the distance at which light decreases to 2% of the original power; in terms of human perception, visibility is the distance at which it is just possible to distinguish a dark object against the horizon [9]. The method adopted by ITU allows a geo-local performance evaluation of FSO systems if the visibility distribution is known.

The ITU recommendations regarding the characteristics of precipitation for propagation modeling [11] provide a simple metric to compute the rainfall rate exceeded for any given percentage of the average year and for any location on Earth. However, neither the ITU recommendations for FSO systems design nor the fog statistical models proposed in the literature have an equivalent metric for the visibility distribution. Although the visibility parameter is usually available in meteorological stations or airports databases, for many sites the only statistical information at the disposal of an FSO link designer is the average number of foggy hours per year.

The goal of this work is to provide a simple but reliable framework that estimates the visibility distribution and has the number of foggy hours per year as its single statistical input. The innovative tool proposed here is, to the best of our knowledge, the first one that adopts a straightforward metric to provide reliable estimates of visibility values for different locations. This paper is organized as follows: after this introduction, Section II describes the visibility influence on FSO links design; Section III introduces the visibility measurements data of various sites over ten years, which were used to propose the visibility distribution estimation models discussed in Section IV; Section V provides some results regarding the framework assessment; finally, Section VI concludes the paper.

The authors would like to thank FCT for the support by the project UID/EEA/50008/2013.

II. Visibility Influence on FSO links design

Fog is a type of atmospheric attenuator whose particles size is comparable to the FSO beams wavelength, hence the induced attenuation can be described as a Mie scattering process [9], [10]. This kind of attenuation is a function of frequency and visibility, and visibility is related to the particle size distribution. As mentioned in the introduction, fog constitutes the most restrictive factor to the deployment of FSO systems at long distances. The attenuation in the optical wave region can reach 300 dB/km, in contrast to the millimeter wave region, where rain attenuation is typically a few dB/km [10].

The designers of FSO links have adopted empirical models to compute the attenuation due to Mie scattering, since an analytical approach is often impractical. One of these models, known as Kruse relation [12], is part of the ITU recommendations for FSO systems design [9]; it computes this specific attenuation, $\gamma_{fog}(\lambda)$ (in dB/km), as

$$\gamma_{fog}(\lambda) = \frac{3.912}{V_{[\text{km}]}} \left(\frac{\lambda_{[\text{nm}]}}{550} \right)^{-q}, \quad (1)$$

where V stands for the visibility, λ corresponds to the FSO beam wavelength and q denotes a coefficient dependent on the size distribution of the scattering particles. In the Kruse relation, this coefficient is given by

$$q = \begin{cases} 1.6 & V > 50 \text{ km} \\ 1.3 & 6 \text{ km} < V < 50 \text{ km} \\ 0.585\, V^{1/3} & V < 6 \text{ km} \end{cases}, \quad (2)$$

while a more recent study, known as Kim relation [12], proposes the following expression for the parameter q:

$$q = \begin{cases} 1.6 & V > 50 \text{ km} \\ 1.3 & 6 \text{ km} < V < 50 \text{ km} \\ 0.16\, V + 0.34 & 1 \text{ km} < V < 6 \text{ km} \\ V - 0.5 & 0.5 \text{ km} < V < 1 \text{ km} \\ 0 & V < 0.5 \text{ km} \end{cases}. \quad (3)$$

Al Naboulsi et al. developed simple relations that allow the evaluation of the attenuation for two types of fog: advection fog and convection fog [12]. Advection fog is formed by the movement of wet and warm air masses above colder maritime or terrestrial surfaces; convection fog appears when the ground starts cooling by releasing the heat that is accumulated during the day and the air is sufficiently cool and becomes saturated. The attenuation by advection fog is expressed by

$$\sigma_{adv}(\lambda) = \frac{0.11478\, \lambda_{[\text{m}]} + 3.8367}{V_{[\text{m}]}}, \quad (4)$$

while the attenuation by convection fog is given by

$$\sigma_{conv}(\lambda) = \frac{0.18126\, \lambda^2_{[\text{m}]} + 0.13709\, \lambda_{[\text{m}]} + 3.7502}{V_{[\text{m}]}}. \quad (5)$$

The specific attenuation $\gamma_{fog}(\lambda)$ (in dB/km) for both types of fog is computed as

$$\gamma_{fog}(\lambda) = \frac{10}{\log_e(10)} \sigma(\lambda). \quad (6)$$

Regarding FSO links design, the previous expressions can be used to easily compute the attenuation due to fog if the visibility values are known. Furthermore, an FSO link is also characterized by the unavailability due to fog that it can afford. This means that the respective visibility distribution is also required, namely the value of the visibility that is not exceeded for a given percentage of time p, in order to obtain the attenuation value exceeded for this percentage p.

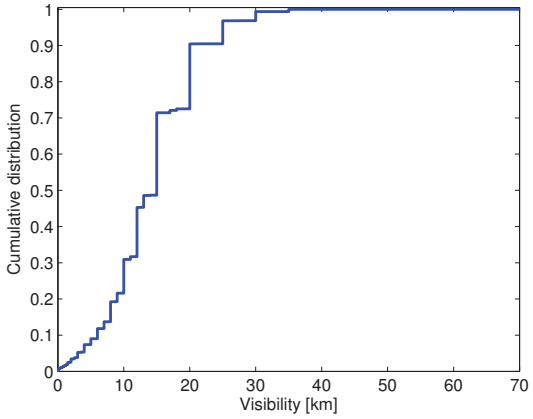

Fig. 1. Cumulative distribution of the visibility for site #7 (Lisboa).

By definition, one is in the presence of fog when water droplets suspended in the atmosphere reduce the visibility to less than 1 km [13]. However, this definition is not enough to make a correspondence between the average number of foggy days per year and a certain value of the visibility distribution; the average duration of a fog event is also required, so as to compute the average number of foggy hours per year. In other words, and assuming that a day is reported as a foggy day when part of that day has visibility below 1 km, the percentage of time (in a year) in which the visibility does not exceed 1 km is given by

$$p_{(1\,\text{km})\ [\%]} = \frac{\overline{N_{fd}}}{365.25} \times \frac{\overline{D}_{[\text{h}]}}{24} \times 100, \quad (7)$$

where $\overline{N_{fd}}$ denotes the average number of foggy days per year and $\overline{D}_{[\text{h}]}$ represents the average duration of fog in hours, which means that the product of these two variables corresponds to the average number of foggy hours per year.

III. Visibility Measurements Data

In order to obtain reliable visibility distributions, real visibility measurements samples from 17 different sites were acquired from the Portuguese Sea and Atmosphere Institute (IPMA). These sites are located across the Portuguese territory (cf. Fig. 2): the archipelagos of the Azores (3 sites) and Madeira (1 site), and mainland Portugal (4 coastal and 9 inland sites).

The visibility samples were obtained everyday during ten years (between January 1st of 1991 and December 31st of 2000), they have a high degree of resolution (the visibility values range from 100 m to 70 km) and they were taken many times per day (in some cases every hour). With these data, it is possible to build the cumulative distribution of the visibility for each different site (an example is depicted in Fig. 1).

The IPMA also provided additional data for the sites under study (regarding the ten years evaluation period), namely the

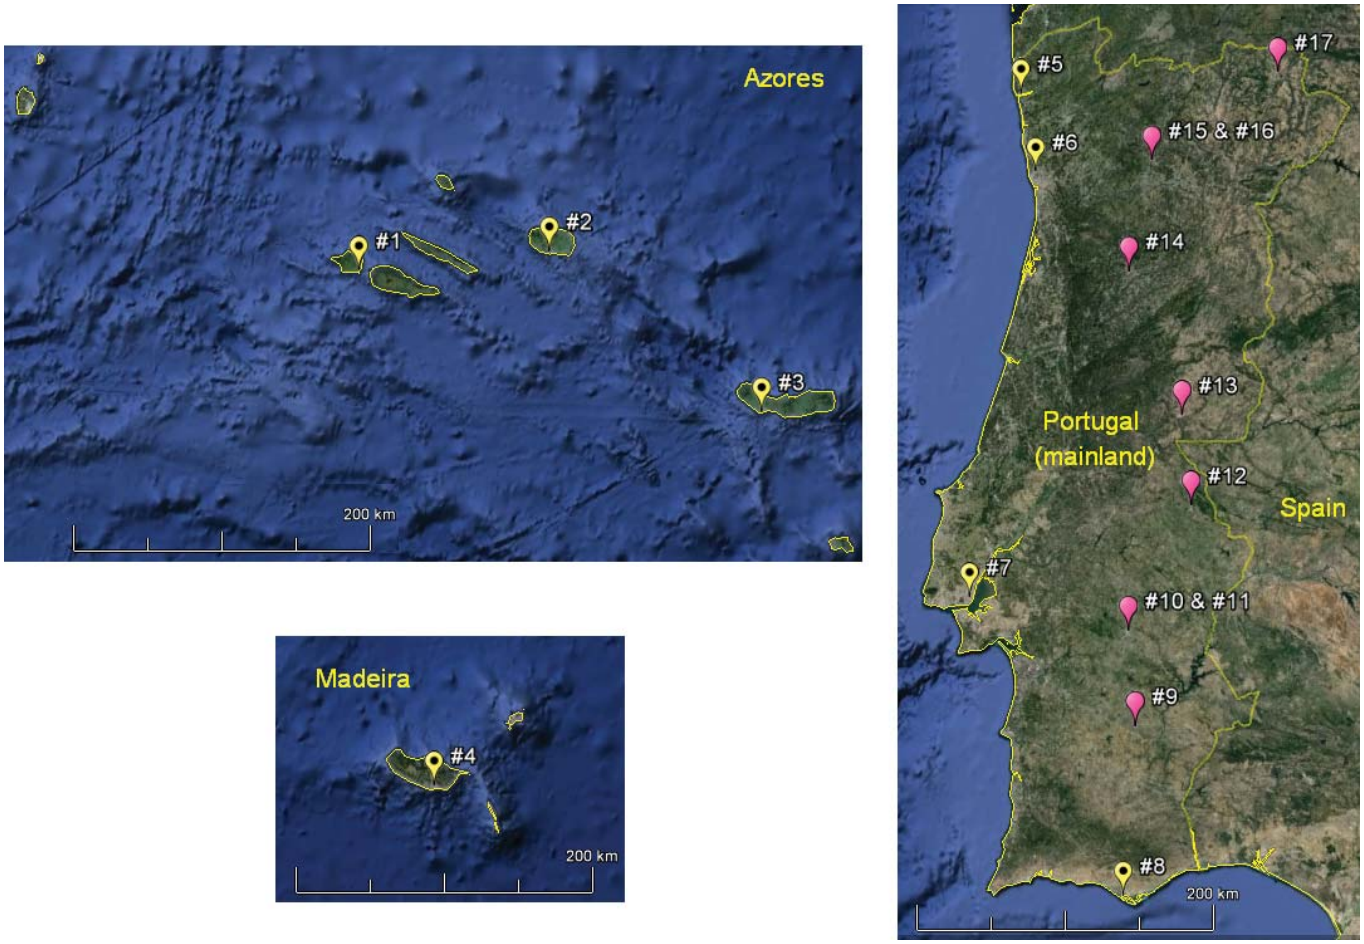

Fig. 2. Portuguese territory (map data: Google, Landsat).

number of days that were considered as foggy days and the duration of these fog events. With this information, it is possible to compute the average number of foggy days per year and the average duration of fog – these values are presented in Table I.

IV. PROPOSED MODELS

As mentioned in Section II, an FSO link is characterized by the unavailability due to fog that it can afford, i.e., the measure of downtime of an FSO system allowed by the Service-Level Agreement (SLA). The availability index (measure of uptime rather than downtime) is usually expressed as a percentage per year, typically ranging from 90% (i.e., 36.5 days of downtime per year) to 99.9999999% (i.e., 31.6 milliseconds of downtime per year). Thus, and from an FSO link designer perspective, the most interesting part of the visibility distribution is the one corresponding to percentages of the time ranging from 0 to 10%. Henceforth, the work in this paper focus on providing a simple but reliable framework which estimates this specific portion of the visibility distribution.

By analyzing the visibility measurements data, we first noticed that the visibility distributions under study presented two different types of behavior, depending on whether it refers to coastal or inland sites, as exemplified in Fig. 3. Therefore, we split the study of the visibility distribution into two cases: coastal sites versus inland sites.

Considering the examples presented in Fig. 3 for coastal sites, both visibility distributions seem to follow a curve that resembles the charge on a capacitor versus time when it is charging. Taking this into account, we propose to model the coastal visibility distribution as

$$V_{coastal\ [\mathrm{km}]} = \alpha \left[1 - \exp\left(-\beta \frac{p_{[\%]}}{100}\right)\right], \quad 0 \leq p \leq 10\%, \tag{8}$$

where p stands for the percentage of time (independent vari-

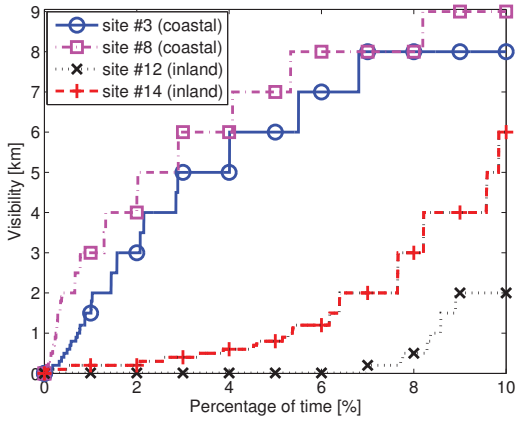

Fig. 3. Visibility values that were not exceeded for a given percentage of time – typical examples for coastal and inland sites.

able) while α and β denote the parameters of this model. To compute these parameters, first we assume that the visibility distribution stabilizes at some point, which is equal for all coastal sites, i.e., α is fixed. Afterwards, we force the proposed visibility distribution model (8) to pass through a particular point, namely the one related to the percentage of time for which the visibility does not exceed 1 km ($p_{(1\,\mathrm{km})}$, which can be obtained using (7)). Consequently, the relationship between α and β is given by

$$1 = \alpha\left[1 - \exp\left(-\beta\frac{p_{(1\,\mathrm{km})\ [\%]}}{100}\right)\right] \Leftrightarrow$$
$$\beta = \frac{-\log_e\left(1-\frac{1}{\alpha}\right)}{p_{(1\,\mathrm{km})\ [\%]}/100}. \quad (9)$$

Therefore, the proposed visibility distribution model for coastal sites is tuned by varying α (a value for this parameter is proposed in the following section).

As for inland sites, the visibility distribution examples presented in Fig. 3 resemble exponential functions that pass through the origin. For this reason, we propose to model the inland visibility distribution as

$$V_{inland\ [\mathrm{km}]} = \mu\left[\exp\left(\delta\frac{p_{[\%]}}{100}\right) - 1\right], \quad 0 \le p \le 10\%, \quad (10)$$

where μ and δ represent the parameters of this model. For inland sites, we noticed that as $p_{(1\,\mathrm{km})}$ increases, the more rapidly the visibility values grow after crossing the 1 km mark. In other words, we propose to model δ as

$$\delta = \eta\frac{p_{(1\,\mathrm{km})\ [\%]}}{100}, \quad (11)$$

where η is assumed to be a fixed value. Likewise the coastal case, we force the proposed visibility distribution model (10) to pass through the point related with $p_{(1\,\mathrm{km})}$, which means that the relationship between the different parameters can be expressed as

$$1 = \mu\left[\exp\left(\delta\frac{p_{(1\,\mathrm{km})\ [\%]}}{100}\right) - 1\right] \Leftrightarrow$$
$$\mu = \frac{1}{\exp\left(\eta\frac{p^2_{(1\,\mathrm{km})\ [\%]}}{100^2}\right) - 1}. \quad (12)$$

TABLE II. TUNED VALUES OF α AND η.

Parameter	Value
α	13.1
η	560

TABLE III. COEFFICIENT OF DETERMINATION.

Site	R^2	Site	R^2
#1 (Horta)	0.55	#9 (Beja)	0.81
#2 (Angra do Heroísmo)	0.76	#10 (Évora *i*)	0.87
#3 (Ponta Delgada)	0.89	#11 (Évora *ii*)	0.83
#4 (Funchal)	0.47	#12 (Portalegre)	0.85
#5 (Viana do Castelo)	0.92	#13 (Castelo Banco)	0.82
#6 (Porto)	0.95	#14 (Viseu)	0.94
#7 (Lisboa)	0.92	#15 (Vila Real *i*)	0.86
#8 (Faro)	-0.39	#16 (Vila Real *ii*)	0.89
		#17 (Bragança)	0.87

Therefore, the proposed visibility distribution model for inland sites is tuned by varying η (a value for this parameter is proposed in the following section).

V. RESULTS

As seen in the previous section, the proposed visibility distribution models require, as main input, the percentage of time for which the visibility does not exceed 1 km. Even though the data acquired from IPMA provided us direct access to this percentage value for each site through the respective cumulative distribution of the visibility, we want to evaluate the performance of the proposed models as if the number of foggy hours was the only statistical information available. Thus, the estimated visibility results presented hereafter are obtained by first estimating $p_{(1\,\mathrm{km})}$ using (7) and the values presented in Table I.

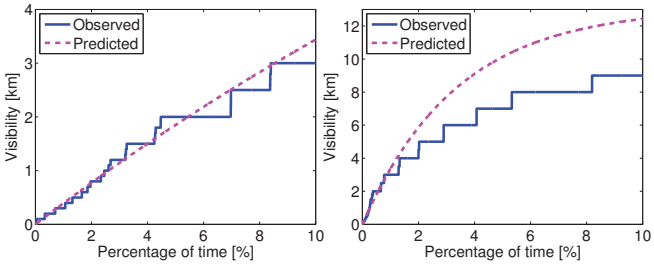
The coefficient of determination R^2 is adopted in this work as a measure of the goodness of fit of the proposed models to the real visibility data; it is defined as

$$R^2 = 1 - \frac{\sum_{k=1}^{N}(O_k - P_k)^2}{\sum_{k=1}^{N}(O_k - \overline{O})^2}, \quad (13)$$

where O and P correspond to the observed and predicted visibility values, and N stands for the total number of samples. Hence, the coefficient of determination ranges from minus infinity to one, with higher values indicating better agreement, while negative values indicate that the observed mean $\overline{O}$ provides a better fit to the outcomes than the prediction model, according to this particular criterion.

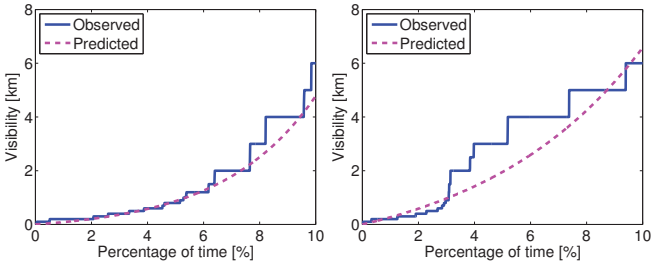
In order to tune the visibility distribution models proposed in this work (cf. Section IV), we first varied the value of α and then we selected the one that yielded the highest average fitness value $\overline{R^2}$ concerning coastal sites. The same procedure was adopted for the parameter η regarding inland sites. Table II contains the tuned values of α and η, while Table III presents the coefficient of determination obtained for the different sites under study.

The results show that the average coefficient of determination value concerning coastal sites is equal to 0.63, where



(a) Site #6 (Porto, $R^2 = 0.95$) (b) Site #8 (Faro, $R^2 = -0.39$)

Fig. 4. Analysis of the proposed visibility distribution model for coastal sites.



(a) Site #14 (Viseu, $R^2 = 0.94$) (b) Site #9 (Beja, $R^2 = 0.81$)

Fig. 5. Analysis of the proposed visibility distribution model for inland sites.

the best performance was obtained for site #6 with a suitable fit, Fig. 4(a). On the other hand, the worst performance was obtained for site #8, although the predicted visibility distribution has an adequate fit for values of the percentage of time below 1%, Fig. 4(b) – this last behavior was observed for all sites under study (not shown here due to the lack of space), meaning that the proposed models not only show a good fit but also they are specially efficient in estimating the visibility distribution for percentages of time below 1%, which is useful when designing FSO systems with availability indexes over 99%.

As for inland sites, the average coefficient of determination value is equal to 0.86, where the best performance was obtained for site #14 with an appropriate fit, Fig. 5(a). Moreover, even the worst inland case, which was obtained for site #9, presented a satisfactory fit, Fig. 5(b).

VI. Conclusions

In this work we presented a simple framework that estimates the visibility distribution for any given percentage of time below 10% and has as single statistical input the number of foggy hours per year. The proposed visibility distribution models were assessed using real data from 17 different sites in Portugal, with a wide diversity of environments: sites in islands, costal and inland sites in mainland Portugal. The main goal was to provide a straightforward and reliable tool that can be used by the designers of FSO systems.

Based on the obtained results, which showed a suitable correspondence between observed and predicted data for all sites under study, the adoption of the simple metric proposed herein can provide reliable estimates for visibility values just by knowing the number of foggy hours per year. Furthermore, even when the real visibility distribution is known, the proposed models can be used to somewhat enhance the resolution of the visibility information, e.g., to determine the visibility value that yields a 99.999% availability of an FSO link using real data that have a percentage resolution of only 1%.

***Abstract*—One of the most usual implementation errors that occurs when deploying radio access base-stations for mobile networks is to erroneously swap the antenna cables of two sectors, creating a crossed sector scenario. When this happens, the two swapped sectors still provide radio coverage, but not in the desired cell area. Hence, this paper proposes an enhanced approach for crossed sector detection, taking into account radio signal strength measurements, network topology, and also antennas' radiation pattern and orientation. The algorithm was applied to a live 2^{nd} Generation (2G)/3^{rd} Generation (3G)/4^{th} Generation (4G) mobile network, for accuracy and validation purposes. Large-scale analysis was set in UK and Portugal areas, and 16 crossed sectors were detected within a universe of 883 sites.**

***Index Terms*—Wireless Communications, Mobile Networks, Self-Organizing Networks Crossed Sector Detection.**

I. Introduction

According to a recent traffic report published by Cisco®, global mobile data traffic reached 4.2 exabytes per month at 2015, and up to 2.5 exabytes per month at 2014. In addition, in 2014, a 4G connection generated already 10 times more traffic on average than a non-4G connection. Although 4G connections represent only 6 percent of mobile connections today, they already account for 40 percent of mobile data traffic [1].

The Long Term Evolution (LTE) [2] is just one of the latest steps in an advancing series of mobile telecommunications systems. To support data traffic changes in mobile networks, in order to boost performance and deal with the increasing complexity within the operating 3G/4G networks, the Self-Organizing Networks (SON) concept was introduced as one of the main features of LTE. The main goal of SON mechanisms are to incorporate auto-configuration and self-optimization capabilities in evolved NodeBs (eNBs), where automatic crossed feeder detection and creating optimized neighbor cell lists [3] are some good examples.

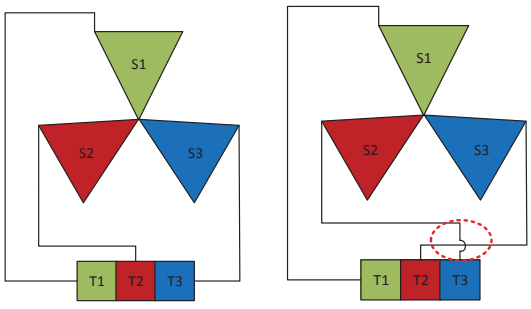
Inside SON improvements, the network should auto-detect if the sectorized antennas are connected to the wrong transceivers, which can happen due to human implementation error. This erroneous implementation degrades user performance, since radio resource planning and reuse strongly depend on antenna directivity and orientation.

The aim of this paper is to present an enhanced crossed sector detection algorithm, taking into account signal strength measurements, antenna radiation patterns, and antenna orientation. The algorithm performance was validated using data from live networks.

The paper is organized as follows. Section II overviews the crossed sector issue, presenting its definition and related problems. Section III highlights the proposed algorithm. Section IV discusses results when applied to a live network, followed by the conclusions in section V.

II. Crossed Sector Issue

One of the most common implementation errors when deploying base-stations is to accidentally swap cables of two sectors, creating a crossed sector scenario, as shown in Fig. 1. Each triangle represents an antenna sector (S), connected to the respective transmitter (T).



(a) Correct configuration. (b) Swapped cables of S2 and S3.

Fig. 1. Crossed sector illustration.

When it occurs, the two swapped sectors still provide coverage but not in the desired cell area. Therefore, orientation dependent configuration parameters like Physical Cell Identity (PCI), carrier frequency and Neighbour Cell List (NCL) are not the most suitable to the area covered by the sector, which can lead to performance degradation. A crossed sector

situation can generate several problems, such as high-level interference, leading to high dropped call ratio and poor data connectivity. Additionally, handover performance can be highly degraded, due to erroneous neighbor definition. Nowadays, this situation is manually detected by the radio engineer [4]. Some network statistics like Handover Sucess Rate (HOSR) help to detect probable crossed sector situations, which are confirmed in the following by Drive Testing (DT) and signal strength analysis [5].

Fig. 2 presents a detected crossed sector situation from a DT, where the colored slices represent the base station sectors, and the small filled circles present the DT samples, being mapped with the color from the best server sector.

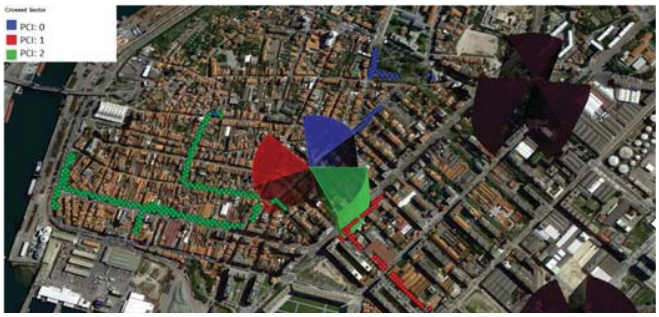


Fig. 2. A crossed sector thematic example based on drive-test best server data.

Fig. 2 shows that the samples which are supposed to be served by the red sector (PCI:1) are located on the opposite side of the site. Similarly, the samples which are supposed to be served by the green sector (PCI:2) are located on the "red" area, suggesting a crossed sector situation.

III. The Proposed Algorithm

The algorithm's aim is to detect crossed sectors based on signal strength measurements and antenna radiation pattern. The implemented concept correlates the difference between the received signal strength from two given sectors at a certain position, and the associated antenna gain prediction from these two sectors. The algorithm is composed by two modules: detection and decision module.

A. Detection Module

The detection module assures that appropriate samples are taken and examined by the decision module, so that only samples in dominant areas should be used, *i.e.*, only the samples which are in the area delimited by the sites coverage area will be considered. These dominant areas are delimited in azimuth and distance and consider the Half Power Beamwidth (HPBW) and the distance to the 1^{st} tier. This approach filters out ambiguous samples located in the central region between the two sectors. This approach is illustrated in Fig. 3, where a bisectorized site is considered. Red crosses and green squares represent ignored and considered samples, respectively.

The algorithm can be summarized as per the following pseudo code, where n is the number of the samples which will

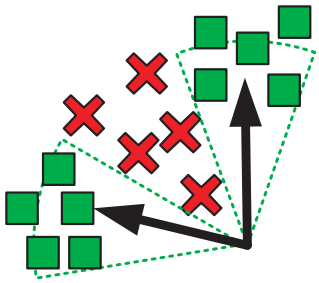

Fig. 3. Ignored and considered samples to be used in detection module.

be analysed. $\Delta P(i)$ and $\Delta G(i)$ are the difference between the received signal strength from sectors A (Pr_A) and B (Pr_B), and the difference between antenna gains from the same sectors (G_A and G_B), respectively. $crossed$ is a boolean array with the analysis results from each analysed sample. If $\Delta P(i)$ and $\Delta G(i)$ have the same signal, the boolean $crossed$ returns *false*, and the sample indicates that the sector is well defined. Otherwise, the boolean $crossed$ is affected with *true*.

repeat
  for $i \leftarrow 1, n$ **do**
    $\Delta P(i) \leftarrow sign(Pr_A - Pr_B)$
    $\Delta G(i) \leftarrow sign(G_A - G_B)$
    if $(\Delta P(i) \oplus \Delta G(i))$ **then**
      $crossed(i) \leftarrow true$
    else
      $crossed(i) \leftarrow false$
    end if
  end for
until all sectors are not compared

B. Decision Module

For the decision module, a statistical hypothesis test is applied to the detection module result, in order to classify the scenario as a function of all the analysed samples. With the difference between the received signal strength from two sectors at a given position *i*, and the difference between the antenna gains from these two sectors, α_i must be calculated as,

$$\alpha_i = \begin{cases} +(|\Delta G_i| + |\Delta P_i|), & if(\Delta G_i \otimes \Delta P_i) == 1 \\ -(|\Delta G_i| + |\Delta P_i|), & if(\Delta G_i \otimes \Delta P_i) == 0 \end{cases} \quad (1)$$

From this, the so called empirical probability density function of α is introduced and defined by

$$f(\alpha) = \begin{cases} P_i & if \quad \alpha = \alpha_i \quad (i = 1, 2...) \\ 0 & otherside \end{cases} \quad (2)$$

where,

$$P(\alpha = \alpha_i) = P_i \quad (3)$$

and

$$\sum_{i=1}^{max(i)} f(\alpha_i) = 1. \quad (4)$$

From this, a histogram based on α_i will be built, which will support the decision algorithm. The negative side of the histogram indicates the probability function that does not contribute to the crossed sector for the analysed pair. Moreover, the positive side, gives the probability density that contributes to the crossed sector decision.

Consider now two complementary sets of data so that,

$$\begin{aligned} \alpha_j &= \alpha_i \quad if \quad \alpha_i \geq 0 \\ \overline{\alpha_j} &= |\alpha_i| \quad if \quad \alpha_i < 0 \end{aligned} \tag{5}$$

and let,

$$\begin{aligned} \beta_c &= \frac{\sum_{j=1}^{max(j)} \alpha_j f(\alpha_j)}{\sum_{i=1}^{max(i)} |\alpha_i| f(\alpha_i)} \\ \beta_{\overline{c}} &= \frac{\sum_{j=1}^{max(j)} \overline{\alpha_j} f(\overline{\alpha_j})}{\sum_{i=1}^{max(i)} |\alpha_i| f(\alpha_i)} \end{aligned} \tag{6}$$

where β_c and $\beta_{\overline{c}}$ are the crossed and not crossed sample weight, respectively. The two values will be considered in the detection algorithm by direct comparison.

IV. Simulation Results and Analysis

This section describes the simulation outcomes. Extensive radio signal strength measurements from a 2G, 3G and 4G live networks were fed to the algorithm, in order to detect possible crossed sector cases. An extensive set of tests was done in UK and Portugal areas, and some crossed sectors were detected, according to the Table I.

TABLE I
Leeds and Oporto cluster analysis.

Area	Technology	Number of Sites	Crossed Sectors
Leeds, UK	2G	276	8
Leeds, UK	3G	259	2
Leeds, UK	4G	192	3
Oporto, PT	4G	156	3

Three specific case studies will be analysed in the following. Firstly, a trisectorized site with a double crossed sector, then a bi-sectorized site single crossed sector situation and finally a trisectorized site but with missing radio signal strength measurements from one of the sectors.

A. Scenario 1 - Trisectorized Site

In this scenario it will be analysed a 4G trisectorized site, in Oporto, with two crossed sectors. The third sector is well configured. The main site topology and color description is defined in Table II. Fig. 4 presents the crossed sector thematic map.

As can be seen in Fig. 4, the green samples are in the correct area service, hence, the sector (PCI:8) is well defined.

TABLE II
Scenario 2 - Analysed site details.

Cell Name	Antenna azimuth	PCI	Color
CELL A	80°	6	Blue
CELL B	170°	7	Red
CELL C	350°	8	Green

Fig. 4. Best server thematic for scenario 1.

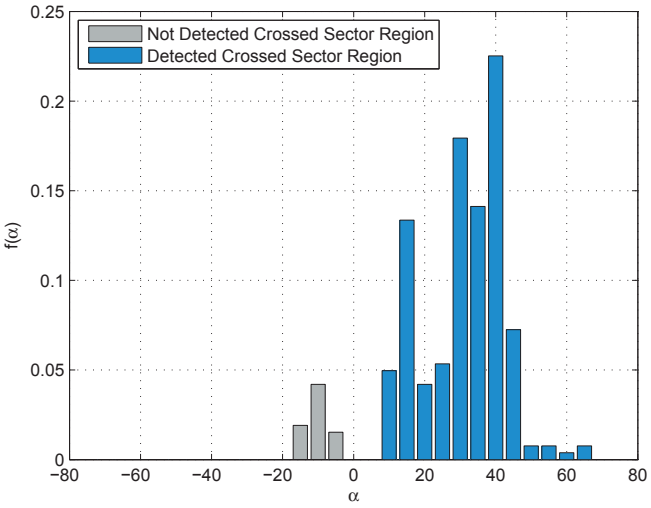

Fig. 5. α empirical probability density function for scenario 1.

Nevertheless, for the remaining sectors, the samples for each service area, do not correspond to the considered sector.

According to Section III, the empirical probability density function is presented in Fig. 5. From the histogram analysis it

is easily seen that most of the samples indicate crossed sector existence between blue (PCI:6) and red (PCI:7) sectors, since the occurrences are located in the positive side. Even so, there are also samples that indicate otherwise. These samples are located in the respective sector area service, but in smaller number. In order to decide and applying (6), the β_c and $\beta_{\overline{c}}$ distribution is created, see Fig. 6. It clearly suggests a scenario in which the blue sector is crossed with the red. In fact, the algorithm indicates that the blue sector is serving in a red sector area service. Additionally, the reverse process must be applied, *i.e.*, to verify if also the red sector is serving in the other area. In this scenario, as the green sector is well configured, the samples in its service area belong to the expected PCI. Finally, from Fig. 6, the β_c distribution suggests a probability of 0.97 in crossed sector detection, based on the available radio signal strength measurements.

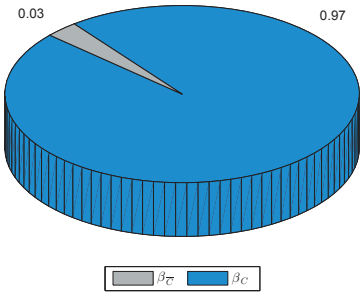

Fig. 6. β_c and $\beta_{\overline{c}}$ distribution function for scenario 1.

B. Scenario 2 - Bisectorized Site

In this scenario it will be analysed a 3G bisectorized site, in Leeds, with two crossed sectors. The site configuration, as antenna azimuth and Primary Scrambling Code (PSC), can be found in Table III.

TABLE III
SCENARIO 2 - ANALYSED SITE DETAILS.

Cell Name	Antenna azimuth	PSC	Color
CELL D	70°	184	Blue
CELL E	320°	185	Red

As in Fig. 7, the available samples in each service area do not match the corresponding sector. It is then expected that the algorithm can identify both crossed sectors. For the empirical probability density function of α visualization, see Fig. 8.

Most of the samples indicate a crossed sector situation between red (PSC:185) and blue (PSC:184) sectors, since most of the occurrences are located in the positive side. Contrary to the previous scenario, the analysed sectors are oriented in opposite azimuths, with a difference of 110°. Therefore, the difference between antenna gains and the difference between the received signal strength from sectors are greater. So, the α amplitude is is much higher. It is concluded that the red sector

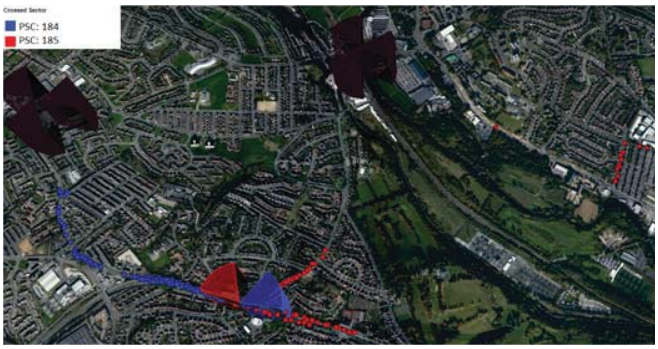

Fig. 7. Best server thematic for scenario 2.

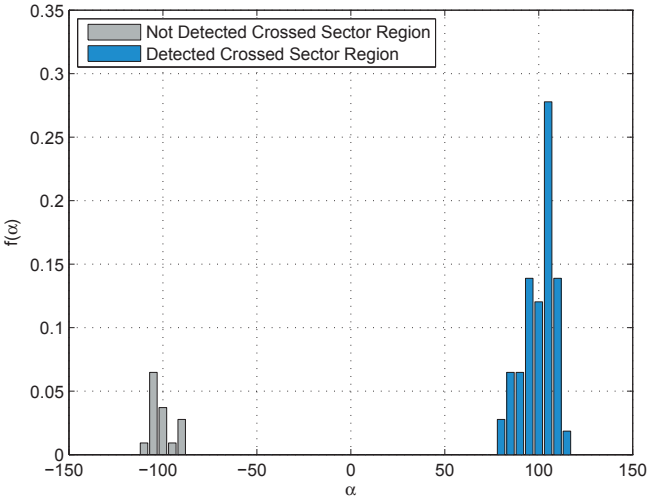

Fig. 8. α empirical probability density function for scenario 2.

is serving in the blue sector area service and vice-versa, as illustrated in Fig 9. The algorithm estimates a probability of 0.85 for a crossed sector scenario.

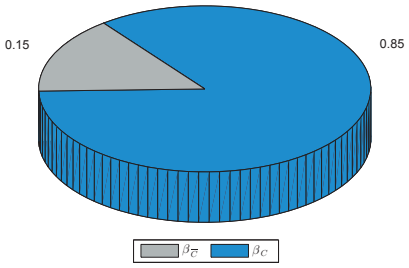

Fig. 9. β_c and $\beta_{\overline{c}}$ distribution function for scenario 2.

C. Scenario 3 - Trisectorized Site Without Samples

In this last scenario a 4G trisectorized site, also in Leeds, will be analysed, with two possible crossed sectors. However, one of them doesn't contain signal strength measurements, since a rural area with no roads exists through the northern

part of the site, see Fig. 10. The site configuration is displayed in Table IV.

TABLE IV
SCENARIO 3 - ANALYSED SITE DETAILS.

Cell Name	Antenna azimuth	PCI	Color
CELL F	0°	65	Green
CELL G	120°	63	Blue
CELL H	240°	64	Red

Fig. 10. Best server thematic for scenario 3.

According to Fig. 10, the samples in each service area do not correspond to the due sector. Furthermore, there are no available samples of the blue sector. Applying the algorithm, the usual decision chart is presented, in Fig. 11.

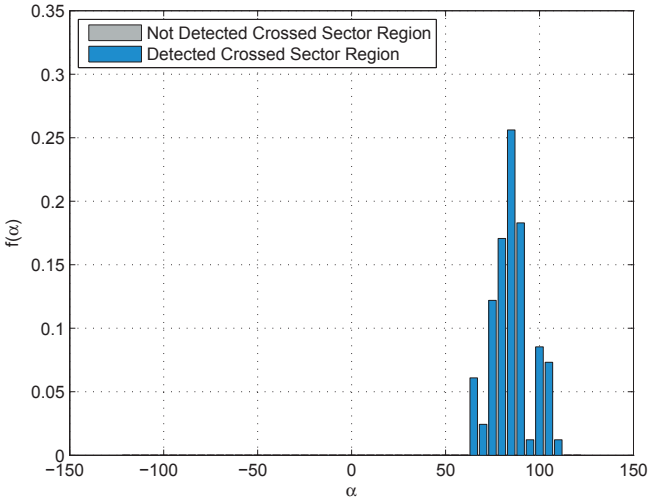

Fig. 11. α empirical probability density function for scenario 3.

All samples indicate the crossed sector between blue and red antennas, since the occurrences are located in the positive side. In other words, the algorithm stresses out that the red sector is dominant in the blue service area. However, unlike previous scenarios, the opposite does not occur. As there are no blue sector (PCI:63) samples, it is not possible to be sure that this is an effective crossed sector.

V. CONCLUSIONS

In this paper, an algorithm to detect crossed sectors is proposed. In order to identify these undesired cases, the algorithm uses strength signal measurements from DT, and information from mobile network operator topology, with the purpose of determining the antenna patterns.

The algorithm considers a statistical analysis, which supports the crossed sector detection with a certain degree of probability from empirical probability distribution functions. The algorithm performance was tested in real scenarios, both for bisectorized and trisectorized sites, as demonstrated in three scenarios above. Large-scale analysis was set in UK and Portugal areas, and 16 crossed sectors were detected within a universe of 883 sites. It is important to note that, the detected situations were reported to operators which did take the necessary correcting measures.

VI. ACKNOWLEDGEMENTS

***Abstract*—In this paper, we consider a cooperative spectrum sharing system in which primary communications take place bidirectionally with the assistance of one of the best-selected among multiple secondary users (relays) by using two-phase analog network coding protocol. Hereby, the primary system realizes a two-way cellular communication between a multi-antenna base station and a single-antenna mobile station. The best relay is selected based on minimizing the overall outage probability of the primary system. As such, we derive a tight expression for the overall outage probability of the primary system over Nakagami-*m* fading channels. We corroborate our analysis through numerical and simulation results, and provide valuable insights about the relay positioning and power allocation factor to ensure spectrum sharing.**

I. Introduction

Cognitive radio has emerged as a potential candidate to improve spectrum utilization efficiency in wireless networks [1]. Without causing any deleterious effect on primary transmissions, the unlicensed secondary users (SUs) are allowed to share the spectrum leased to primary users (PUs). Recently, cooperative spectrum sharing systems have been proposed by integrating relaying techniques with cognitive radio, and they have been shown to offer significant performance improvement under limited power and spectrum resources [2]-[4].

In an effort to further improve the efficiency of cooperative spectrum sharing systems, two-way relaying (TWR) approach [5] has been considered in [6]- [9], whereby one or more SUs can serve as relays to assist the primary communications. The authors in [6] have investigated a spectrum sharing system model with a decode-and-forward based TWR protocol. Recently, the concept of relay selection has been exploited in [7]-[9] to enhance system performance in combination with spectrum sharing. Moreover, in some of these works, analog network coding (ANC) [10] based TWR protocol has been used that allows bidirectional primary message exchange with spectrum sharing through an amplify-and-forward (AF) relay processing. More specifically, the authors in [9] have investigated the overall outage performance of a two-phase (2P) ANC-based spectrum sharing protocol with SU selection diversity in the absence of a direct link between two end PUs. Whereas, the authors in [11] and [12] have conducted single-user outage analysis of PUs by removing self-interference and mutual interference of the known primary signal and secondary signal respectively, followed by characterizing the spectrum sharing regions. However, all of these works have focussed on employing single-antenna devices at all nodes and their analyses are restricted to Rayleigh fading case only. Some of the earlier works have considered deploying multiple antennas at one of the end nodes to boost the performance of one-way relay [13], [14] and two-way relay [15] systems without spectrum sharing. To the best of our knowledge, the performance of 2P ANC-based cooperative spectrum sharing system with deployment of multiple antennas at the end-PU has not yet been analyzed, even for the case of Rayleigh fading. We emphasize hereby that such performance investigation over versatile Nakagami-*m* fading channels is mathematically more involved and important to understand the system behavior.

In this paper, we evaluate the performance of a 2P ANC-based cooperative spectrum sharing system under cellular scenario, wherein the bidirectional communication between a multi-antenna base station and a single-antenna mobile station is facilitated by one of the best selected among several SUs. Moreover, considering Nakagami-*m* fading channels, we derive a tight approximation for overall outage probability (OOP) of the primary system. Numerical and simulation results validate our theoretical analysis and provide useful insights about the relay location and power allocation factor to ensure spectrum sharing.

Notations: We use boldface lowercase letters to denote vectors, superscripts $(\cdot)^T$ and $(\cdot)^\dagger$ to denote transpose and complex transpose, respectively. $\mathbf{I}_N$ denotes the $N \times N$ identity matrix. $f_{\mathrm{X}}(\cdot)$ denotes the probability density function (PDF) of X. $\mathcal{CN}(\mu, \sigma^2)$ denotes a circular symmetric complex Gaussian random variable with mean μ and variance σ^2. $||\cdot||$ and $|\cdot|$ denote respectively the Frobenius norm and the absolute value, and $\binom{\cdot}{\cdot}$ denotes the binomial coefficient. $\Upsilon(\cdot,\cdot), \Gamma(\cdot,\cdot)$ and $\Gamma(\cdot)$ respectively represent the lower incomplete, the upper incomplete and the complete Gamma functions [16, eq. 8.350].

II. System and Channel Model

We consider a cooperative spectrum sharing system as shown in Fig. 1, where two end PUs T_a and T_b communicate bidirectionally with each other with the help of K SUs (relays) $S_k, k = 1, ..., K$, and S_e is secondary destination. The primary system may correspond to a cellular scenario, wherein T_a is a base station (equipped with N_a antennas) and T_b is a single-antenna mobile user. All the nodes are assumed to operate in

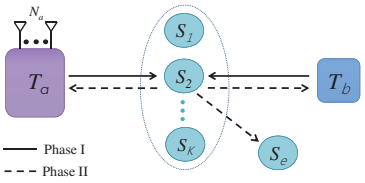

Fig. 1. Cellular two-way relay system with spectrum sharing.

a half-duplex manner and there is no direct link between T_a and T_b. We further assume that all channels are reciprocal, quasi-static and subject to independent block Nakagami-*m* fading. Let $\mathbf{h}_{a,k} = [h_{a,k}^1 h_{a,k}^2 ... h_{a,k}^{N_a}]^T$ denote the $N_a \times 1$ channel vector from T_a to S_k, $k = 1, ..., K$, where $\{h_{a,k}^l\}_{l=1}^{N_a}$ are independent and identically distributed (i.i.d.) Nakagami-*m* random variables with fading severity parameter m_a and average fading power Ω_a. Similarly, $h_{b,k}$ denotes the channel coefficient for the link between T_b and S_k, $k = 1, ..., K$, where $\{h_{b,k}\}$ are i.i.d. Nakagami-*m* random variables with fading severity parameter m_b and average fading power Ω_b. We also assume additive white Gaussian noise (AWGN) in each link with mean zero and variance unity. The transmit powers for T_a and T_b are assumed to be same and denoted by P.

The bidirectional communication between T_a and T_b occurs in two time phases by employing 2P ANC protocol with a single relay selection (say S_k). In the first phase, T_a and T_b simultaneously transmit their signals to the relay node S_k and the received signal is given by

$$y_k = \sqrt{P}\mathbf{h}_{a,k}^T \mathbf{w}_a x_a + \sqrt{P} h_{b,k} x_b + n_k, \tag{1}$$

where x_a and x_b are unit-energy transmit signals at T_a and T_b respectively, $\mathbf{w}_a$ is the transmit weight vector, chosen to be $\left(\frac{\mathbf{h}_{a,k}^\dagger}{||\mathbf{h}_{a,k}||}\right)^T$ for maximum-ratio-transmission at T_a, and n_k is the AWGN at S_k. During the second phase, the SU S_k allocates its transmit power P_R to combine its own signal x_e with the received signal y_k to generate

$$x_k = \beta_k y_k + \sqrt{(1-\mu)P_R} x_e, \tag{2}$$

where x_e has unit-energy and $\beta_k = \sqrt{\frac{\mu P_R}{P||\mathbf{h}_{a,k}||^2 + P|h_{b,k}|^2 + 1}}$, such that a fraction μ of power P_R is allocated for relaying primary signals and the rest for secondary transmission. Then, the S_k broadcasts this x_k signal to the primary and secondary terminals. The $N_a \times 1$ received signal at T_a can be given as

$$\mathbf{y}_a = \mathbf{h}_{a,k}\Big[\beta_k(\sqrt{P}||\mathbf{h}_{a,k}||x_a + \sqrt{P}h_{b,k}x_b + n_k) + \sqrt{(1-\mu)P_R}x_e\Big] + \mathbf{n}_a, \tag{3}$$

where $\mathbf{n}_a \sim \mathcal{CN}(\mathbf{0}, \mathbf{I}_{N_a})$ is the AWGN vector at T_a. For maximum-ratio-combining, the received signal $\mathbf{y}_a$ is multiplied by a $1 \times N_a$ receive weight vector $\mathbf{w}_a^T = \frac{\mathbf{h}_{a,k}^\dagger}{||\mathbf{h}_{a,k}||}$ and the resultant signal after self-interference cancellation is given by

$$\tilde{y}_a = \Big[\beta_k\sqrt{P}||\mathbf{h}_{a,k}||h_{b,k}x_b + \beta_k||\mathbf{h}_{a,k}||n_k + \sqrt{(1-\mu)P_R}||\mathbf{h}_{a,k}||x_e\Big] + \tilde{n}_a, \tag{4}$$

where $\tilde{n}_a = \frac{\mathbf{h}_{a,k}^\dagger \mathbf{n}_a}{||\mathbf{h}_{a,k}||} \sim \mathcal{CN}(0,1)$. Similarly, the signal received at T_b (after self-interference cancellation) is obtained as

$$\tilde{y}_b = \Big[\beta_k\sqrt{P}||\mathbf{h}_{a,k}||h_{b,k}x_a + \beta_k h_{b,k}n_k + \sqrt{(1-\mu)P_R}h_{b,k}x_e\Big] + \tilde{n}_b, \tag{5}$$

where $\tilde{n}_b \sim \mathcal{CN}(0,1)$ is the AWGN at T_b.

Thus, the resultant end-to-end signal-to-noise ratio (SNR) for transmission from T_b to T_a via S_k is given by

$$\gamma_{ba,k} = \frac{\mu P_R \mathrm{XY}}{(1-\mu)P_R\mathrm{X}^2 + (1-\mu)P_R\mathrm{XY} + \epsilon\mathrm{X} + \mathrm{Y}}, \tag{6}$$

and for transmission from T_a to T_b via S_k is given by

$$\gamma_{ab,k} = \frac{\mu P_R \mathrm{XY}}{(1-\mu)P_R\mathrm{Y}^2 + (1-\mu)P_R\mathrm{XY} + \epsilon\mathrm{Y} + \mathrm{X}}, \tag{7}$$

where $\mathrm{X} = ||\mathbf{h}_{a,k}||^2$, $\mathrm{Y} = |h_{b,k}|^2$ and $\epsilon = \left(\frac{P_R}{P} + 1\right)$.

III. Performance Analysis of the Primary System

In this section, we first derive a closed-form expression of overall outage probability (OOP) for the primary transmissions under Nakagami-*m* fading, and then investigate the condition for cooperative spectrum sharing.

A. Overall Outage Probability (OOP)

For the ANC protocol under consideration, the primary system is said to be in outage when either T_a or T_b is in outage. Therefore, the OOP for the bidirectional primary transmissions through the relay S_k can be given as

$$\mathcal{P}_{\mathrm{out},k}(\gamma_{\mathrm{th}}) = \Pr\left[\min\left(\gamma_{ab,k}, \gamma_{ba,k}\right) < \gamma_{\mathrm{th}}\right], \tag{8}$$

where γ_{th} is a predetermined threshold. Hereby, the relay can be chosen to maximize the worse of the two end-to-end instantaneous SNRs and is tantamount to minimize the OOP. As such, we can employ the best relay selection criteria as

$$k^* = \arg \max_{k \in \{1,2,...,K\}} \min\left\{\gamma_{ab,k}, \gamma_{ba,k}\right\}. \tag{9}$$

Based on the above formulation, we can apply order statistics to compute system OOP with best relay selection as

$$\mathcal{P}_{\mathrm{out}}(\gamma_{\mathrm{th}}) = \prod_{k=1}^{K} \mathcal{P}_{\mathrm{out},k}(\gamma_{\mathrm{th}}). \tag{10}$$

Hence, we first need to find $\mathcal{P}_{\mathrm{out},k}(\gamma_{\mathrm{th}})$ which can be splitted effectively into two parts as

$$\mathcal{P}_{\mathrm{out},k}(\gamma_{\mathrm{th}}) = \Pr\{\gamma_{ab,k} < \gamma_{\mathrm{th}}, \gamma_{ab,k} < \gamma_{ba,k}\} + \Pr\{\gamma_{ba,k} < \gamma_{\mathrm{th}}, \gamma_{ab,k} > \gamma_{ba,k}\}. \tag{11}$$

Using the expressions of $\gamma_{ba,k}$ and $\gamma_{ab,k}$ from (6) and (7) respectively, it can be readily shown that $\gamma_{ab,k} < \gamma_{ba,k}$ when $\mathrm{X} < \mathrm{Y}$ and vice-versa. Therefore, to proceed further with the analysis, the above expression becomes

$$\mathcal{P}_{\mathrm{out},k}(\gamma_{\mathrm{th}}) = \underbrace{\Pr\left\{\gamma_{ab,k} < \gamma_{\mathrm{th}}, \mathrm{X} < \mathrm{Y}\right\}}_{\mathcal{P}_1} + \underbrace{\Pr\left\{\gamma_{ba,k} < \gamma_{\mathrm{th}}, \mathrm{Y} < \mathrm{X}\right\}}_{\mathcal{P}_2}. \tag{12}$$

Let us now derive the expressions for $\mathcal{P}_1$ and $\mathcal{P}_2$. Starting with $\mathcal{P}_1$, we have

$$\mathcal{P}_1 = \Pr\left\{\mu P_R \mathrm{XY} < \gamma_{\mathrm{th}}(1-\mu)P_R \mathrm{Y}^2 + \gamma_{\mathrm{th}}(1-\mu)P_R \mathrm{XY} + \gamma_{\mathrm{th}}\epsilon \mathrm{Y} + \gamma_{\mathrm{th}} \mathrm{X}, \mathrm{X} < \mathrm{Y}\right\}, \tag{13}$$

which, after some simplifications, can be expressed as

$$\mathcal{P}_1 = \Pr\{X(Y\xi - \gamma_{\mathrm{th}}) < \gamma_{\mathrm{th}}(1-\mu)P_R Y^2 + \gamma_{\mathrm{th}}\epsilon Y, X < Y\}, \tag{14}$$

where $\xi = \mu P_R - \gamma_{\mathrm{th}}(1-\mu)P_R$. The evaluation of (14) can be performed under two feasible cases based on the power allocation factor μ as follows:

Case 1: If $\xi < 0$ or equivalently $0 < \mu < \frac{\gamma_{\mathrm{th}}}{1+\gamma_{\mathrm{th}}}$, the first inequality inside the curly brackets in (14) holds true irrespective of the values of X and Y (as X and Y are always positive) and hence, $\mathcal{P}_1$ for this case is given by

$$\mathcal{P}_1 = \Pr\left\{0 < \mathrm{Y} < \infty, 0 < \mathrm{X} < \mathrm{Y}\right\}. \tag{15}$$

Case 2: If $\xi > 0$ or equivalently $\mu > \frac{\gamma_{\mathrm{th}}}{1+\gamma_{\mathrm{th}}}$, the following two separate events can be formulated over X and Y:

- if $\mathrm{Y}\xi - \gamma_{\mathrm{th}} < 0$, the first inequality inside the curly brackets in (14) holds true regardless of the values of X and Y (always positive) and thus, the corresponding event is described by $\{0 < \mathrm{Y} < \delta, 0 < \mathrm{X} < \mathrm{Y}\}$, where $\delta = \frac{\gamma_{\mathrm{th}}}{\xi}$.
- if $\mathrm{Y}\xi - \gamma_{\mathrm{th}} > 0$, the first inequality inside the curly brackets in (14) reduces to $\mathrm{X} < \mathrm{g(Y)}$, where $\mathrm{g(Y)} = \frac{\gamma_{\mathrm{th}}(1-\mu)P_R \mathrm{Y}^2 + \gamma_{\mathrm{th}}\epsilon \mathrm{Y}}{\mathrm{Y}\xi - \gamma_{\mathrm{th}}}$. The joint event in this case is given by $\{\delta < \mathrm{Y} < \infty, 0 < \mathrm{X} < \lambda(\mathrm{Y})\}$, where $\lambda(\mathrm{Y}) = \min\{\mathrm{Y}, \mathrm{g(Y)}\}$.

Thus, for Case 2, the expression for $\mathcal{P}_1$ can be given by

$$\begin{aligned}\mathcal{P}_1 &= \Pr\{0 < \mathrm{Y} < \delta, 0 < \mathrm{X} < \mathrm{Y}\} \\ &\quad + \Pr\{\delta < \mathrm{Y} < \infty, 0 < \mathrm{X} < \lambda(\mathrm{Y})\}.\end{aligned} \tag{16}$$

We can further simplify $\lambda(\mathrm{Y})$ in (16), as it is either equal to Y or $\mathrm{g(Y)}$ depending upon the values of Y and the power allocation factor μ. So, after performing certain manipulations, $\lambda(\mathrm{Y})$ can be expressed as

$$\lambda(\mathrm{Y}) = \begin{cases} \mathrm{Y} & \text{for Case 2.1,} \\ \begin{cases} \mathrm{Y} & \text{for } \mathrm{Y} < \vartheta \\ \mathrm{g(Y)} & \text{for } \mathrm{Y} > \vartheta \end{cases} & \text{for Case 2.2,} \end{cases} \tag{17}$$

where Case 2.1: $\frac{\gamma_{\mathrm{th}}}{1+\gamma_{\mathrm{th}}} < \mu < \frac{\gamma_{\mathrm{th}}}{\frac{1}{2}+\gamma_{\mathrm{th}}}$, Case 2.2: $\frac{\gamma_{\mathrm{th}}}{\frac{1}{2}+\gamma_{\mathrm{th}}} < \mu < 1$, and $\vartheta = \frac{(\epsilon+1)\gamma_{\mathrm{th}}}{\mu P_R - 2\gamma_{\mathrm{th}}(1-\mu)P_R}$. Consequently, $\mathcal{P}_1$ for Case 2 can be obtained by substituting each of these sub-cases one-by-one in (16). On invoking Case 2.1 in (16), $\mathcal{P}_1$ reduces to

$$\begin{aligned}\mathcal{P}_1 &= \Pr\{0 < \mathrm{Y} < \delta, 0 < \mathrm{X} < \mathrm{Y}\} \\ &\quad + \Pr\{\delta < \mathrm{Y} < \infty, 0 < \mathrm{X} < \mathrm{Y}\} \\ &= \Pr\left\{0 < \mathrm{Y} < \infty, 0 < \mathrm{X} < \mathrm{Y}\right\},\end{aligned} \tag{18}$$

which coincides with the same result as presented in (15) for Case 1. Therefore, based on the conditions on μ, Case 1 and Case 2.1 can be combined together. Thereby, we can re-define the two cases and formulate the $\mathcal{P}_1$ accordingly as

Case 1: For $0 < \mu < \frac{\gamma_{\mathrm{th}}}{\frac{1}{2}+\gamma_{\mathrm{th}}}$, the expression of $\mathcal{P}_1$ can be presented using (15) and (18) as

$$\begin{aligned}\mathcal{P}_1 &= \Pr\left\{0 < \mathrm{Y} < \infty, 0 < \mathrm{X} < \mathrm{Y}\right\} \\ &= \int_{y=0}^{\infty}\int_{x=0}^{y} f_{\mathrm{X}}(x) f_{\mathrm{Y}}(y)\,\mathrm{d}x\,\mathrm{d}y.\end{aligned} \tag{19}$$

Case 2: For $\frac{\gamma_{\mathrm{th}}}{\frac{1}{2}+\gamma_{\mathrm{th}}} < \mu < 1$, the expression of $\mathcal{P}_1$ can be obtained by invoking Case 2.2 from (17) into (16) as

$$\begin{aligned}\mathcal{P}_1 &= \Pr\{0 < \mathrm{Y} < \vartheta, 0 < \mathrm{X} < \mathrm{Y}\} \\ &\quad + \Pr\{\vartheta < \mathrm{Y} < \infty, 0 < \mathrm{X} < \mathrm{g(Y)}\} \\ &= \int_{y=0}^{\vartheta}\int_{x=0}^{y} f_{\mathrm{X}}(x) f_{\mathrm{Y}}(y)\,\mathrm{d}x\,\mathrm{d}y + \int_{y=\vartheta}^{\infty}\int_{x=0}^{\mathrm{g}(y)} f_{\mathrm{X}}(x) f_{\mathrm{Y}}(y)\,\mathrm{d}x\,\mathrm{d}y.\end{aligned} \tag{20}$$

Now, we first evaluate $\mathcal{P}_1$ for Case 2 using (20). However, computation of the second integral term in (20) is not so straightforward since $\mathrm{g}(y)$ is a non-linear function in y. Therefore, in order to make the analysis tractable, we simplify $\mathrm{g}(y)$ for the case of large P_R as

$$\begin{aligned}\mathrm{g}(y) &= \frac{\gamma_{\mathrm{th}}(1-\mu)P_R y^2 + \gamma_{\mathrm{th}}\epsilon y}{y\xi - \gamma_{\mathrm{th}}} = \frac{\frac{\gamma_{\mathrm{th}}(1-\mu)P_R y^2}{\xi} + \frac{\gamma_{\mathrm{th}}\epsilon y}{\xi}}{y - \frac{\gamma_{\mathrm{th}}}{\xi}} \\ &\approx \delta(1-\mu)P_R y + \epsilon\delta,\end{aligned} \tag{21}$$

where $\delta = \frac{\gamma_{\mathrm{th}}}{\xi} << 1$ for large values of P_R.

Since the channel coefficients $\{h_{a,k}^l\}_{l=1}^{N_a}$ are assumed i.i.d. Nakagami-m random variables, the $\mathrm{X} = ||\mathbf{h}_{a,k}||^2$ follows Gamma distribution and hence the PDF of X is given by $f_{\mathrm{X}}(x) = \left(\frac{m_a}{\Omega_a}\right)^{m_a N_a} \frac{x^{m_a N_a - 1}}{\Gamma(m_a N_a)} e^{-\left(\frac{m_a}{\Omega_a}\right)x}$, $x \geq 0$. Likewise, the PDF of $\mathrm{Y} = |h_{b,k}|^2$ is given by $f_{\mathrm{Y}}(y) = \left(\frac{m_b}{\Omega_b}\right)^{m_b} \frac{y^{m_b-1}}{\Gamma(m_b)} e^{-\left(\frac{m_b}{\Omega_b}\right)y}$, $y \geq 0$. On substituting these PDFs along with approximation of $\mathrm{g}(y)$ from (21) into (20), and then simplifying with the aid of [16, eqs. 3.351.1, 3.351.2], we obtain $\mathcal{P}_1$ for Case 2 as

$$\mathcal{P}_1 = 1 - \mathcal{A}_1 - \mathcal{B}_1, \tag{22}$$

where

$$\mathcal{A}_1 = \frac{\left(\frac{m_b}{\Omega_b}\right)^{m_b}}{\Gamma(m_b)} \left[\sum_{m=0}^{m_a N_a - 1} \frac{\left(\frac{m_a}{\Omega_a}\right)^m}{m!} \left(\frac{m_a}{\Omega_a} + \frac{m_b}{\Omega_b}\right)^{-(m+m_b)} \times \Upsilon\left(m + m_b, \vartheta\left(\frac{m_a}{\Omega_a} + \frac{m_b}{\Omega_b}\right)\right)\right], \tag{23}$$

and

$$\mathcal{B}_1 = \frac{\left(\frac{m_b}{\Omega_b}\right)^{m_b}}{\Gamma(m_b)} e^{-\left(\frac{m_a}{\Omega_a}\right)\epsilon\delta} \sum_{m=0}^{m_a N_a - 1} \frac{\left(\frac{m_a}{\Omega_a}\right)^m}{m!} (\epsilon\delta)^m \times \sum_{l=0}^{m} \binom{m}{l} \left[\frac{(1-\mu)P_R}{\epsilon}\right]^l \frac{\Gamma(l + m_b, \vartheta\Theta_{ab})}{(\Theta_{ab})^{l+m_b}}, \tag{24}$$

with

$$\Theta_{ij} \triangleq \frac{m_i}{\Omega_i}\delta(1-\mu)P_R + \frac{m_j}{\Omega_j}, \tag{25}$$

for $i, j \in \{a, b\}$ and $i \neq j$.
Thus, from (19) and (22), $\mathcal{P}_1$ can be given as

$$\mathcal{P}_1 = \begin{cases} \int_{y=0}^{\infty}\int_{x=0}^{y} f_{\mathrm{X}}(x) f_{\mathrm{Y}}(y)\,\mathrm{d}x\,\mathrm{d}y & \text{for Case 1,} \\ 1-\mathcal{A}_1-\mathcal{B}_1 & \text{for Case 2,} \end{cases} \tag{26}$$

where Case 1: $0 < \mu < \frac{\gamma_{\mathrm{th}}}{\frac{1}{2}+\gamma_{\mathrm{th}}}$ and Case 2: $\frac{\gamma_{\mathrm{th}}}{\frac{1}{2}+\gamma_{\mathrm{th}}} < \mu < 1$.

Proceeding in a similar manner as for $\mathcal{P}_1$, we derive the expression for $\mathcal{P}_2$ which is given by

$$\mathcal{P}_2 = \begin{cases} \int_{x=0}^{\infty}\int_{y=0}^{x} f_{\mathrm{Y}}(y) f_{\mathrm{X}}(x)\,\mathrm{d}y\,\mathrm{d}x & \text{for Case 1,} \\ 1-\mathcal{A}_2-\mathcal{B}_2 & \text{for Case 2,} \end{cases} \tag{27}$$

where

$$\mathcal{A}_2 = \frac{\left(\frac{m_a}{\Omega_a}\right)^{m_a N_a}}{\Gamma(m_a N_a)}\left[\sum_{m=0}^{m_b-1}\frac{\left(\frac{m_b}{\Omega_b}\right)^{m}}{m!}\left(\frac{m_a}{\Omega_a}+\frac{m_b}{\Omega_b}\right)^{-(m+m_a N_a)} \times \Upsilon\left(m+m_a N_a, \vartheta\left(\frac{m_a}{\Omega_a}+\frac{m_b}{\Omega_b}\right)\right)\right], \tag{28}$$

and

$$\mathcal{B}_2 = \frac{\left(\frac{m_a}{\Omega_a}\right)^{m_a N_a}}{\Gamma(m_a N_a)} e^{-\left(\frac{m_b}{\Omega_b}\right)\epsilon\delta}\sum_{m=0}^{m_b-1}\frac{\left(\frac{m_b}{\Omega_b}\right)^{m}}{m!}(\epsilon\delta)^m \times \sum_{l=0}^{m}\binom{m}{l}\left[\frac{(1-\mu)P_R}{\epsilon}\right]^{l}\frac{\Gamma(l+m_a N_a, \vartheta\Theta_{ba})}{(\Theta_{ba})^{l+m_a N_a}}. \tag{29}$$

Finally, on substituting (26) and (27) into (12), and the result into (10), we get the required expression for OOP as

$$\mathcal{P}_{\mathrm{out}}(\gamma_{\mathrm{th}}) = \begin{cases} 1 & \text{for Case 1,} \\ [(1-\mathcal{A}_1-\mathcal{B}_1)+(1-\mathcal{A}_2-\mathcal{B}_2)]^K & \text{for Case 2.} \end{cases} \tag{30}$$

It is worthwhile to mention that our derived expression for OOP reduces to the result as presented in [9] for the special case of Rayleigh fading ($m_a = m_b = 1$) and single antenna at the base station ($N_a = 1$). Thereby, our analysis is more generalized and applicable over versatile Nakagami-*m* fading.

B. Spectrum Sharing Region

For the system under consideration, it requires that the OOP of the primary system must be lower than or equal to that for the direct transmission in order to facilitate spectrum sharing. That is,

$$\mathcal{P}_{\mathrm{out}}(\gamma_{\mathrm{th}}) \leq \mathcal{P}_{\mathrm{out}}^{\mathrm{DT}}(\gamma_{\mathrm{th}}), \tag{31}$$

where $\mathcal{P}_{\mathrm{out}}^{\mathrm{DT}}(\gamma_{\mathrm{th}})$ represents OOP of the primary system without spectrum sharing (direct transmission only). Let us consider that the direct link between T_a and T_b follows Nakagami-*m* distribution with fading severity parameter m_0 and average fading power Ω_0. Therefore, the OOP $\mathcal{P}_{\mathrm{out}}^{\mathrm{DT}}(\gamma_{\mathrm{th}})$ can be given by

$$\mathcal{P}_{\mathrm{out}}^{\mathrm{DT}}(\gamma_{\mathrm{th}}) = \frac{1}{\Gamma(m_0 N_a)}\Upsilon\left(m_0 N_a, \frac{m_0\gamma_{\mathrm{th}}}{\Omega_0 P}\right). \tag{32}$$

The condition for spectrum sharing in (31) can be re-expressed using (30) and (32) as

$$[(1-\mathcal{A}_1-\mathcal{B}_1)+(1-\mathcal{A}_2-\mathcal{B}_2)]^K \leq \frac{\Upsilon\left(m_0 N_a, \frac{m_0\gamma_{\mathrm{th}}}{\Omega_0 P}\right)}{\Gamma(m_0 N_a)}, \tag{33}$$

wherein $\frac{\gamma_{\mathrm{th}}}{\frac{1}{2}+\gamma_{\mathrm{th}}} < \mu < 1$. As evident from (22), (27) and (33), it is difficult to obtain the exact solution for optimal power allocation factor μ^* to ensure spectrum sharing and therefore, it should be computed using standard numerical methods.

IV. Results and Discussions

In this section, we carry out numerical studies for the outage performance of the primary system as described previously and substantiate our analysis with Monte Carlo simulations. We adopt the path loss model with the exponent $\nu = 4$ and consider the distance between T_a and T_b as d_0, the distance between T_a and S_k as d_1, and that between T_b and S_k as d_2, for all k. Thus, we have $\Omega_a = d_1^{-4}$, $\Omega_b = d_2^{-4}$, and $\Omega_0 = d_0^{-4}$. Also, the distances d_0, d_1, and d_2 are normalized such that $d_0 = d_1 + d_2 = 1$. For all the analytical plots (except the curve marked with $\triangleleft$ sign), we have considered $P_R = P$.

Fig. 1 plots the outage performance of the primary system as a function of SNR (P/σ^2) for various values of N_a. Here, we set $K = 4$, $m_a = m_b = 1$, and $\gamma_{\mathrm{th}} = 2$ dB. As can be observed, our analytical and simulation results are in well agreement with each other, especially in the mid to high SNR region. Though, a slight gap exists in the low SNR region due to the approximation of integral limit in (20) with a large P_R assumption. Further, the curves are shown to attain outage floor at high SNRs, suggesting an absence of diversity. Also, it can be seen that reliable communication is sustained when N_a is increased from 1 to 2. However, the outage performance degrades when N_a is increased to 3. Thus, we have two ways to improve outage performance, that is either to increase P_R or to allocate more power to primary transmissions by increasing μ. It is evident that there is little improvement in the outage performance when P_R is increased by 10 times, whereas the OOP reduces drastically when μ is increased from 0.9 to 0.95. Based on these observations, one can infer that the power allocation factor μ plays a critical role for the considered 2P ANC-based spectrum sharing system.

Fig. 2 shows the variation of OOP with power allocation factor μ for different pairs of distances, where we have fixed $K = 3$, $N_a = 1$, $P_R = P = 10$ dB, $m_0 = 1$, and $\gamma_{\mathrm{th}} = 2$ dB. As can be seen, the analytical curves match with the simulation results. All the solid plots corresponding to $m_a = m_b = 1$ are the same as [9, Fig. 2] and have been reproduced here for making comparison with our results. It can be observed that keeping other parameters fixed (comparing all the solid lines), the system attains the lowest OOP when the selected

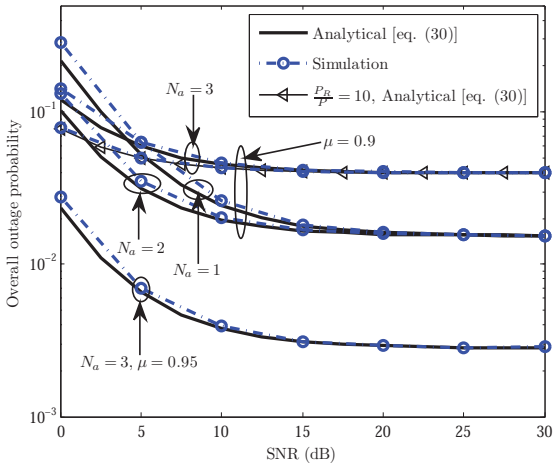

Fig. 2. Overall outage performance versus SNR for different values of N_a.

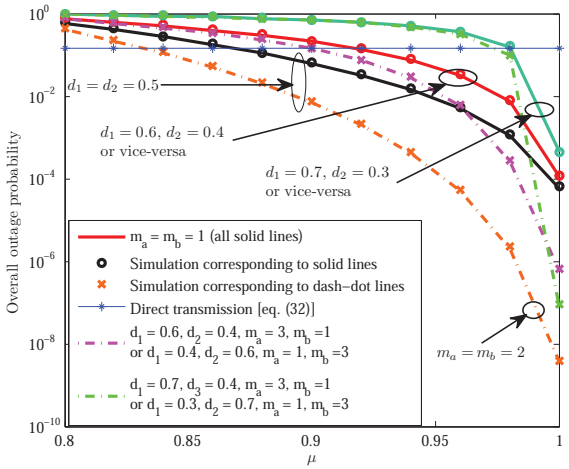

Fig. 3. Overall outage performance versus power allocation factor μ.

relay is placed at the middle of T_a and T_b, which can be further reduced as the fading severity reduces (referring to $m_a = m_b = 2$). Also, there exists an optimal power allocation threshold μ^* for all pairs of distances, which can be fetched at the intersection point with direct transmission curve. For instance, the optimal allocation threshold when $d_1 = d_2 = 0.5$ and $m_a = m_b = 2$ is $\mu^* \approx 0.832$, suggesting that the considered primary system (with spectrum sharing scheme) can achieve better performance than the direct transmission (without spectrum sharing) when $\mu^* < \mu < 1$. Furthermore, it is clearly visible that for $d_1 = d_2 = 0.5$, μ^* reduces from 0.868 when $m_a = m_b = 1$ to 0.832 when $m_a = m_b = 2$. In other words, the spectrum sharing region is increased when the fading severity gets reduced for both the links ($T_a \rightarrow S_{k^*}$ and $S_{k^*} \leftarrow T_b$) in this case. Moreover, for unbalanced cases, when the relay is not exactly at the middle of the two primary nodes, spectrum sharing region is enhanced if there is a reduction in fading severity over the longer link. As an example, when $d_1 = 0.6, d_2 = 0.4$, the outage performance is limited by the link $T_a \rightarrow S_{k^*}$. Thus, when $m_a > m_b$, the OOP is reduced and the spectrum sharing region is increased.

V. Conclusion

We evaluated the performance of a 2P ANC-based cooperative spectrum sharing system under cellular scenario. Specifically, a tight approximation to overall outage probability for the primary system is derived for Nakagami-*m* fading channels. Our results showed that an outage floor appears in the high SNR regime. The multiple antennas at one end PU help improving the outage performance when the relay allocates sufficiently high power for primary transmissions. Moreover, we have attained valuable insights for relay positioning and power allocation factor to ensure spectrum sharing under various fading conditions.

Abstract— **Multimedia-centric and graphic-intensive applications running on a mobile device consume high amounts of energy, resulting in shorter battery life. Importantly, there is still not enough work done in developing energy-aware solutions to prolong the battery life of devices without affecting the quality of the distributed video/multimedia content. In this context, this paper proposes *DEAR* - a device energy-centric adaptive region-of-interest quality-based mechanism, whereby the displayed video quality is varied dynamically depending on both user interests in the content and device battery level. Notably, user region-of-interests in video frames and device screens are considered and different quality levels are associated by altering dynamically both the video content properties (data-rate) and device display characteristics such as brightness and backlight. The energy consumption is measured using an Arduino board while video quality is analyzed using extensive subjective tests. The results indicate that up to 53% energy could be saved in the device while retaining above average perceptual video quality.**

Keywords - ***Bit-rate, brightness, backlight, region-of-interest, video streaming***

I. INTRODUCTION

Over the last years, with the advent of mobile Internet and smart-phones, there has been an exponentially increasing demand by the mobile users to support real-time multimedia delivery to their wireless mobile devices. However, multimedia and graphic-intensive applications consume significant amounts of energy when running on these devices, thereby resulting in reducing their overall battery life. There have been some efforts on finding different possible and efficient solutions for decreasing the energy consumption, while playing video and also at the same time, maintain video stream quality at high levels [1-4].

A particularly interesting concept that has been introduced is the region-of-interest (RoI)-awareness for video content. RoI indicates a specific video-frame region that is of greater interest to the viewers as compared to other frame regions [5]. In reality, it is very difficult to judge the exact RoI, though it is held that the viewer's eyes focus changes from the center of the screen to the screen edge. The goal of our research is to minimize the energy consumption in the device, without affecting the overall video perceived quality.

This work proposes **DEAR - a device energy-centric adaptive region-of-interest quality-based mechanism** which adjusts energy consumption in wireless mobile devices. This energy adjustment is based on adaptively varying RoI display properties in both device screen and video content in such a way that it remains largely imperceptible to the end-user.

The paper is organized as follows. Section II discusses related works on different aspects of RoI. Section III introduces the proposed DEAR algorithm and explains its different aspects in detail. Further, section IV describes testing methodology and scenarios, and presents the results of different tests. Finally, section V concludes the paper and provides some future research directions.

II. RELATED WORK

Recent noteworthy techniques in optimizing energy consumption of video applications consider different aspects of RoI. Among these are RoI-based video adaptive solutions whose essential idea is to display the region of the screen where the user is more likely to focus on at higher quality than the surrounding areas. For example, while watching a tennis match, the viewer may be most interested in looking at the area around the ball (though this may not be the case for all videos). However, in reality, there are always regions in every video frame on which users focus more, as compared to other frame areas. It has been shown in [6] that by adapting a high-resolution window at the point-of-gaze and low-resolution window in the peripheral areas, the users had longer initial saccadic latencies in peripheral areas as compared to the scenario wherein a low resolution was uniformly displayed across the whole screen of the device. Importantly, it was found in [7] that in order to maintain a particular user-perceived video quality, if the degradation is increased in the peripheral areas, the size of the adapted high-resolution window would also have to be increased at the point of gaze. Recently, a scalable RoI (SROI) was proposed which supports fine grained granularity adaptation in RoI with low computing complexity [8]. Further, a RoI adaptive delivery scheme (ROIAS) is proposed and a detailed objective and subjective assessment and analysis has been carried out for RoI-aware adaptive streaming [9, 10]. However, the adaptation focused mainly on network-related aspects to control RoI quality adaptation. The adaptations are done in order to realize better video quality both objectively and subjectively. In principle, there are numerous techniques for discovering RoI in a video including eye-tracking (with cameras),

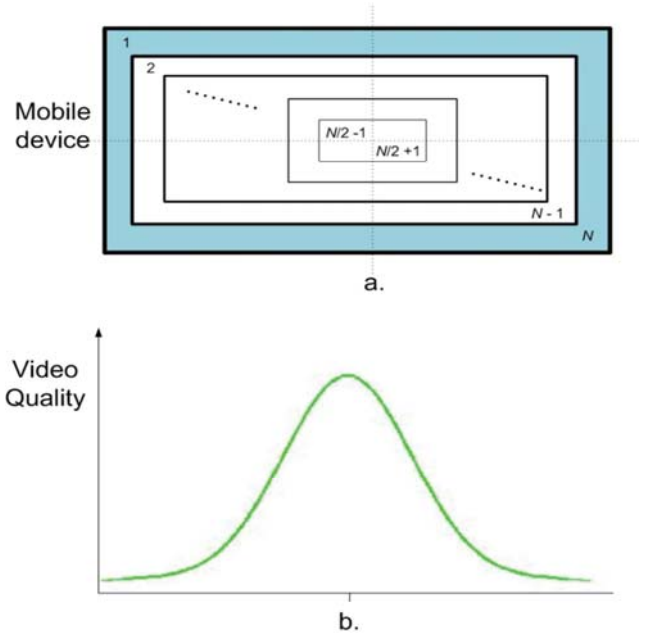

Fig. 1 Region of Interest (RoI) adaptation in screen
(1a) A *N*-step RoI in the mobile screen
(1b) Variation in video quality from the centre of screen

video processing and analysis. However, most of these mechanisms add significant complexity to the solution, focus on a single RoI, are network delivery-oriented or involve additional hardware. To the best knowledge of the authors, there has been no work on adaptively varying the number of RoI considered and investigating from the energy perspective. The next section proposes an adaptive RoI mechanism and discusses the associated potential energy savings in the device.

III. DEAR – RoI-based Video Adaptive Solution

This section describes the proposed DEAR - a novel dynamic adaptive video mechanism for real-time adjustment of the energy consumption in the mobile device. This involves having a RoI-based video adaptation in the device, wherein certain highly interesting regions of the video frame are displayed with the best video quality whereas other less-interesting regions are provided at a reduced video quality. Fig. 1 illustrates the mechanism. In this case, it is assumed that the viewer's area of most interest is in the centre of the video frame and hence, the highest quality video is shown at the centre of the device screen. Further, as the distance from the centre of the screen is increased, an ideal scenario would be to gradually decrease the video quality using a normal distribution, as shown in Fig. 1b. This is done by changing several parameters in both the device and in the video/multimedia content transmitted to the device. In order to realistically achieve a gradual degradation in the video quality, multiple-RoIs are considered for the device screen and multimedia frame, as shown in Fig. 1a. The multiple RoIs approach has as main advantage the fact that each RoI can be considered independently. This enables treating and adjusting different parameters (brightness, backlight/colour, etc.) across each region independently. Notably, multiple RoI control provides support for smoother video quality adjustments that would be almost imperceptible to the user. There are two major aspects in the design of DEAR: setting the RoIs and setting the parameters to adjust across the RoIs. Both these aspects play a major role in determining the real-time energy consumption of device.

3.1 Setting RoIs: Typically, the video played in RoI screen areas is at higher quality than that played in non-RoI zones. This result in the video played in RoI areas consuming higher energy as compared to that played in non-RoI zones. DEAR considers multiple RoIs with different quality levels. Consequently they will have different energy readings. The overall energy consumed by mobile device employing DEAR can be adjusted by varying two major parameters: the number of RoIs (N) and the area (A_x) of each RoI x of the N RoIs.

3.2 Parameters to Adjust across Different RoIs Several parameters related to both the video content and device screen affect the energy consumption of the device. They include:

i. Data rate of the video/multimedia content (R)
ii. Brightness/gamma of the screen (G)
iii. The backlight intensity of the device screen (B)
iv. The colour displayed in the screen (C)
v. Frame rate of the video/multimedia content (F)

The energy consumed in the device can be altered by adjusting the values of one or more of these parameters. As DEAR considers multiple RoIs, DEAR adaptation requires that each RoI be considered and controlled independently in terms of data rate, brightness, colour, backlight, etc. As changing some of these parameters for areas within a frame, particularly frame rate and the colour of the video content is either extremely challenging or very complex, DEAR adjusts only the first three variables (R, G, B) per RoI in real-time.

The principle of DEAR adaptation algorithm can be understood from the detailed flowchart shown in Fig. 2. The initial values of parameters are first set. Subsequently, the video quality is measured and ensured to be above the fair value (3.0 as per ITU-T P. 913 standard [13], refering to user subjective quality), Further, a two-step approach is adopted. In the first step, the actual video quality is measured; while in the second step, the energy consumption in each RoI is varied. To begin with, only one RoI is considered and different parameters associated with this RoI are varied. Depending on the situation, the following is carried out:

i. If the energy consumption of the screen is very high (above a threshold) relative to the current device battery level, then the number of RoIs is changed (increased or decreased). The parameters associated with the RoIs are modified to reduce energy consumption and the energy consumption is then measured again. This process is repeated iteratively.

ii. If the energy consumption of the screen is low (below a threshold) relative to the current device battery level, the values of the different parameters are such varied to increase the quality of RoIs in the order **o**f increasing their distance to the centre of the video frame. If two RoIs have

the same values for the parameters, they will be merged and the number of RoIs decreases.

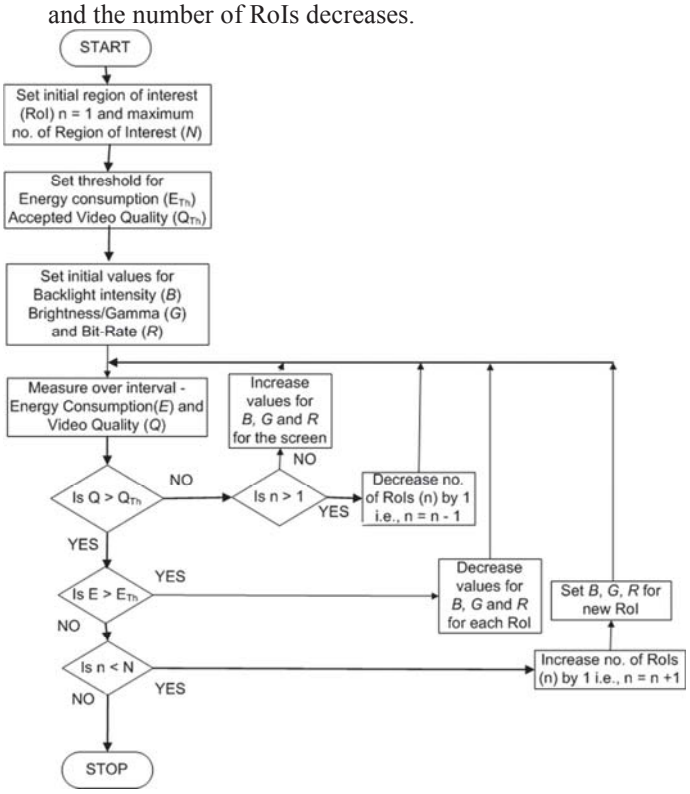

Fig. 2 Overview of the DEAR algorithm

3.3 Energy Consumption Analysis: For DEAR with N RoIs (shown in Fig. 1a), energy consumption of each RoI x is Es_x where $x \in \{1, N\}$. If As_x is the area of RoI x, the total energy consumption relative to entire screen size (divided in RoIs) is:

$$E = \sum_{x=1}^{N} Es_x \, As_x \qquad (1)$$

Further, the energy consumption for each RoI (Es_x) is a function of the above mentioned different variables. This could be written as in equation (2) or as in equation (3) when considering the parameters most feasible to be adjusted only:

$$Es_x = f(Rs_x, Gs_x, Bs_x, Gs_x, Cs_x, , Fs_x) \quad (2)$$
$$Es_x = f(Rs_x, Gs_x, Bs_x) \qquad (3)$$

In equations (2) and (3), Rs_x, Gs_x, Bs_x Cs_x and Fs_x represent the video bit rate, brightness, backlight intensity, display colour and video frame rate associated with a particular RoI x. In case of non-RoI zones, the energy consumption is the same across the whole area and can be written as in (4) or (5) if only the selected parameters are considered.

$$Es = f(Rs, Gs, Bs, Cs, Fs) \qquad (4)$$
$$Es = f(Rs, Gs, Bs) \qquad (5)$$

In equations (4) and (5), Rs, Gs, Bs, Cs and Fs represent video bit rate, brightness, backlight intensity, display colour and video frame rate associated with non-RoI. If the non-RoI adaptive approach is considered, the energy consumption across the entire non-RoI video frame could be written as:

$$E_{non\text{-}RoI} = N \, Es \qquad (6)$$

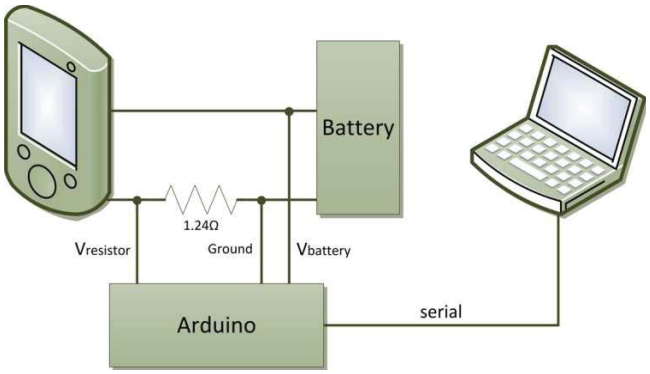

Fig. 3 Schematic representations for measuring energy consumption in mobile device

It should be noted that a change in any variable results in a change in the energy consumption of the device screen (in fact, of the area of the screen affected). Hence, considering the energy consumption modification due to each variable change to be independent, the difference in the energy consumption in the screen due to DEAR (as compared to a non-RoI approach) could be written as:

$$\Delta E = \Delta E_R + \Delta E_G + \Delta E_B \qquad (7)$$

In order to investigate the potential amount of energy savings due to RoI, the different parameters that affect the design are considered separately. Further, varying each parameter individually, the effect on the energy consumption is studied along with the effect on the overall video quality. In the next section, non-RoI and multiple RoIs approaches are considered with changes in only one parameter and the difference in the energy consumption is then measured.

IV. Scenarios, Testing and Results

The goal of the experimental tests is to adjust the video display at the mobile device using DEAR algorithm. However, in order to assess both the energy consumption and the video quality, only one parameter is varied at a time and its effect is measured. Further, the energy consumption in the mobile device is measured and compared with a non-RoI approach. Notably, for each experiment, the average video quality is observed using a subjective method. This is done in order to ensure that in the process of optimizing the energy consumption in the device, the video quality is maintained at an acceptable level.

4.1 Experimental Set-up: The experimental set-up employed is shown in Fig. 3. The device used is Samsung Galaxy GT-I5500 mobile phone, (Android 2.3, 2.8 inch LCD touch screen with 320 x 240 pixels, battery capacity of 1200mAh). The reason for selecting a low-end smart-phone is because, it is expected that all smart-phone users will have this or a better smart-phone. The energy consumption of the device is measured using Arduino – an open source micro-controller board [11]. The Arduino board can receive multiple types of input signals and can be connected between the device and device battery. Arduino board supports USB connections and hence all measurements are logged onto a laptop via USB. The Arduino board measures the energy consumed while playing a video only. Hence, in order to calculate the energy saved due

to the use of the proposed DEAR algorithm, the energy consumption is first measured for the idle state/flight mode. Once the baseline consumption of device is known (E_{base}) and the energy consumption of device during the video playing is measured (E_{play}), the energy cost of video playing can be calculated as $E_{play} - E_{base}$. The set-up for carrying out the energy measurements is based on a similar set-up for measuring the energy of different components in the device, as explained in [12, 13].

There are two different video clips considered in the experimental set-up. The first video clip *video1* is a 15-second trailer of the movie *Toy-Story* that is encoded using MPEG4 at 301 kbps. The second video clip *video2* is an 18-second trailer of the movie *Harry Potter* which is also encoded using MPEG-4 at a rate of 180 kbps. It should be noted that *Toy-Story* has a lower contrast ratio, higher brightness, higher gamma level and higher data rate as compared to *Harry Potter*. The reason for selecting the second video is to test the difference in the energy consumption, especially if and when the energy savings is considerably higher for variation in DEAR design.

The tests measure the energy consumed in the device for different videos and for different scenarios. For each scenario, the average video quality is determined by a subjective analysis on a scale of 1-5 (mean opinion score, standardized by ITU-T) that provides a scale for perceived video quality from user's perspective [14].

4.2 Scenarios and Results

Table 1 Variation in energy consumption and average video quality for different data rates

Sr. No.	No. of RoIs	Data Rate (Kbps)	Energy (mW)	Quality (1-5)
1.1	No RoI (Full screen)	180	251.88	4.93
1.2		128	243.76	4.35
1.3		64	241.03	3.02
2.1	1 RoI (Pixel Area: 160x90)	RoI: 180 Non-RoI: 128	245.97	3.93
2.2			241.97	3.70
3.1	1 RoI (Pixel Area: 90x90)	RoI: 180 Non-RoI: 128	246.13	3.65
3.2			241.36	3.50

4.2.1 Varying Data-Rates: This test is performed with 90% device brightness. A multiple concurrent RoI area is considered with different data rates across different RoIs. The RoIs are assumed to be concentric at the centre of the screen. Given the screen size of hand-held device (320x180 pixels), two different situations are considered. The first situation sees a RoI bounded by a rectangle of size 160x90 pixels, whereas in the second case, the RoIs are bounded by a square of 90x90 pixels area. Further, two different data rates are considered for the out-of-RoI area of the screen. The first data rate considered is 128 kbps while the second data rate considered is 64 kbps.

Table 1 shows the results of the energy consumption and the subjective video quality, across both a complete frame and a frame having both RoI and non-RoI areas. As the data rate is decreased, the overall quality also decreases (e.g. scenario 1.1 and 1.3). Importantly, this pattern remains consistent even when there are different data rates across different RoIs in the frame. Notably, if one compares a non-RoI frame with 64 kbps (scenario 1.3) with two frames containing two different RoIs patterns (128 kbps across non-RoI area, scenario 3.1), it can be observed that a reduction in data rate across non-RoI area gives the same energy consumption, while the quality of the video is slightly improved (3.5 instead of 3.02). Notably, only up to 4% savings in energy consumption could be obtained while still retaining quality above 3.0.

Table 2 Variation in energy consumption and average video with variation in brightness/gamma

Sr. No.	No. of RoIs	Brightness@ RoI & non-RoI	Energy Consumed (mW)	Video Quality
1.1	No RoI	100% brightnes	266.15	4.15
1.2	No RoI	80% brightness	258.93	3.71
1.3	No RoI	60% brightness	253.93	3.32
1.4	No RoI	40% brightness	248.53	2.71
2.1	1 RoI	RoI: 100% Non RoI: 80%	256.79	3.82
2.2	1 RoI	RoI: 100% Non RoI: 60%	253.03	3.42
3.1	4 RoIs	RoI:(100,75,50,25)% Non RoI: 1%	241.34	4.11
4.1	9-RoIs	RoI: (100,90,.., 20)% Non-RoI: 10%	249.76	4.04
5.1	19-RoIs	RoI:(100,95,....,10)% Non-RoI: 5%	243.43	3.96

4.2.2 Varying Brightness/Gamma: In these tests, DEAR algorithm with different brightness/gamma levels for different RoIs is considered. The brightness/gamma decreases from 100% for RoI at the centre of the screen to low levels at RoIs further from the centre, with a minimum value of screen brightness at the screen edge. Table 2 shows the effect of this reduction on the energy consumption and resulting video quality levels when DEAR with multiple RoIs and different brightness/gamma levels is employed; in comparison with non-RoI adjustment of the brightness across whole screen area. A non-RoI video with 100% brightness across entire screen has a very high video quality (4.15) and consumes 266.15 mW. On the other hand, a non-RoI video with 40% of maximum brightness value reduces energy consumption by roughly 7% (248.53 mW) only, while it decreases the video quality drastically by more than 33%. Hence, reducing brightness across the whole screen is not a good option. Hitherto, a RoI-based reduction in brightness/gamma results in significant decrease in energy consumption, while maintaining good video quality. For example, having 19 RoIs with decreasing brightness levels (100 to 10 in steps of 5%) for different RoIs and even lower brightness (5%) for non-RoI area results in energy consumption of 243.43 mW (9% decrease in energy consumption as compared to non-RoI approach with 100% brightness), and the video quality reduces by less than 4%. This shows that device energy consumption could be reduced by employing DEAR-based variation focusing on the brightness with negligible effect on quality.

4.2.3 Varying Backlight: The wireless devices/smart-phones that exist today do not allow variable backlight across different regions of the device. In order to investigate the potential benefit of varying backlight across different *regions,* the energy consumption of the device was measured for different backlight intensities. In order to measure the effect of different backlight levels on the energy consumption of the device and the overall video quality, a linear reduction in the device backlight is considered in the tests. The backlight is reduced from 100% to 25%. Table 3 shows the energy consumption and average subjective video quality when the brightness of the device is varied from 100% to 25%. It can be observed from Table 3 that in case of video1, decreasing the backlight to 50% reduces the energy consumption by 30% while decreasing the backlight to 25% reduces the energy consumption by 36%. The video quality reduces by only 1.6% and 9.4% respectively. This represents a significantly high energy savings as compared to varying the data-rate and the brightness levels in the device screen. In order to verify the large energy savings obtained by varying the backlight in the case of *video1*, *video2* with darker background was used.

The tests for *video2* showed that decreasing the backlight to 50% and 25% reduces the energy consumption by 29.6% and 35.4% while reducing the video quality by 14.5% and 21.3% respectively. Given that *video2* was already a 'dark' video, the reduction in energy consumption also resulted in important decrease in the video quality. Further, if the results of two videos are extrapolated till the video quality drops to an average of 3.0, then for these two videos, an energy saving of up to 40% could be obtained by employing DEAR focusing only on screen backlight adaptation.

4.2.4 Overall Energy Savings: The three test results indicate that having multiple adaptive RoI-based mechanism with variation in three parameters (bit-rate, brightness/gamma and backlight intensity) across different RoIs could result in significant energy savings. Notably, the tests indicate that up to 53% energy can be saved in total – bit-rate variation (atleast 4%), brightness/gamma variation (at least 9%) and variation in device backlight intensity (at least 40%).

V. CONCLUSIONS

This paper proposed an adaptive multiple region-of-interest mechanism, DEAR, for adjusting energy consumption in video-centric mobile devices while maintaing good video quality levels. Three main parameters: video bit-rate, display brightness/gamma levels and the screen backlight intensity were identified and the achievable energy savings due to each of these factors were studied in context of DEAR. The measurement of energy consumption and the subjective video assessment test results indicated that, using the proposed DEAR algorithm, it was possible to save upto 53% of energy in the wireless device while still maintaining above average video quality level; with the actual saving being also depending on the nature of the selected video.

There are two major research tasks envisaged for further enhancement of DEAR. The first aspect is to investigate the amount of variation in the three parameters that would optimally reduce the energy consumption in the device. Secondly, since the amount of energy savings depends on the number of RoIs and the variation across parameters, a future work would be to develop an analytical framework for investigating the number of RoIs that would provide maximum savings in the energy consumption in the device.

Table 3 Variation in energy consumption and average video quality with variation in device backlight

Device Backlight	Energy Consumption(mW)		Video Quality(1–5)	
	Video 1	Video 2	Video 1	Video 2
100%	260.89	265.75	4.76	4.66
75%	214.75	220.37	4.76	4.33
50%	182.32	187.01	4.68	3.98
25%	166.07	171.04	4.31	3.62

***Abstract*—Energy detection is a well-known method for spectrum sensing in cognitive radio (CR) systems. Classical energy detection (CED) algorithm suffers from detection performance limitations in the presence of Gaussian noise. Improved energy detection (IED) algorithm has been suggested recently that outperforms the CED algorithm in AWGN channel. Further, generalized p-norm detector exists which performs better than the CED algorithm for the detection of random signals in the presence of Gaussian noise. The present paper highlights the combined benefit of IED algorithm and the generalized p-norm detector with multi-antenna assisted soft combining in AWGN channel to achieve a higher performance gain.**

***Index Terms*—Cognitive radio, Spectrum sensing, Energy detection, p-norm detector**

I. Introduction

Cognitive radio (CR) refers to an intelligent wireless communication device that has emerged since last decade to mitigate the spectrum scarcity problem by the efficient use of radio spectrum. It can sense its operational radio environment and can dynamically and autonomously adjust its operating parameters [1]. Dynamic spectrum access (DSA) is the key concept which allows a CR device to opportunistically access the frequency band allocated to an incumbent/primary user (PU), when the PU is not using the band. For DSA, the CR devices has to sense the radio environment licensed to the PUs. Various methods for spectrum sensing have been reported in the literature [2], [3], which include Energy detection, Cyclostationary detection, Matched filtering, etc. Among all aforementioned techniques, the classical energy detection (CED) is the most preferred one because of its low computational requirement and implementation cost. The main drawback of CED is that the detection threshold is highly susceptible to the changing background noise and the interference.

In order to improve the performance of energy detection based spectrum sensing systems, an improved energy detection (IED) algorithm has recently been suggested [4] which outperforms the CED in AWGN channel with almost identical complexity. Another interesting improvement strategy for energy detection based on p-norm detector was first proposed by Chen [5], where the CED is modified by replacing the squaring operation of signal amplitude by arbitrary positive power p. The application of p-norm detector in the fading channel and for diversity reception has been well investigated recently [6].

In [7], maximal ratio combining (MRC) based soft-combining scheme for CED has been investigated in which the accurate energy values observed by the different CR antennas are combined to make a better decision for spectrum occupancy, assuming the perfect reporting channels. In the present work, we aspire to evaluate the achievable performance gain in a multi-antenna assisted spectrum sensing system taking the combined benefit of the IED and the p-norm energy detector. Here the energy value (power p operation) calculated by each antenna is combined at the fusion center (FC) using the MRC and then the decision about the presence/absence of PU is made according to the improved energy detection algorithm. It is difficult to obtain analytically the optimized p-value for a given target performance criterion and therefore a numerical evaluation is adopted.

The organization of the rest of the paper is as follows: Section II provides the mathematical details of CED, IED, p-norm detector and the improved p-norm detector with soft combining scheme. Section III provides the detailed theoretical results as well as practical design guidelines. Finally the conclusion is drawn in section IV.

II. System Model

In CR, the secondary user (SU) looks for the PU in the band of interest and try to sense the surrounding spectrum space. Consider a CR sensing node with N receiving antennas. The observed normalized energy value at the j^{th} antenna is given by [7]

$$Y_j = \begin{cases} \frac{1}{M}\sum_{i=1}^{M} w_{ji}^2 & : H_0 \\ \frac{1}{M}\sum_{i=1}^{M} \left(h_{ji}s_{ji} + w_{ji}\right)^2 & : H_1 \end{cases} \quad (1)$$

where, s_{ji}, h_{ji} and w_{ji} denote the i^{th} sample of the PU signal, channel fading coefficient and the zero-mean additive white Gaussian noise with unit variance at the j^{th} antenna with $i = 1, 2, \ldots, M$ and $j = 1, 2, \ldots, N$. H_0 denotes the null hypothesis and H_1 denotes the alternate hypothesis corresponding to the vacant and the busy spectrum respectively. Fig. 1 shows the corresponding system model.

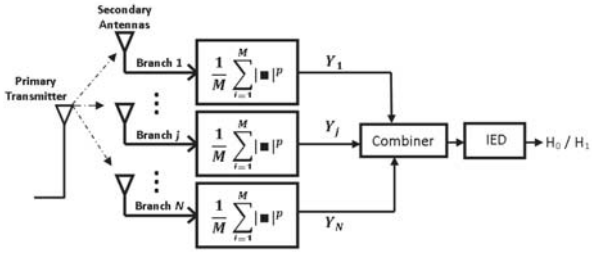

Fig. 1. The system model

For $M \gg 1$, Y_j will be Gaussian distributed as:

$$Y_j \sim \begin{cases} \mathcal{N}(1, 2/M) & : H_0 \\ \mathcal{N}\left((1+\gamma_j), 2/M\,(1+\gamma_j)^2\right) & : H_1 \end{cases} \tag{2}$$

where, γ_j is the instantaneous signal-to-noise-ratio (SNR) at the j^{th} antenna.

A. CED with Soft Combining

In soft combination, the weighted normalized energy from each antenna is added and this weighted sum of energy is then compared with the predefined threshold to decide the presence/absence of the PU. The weighted summation for the m^{th} sensing event is given as [7]:

$$\mathcal{T}_m = \sum_{j=1}^{N} \mathcal{W}_j Y_j \tag{3}$$

where, $\mathcal{W}_j$ is the weight coefficient for the j^{th} branch. The decision rule can be adopted as:

$$\begin{aligned} H_0 &: \mathcal{T}_m \leq \lambda \\ H_1 &: \mathcal{T}_m > \lambda \end{aligned} \tag{4}$$

where, λ is the decision threshold. Assuming Y_j's and $\mathcal{W}_j$'s to be independent for different j's, $\mathcal{T}_m$ will be Gaussian with

$$\mathcal{T}_m \sim \begin{cases} \mathcal{N}\left(\sum_{j=1}^{N}\mathcal{W}_j, \frac{2}{M}\sum_{j=1}^{N}\mathcal{W}_j^2\right) & : H_0 \\ \mathcal{N}\left(\sum_{j=1}^{N}\mathcal{W}_j(1+\gamma_j), \frac{2}{M}\sum_{j=1}^{N}\mathcal{W}_j^2(1+\gamma_j)^2\right) & : H_1 \end{cases} \tag{5}$$

For analyzing the performance of the spectrum sensing system, the probability of false alarm, P_{fa} and probability of detection P_d need to evaluated. A high value of P_d and a low value of P_{fa} is always desirable for an accurate spectrum sensing system. The parameters are defined as:

$$\begin{aligned} P_{fa} &= P[H_1|H_0] \\ P_d &= P[H_1|H_1] \end{aligned} \tag{6}$$

where, $P[\cdot|\cdot]$ denotes the conditional probability. In the case of CED with soft combining, the probability of false alarm and the probability of detection are given as [7]:

$$P_{fa} = Q\left(\frac{\lambda - \sum_{j=1}^{N}\mathcal{W}_j}{\sqrt{\left(\frac{2}{M}\right)\sum_{j=1}^{N}\mathcal{W}_j^2}}\right) \tag{7}$$

$$P_d = Q\left(\frac{\lambda - \sum_{j=1}^{N}\mathcal{W}_j(1+\gamma_j)}{\sqrt{\frac{2}{M}\sum_{j=1}^{N}\mathcal{W}_j^2(1+\gamma_j)^2}}\right) \tag{8}$$

where, $Q(x) = \int_x^\infty e^{-t^2}dt$ represents the Gaussian tail probability function and can be evaluated easily using the command *qfunc(x)* in MATLAB. From (7), the threshold λ can be given as:

$$\lambda = \sqrt{\left(\frac{2}{M}\right)\sum_{j=1}^{N}\mathcal{W}_j^2}\; Q^{-1}(P_{fa}) + \sum_{j=1}^{N}\mathcal{W}_j \tag{9}$$

where, $Q^{-1}(x)$ is the inverse-Q function and can be easily evaluated using the command *qfuncinv(x)* in MATLAB. From (8) and (9), P_d can be expressed as [7]:

$$P_d = Q\left(\frac{Q^{-1}(P_{fa}) - \sqrt{\frac{M}{2}}\sum_{j=1}^{N}\alpha_j\gamma_j}{\sqrt{\sum_{j-1}^{N}\alpha_j^2(1+\gamma_j)^2}}\right) \tag{10}$$

where, α_j is the normalized weight coefficient, given as:

$$\alpha_j = \frac{\mathcal{W}_j}{\sqrt{\sum_{k=1}^{N}\mathcal{W}_k^2}} \tag{11}$$

The optimal weight coefficients can be evaluated by maximizing P_d in (10), subject to

$$\sum_{j=1}^{N}\alpha_j^2 = 1; \quad 0 < \alpha_j \leq 1, \ \forall\ j \tag{12}$$

For low SNR conditions i.e., $\gamma_j \ll 1$, (10) can be approximated as [7]:

$$P_d = Q\left(Q^{-1}(P_{fa}) - \sqrt{\frac{M}{2}}\sum_{j=1}^{N}\alpha_j\gamma_j\right) \tag{13}$$

The optimal weight coefficients subject to (12) is given as [7]:

$$\alpha_j^* = \frac{\gamma_j}{\sqrt{\sum_{k=1}^{N}\gamma_k^2}} \tag{14}$$

which is identical to the maximal ratio combining (MRC) scheme [7]. Hence the optimal weight coefficients are given as:

$$\mathcal{W}_{mrc_j} = \alpha_j^* \tag{15}$$

B. IED with Soft Combining

The improved energy detection (IED) is the modified version of CED, as it gives better detection results with nearly identical complexity. In IED, the decision for the presence of the PU is done based on the average of last L test statistic $\mathbb{T}_m^{avg}$ at the m^{th} sensing interval defined as [4]:

$$\mathbb{T}_m^{avg}(\mathcal{T}_m) = \frac{1}{L}\sum_{l=1}^{L}\mathcal{T}_{m-L+l} \tag{16}$$

Out of these last L sensing events, $P \in [0, L]$ is the total number of events in which the primary signal was actually present. In IED algorithm, two additional checks are aimed to improve the detection probability as well as the probability of false alarm.

If $\mathcal{T}_m \leq \lambda$, the first additional check for $\mathbb{T}_m^{avg}(\mathcal{T}_m) > \lambda$ would improve the detection probability and the second additional check for $\mathcal{T}_{m-1} > \lambda$ would prevent the significant false alarm degradation. Since $\mathbb{T}_m^{avg}(\mathcal{T}_m)$ is the average of independently and identically distributed Gaussian random variables, it is also normally distributed:

$$\mathbb{T}_m^{avg}(\mathcal{T}_m) \sim \mathcal{N}\left(\mu_{avg}, \sigma_{avg}^2\right) \tag{17}$$

where, μ_{avg} and σ_{avg}^2 for the multi-antenna case is obtained as:

$$\begin{aligned}\mu_{avg} &= \frac{P}{L}\sum_{j=1}^{N}\mathcal{W}_j(1+\gamma_j) + \frac{L-P}{L}\sum_{j=1}^{N}\mathcal{W}_j \\ \sigma_{avg}^2 &= \frac{P}{L^2}\left[\frac{2}{M}\sum_{j=1}^{N}\mathcal{W}_j^2(1+\gamma_j)^2\right] + \frac{L-P}{L^2}\left[\frac{2}{M}\sum_{j=1}^{N}\mathcal{W}_j^2\right]\end{aligned} \tag{18}$$

Based on the above assumption, the probability of false alarm P_{fa}^{IED} and the probability of detection P_d^{IED} can be given as:

$$\begin{aligned}P_{fa}^{IED} &= P_{fa}^{CED} + P_{fa}^{CED}\left(1 - P_{fa}^{CED}\right) Q\left(\frac{\lambda_{IED} - \mu_{avg}}{\sigma_{avg}}\right) \\ P_d^{IED} &= P_d^{CED} + P_d^{CED}\left(1 - P_d^{CED}\right) Q\left(\frac{\lambda_{IED} - \mu_{avg}}{\sigma_{avg}}\right)\end{aligned} \tag{19}$$

C. p-norm Detector with Soft Combining

In the case of p-norm detector, the observed normalized energy value at the j^{th} antenna is given by:

$$Y_j = \begin{cases} \dfrac{1}{M}\displaystyle\sum_{i=1}^{M} w_{ji}^p & : H_0 \\ \dfrac{1}{M}\displaystyle\sum_{i=1}^{M}\left(h_{ji}s_{ji} + w_{ji}\right)^p & : H_1 \end{cases} \tag{20}$$

where, $p > 0$. It may be noted that $p = 2$ in (20) leads to the CED case. For $M \gg 1$, $\mathcal{T}_{m,p}$ will be Gaussian distributed as [5]:

$$\mathcal{T}_{m,p} \sim \begin{cases} \mathcal{N}\left(\mu_{0,p}, \sigma_{0,p}^2\right) & : H_0 \\ \mathcal{N}\left(\mu_{1,p}, \sigma_{1,p}^2\right) & : H_1 \end{cases} \tag{21}$$

where,

$$\mu_{0,p} = \frac{2^{p/2}}{\sqrt{\pi}}\Gamma\left(\frac{p+1}{2}\right)\sum_{j=1}^{N}\sqrt{\mathcal{W}_j^p}$$

$$\mu_{1,p} = \frac{2^{p/2}}{\sqrt{\pi}}\Gamma\left(\frac{p+1}{2}\right)\sum_{j=1}^{N}\sqrt{\mathcal{W}_j^p\left(1+\gamma_j\right)^p}$$

$$\sigma_{0,p}^2 = \left[\frac{2^p\Gamma\left(\frac{2p+1}{2}\right)}{M\sqrt{\pi}} - \frac{2^p}{M\pi}\left\{\Gamma\left(\frac{p+1}{2}\right)\right\}^2\right]\sum_{j=1}^{N}\mathcal{W}_j^p$$

$$\sigma_{1,p}^2 = \left[\frac{2^p\Gamma\left(\frac{2p+1}{2}\right)}{M\sqrt{\pi}} - \frac{2^p}{M\pi}\left\{\Gamma\left(\frac{p+1}{2}\right)\right\}^2\right] \times \sum_{j=1}^{N}\mathcal{W}_j^p\left(1+\gamma_j\right)^p \tag{22}$$

In (22), $\Gamma(\cdot)$ denotes the gamma function. The probability of false alarm and the probability of detection for the p-norm detector with soft combining scheme is given by:

$$\begin{aligned}P_{fa,p} &= Q\left(\frac{\lambda_p - \mu_{0,p}}{\sigma_{0,p}}\right) \\ P_{d,p} &= Q\left(\frac{\lambda_p - \mu_{1,p}}{\sigma_{1,p}}\right)\end{aligned} \tag{23}$$

D. Improved p-norm Detector with Soft Combining

Replacing the squaring operation of the signal amplitude in IED by an arbitrary positive power p, $\mathbb{T}_m^{avg}(\mathcal{T}_{m,p})$ may be well approximated by the Gaussian distribution as:

$$\mathbb{T}_m^{avg}(\mathcal{T}_{m,p}) \sim \mathcal{N}\left(\mu_{avg,p}, \sigma_{avg,p}^2\right) \tag{24}$$

where,

$$\begin{aligned}\mu_{avg,p} &= \frac{P}{L}\mu_{1,p} + \frac{L-P}{L}\mu_{0,p} \\ \sigma_{avg,p}^2 &= \frac{P}{L^2}\sigma_{1,p}^2 + \frac{L-P}{L^2}\sigma_{0,p}^2\end{aligned} \tag{25}$$

Modifying (19) to the present case, one obtains the probability of false alarm and the probability of detection in the following form:

$$\begin{aligned}P_{fa}^{IED,p} &= P_{fa,p} + P_{fa,p}\left(1 - P_{fa,p}\right) Q\left(\frac{\lambda_{IED,p} - \mu_{avg,p}}{\sigma_{avg,p}}\right) \\ P_d^{IED,p} &= P_{d,p} + P_{d,p}\left(1 - P_{d,p}\right) Q\left(\frac{\lambda_{IED,p} - \mu_{avg,p}}{\sigma_{avg,p}}\right)\end{aligned} \tag{26}$$

III. Results and Discussion

In this section, the results for the combined benefit of the improved algorithm and the p-norm detector are highlighted for the multi-antenna assisted spectrum sensing in AWGN channel. For a given target false alarm probability, the threshold, λ is chosen and for a given SNR, γ the optimal value of p is determined which yields the highest value of the probability of detection.

To provide practical design guidelines for a spectrum sensing system with improved p-norm detector, Fig. 2 and Fig. 3 provide the surface plots for the probability of detection with the variation of p and the probability of false alarm for AWGN channel. The optimal value of p is determined from the surface plot. The number of samples per sensing event M is considered as 30 and number of antennas N is 4 with SNR γ_j = - 10 dB $\forall$ j.

In Fig. 4, a comparison of receiver operating characteristics (ROCs) for multi-antenna assisted CED and IED with $p = 2$ and optimal p has been depicted. The ROC for single antenna CED ($p = 2$, $N = 1$) has also been drawn in order to show the

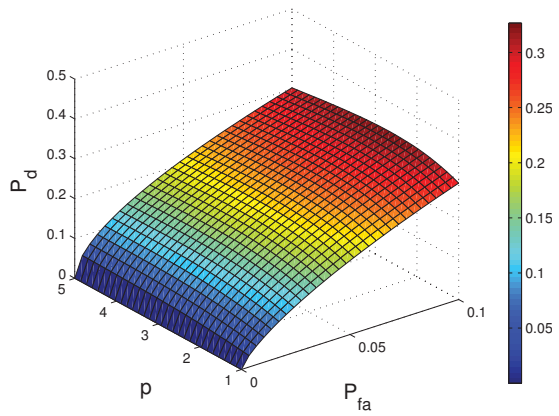

Fig. 2. Surface plot for detection probability using CED in AWGN channel with $M = 30$, $N = 4$ and $\gamma_j = -10$ dB $\forall\ j$.

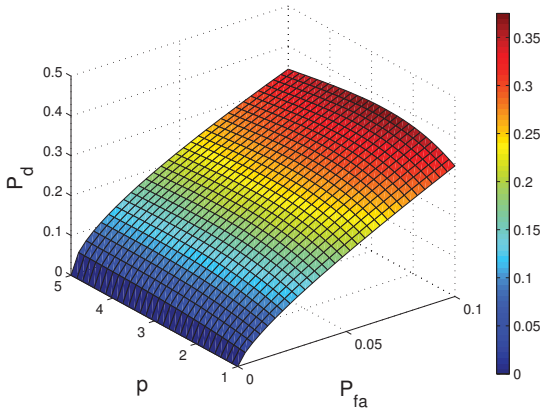

Fig. 3. Surface plot for detection probability using IED in AWGN channel with $M = 30$, $N = 4$ and $\gamma_j = -10$ dB $\forall\ j$.

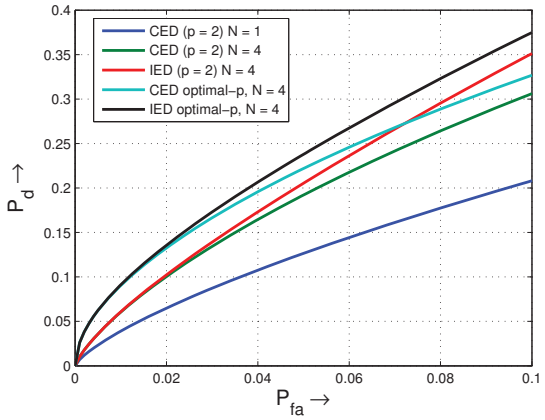

Fig. 4. Comparison of ROCs for multi-antenna assisted CED and IED in AWGN channel using $p = 2$ and optimal-p with $M = 30$, $N = 4$ and $\gamma_j = -10$ dB $\forall\ j$

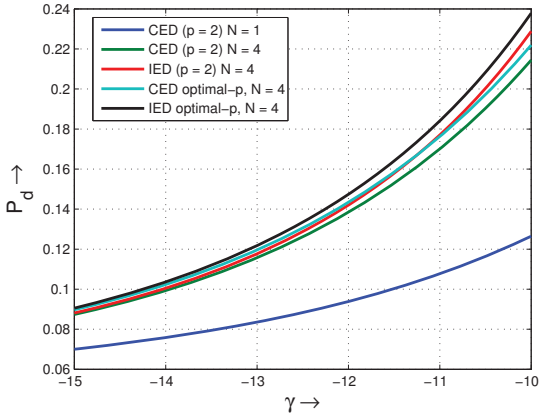

Fig. 5. Probability of detection versus SNR for multi-antenna assisted CED and IED in AWGN channel using $p = 2$ and optimal-p with $M = 30$, $N = 4$ and target $P_{fa} = 0.05$.

achieved diversity gain in other cases ($N > 1$). The optimal p-value for CED and IED is determined from Fig. 2 and Fig. 3 respectively, such that for a given target false alarm probability and SNR, the probability of detection becomes maximum. It is clearly evident from the figure that multi-antenna assisted improved-p norm detector outperform all the other schemes considered here.

The variation of detection probability against SNR at a fixed target false alarm probability of 0.05 has been shown in Fig. 5 with the number of samples per sensing event $M = 30$, and number of antennas $N = 4$. In addition, the result for the single antenna CED ($p = 2$, $N = 1$) has also been shown.

IV. Conclusion

We have analyzed the performance of a multi-antenna assisted improved-p norm energy detector in the AWGN channel for spectrum sensing. Theoretical results confirm significant gain over that of the multi-antenna assisted CED and IED algorithms. Results confirm that there exist an optimal value p (> 0), other than 2 for which the detector gives the best performance under low SNR conditions. The performance gain is not much significant if the number of samples per sensing event, M is considerably high, but for a low value of M, the p-norm detector works well for IED as compared to CED which in turn may lead to improve the total throughput of the secondary network. By combining both, the IED and the p-norm detector under multi-antenna assisted soft combining scheme, one can achieve a considerable performance gain.

Abstract—**Next generation wireless networks are poised to support real-time video-on-demand and high quality multimedia streaming applications. In order to support them, several adaptation strategies have been proposed at different layers of the OSI network stack. Also, certain cross-layer strategies across physical/data link and transport/application layers have been proposed over the years. However, given the battery constraints of a smart-phone, it is imperative that new cross-layer design be developed that would bring into account an energy-oriented mechanism from a device perspective. In this paper, a new adaptive solution, EDAS – *energy-efficient device oriented adaptive cross-layer scheme* for multimedia transmission in wireless network environments is proposed. Importantly, *EDAS* provides a novel framework spanning across several OSI layers that would dynamically vary the energy consumption in mobile devices while maintaining a high peak signal to noise ratio (PSNR) in order to ensure a good video quality. It has been observed that *EDAS* significantly outperforms other schemes in terms of PSNR, loss-rate and importantly, the energy consumption in device.**

Keywords—Adaptive scheme, cross-layer design, energy-efficiency

I. INTRODUCTION

Over the last years, there has been a phenomenal increase in the demand by the mobile device users to have delivered real-time multimedia content at high quality. However, achieving high quality real time multimedia streaming is very challenging, mainly because it is delay sensitive, and requires high bandwidth for continuous high quality transmission. At the same time, multimedia and graphic-intensive applications consume high amounts of energy in the mobile device, thereby resulting in significant reduction of the overall device battery life.

There have been different works [1] that have proposed rate adaptation based protocols for high quality multimedia transmissions. However, most of these are deployed at a single layer of Open System Inter-connection (OSI) network stack. Although acceptable in case of a wired network where each layer treats the other layers as black boxes, in case of a wireless network, the OSI layer working cannot be optimized without being aware of other layers. For example, a network layer protocol could be optimized only if it has real-time information about instantaneous delivery channel conditions. Additionally, some research works have focused on adapting existing algorithms and protocols for multimedia compression and transmission to the rapidly changing wireless channel. However, many-a-times, these solutions do not necessarily provide adequate support for multimedia applications in areas of high interference. This is because the resource management and the available adaptation and protection strategies in the lower layers of the stack are optimized without the particular characteristics of multimedia applications being considered [2]. It should be noted that this "layered" optimization in the past led to a simple and independent implementation and to a non-optimal multimedia delivery performance. With the ability of the networks to process complex information and computational intelligence today, it is imperative to have cross-layer strategies in order to optimize the adaptation process for efficient multimedia delivery.

This paper proposes **a novel cross-layer energy-efficient device-oriented adaptive scheme (EDAS).** EDAS is active at *four* layers - physical layer, link layer, transport layer and application layer. EDAS is mainly a device-oriented energy-adaptive mechanism which adjusts the video bit-rate at the application layer dynamically, according to real time statistics of battery level of mobile device, effective network throughput and user perceived video quality, monitored at the receiving side at different network layers.

The paper is organized as follows. Section II describes the related work on cross-layer adaptive video delivery solutions, while section III describes *EDAS*. The simulation set-up and results are presented in section IV, while section V concludes the paper.

II. RELATED WORK

A medium access control (MAC) layer protocol proposed for rate adaptation at low network layers is the receiver based auto-rate (RBAR) protocol. Using RBAR results in high overall throughput, especially in wireless LANs. Over the years, the authors proposed a feedback-based Quality Oriented Adaptive Scheme (QOAS) [3, 4] for efficient multimedia transmission in wireless networks. QOAS is an application layer solution which employs end-user perceived quality estimation in the feedback loop and outperforms other protocols such as the TCP Friendly Rate Control Protocol (TFRCP) [5] and the enhanced Loss-Delay-based Adaptation

Algorithm (LDA+) [6] in a wireless environment, in terms of perceived quality, loss rate and the achievable throughput [7]. However, QOAS does not have any in-built energy-saving mechanism. Hence, a significant addition was required to be incorporated across the layers for energy-efficient cross-layer wireless multimedia transmissions [8]. Further, in case of real-time multimedia transmission, not only the system throughput, but also other parameters like delay, packet loss and overall quality of service (QoS) should be considered. In addition, the fluctuations in the wireless channel, limited bandwidth, contention among several subscribers and dynamic topology make QoS a very significant issue.

Recently, the authors have carried out a detailed analysis of a joint optimization of user experience and energy efficiency of wireless multimedia broadcast receivers with varying display and energy constraints [9]. This work focused mainly on the physical and link layer aspects, wherein the solution combined user composition aware source coding rate optimization, optimum time slicing for layer coded transmission and a low-level cross-layer adaptive modulation and coding scheme. However, this solution did not integrate the higher layers in the cross-layer design. Other works include an energy-quality-cost tradeoff solution for mobile video delivery [10], a battery power-aware adaptive multimedia delivery scheme for wireless mobile devices [11], energy-aware mobile learning solutions [12], an energy-aware multipath content delivery scheme [13] and a mechanism for energy-aware multimedia content adaptation. [14].

III. System Model of EDAS

This section describes the design of the proposed cross-layer energy-efficient device-oriented adaptive scheme *EDAS*. The design comprises of two aspects: the system architecture and the energy-efficient mechanism. The cross-layer *EDAS* is designed to optimize those parameters that affect the most the video delivery process, and consequently end-user perceived quality *Q*: loss rate, delay, jitter, bit rate and throughput. *EDAS* acts at various layers, from physical and MAC layers to transport and application layers. It should be noted that the proposed solution takes into account the system architecture while designing joint delivery improvement strategies across the layers. This is achieved by making use of information from layers such as physical layer on bit error rate for each link and data link layerto learn about the current network conditions and therefore quality of each link.

A. *Architecture of EDAS*

EDAS is an adaptive, information-centric solution spread across four layers. Its main characteristic is that it adapts its operation depending on the requirements of multimedia data traffic. In addition, a completely localized data management framework is presented in *EDAS* that helps capture information about traffic patterns in the network. Simultaneously, it deals with the end user perceived quality for multimedia streams at the receiver end. This information is subsequently used by application/transport layer scheme at the sender to modify its operation accordingly. The backbone of this scheme is the shared centralized database, as illustrated in the framework presented in Fig. 1. The database contains network parameters that affect individual layers or more than one layer, as well as parameters that get affected or modified by different layers. After accessing this cross layer information, each layer makes modifications of the parameters that they are concerned with applying the best adaptation strategy they can in order to imkprove delivery performance from their point of view. Note how the interaction between layers not connected directly takes place through the centralized database.

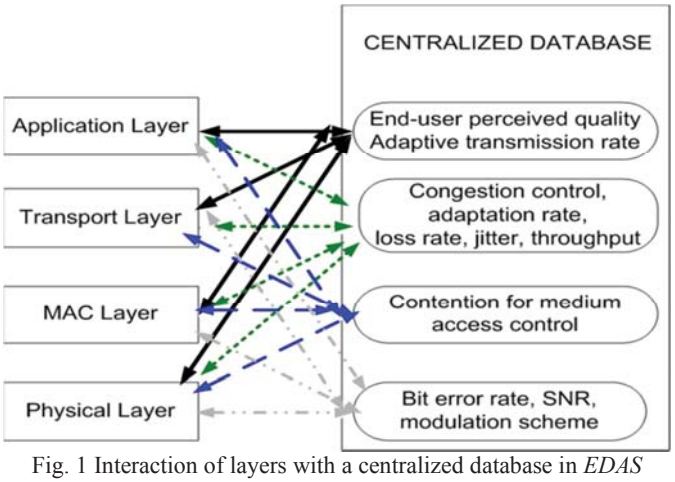

Fig. 1 Interaction of layers with a centralized database in *EDAS*

As part of this process, the physical layer provides adaptive rates to transport layer and also helps the MAC layer to select the best contention strategies for efficient delivery of traffic i.e., choosing a non-interfering set of senders and receivers at a particular time. Importantly, in the design of *EDAS*, instead of carrying the duration of the reservation as done in a non-adaptive protocol, the information on the modulation rate and size of data packets is stored in this database and only updates are being carried by packets. This serves the dual purpose of providing a mechanism by which the receiver can communicate the chosen rate to the sender, while still providing neighboring nodes with enough information to calculate the duration of the requested reservation. Hence, for e.g., the MAC layer would not only choose a modulation rate that would maximize the throughput, but also communicate the same to the server, thereby developing a continuous interactive mechanism. This considerably reduces the overhead. Further, at application layer *EDAS* extends the QOAS's client-side multimedia quality of delivery monitoring mechanism Quality of Delivery Grading Scheme (QoDGS) and uses QOAS's server-side Server Arbitration Scheme (SAS) [3] as described next.

B. *Energy-Efficient Mechanism in EDAS*

As already mentioned, *EDAS* uses SAS at sever side and a cross layer quality of delivery grading scheme (CR-QoDGS), which extends the QoDGS, at the client.

The most important feature of CR-QODGS is the calculation of a score based on the parameters from the Physical and MAC layers. These include: *bit error rate* (BER), *signal-to-noise ratio* (SNR), *modulation scheme* and *contention mode at MAC layer*. A higher BER or lower SNR would lower the CR-QODGS score which-in-turn would suggest to reduce the bit rate transmitted by the sender.

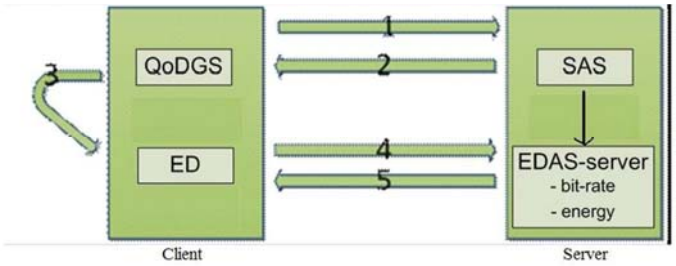

Fig. 2 Client-server model for energy-efficient bit-rate selection mechanism in EDAS

Further, a significant aspect of EDAS is to reduce the energy consumption. Regularly, the EDAS component at the client side monitors continuously the battery level of the device and request adjustments of the bit-rate based on the most recent readings. This is done in a process which includes six steps. The tasks in each step are repeated until the full video is played.

1. The client sends a video streaming request to the server. The video bit-rate in this request is at the highest possible level given the battery power readings.
2. The sever checks the receiving request and sends the video streaming at the corresponding rate.

3a. The device receives the information and while displaying the video, also finds out the remaining battery level of the device.

3b. Further, the client calculates the CR-QoDGS score based on the video quality displayed and also an ED (energy of device) score that is calculated based on the remaining battery level of the device. The ED score is calculated based on the remaining battery life ('b') and the set battery threshold level ('B_T'); explained in section 3.1

4. Both these scores are sent back to the server.
5. The EDAS mechanism at the server first calculates the bit-rate based on the CR-QoDGS score and then the actual bit-rate depending on the ED score. This is such computed in order to enable complete playout of the video content given the battery power levels at the client device. The server then transmits the video content at the data rate that is adapted to both delivery conditions and client device energy level.

C. *Instantaneous Battery Level*

The "instantaneous battery level" in the device indicates the battery of the device at the instant when the client has just received the latest video data from the server. A battery coefficient 'b' is defined as the ratio of the current energy level to the initial energy level of the device [15].

$$b = \text{Ec/Ei},$$

where Ec is device's current energy level and Ei is device's initial energy level.

'b' shows the instantaneous energy level of the device and decreases monotonically from 100% to 0%. Further, a battery threshold level, 'B_T' is considered which defines the level below which the energy-efficient mechanism of *EDAS* would be applied. 'B_T' can be set dynamically depending on user preference regarding trading-off between video quality and multimedia content duration. For instance, 'B_T' = 0.5 implies that the bit-rate reduction in the device would apply only when the value of 'B' reaches below 'B_T' = 0.5. If 'B_T' = 0.75, then the energy-efficient bit-rate adaptation mechanism is applied only when 'B' drops below 'B_T' = 0.75'. In order to alter the data rate, a 5-state bit-rate level L_i, is defined for each video content relative to its highest bit-rate level, where $i \in \{1, 2, 3, 4, 5\}$. Iteratively, when b drops below a certain value during an iteration, during the next iteration the bit-rate is reduced by half its previous level, i.e., $L_{i+1} = \lfloor L_i/2 \rfloor$. If the last decided bit rate does not have adverse effect on the network performance, the next session bit-rate is either kept at same level or increased by one-step, i.e., $L_{i+1} = L_i$ or $L_i + 1$, depending on the instantaneous user-experienced video quality. If the quality-level is above a satisfactory level (set by threshold Qt), the bit-rate level is maintained; else the rate is increased by one level. The B_T and Qt can be set in the device.

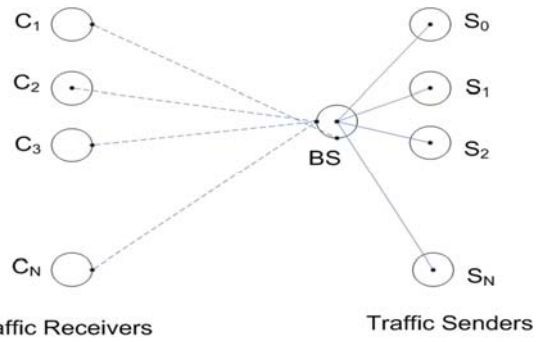

Fig. 3 Network topology for traditional multimedia wireless network architecture

D. *Experimental Set-up*

The tests involved a Samsung Galaxy Nexus One device as the client, as it is anticipated that most of the users today would have a smart-phone with at-least the capabilities of this model. The test system comprises of the phone and a video server streaming content over a wireless IEEE 802.11g network. The phone is connected to an external measurement setup that monitors and logs its power consumption during the execution of various tests. A shunt resistor (0.22 Ω; ± 1%) is inserted between the phone and battery to allow calculating the current by measuring the voltage drop across the resistor. The low-value shunt resistor of 0.22Ω ensures that energy is not wasted during the measurement phase. The instantaneous energy consumed is measured using an Arduino board as shown in Fig. 4.

In order to test the energy efficiency of the proposed *EDAS* mechanism and to investigate the impact on potential energy savings in the device, the system is simulated for an IEEE 802.11g based wireless network, with a single-hop communication between the client (device) and server (base station). The simulation setup consists of a number of mobile nodes distributed in a circular coverage area of 1 square km. There is a sender located at centre of the area. The server communicates directly with all wireless terminals in the network, as shown in Fig. 3. There are a number of sources (i.e. S_0 is the video source multimedia and S_1, S_2,…, S_N are the background traffic senders) connected to the server (BS) that transmits multimedia content to N clients - C_0, C_1, C_2.., C_N. The links between S_0, S_1, S_2…, S_N and the server are sufficiently provisioned, so as not to cause any delay or loss. The performance of EDAS scheme is evaluated in terms of four parameters: *average bit rate*, *loss rate, energy consumption* and *peak signal-to-noise ratio* (PSNR).

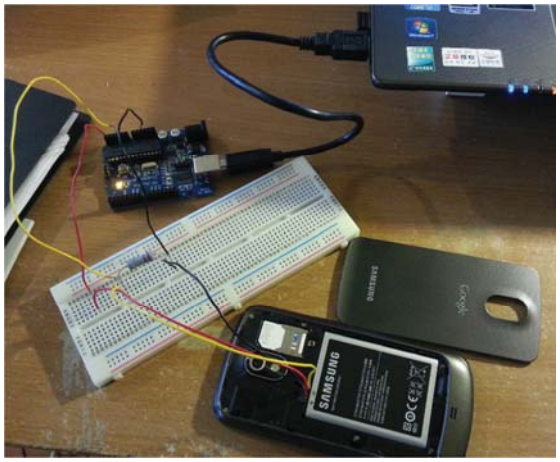

Fig. 4 Set-up for measuring energy consumption in mobile device

In order to test the performance of EDAS during multimedia streaming, the original version of test video were downloaded with bit-rate of 2657kbps and 145 seconds length. It is compressed by WisMencoder 2.3.0 (with built-in FFMPEG) into 5 different bit-rates videos: 180kbps, 500kbps, 900kbps, 1200kbps, 1600kbps respectively. Notably, different video levels were assigned for the different bit-rates. These include: 180 kbps (L1), 500 kbps (L2), 900 kbps (L3), 1200 kbps (L4) and 1600 kbps (L5). Further, the performance of EDAS is evaluated for different instantaneous battery levels. Four instantaneous battery levels are considered: 100%, 75%, 50% and 25%. The four scenarios are simulated from the same video starting point.

Fig. 5 to Fig. 8 show the results of the cross-layer based EDAS scheme for different battery threshold ('B_T') and the results are compared to QOAS. Fig. 5 shows the remaining battery level of the device while Fig. 6 shows the average PSNR of four different cases of EDAS and QOAS. It can be observed from Fig. 5 that EDAS with B_T = 1.0 has a much longer battery life as compared to other B_T levels. For instance, the remaining battery at 14,400s, i.e., at 4 hours is 0.38 in case of B_T = 1.0; only 0.097 in case of B_T = 0.25 and 0.2 in case of QOAS. In fact, this battery improvement is consistent throughout the simulation. This shows the significant battery improvement of EDAS. Notably, Fig. 6 shows that the resulting PSNR is also the highest for B_T = 1.0 as compared to other schemes. Interestingly, PSNR of EDAS for all four considered thresholds as well as that of QOAS are considerably good. This shows that application of EDAS does not result in a degradation of video quality in the network.

E. Results

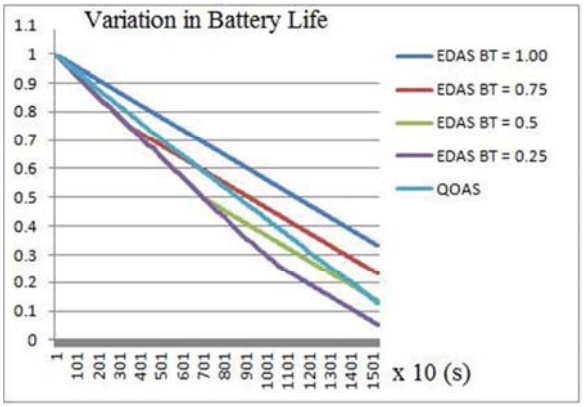

Fig. 5 Variation of battery level with time for EDAS (different threshold, B_T) with the QOAS scheme

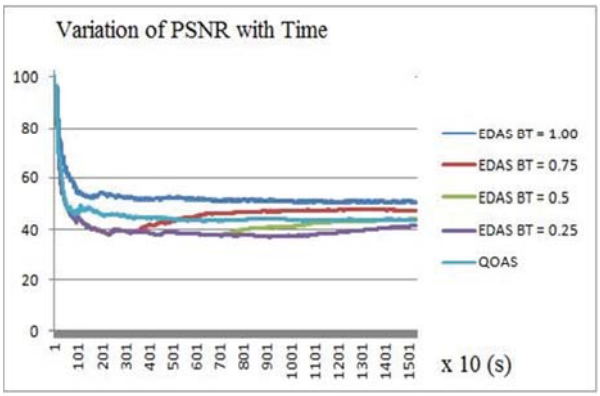

Fig. 6 Variation of PSNR with Time for EDAS (different threshold, B_T) mechanisms with the QOAS scheme

The variation of bit-rate with time in Fig. 7 gives a very interesting result. It can be observed that EDAS results in considerably higher variation in the instantaneous bit rate at for different B_T thresholds. Notably, B_T = 1.0 results in a very low bit rate; which in turn indicates a lower average video quality transmitted from the network itself. On the other hand, EDAS with low B_T values implies a higher transmission rate in the initial stages from the network itself, till the battery of the device reaches the B_T threshold value. Once this threshold is reached, the bit-rate decreases rapidly; as the primary focus is now on saving the battery life and extending the device life. In particular, the bit-rate of EDAS is higher than that of QOAS until the threshold; after which it degrades sharply. This indicates a significant feature of EDAS. Firstly, the bit-rate offered by the transmitter in case of EDAS is adaptive yet

significantly higher than that of QOAS; especially until the threshold B_T is reached. Secondly, when the battery level is low, the EDAS decreases the transmission bit rate itself, so as to reduce the overall energy consumption and also to have a smooth degradation in video quality not to be perceptible to end-users, while increasing the battery life.

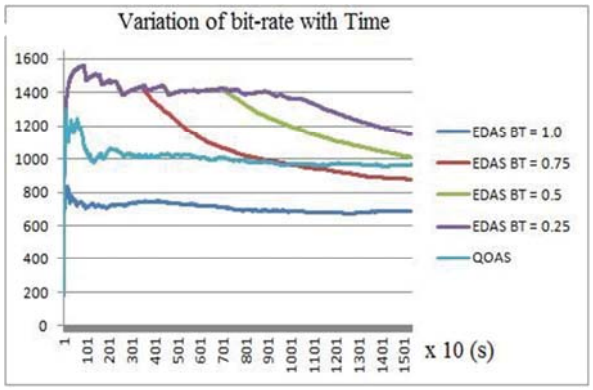

Fig. 7 Variation of Bit-Rate with time for EDAS (different threshold, B_T) with the QOAS scheme

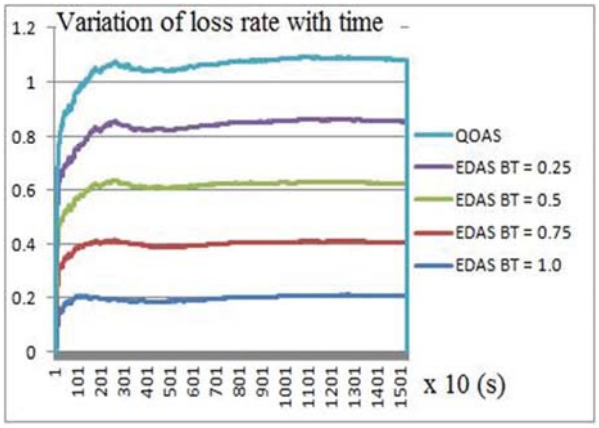

Fig. 8 Variation of Loss-Rate with time for EDAS (different threshold, B_T) with QOAS

Finally, Fig. 8 shows the variation in loss rate in percentage, for four scenarios in EDAS as compared with QOAS. It can be observed that the loss rate of all the schemes are less than 1%, resulting in good video quality level. Note how EDAS results in an extremely low value of 0.2% when the battery threshold is set at B_T = 1.0. This shows that the cross-layered EDAS provides a flexible solution to adapt the bit rate and extend the battery life while maintaining good quality level.

IV. Conclusions and Future Work

A novel cross-layer energy-efficient device-oriented solution *EDAS* was proposed in this work for efficient multimedia streaming to wireless mobile devices. The functionality of EDAS spans across four layers of the OSI network stack: physical, MAC, transport and application. EDAS provides a flexible mechanism for dynamically reducing the energy consumption of mobile devices and thereby extending their battery life, without affecting user perceived video quality. Future work will focus on developing an analytical framework to reflect closer interaction between the four network layers. This framework should also consider a comprehensive mathematical analysis that would indicate the relation between energy savings and the resulting bit-rate in order to better support the adaptation decisions. Another further work in this direction is to enhance this cross-layer design over all layers of OSI stack and considering more parameters, taking into account the current deployed network architectures.

SRM University, Chennai, India.
vijaramya@gmail.com; ramaraotr@gmail.com

Abstract— **Developments in automotive industries attempt to deliver secured and enjoyable journey by exchanging information among the vehicles, inside vehicles, between vehicle and infrastructure utilizing wireless communication networks (WCN). In order to meet the requirements, a new printed spiral antenna with tapered feed is proposed to cover the navigational frequencies viz., 1.2 GHz, 1.5 GHz and WCN frequencies viz., 2.45 GHz, 3.3 GHz and Dedicated Short Range Communication (DSRC) frequency 5.8 GHz for vehicular network communications. 3D Electromagnetic (EM) tool is used for design and validated with Radio Frequency (RF) equipment. Further, path loss analysis for different vehicular environments are simulated using EM propagation tool and compared the simulated results with empirical model viz., ITU, Two-ray reflection, Dual slope model and COST 231 Walfisch Ikegami model.**

Keywords— Multiband; circular plarization; spiral antena; propagation model; vehicular communication.

I. INTRODUCTION (*HEADING 1*)

Today's transport systems are quite tricky and emerging vehicles are smart due to the rapid developments of technology. This requires effective reliable communication systems and speedy communication among vehicles for wireless automotive applications. Several researches have been dedicated to provide such communication between vehicles and with infrastructure and regarded as a vital part of upcoming Intelligent Transportation Systems (ITS) [1]. Dedicated Short Range Communication (DSRC) technology [2] is a part of ITS used for empowering wireless communication between vehicles and outside world. Currently in addition to the DSRC, ITS looking out for the vehicles with multi band capability to address various applications like navigation and wireless communications (Wi-Fi, Bluetooth) [3].

Several research works has been carried out for resonating multiple frequencies with single radiating element. This comprises fractal antenna [4-5], slot antenna [4], inverted F antennas [6-7], and Microstrip patch antenna [8]. The European standard EN 12253 [9] delivers the requirement for vehicular communication antenna. As per standard vehicular antenna need to be omni directional with left hand circular polarization (LHCP). The omnidirectional radiation pattern covers the wide range of communication area and circular polarization reduces the interference caused by reflection and provides independent antenna orientation. Currently, printed monopole antenna became prevalent for automotive systems because it could meet above-mentioned characteristics, i.e. omnidirectional pattern, compact size, low cost and ease to fabricate [10]. A dual band omnidirectional vertical polarized, coplanar monopole (cactus shaped) antenna is proposed [11] to meet vehicular antenna characteristics. In [12], two – hook facing opposite side in one plane and cross shaped monopole at the back plane is introduced to operate at 2.4 GHz, 5.2 GHz and 5.8 GHz. In [13], a thin ferrite rod is inserted between a patch and ground plane to reduce the antenna height. However, due to the magnetic loss gain is reduced. A 0.062λ wire-patch antenna gives an omnidirectional radiation pattern, but operates at a single frequency with vertical polarization [14]. The antennas observed in literature does contain omnidirectional pattern with linear polarization.

A key to miniaturize the antenna is maximizing the current flow in the conducting element. This is can be easily achievable with spiral structure. Several spiral monopole antenna are proposed to achieve multi band, circular polarization and omnidirectional radiation pattern [15 - 18]. Impedance matching is not uniform in spiral structure. A tapered feed helps to have smooth current flow from feed to patch, which improve the impedance matching. Hence, In this work we propose, a multiband single- arm spiral antenna with tapered feed which supports wireless communication services along with navigation services operates at IRNSS (1.2 GHz), GPS (1.5 GHz), Wi-Fi (2.4 GHz), WiMax (3.3 GHz) and DSRC (5.8 GHz). In spiral antenna, impedance matching is not uniform in all bands. To address this issue we introduced tapered feed line.

Furthermore, the awareness of propagation channel plays a vital role for vehicle-to-vehicle (V2V) and infrastructure - to – vehicle (I2V) communication systems since their property speaks system performance. Of precise curiosity, the path loss is the most important property of any wireless channel. Reflection, diffraction and scattering are the three basic propagation mechanisms which impact the propagation in any wireless communication system. Path loss for V2V communications that are in the literature [19-21] similar to other wireless systems and are depends on environment. Hence, we took different environments to understand the performance of the proposed antenna with respect to V2V and I2V communication systems. EM propagation simulation tool is utilized to analyze the performance of the proposed antenna. Also, we compared our simulated result with empirical model like ITU [22], two-ray reflection, COST 231 Walfisch Ikegami model [23] and dual slope model [24].

The paper is arranged as, in Section II outlines the design of the proposed antenna and simulation model for propagation analysis followed by Section III, the results and discussions on performance of the antenna.

II. Antenna Design and Characterization

A. Antenna Design

The proposed single arm multiband planar spiral antenna with tapered feed is constructed on the Rogers's 5880 substrate with permittivity of 2.2 and loss tangent of 0.0009 is shown in Fig. 1. The size of the dielectric substrate is calculated using microstrip patch antenna design formula [25]. In spiral antenna, the inner and outer radius decides frequency bands. In our work, for desired multiband operation, we modified the general spiral antenna design equation [26] such that the circumference of the inner circle radius as one fourth of the wavelength of lower frequency and outer circle radius as one fourth of the wavelength of upper frequency. The strip line dimensions are calculated using strip line equation [25]. In order to achieve better impedance matching, we introduced tapered microstrip feed line. The slope of the tapper is optimized to get better impedance matching.

Fig. 1. Prototype of the proposed antenna

B. Simulation Model

A large-Scale propagation model predicts the received power as a function of distance between transmitter and receiver. The propagation characteristics of V2V communication vary significantly based on surroundings. Reflection, diffraction and scattering are the three basic factors which impact the propagation of EM waves.

Propagation study is carried out using Remcom's Wireless InSite EM propagation tool [27]. It is a suite of ray- tracing model and EM solver for the examination of site-specific radio propagation. In this model, the straight road and buildings on both sides of the road are considered. Multiple reflections from the building surfaces and the road are considered. Minimum of single diffraction at buildings corner are taken into account. Though, it is assumed that the propagation paths have no shadowing by any other obstacles. The three different scenarios taken into account for our simulation model.

- Scenario 1 for V2V: The transmitter - receiver vehicles with proposed antenna system on the rear roof-top travelling on same direction with same velocity on the road with no buildings and other obstructions on each side.
- Scenario 2 for V2V: The transmitter - receiver vehicles with proposed antenna system on the rear roof-top travelling on same direction with same velocity on the road with buildings of uniform height and spacing and no obstructions on each side.
- Scenario 3 for V2V: The transmitter - receiver vehicles with proposed antenna system on the rear roof-top travelling on same direction with same velocity on the road with buildings of different height, uniform spacing and no obstructions on each side.
- Scenario 1 for I2V: The receiver vehicles with proposed antenna system on the rear roof-top travelling away from the transmitter on the road with no buildings and other obstructions on each side.
- Scenario 2 for I2V: The receiver vehicles with proposed antenna system on the rear roof-top travelling away from the transmitter on the road with buildings of uniform height and spacing and no obstructions on each side.
- Scenario 3 for I2V: The receiver vehicles with proposed antenna system on the rear roof-top travelling away from the transmitter on the road with buildings of different height, uniform spacing and no obstructions on each side.

The simulation parameters used for V2V and I2V are listed in Table I.

TABLE I. Simulation Parameters

Parameters	**V2V Values (units)**	**I2V Values (units)**
Maximum Reflection	10	10
Minimum Diffraction	1	1
ε_r, σ (Concrete Building)	7 , 0.015 S/M	7 , 0.015 S/M
ε_r, σ (Road) (S/M)	5.72, $5x10^{-4}$	5.72, $5x10^{-4}$
Antenna	Proposed	Proposed
Frequency	5.8 GHz	2.4/3.3/5.8 GHz
Transmitter Antenna Gain (G_T) (dB)	5.48	0
Receiver Antenna Gain (G_R) (dB)	5.48	1.88/1.52/5.48
Transmitted Power (P_t)	24 dBm[10]	30 dBm[28]
Polarization	LHCP	LHCP
Road Width	30 m	30 m
Transmitter Height	1.6 m	1.6 m
Receiver Height	30 m	1.6 m
Building Height	5 – 15 m	5 – 15 m

III. Results and Discussions

Keysight's Vector Network Analyzer (N9925A) is used to validate the antenna performance. The measured return loss is shown in Fig. 2. It has a good agreement with simulated result. The result shows that the proposed antenna resonates at desired multi bands. Table II gives the performance of the proposed antenna. Further, in this work we considered V2V communication at 5.8 GHz and I2V communication at WCN frequencies, 2.4 GHz and 3.3 GHz and DSRC, 5.8 GHz for further analysis. Table II gives the performance of the proposed antenna.

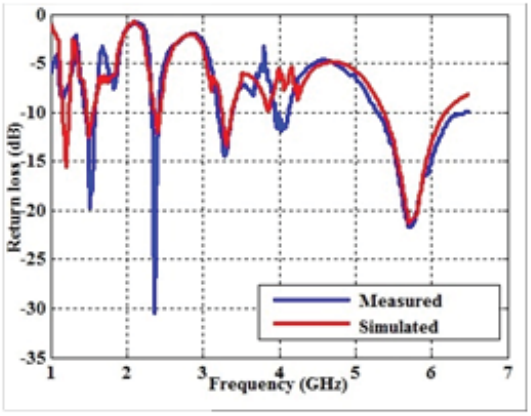

Fig. 2. Return loss of the proposed antenna.

TABLE II. Antenna Performance

Parameters	Frequency in GHz				
	1.2	*1.5*	*2.4*	*3.3*	*5.8*
Impedance BW(GHz)	0.17	0.11	0.09	0.19	1.10
Return loss (dB)	9.8	15.43	13.85	14.2	20.4
Gain (dB)	1.07	1.75	1.88	1.52	5.48
AR BW (%)	4.16	4.0	4.58	5.15	6.37
Radiation Efficiency (%)	82.1	89.7	89.8	85.0	94.7

Further, compared the performance of our work with recent multiband antennas on vehicular communications. Table III gives the performance comparison of proposed antenna with recent works. It shows that proposed antenna has better ARBW with reasonable gain.

For the analysis of V2V communication, initially two vehicles of 1.6 m height with proposed antenna systems moving on the same direction maintaining the separated distance as 10 m are considered and obtained the received power. By varying the separated distance in steps of 10 m observed the received power. This is carried out for all three V2V scenarios. For the analysis, the road's permittivity and building permittivity are considered.

TABLE III. Antenna Performance Comparisons

Ref.	Operating Frequencies (GHz)	Radiation Pattern	Gain (dB)	ARBW (%)
This Work	1.2 1.5 2.4 3.3 5.8	Omni directional with circular polarization	1.07 1.75 1.88 1.52 5.48	4.16 4.00 4.58 5.15 6.37
[6]	1.575 2.5 5.8	Omni Directional with circular polarization	** 2.1 3	1.26 2.40 5.00
[8]	1.8 2.4 3.5 5.8	Omni directional with linear polarization	2.6 2.3 3 2	NA
[9]	1.57 3.7 5.9	Directional with linear polarization	5.5 8.0 9.0	NA

For the analysis of I2V communication, at first the receiver vehicle of 1.6 m height with proposed antenna system on the rear roof – top at a distance of 10 m from transmitter is considered and obtained the received power. By moving the receiver vehicle received signal is observed. This is carried out for all three I2V scenarios. For further understanding, we considered empirical models like ITU® M 2135, COST 231 Walfisch Ikegami and Dual slope models and Two-ray reflection model.

We modified the Two-ray model equation according to circular polarization by applying superposition concept. The path loss is calculated for mentioned empirical models considering simulation parameters specified in Table I using path loss formula [22-24]. The received power is calculated using the general Friis equation,

$$R_R = T_P + G_T + G_R - L \qquad (1)$$

Where, L is path loss obtained from empirical models, T_P is the transmitted power, R_R is the received power and G_T and G_R are the transmitter and receiver gain.

The Fig. 3, Fig. 4 and Fig. 5 shows the comparison of I2V simulated and calculated received signal strength at 2.4 GHz, 3.3 GHz and at 5.8 GHz.

We infer that in I2V communication the surrounding building height does have less impact on propagation. Though the same transmitter and receiver height is considered in all scenarios, irrespective of frequency the received signal strength is of range -40 dBm to -50 dBm. Simulated received power is closer to the received power calculated through dual slope model. Whereas in V2V the environment has significant impact in propagation, shown in Fig. 6. We could infer that due to presence of buildings of same height there is a reduction of around 20 dB in received power is observed. In scenario 3 in the presence of different height comparatively slight increment in received power than received power without buildings. The received power obtained is closer to the COST 231 Walfisch Ikegami model.

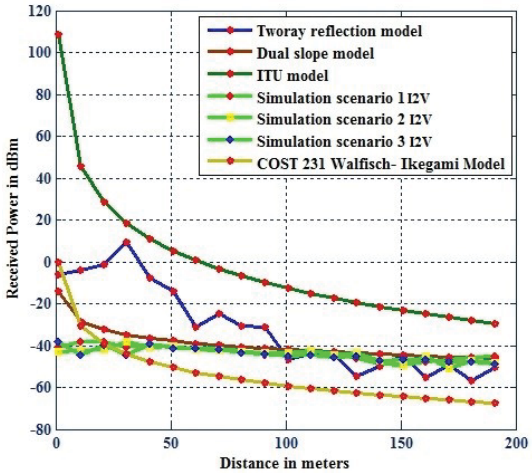

Fig. 3. Comparison of simulated I2V received signal strength with emperical models at 2.4 GHz.

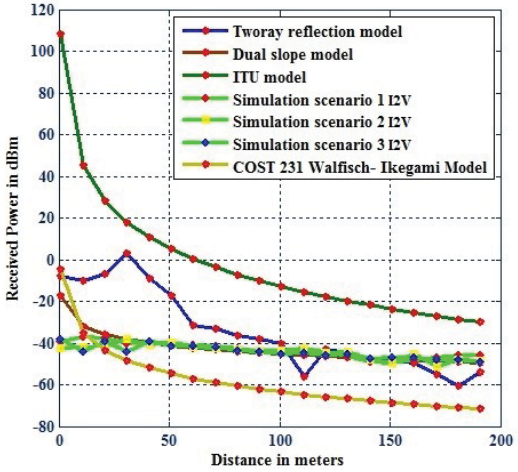

Fig. 4. Comarison of simulated I2V received signal strength with emperical model at 3.3 GHz.

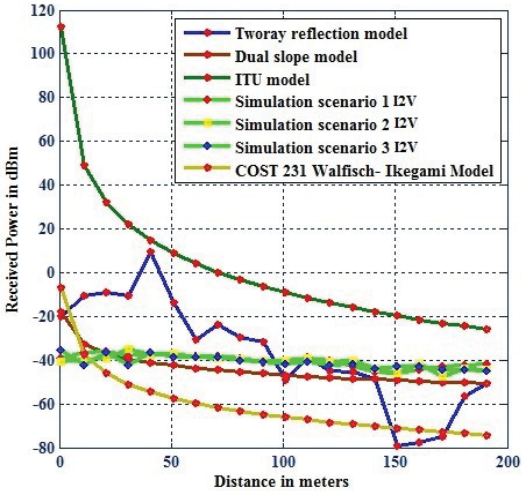

Fig. 5. Comarison of simulated I2V received signal strength with emperical model at 5.8 GHz.

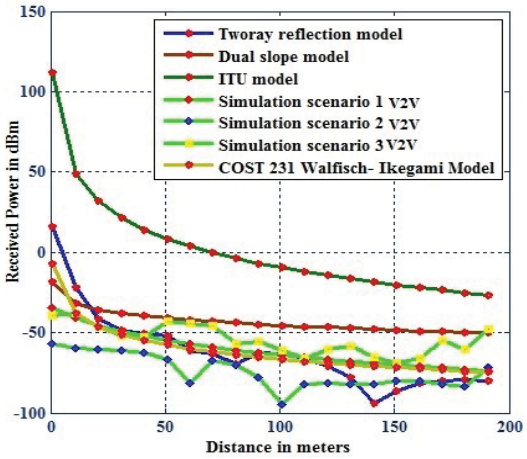

Fig. 6. Comparison of simulated V2V received signal strength with emperical model at 5.8 GHz.

IV. Conclusions

The design of a circularly polarized penta-band, single arm spiral antenna is presented with a compact size of size 51 x 35 x 1.574 mm3 to address Vehicular Wireless Applications for Navigational Communications and Terrestrial Wireless Network Communications. By introducing tapering in the feed line, better impedance matching is achieved at all desired bands. Further, path loss for V2V communications at different scenarios are analyzed and compared with empirical model. Through analysis, we infer I2V has less impact on propagation due to environment, whereas in V2V propagation has significant impact due environment. With the proposed antenna it is predicted that it is possible to have more than 200 m of line of sight communication. Thus the penta-band, omnidirectional pattern and circular polarization and good gain make the proposed antenna an appropriate applicant short range vehicular communications.

***Abstract*—Single Carrier Frequency Division Multiple Access (SC-FDMA) is becoming popular compared to Orthogonal Frequency Division Multiple Access (OFDMA) on uplink transmission because of its low peak to average power ratio (PAPR), however SC-FDMA is more sensitive to carrier frequency offset (CFO). This paper proposes an efficient blind CFO estimation algorithm for SC-FDMA scheme. In this method two folded oversampled SC-FDMA symbol with cyclic prefix (CP) is used to generate two SC-FDMA symbols with time difference.Using these two SC-FDMA symbols, a cost function is modelled that can be expressed as a cosine function. The property of this cosine function is used to derive an expression for estimating CFO. Unlike Maximum Likelihood (ML) method, there is no need to search all frequency offset range for CFO estimation. In the proposed method, only three cost function values are required at three different values of frequency offsets. The proposed algorithm is best suited for wireless applications as it only requires one SC-FDMA symbol for reliable blind estimation of CFO. The simulation results show that the proposed algorithm for CFO estimation outperforms ML method at high SNR, and it is also seen that accuracy of proposed algorithm is independent of the searching step size.**

***Index Terms*—Carrier frequency offset, Single Carrier Frequency Division Multiple Access (SC-FDMA), Blind Deterministic (BD), Maximum Likelihood (ML).**

I. Introduction

Over the last decade, the demand for higher data rates has increased rapidly making the channel frequency selective and resulting into Inter Symbol Interference (ISI) [1]. In order to mitigate this effect, multi-carrier modulation technique is used. Orthogonal Frequency Division Multiplexing (OFDM) is one of the efficient multi-carrier modulation technique in which the bandwidth of sub-carrier is designed to be smaller than the coherence bandwidth of the channel, resulting into frequency flat channel and thus simplifying the equalization process. Long Term Evolution (LTE) adopt SC-FDMA for uplink transmission due to its low Peak to Average Power Ratio (PAPR), as power is an important concern for Mobile Station (MS). But SC-FDMA is more sensitive to CFO compared to OFDMA [2]. If CFO is present between transmitter and receiver, the orthogonality between sub-carriers is destroyed which results into inter-carrier interference (ICI) and multi-user Interference (MUI).

Several schemes has been proposed to estimate the CFO from last two decades, still there is a need of an efficient and less complex scheme for CFO estimation of SC-FDMA and thereby correcting its effect. A frequency domain Compensation scheme for SC-FDMA using pilot signal has been proposed in [3] also a blind deterministic CFO estimation using oversampling has been proposed for OFDM [4].

This paper proposes an efficient blind deterministic CFO estimation algorithm for SC-FDMA.This work is the application of solution presented in [5] for OFDM in a new scenario i.e. SC-FDMA. In this method two folded oversampled SC-FDMA symbol with cyclic prefix (CP) is used to generate two SC-FDMA symbols with time difference. These two SC-FDMA symbols are then used to model a cost function in terms of cosine function which is used to estimate CFO. This paper is organised as follows, the system model for SC-FDMA scheme is introduced in section II. In section III a novel deterministic algorithm is proposed for blind estimation of CFO. In section IV simulation result is discussed. Finally, in section V conclusions are presented.

II. Proposed Deterministic Algorithm for Blind CFO Estimation

A. System Model

System model for SC-FDMA with interleaved sub-carrier allocation has been considered, where N is number of sub-carriers that can support a maximum of U users, therefore number of sub-carriers that can be allotted to each user is $R = N/U$ and only one user is active at a time (uplink situation). The data of each user is mapped to QPSK symbols which is given to M point DFT block. The l^{th} sample after DFT operation is represented as ,

$$X_k(l) = \sum_{m=0}^{M-1} x_u(m) e^{-j2\pi ml/N}, \quad 0 \le l \le R-1 \qquad (1)$$

where $x_u(m)$ represents modulated source symbols of u^{th} user. The M point DFT produces M frequency domain symbols that modulate orthogonal sub-carriers. The sub-carrier index of u^{th} user after mapping is $I_u = \{v_u + lU\}$, where l represents the l^{th} sample of symbol after DFT block and v_u denotes the starting sub-carrier index of the u^{th} user. After that IDFT is applied to $S_u(k)$,which is frequency domain samples after sub-carrier allocation at k^{th} sub-carrier produces transmitted time domain

channel symbols s_u.

$$s_u(m) = \frac{1}{N}\sum_{k=0}^{N-1} S_u(k) e^{j2\pi km/N}, \quad 0 \le k \le N-1 \tag{2}$$

where, $S_u(k) \neq 0$, for $k \in I_u$. A cyclic prefix (CP) of length N_{cp} is inserted at the beginning of each transmitted SC-FDMA frame. CP length should be large as compared to channel impulse response(CIR) length.

B. Cost Function for CFO Estimation

This paper proposes an algorithm to estimate the fractional part of the normalized CFO in SC-FDMA transmission scheme [5]. In absence of CFO the two folded oversampled received SC-FDMA symbol can be expressed as,

$$r_u(q) = \frac{1}{N}\sum_{k=0}^{R-1} H(k) X_u(k) e^{j2\pi(v_u+kU)q/2N} \tag{3}$$

where, $X_u(k)$ and $H(k)$ denotes the transmitted SC-FDMA symbol and channel impulse response for k^{th} sub-carrier in frequency domain respectively and R denotes the number of sub-carriers allocated to each user. The normal received SC-FDMA symbol $r_u(2m)$ is obtained from $r_u(q)$ by removing CP and considering even samples as shown in Fig.1.

$$r_u(2m) = \frac{1}{N}\sum_{k=0}^{R-1} H(k) X_u(k) e^{j2\pi(v_u+kU)m/N} \tag{4}$$

The early received SC-FDMA symbol $r_u(2m-2i-1)$ can be

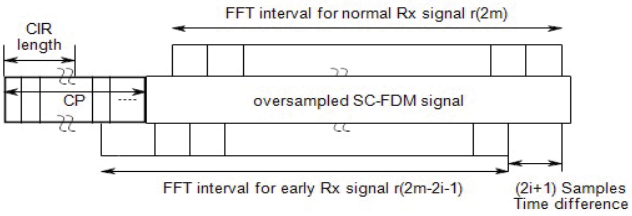

Figure 1: Normal and early Rx-SC-FDMA symbols from two folded oversampled received SC-FDMA symbol

obtained by shifting the starting point of the normal received SC-FDMA symbol to $(2i+1)$.

$$r_u(2m-2i-1) = \frac{1}{N}\sum_{k=0}^{R-1} H(k) X_u(k) e^{j2\pi(v_u+kU)(m-i-1/2)/N} \tag{5}$$

Here the time difference factor i is an integer that is used to overcome ISI, given $N_{cp} - CL \ge i$, where N_{cp} and CL denotes the CP length and channel impulse response (CIR) length. In the absence of CFO, the normal and early received SC-FDMA symbol holds the time invariant property in frequency domain and that can be written as,

$$\begin{aligned} R_u(k) &= \frac{1}{N}\sum_{m=0}^{R-1} r_u(2m) e^{-j2\pi(v_u+kU)m/N} \\ &= H(k) X_u(k) \end{aligned} \tag{6}$$

Similarly,

$$R_{ui}(k) = H(k) X_u(k) e^{-j2\pi(i+1/2)(v_u+kU)/R} \tag{7}$$

If the phase shift due to time shifting is compensated then both the signals are identical in frequency domain.

$$R_u(k) = R_{ui}(k) e^{j2\pi(i+1/2)(v_u+kU)/N} \tag{8}$$

On the other hand, if CFO (ε) is present, then phase shift of $e^{j2\pi\varepsilon/2R}$ comes in each sample of the received oversampled symbol $r_u(q)$. Therefore, the normal and early received SC-FDMA symbol can be obtained as,

$$r_u(2m) = \frac{1}{N}\sum_{k=0}^{R-1} H(k) X_u(k) e^{j2\pi(v_u+(k+\varepsilon)U)m/N} \tag{9}$$

and

$$r_u(2m-2i-1) = \frac{1}{N}\sum_{k=0}^{R-1} H(k) X_u(k) e^{j2\pi(v_u+(k+\varepsilon)U)(m-i-1/2)/N} \tag{10}$$

This CFO now results in ICI due to which $r_u(2m)$ and $r_u(2m-2i-1)$ does not hold time shift invariant property anymore. Therefore, before DFT operation CFO should be compensated, and to do this a trial CFO $\hat{\varepsilon}$ is introduced. The compensation is done by multiplying $e^{-j2\pi\hat{\varepsilon}m/R}$ and $e^{-j2\pi\hat{\varepsilon}(m-i-1/2)/R}$ with $r_u(2m)$ and $r_u(2m-2i-1)$ respectively. The CFO compensated signal in frequency domain can be expressed as,

$$D(l,\hat{\varepsilon}) = \sum_{m=0}^{R-1} \left\{ r_u(2m) e^{-j2\pi m\hat{\varepsilon}/R} \right\} e^{-j2\pi m(v_u+lU)/N} \tag{11}$$

and

$$\begin{aligned} D_i(l,\hat{\varepsilon}) = \sum_{m=0}^{R-1} &\left\{ r_u(2m-2i-1) e^{-j2\pi(m-i-1/2)\hat{\varepsilon}/R} \right\} \\ &\times e^{-j2\pi m(v_u+lU)/N} \end{aligned} \tag{12}$$

The CFO is exactly compensated when $\hat{\varepsilon} = \varepsilon$.

$$D(l,\hat{\varepsilon}) - D_i(l,\hat{\varepsilon}) e^{j2\pi(i+1/2)(v_u+lU)/N} = 0 \tag{13}$$

Using equation (13), a least square function or cost function can be defined as,

$$\xi(\hat{\varepsilon}) = \sum_{l=0}^{R-1} \left| D(l,\hat{\varepsilon}) - D_i(l,\hat{\varepsilon}) e^{j2\pi(i+1/2)(v_u+lU)/N} \right|^2 \tag{14}$$

Therefore, the estimated CFO $\hat{\varepsilon}$ for which cost function (14) can be minimized is

$$\begin{aligned} \hat{\varepsilon} &= arg \min_{\hat{\varepsilon}} \xi(\hat{\varepsilon}) \\ &= arg \min_{\hat{\varepsilon}} \sum_{l=0}^{R-1} \left| D(l,\hat{\varepsilon}) - D_i(l,\hat{\varepsilon}) e^{j2\pi(i+1/2)(v_u+lU)/N} \right|^2 \end{aligned} \tag{15}$$

To estimate the CFO, we iteratively calculate the cost function by gradually increasing the value of $\hat{\varepsilon}$ with predetermined resolution step size, which should be kept very small for better accuracy but on the other hand computation increases with decreasing resolution step size. To solve this problem, an

efficient blind deterministic CFO estimation method has been proposed in which there is no need to search for all the values of $\hat{\varepsilon}$.

C. Evaluating the Cost Function in terms of Cosine Function

1) In the Absence of Noise: In presence of CFO ε, the normal received SC-FDMA and the early received SC-FDMA symbols in time domain become $r_u(2m)e^{j2\pi m\varepsilon/N}$ and $r_u(2m-2i-1)e^{j2\pi(m-i-1/2)\varepsilon/N}$ respectively [5]. The normal received and early received SC-FDMA symbols in frequency domain can be expressed as,

$$R_u(l) = \frac{1}{N}\sum_{k=0}^{R-1} H(k)X_u(k)\sum_{m=0}^{R-1} e^{j2\pi m(k-l+\varepsilon)/R}, \quad (U/N = 1/R) \tag{16}$$

and

$$\begin{aligned} R_{ui}(l) =& \frac{1}{N}\sum_{k=0}^{R-1} H(k)X_u(k)e^{-j2\pi(i+1/2)(v_u+(k+\varepsilon)U)/N} \\ & \times \sum_{m=0}^{R-1} e^{j2\pi m(k-l+\varepsilon)/R} \end{aligned} \tag{17}$$

If $\varepsilon \neq 0$, the phase difference between $R_u(l)$ and $R_{ui}(l)$ can be compensated by multiplying $e^{j2\pi(i+1/2)(v_u+lU)/N}$ with $R_{ui}(l)$.

$$\begin{aligned} & R_{ui}(l)e^{j2\pi(i+1/2)(v_u+lU)/N} \\ & = \frac{1}{N}\sum_{k=0}^{R-1} H(k)X_u(k)e^{-j2\pi(i+1/2)(k-l+\varepsilon)/R} \\ & \times \sum_{m=0}^{R-1} e^{j2\pi m(k-l+\varepsilon)/R} \end{aligned} \tag{18}$$

Now,

$$\begin{aligned} & R_u(l) - R_{ui}(l)e^{j2\pi(i+1/2)(v_u+lU)/N} \\ & = \frac{1}{N}\sum_{k=0}^{R-1} H(k)X_u(k)\frac{1-e^{j2\pi\varepsilon}}{1-e^{j2\pi(k-l+\varepsilon)/R}} \\ & \times (1-e^{-j2\pi(i+1/2)(k-l+\varepsilon)/R}) \\ & = \frac{1}{N}\sum_{k=0}^{R-1} H(k)X_u(k)\ \mu(l,k,\varepsilon)\ (1-e^{j2\pi\varepsilon}) \end{aligned} \tag{19}$$

where,

$$\mu(l,k,\varepsilon) = \frac{1-e^{-j2\pi(i+1/2)(k-l+\varepsilon)/R}}{1-e^{j2\pi(k-l+\varepsilon)/R}} \tag{20}$$

The function $\mu(l,k,\varepsilon)$ is independent of ε [5]. So, $\left|R_u(l) - R_{ui}(l)e^{j2\pi(i+1/2)(v_u+lU)/N}\right|^2$ will be sinusoidal with respect to ε and independent of k and l. Therefore, equation (20) can be written as,

$$\mu(k,l,\varepsilon) = \mu_R(k,l) + j\mu_I(k,l) \tag{21}$$

Substituting the value of $\mu(k,l,\varepsilon)$ in equation (19),

$$\begin{aligned} & R_u(l) - R_{ui}(l)e^{j2\pi(i+1/2)(v_u+lU)/N} \\ & = \frac{1}{N}\sum_{k=0}^{R-1} H(k)X_u(k)\left\{\mu_R(k,l) + j\mu_I(k,l)\right\}(1-e^{j2\pi\varepsilon}) \\ & = (\alpha(l) + j\beta(l))(1-e^{j2\pi\varepsilon}) \end{aligned} \tag{22}$$

where,

$$\alpha(l) = Re\left\{\frac{1}{N}\sum_{k=0}^{R-1} H(k)X_u(k)\left\{\mu_R(k,l) + j\mu_I(k,l)\right\}\right\} \tag{23}$$

and

$$\beta(l) = Im\left\{\frac{1}{N}\sum_{k=0}^{R-1} H(k)X_u(k)\left\{\mu_R(k,l) + j\mu_I(k,l)\right\}\right\} \tag{24}$$

Using equation (22),

$$\begin{aligned} & \left|R_u(l) - R_{ui}(l)e^{j2\pi(i+1/2)(v_u+lU)/N}\right|^2 \\ & = (\alpha^2(l) + \beta^2(l)) \times 2(1-cos2\pi\varepsilon) \end{aligned} \tag{25}$$

Therefore, the cost function given in equation (14) can be formulated in terms of cosine function as,

$$\begin{aligned} \xi(\hat{\varepsilon}) =& \sum_{l=0}^{R-1}\left|D(l,\hat{\varepsilon}) - D_i(l,\hat{\varepsilon})e^{j2\pi(i+1/2)(v_u+lU)/N}\right|^2 \\ =& S(1-cos2\pi(\varepsilon-\hat{\varepsilon})) \end{aligned} \tag{26}$$

where, $S = 2\sum_{l=0}^{R-1}(\alpha^2(l) + \beta^2(l))$.

2) In Presence of Noise: The received two folded oversampled signal in presence of noise can be expressed as,

$$r_u(q) = \frac{1}{N}\sum_{k=0}^{R-1} H(k)X_u(k)e^{j2\pi(v_u+(k+\varepsilon)U)q/2N} + w(q) \tag{27}$$

where, $w(q) = w_R(q) + w_I(q)$ is complex Gaussian noise with mean and variance of both real and imaginary part to be zero and $\sigma_w^2/2$ respectively. As complex Gaussian noise is present, let us define $W(l,\hat{\varepsilon})$ and $W_i(l,\hat{\varepsilon})$ as,

$$W(l,\hat{\varepsilon}) = \sum_{m=0}^{R-1}\left\{w(2m)e^{-j2\pi m\hat{\varepsilon}/R}\right\}e^{-j2\pi m(v_u+lU)/N} \tag{28}$$

$$\begin{aligned} W_i(l,\hat{\varepsilon}) = & \sum_{m=0}^{R-1}\left\{w(2m-2i-1)e^{-j2\pi(m-i-1/2)\hat{\varepsilon}/R}\right\} \\ & \times e^{-j2\pi m(v_u+lU)/N} \end{aligned} \tag{29}$$

Again $D(l,\hat{\varepsilon}) - D_i(l,\hat{\varepsilon})e^{j2\pi(i+1/2)(v_u+lU)/N}$ with noise component can be evaluated as,

$$\begin{aligned} & D(l,\hat{\varepsilon}) - D_i(l,\hat{\varepsilon})e^{j2\pi(i+1/2)(v_u+lU)/N} \\ & = \left\{\alpha(l) + j\beta(l)\right\}(1-e^{j2\pi(\varepsilon-\hat{\varepsilon})}) + \eta_R(l,\hat{\varepsilon}) + j\eta_I(l,\hat{\varepsilon}) \end{aligned} \tag{30}$$

Where,

$$\eta_R(l,\hat{\varepsilon}) = Re\left\{W(l,\hat{\varepsilon}) - W_i(l,\hat{\varepsilon})e^{j2\pi(i+1/2)(v_u+lU)}\right\}$$

and

$$\eta_I(l,\hat{\varepsilon}) = Im\left\{W(l,\hat{\varepsilon}) - W_i(l,\hat{\varepsilon})e^{j2\pi(i+1/2)(v_u+lU)}\right\}$$

respectively, and assumed to have i.i.d. (independent identical distribution) with zero mean and $\sigma_n/2$ variance. Therefore, the cost function with noise can be expressed as,

$$\begin{aligned}\xi(\hat{\varepsilon}) &= S(1-cos2\pi(\varepsilon-\hat{\varepsilon}))\\ &+\sum_{l=0}^{R-1}\eta_R(l,\hat{\varepsilon})\{\alpha(l)(1-cos2\pi(\varepsilon-\hat{\varepsilon}))+\beta(l)sin2\pi(\varepsilon-\hat{\varepsilon})\}\\ &+\sum_{l=0}^{R-1}\eta_I(l,\hat{\varepsilon})\{\beta(l)(1-cos2\pi(\varepsilon-\hat{\varepsilon}))-\alpha(l)sin2\pi(\varepsilon-\hat{\varepsilon})\}\\ &+\sum_{l=0}^{R-1}\left\{\eta_R^2(l,\hat{\varepsilon})+\eta_I^2(l,\hat{\varepsilon})\right\}\end{aligned} \tag{31}$$

D. Blind Deterministic CFO Estimation

The cost function shown in equation (31) can be represented as,

$$\xi(\hat{\varepsilon}) = S(1-cos2\pi(\varepsilon-\hat{\varepsilon}))+V \tag{32}$$

where,V is the DC component of noise, which comes due to $\sum_{l=0}^{R-1}\left\{\eta_R^2(l,\hat{\varepsilon})+\eta_I^2(l,\hat{\varepsilon})\right\}$. Using which,

$$\xi(0) = S(1-cos2\pi\varepsilon)+V \tag{33}$$

$$\xi(0.25) = S(1-sin2\pi\varepsilon)+V \tag{34}$$

and

$$\xi(0.5) = S(1+cos2\pi\varepsilon)+V \tag{35}$$

Using equation (33) and equation (35), we get,

$$S+V = \frac{\xi(0)+\xi(0.5)}{2} \tag{36}$$

Therefore,

$$Scos(2\pi\varepsilon) = \frac{\xi(0.5)-\xi(0)}{2} \tag{37}$$

$$Ssin(2\pi\varepsilon) = \frac{\xi(0.5)+\xi(0)}{2}-\xi(0.25) \tag{38}$$

using equation (37) and (38), a complex variable y is defined to estimate CFO ε as follows,

$$\begin{aligned}y &= Scos(2\pi\varepsilon)+jSsin(2\pi\varepsilon)\\ &=\left\{\frac{\xi(0)-\xi(0.5)}{2}\right\}+j\left\{\frac{\xi(0)+\xi(0.5)}{2}-\xi(0.25)\right\}\end{aligned} \tag{39}$$

Therefore, the deterministically estimated CFO is,

$$\hat{\varepsilon} = \frac{1}{2\pi}tan^{-1}\angle\, y \tag{40}$$

Since, the phase of y is in the range $[-\pi,\pi)$. The above expression can be used to estimate the CFO between the range $-0.5\le\hat{\varepsilon}<0.5$. It is to be noted that the proposed algorithm is independent of step size taken.

E. Cramer-Rao Lower Bound (CRLB) for the Proposed Deterministic Estimator

The Cramer-Rao lower bound can be used to obtain the asymptotic variance of the blind estimator [5]. In equation (30) the additive Gaussian noise is normally distributed, and the large sample variance of least square estimator and maximum likelihood estimator coincide in the equation (30). The log likelihood function using equation (30), after neglecting the constant terms can be written as,

$$\begin{aligned}&lnF(\varepsilon,\alpha(l),\beta(l))\\ &\quad=\frac{1}{P}\sum_{e=-P/2}^{P/2-1}-\frac{1}{\sigma_n^2}\times|k(l,p/P)-\left\{1-e^{j2\pi(\varepsilon-p/P)}\right\}|^2\end{aligned} \tag{41}$$

Here constant terms are omitted and P denotes the total observation that has been taken and $k(l,p/P)=D(l,p/P)-D_i(l,p/P)e^{j2\pi(i+1/2)l/N}$.

In equation (41) $(\varepsilon,\alpha(l),\beta(l))$ are unknown parameters, so the (3×3) Fisher information matrix is obtained as

$$\begin{aligned}E\left[\frac{\partial^2 lnF}{\partial\varepsilon^2}\right] &= -\frac{8\pi^2\left\{\alpha^2(l)+\beta^2(l)\right\}}{\sigma_n^2}\\ E\left[\frac{\partial^2 lnF}{\partial\varepsilon\partial\alpha(l)}\right] &= \frac{4\pi\beta(l)}{\sigma_n^2}\\ E\left[\frac{\partial^2 lnF}{\partial\varepsilon\partial\beta(l)}\right] &= -\frac{4\pi\alpha(l)}{\sigma_n^2}\\ E\left[\frac{\partial^2 lnF}{\partial\alpha(l)\partial\beta(l)}\right] &= 0\\ E\left[\frac{\partial^2 lnF}{\partial\alpha^2(l)}\right] &= -\frac{4}{\sigma_n^2}\\ E\left[\frac{\partial^2 lnF}{\partial\beta^2(l)}\right] &= -\frac{4}{\sigma_n^2}\end{aligned} \tag{42}$$

Therefore, from equation (42) the asymptotic variance of estimated CFO for the l^{th} sub-carrier frequency index can be derived as

$$Var(\hat{\varepsilon}) \ge \frac{\sigma_n^2}{4\pi^2\left\{\alpha^2(l)+\beta^2(l)\right\}} \tag{43}$$

The above equation can also be derived for total sub-carriers $0\le l\le R-1$ as

$$Var(\hat{\varepsilon}) \ge \frac{\sigma_n^2}{4\pi^2\sum_{l=0}^{R-1}\left\{\alpha^2(l)+\beta^2(l)\right\}} \tag{44}$$

III. Simulation Result and Discussion

In this section BER performance of ML(Maximum Likelihood), BD(Blind Deterministic), CRLB(Cramer-Rao Lower Bond for BD), and PE(Perfect estimation) frequency offset

estimation algorithm is discussed. The six independent multi-path rayleigh fading channel has been considered. Table I shows the delay profile for multi-paths with 29 samples CIR length. The SC-FDMA symbols are transmitted at 25 *ksps* with symbol duration of 40 μsec. The duration of cyclic prefix is 8 μsec. Normal sampling interval is 0.25 μsec in such a way that one SC-FDMA symbol consists of 160 sampling points in which 32 sampling points are for CP ($N_{cp} = 32$). The total number of sub-carriers is 128. It is considered that every user uses 32 sub-carriers with interleaved sub-carrier allocation and for simulation purpose, normalized CFO is assumed to be 0.212.

Table I: Multi-path Delay Profile

	1st Tap	2nd Tap	3rd Tap
Relative delay	0.0	5.5	11.5
Initial complex gain	1.05-j0.82	0.71+j0.45	0.63-j0.72
	4th Tap	5th Tap	6th Tap
Relative delay	17.0	23.5	29.0
Initial complex gain	0.53+j0.62	0.41+j0.37	0.20-j0.34

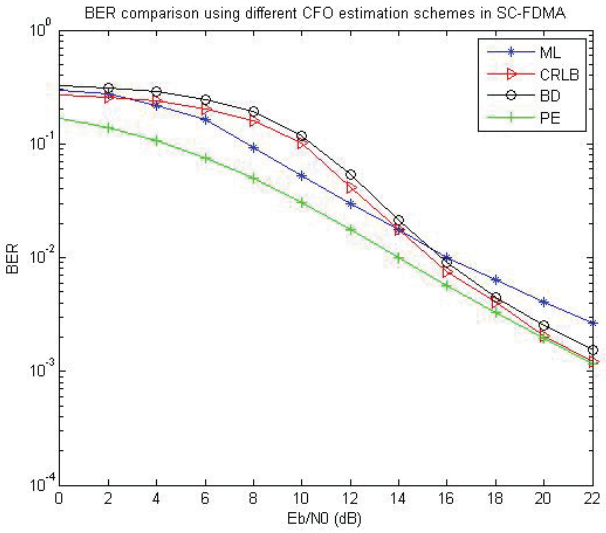

Figure 2: BER performance comparison in SC-FDMA system using ML, Blind Deterministic,CRLB and Perfect Estimation.

Fig.2 shows the BER performance comparison using QPSK modulation with different CFO estimator. It is considered that channel frequency response at the receiver is known. and a time difference factor of $i = 3$ has been considered. Notice that the BER using blind deterministic method and ML method is approximately same at 15 dB. The proposed scheme outperforms ML estimation method by approximately 1.5 dB with searching step size 0.024 at 10^{-3} BER. Fig.3 shows comparison of mean square error performance of different estimation schemes.The proposed scheme outperform approximately 3 dB at 10^{-4} mean square error. The complexity of ML method is large compared to blind deterministic method. The performance of ML method gets improved if the step size

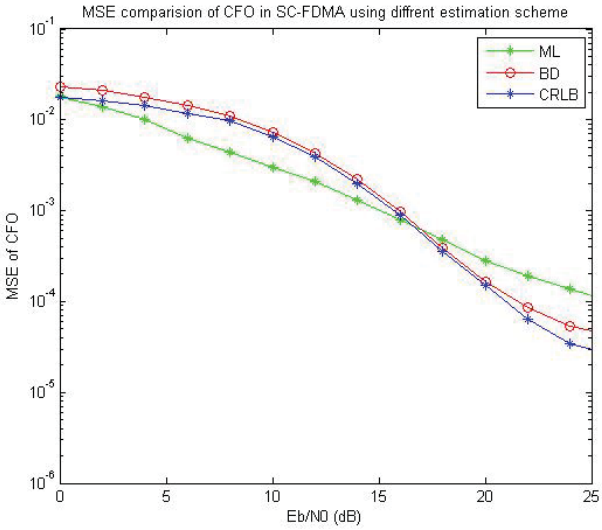

Figure 3: Mean square error performance comparison in SC-FDMA system using ML, Blind Deterministic,CRLB Estimation.

reduces also it is shown that Blind deterministic estimation is suitable to be use in high SNR environment.

IV. CONCLUSION

In this paper, an efficient deterministic algorithm for blind CFO estimation has been proposed for SC-FDMA. Unlike ML scheme, the proposed scheme does not require solution of higher order polynomial equation and only requires two SC-FDMA symbols with a time difference, which is obtained by using oversampling and CP. These two SC-FDMA symbols are then used to calculate a cost function. In proposed scheme a closed form expression is derived which requires only three values of cost function to estimate CFO. The simulation result shows that the proposed scheme out performs ML estimation scheme.

***Abstract*—Lack of available spectrum has severely restricted the increase of network capacity. In 3rd Generation Partnership Project (3GPP) Release 13, Licensed-assisted access to Unlicensed Spectrum (LAA) has been proposed to explore the spectrum in unlicensed band and to meet the rapidly increasing demands of data service. Listen-before-talk (LBT) is regarded as a feasible mechanism for LAA to fairly co-exist with other radio access technologies (RATs) in unlicensed spectrum, such as Wi-Fi. There are two typical LBT mechanisms, Frame-Based-Equipment (FBE) and Load-Based-Equipment (LBE), according to the European regulatory requirements. FBE can achieve frequency reuse among cells by applying simultaneous clear channel assessment (CCA) for channel occupancy every fixed period. Due to the periodic CCA, it does not have much opportunity to utilize the channel. On the other hand, LBE achieves higher probability of channel access as it senses the channel continuously until the channel becomes available. However, its transmit efficiency is low since it is hard to obtain frequency reuse. In this paper, we propose an enhanced LBT mechanism based on FBE to decouple the period of CCA and transmission burst by applying short CCA interval. Thus, it achieves both frequency reuse and high probability of channel access. System level evaluations show that the proposed LBT scheme for LAA ensures the efficiency of intra-operator co-existence of LAA and provide high throughput performance for both Wi-Fi and LAA in inter-operator co-existence between Wi-Fi and LAA.**

Keywords—Listen-before-talk, LAA, Wi-Fi, LBE, FBE, frequency reuse

I. INTRODUCTION

In recent years, Long-Term Evolution (LTE), which is standardized by 3rd Generation Partnership Project (3GPP) and regarded as 4th generation (4G) cellular networks, has been deployed in the most areas of the world. However, lack of available spectrum has severely restricted the increase in network capacity to cope with rising mobile data traffic demand. Unlicensed spectrum is more and more considered by cellular operators as a complementary tool to augment their service offering. In that case, Licensed-Assisted Access to unlicensed spectrum (LAA) has been studied [1] and will be specified [2] in 3GPP Release 13 to achieve more efficient use of unlicensed spectrum and better user experience.

Carrier Aggregation (CA) between a licensed carrier and an unlicensed carrier is considered to support LAA, where one or multiple Secondary Component Carriers (SCells) on unlicensed band and a Primary Component Carrier (PCell) on a licensed band are configured. In such a deployment, PCell in licensed band is targeted to ensure the quality of service (QoS) for user equipments (UEs) and SCells in unlicensed band is used to offload the traffic from licensed spectrum. As LAA is targeted to use the unlicensed spectrum such as 5GHz band, the design of LAA should fulfill the regulatory of the unlicensed spectrum and satisfy the fair co-existence with other Radio Access Technologies (RATs), e.g. Wi-Fi.

Co-existence issue of legacy LTE using unlicensed spectrum, especially the LTE and Wi-Fi co-existence, can be found in literature [3]-[5]. In [3], the authors address the problem that Wi-Fi channel is often blocked by LTE interference and suffer from significant user throughput degradation when Wi-Fi co-exist with LTE. Investigation on semi-static resource sharing mechanisms between LTE and Wi-Fi in either frequency [4] or time domain [5] shows that it is not a flexible approach to utilize the spectrum, since one system could not use the resource dedicated to the other system even there is no transmission from the other system.

Wi-Fi like Listen-before-talk (LBT) mechanism for LAA could ensure fair co-existence and flexible resource utilization. There are two typical LBT mechanisms, Frame-Based-Equipment (FBE) and Load-Based-Equipment (LBE), according to the European regulatory requirements [6]. FBE-based LBT mechanism seems to be aligned with LTE frame structure and easy to achieve frequency reuse among synchronized transmission nodes. But the problem is relatively lower channel access probability when it co-exists with Wi-Fi. On the other hand, LBE-based LBT mechanism senses the channel all the time before seizing the channel. LBT mechanism in Wi-Fi can be categorized into LBE-based LBT mechanism. When LAA co-exists with Wi-Fi, LBE-based LBT for LAA can achieve the same level of opportunity as Wi-Fi to seize the channel. However, since transmission timings of neighboring LAA cells would not be aligned, thus it is hard to obtain frequency reuse and the transmit efficiency of LAA would be low compared with FBE-based LBT case. In this paper, we proposed an enhanced FBE-based LBT mechanism for LAA to increase the channel occupancy probability while keep high frequency reuse among LAA cells. We perform exhaustive system level simulations to investigate the frequency reuse in intra-operator co-existence scenario of LAA and fairness in inter-operator co-existence scenario between Wi-Fi and LAA.

The paper is organized as follows. Section II describes the co-existence scenarios for LAA and Wi-Fi in unlicensed band.

Conventional FBE and LBE based LBT mechanisms are introduced in Section III. Section IV presents and analyzes the proposed LBT mechanism. In Section V, simulation environment and key assumptions are provided. The system level simulation results of proposed LBT mechanisms are also presented in this section. Finally, the conclusions are summarized in Section VI.

II. Deployment Scenarios

Unlicensed spectrum has been widely used by Wi-Fi. Many operators have deployed operator-managed Wi-Fi systems in public areas. Once LAA is introduced, several deployment scenarios could be considered.

Fig. 1 provides the deployment of co-existence scenarios. In each scenario, macro cell with licensed band provides coverage for the UEs in the area and Wi-Fi access points (APs) and/or LAA small cells (SCs) are deployed as a cluster to provide large volume data service for a high traffic area. Fig.1 (a) shows the normal co-existence scenario of LTE network where the distance between cells is appropriately designed by careful cell planning. However, as depicted in Fig.1 (b) to (d), due to lack of cell planning across different operators, small cells in unlicensed spectrum may be planted very close to each other, which introduces severe inter-operator interference.

The LBT mechanism is an effective way of solving the severe interference problem. In the design of specific LBT method for LAA system, we should consider both the high LAA transmission efficiency as well as the fairness between LAA and Wi-Fi system.

III. Conventional LBT Mechanisms for LAA

In this section, we discuss the details of FBE-based and LBE-based LBT mechanisms used for LAA and analyze their advantages and disadvantages.

In FBE, the clear channel assessment (CCA) is performed every fixed frame period, as shown in Fig. 2(a). If the energy detected in CCA duration is larger than a threshold, the channel is confirmed as busy, otherwise the channel is idle. Once idle channel is detected, LAA could occupy the channel for transmission. But if busy channel is detected, it should not use the channel until next CCA occasion. It is specified in [6] that the channel occupancy time, i.e., the maximum burst length shall be in the range 1 ms to 10 ms, and the minimum idle period including CCA duration shall be at least 5% of the channel occupancy time. FBE-based LBT could easily achieve frequency reuse of an operator by aligning the CCA and transmission period among synchronized cells within one operator. Compared with Wi-Fi, LAA with FBE-based LBT has lower probability to seize the channel since CCA can only be performed for one time every fixed frame period.

In LBE, if the equipment finds an operating channel occupied, it shall perform an extended CCA (ECCA), as shown in Fig. 2 (b). The ECCA can be repeated until the equipment finds the operating channel is idle when N idle CCA slots are observed. The value N shall be randomly selected in the range 1 to q every time an ECCA is required and the value is stored in a counter. The counter is decremented every time an ECCA

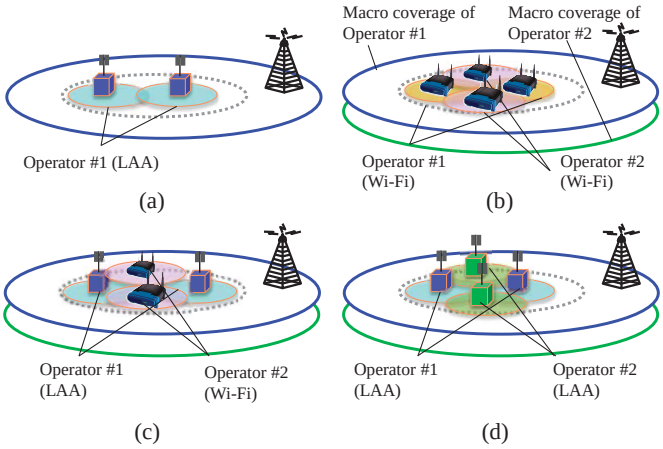

Fig.1 Deployment scenarios: (a) intra-operator LAA co-existence (b) inter-operator Wi-Fi-Wi-Fi co-existence; (c) inter-operator LAA-Wi-Fi co-existence; (d) inter-operator LAA-LAA co-existence

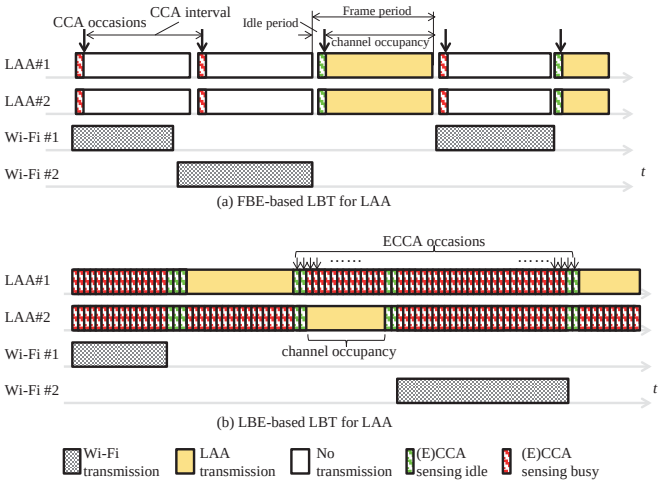

Fig.2. FBE-based LBT and LBE-based LBT for LAA

occasion is confirmed as idle. When the counter reaches zero, the equipment may transmit. The maximum channel occupancy time is limited to $13/32 \times q$ ms. A node equipped with LBE-based LBT can seize a channel immediately after the channel becomes idle, while a node with FBE-based LBT needs to wait next CCA timing and may miss the channel access opportunity due to the interception by other RAT, e.g., Wi-Fi. Therefore, LAA with LBE-based LBT would achieve comparable channel access with Wi-Fi since Wi-Fi is also equipped with a kind of LBE-based LBT. However, even if nodes within one operator are tightly synchronized, it would be difficult to realize frequency reuse since CCA and transmission timings may be unaligned due to diverse interference condition among cells. Such cell within one operator may block each other once CCA timings of cells become unaligned.

IV. Proposed LBT Mechanism for LAA

As in cellular network, such as LTE, frequency reuse is an important property to achieve high network capacity. Based on this fact, we propose FBE-based LBT with Short CCA Interval

(SCI-FBE) mechanism to increasing the channel access probability while ensuring the frequency reuse of LAA.

Fig. 3 shows the CCA timing and frame period of SCI-FBE mechanism. CCA is performed in a shorter interval than frame period when LBT result at the previous subframe is busy, while CCA is not performed during transmission burst after which it is confirmed that LBT result is idle. The transmission burst length should be configurable to fulfill the regulatory requirement of different regions. The SCI-FBE mechanism absorbs the advantages of FBE and LBE. In intra-operator co-existence of LAA, SCI-FBE mechanism helps LAA cells to transmit data bursts in the shared unlicensed carrier simultaneously. Thus transmission efficiency of LAA is improved by realizing frequency reuse. In inter-operator co-existence scenario of Wi-Fi-LAA, the channel occupancy ratio of LAA is increased as the CCA interval becomes shorter than the frame period.

V. Evaluation Results

A. Simulation assumption

In intra-operator co-existence of LAA, LAA cells are deployed in one cluster. In inter-operator co-existence scenario, two operators deploy same number of Wi-Fi or LAA cells in the cluster. There are total 7 hexagonal 3-cell macro sites are deployed with ISD of 500 meters. One cluster is randomly distributed for each macro cell with the minimum distance from macro to cluster center of 105 meters. Each LAA/Wi-Fi operator deploys four SCs/APs in each cluster with the radius of 50 meters. The minimum distance between cells of the same operator is 20 meters, while the minimum distance between cells of different operator is 10 meter. UEs of each operator are randomly and uniformly distributed in the area within 20 meters from each SC/AP. Table I summarizes the simulation parameters for both LAA and Wi-Fi.

Although there are many frequency channels in the unlicensed band, we assume the worst co-existence environment that a single channel is shared by multiple cells of different operators. Single channel of 20MHz in 5.0GHz band is assumed for LAA/Wi-Fi operators. For LAA, only downlink packet throughput is evaluated in unlicensed band as uplink control signaling is carried by licensed band. For Wi-Fi, downlink packet throughput is evaluated as well, and ideal uplink transmission without resource occupation is assumed. For LAA, Channel state information (CSI) is reported in the time granularity of 10ms for link adaptation. Chase combining with maximum 3 re-transmission time is assumed for LTE Hybrid Automatic Repeat request (HARQ). In the evaluation of LBE-based LAA, initial CCA is needed before the procedure of ECCA counter decrement is resumed.

B. Evaluation results

System level evaluations are performed to verify the effectiveness of the proposed LBT mechanisms introduced in Section IV. The co-existence scenario of intra-operator of LAA and inter-operator of Wi-Fi-Wi-Fi and Wi-Fi-LAA is evaluated. In the evaluation, FTP traffic model with Poison distribution of packet arrival rate [5] is considered. Traffic load refers as the

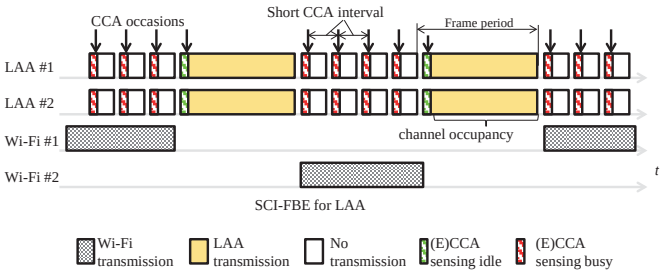

Fig.3 SCI-FBE mechniasm for LAA

Table I Simulation Parameters

Basic parameters	**Value**
Cellular layout	Hexagonal grid, 7 sites, 3 cell per site
Bandwidth	20 MHz per channel, single channel
Frequency	5.0 GHz
DL Tx Power	18 dBm
SC/AP dropping	Random and uniform within 50 m cluster radius
Mini. dist. b/w SC/AP	20 m of same operator, 10 m of different operator
SC/AP # per cluster	4
Cluster # per macro	1
UE dropping	Random and uniform within 20ms from each cell
Indoor UE/STA ratio	0.8
Cell selection	Best RSRP-based with 0dB handover margin
Antenna configuration	2D, 2x2 CPA, Omni-directional
Antenna gain	5 dBi at cell, 0 dBi at UE
Antenna height	10 m for cell, 1.5 m for UE
MIMO	Up to 2 streams
UE/STA receiver	MMSE
Traffic model	FTP model 1 [7] with packet size of 0.5 Mbytes
Channel model	ITU UMi [8] with 3D distance
LAA parameters	**Value**
Simulation step	1 ms (FBE)/8us (LBE)
Link adaptation	Subband CQI and wideband PMI of 10ms periodicity
HARQ	Chase combine
Max. ReTx. times	3
(E)CCA duration	24 us (for both FBE and LBE)
Initial CCA duration	32 us (for LBE)
q	10/25 for 4/10 ms burst length
CCA-ED	-62dBm
Scheduler	Proportional fairness
Wi-Fi parameters	**Value**
Simulation step/slot	8 us
MCS	802.11n
Channel coding	BCC
DIFS	32 us
RTS/CTS	N/A
Contention window	Min: 15 slot; Max: 1023 slot
Max burst length	4 ms
Frame aggregation	A-MPDU
MPDU	1.5 K Byte size
Link adaptation	Open loop using ACK
CCA-CS (Wi-Fi)	-82 dBm
CCA-ED (other RAT)	-62 dBm
Scheduler	Round-robin

arrival UE number per cluster per second. For example, traffic load 2 means the average 2 UEs arrived in the cluster area per second. Total simulation time of 25 seconds, i.e. 25,000ms, is assumed for each evaluated case. A 0.5 M bytes packet is assumed for each new generated UE. In low traffic load, some of the cells have traffic for transmission. In high traffic load, there is probably more than one UE stay in the buffer of the cell simultaneously. The evaluation is performed in traffic loads from low to high.

1) Intra-operator LAA co-existence

In order to comparing the LBT schemes of FBE, LBE and SCI-FBE, maximum 4 ms burst length is assumed.

Fig.4 shows the average, 5% and 95% UE throughput of LAA in different traffic load in scenario of intra-operator LAA co-existence. UE throughput is derived as the number of packet bits successfully transmitted to the sojourn time of the packet in node buffer. Fig.5 shows the averaged cell waiting time ratio and transmit time ratio in different traffic load in scenario of intra-operator LAA co-existence. For one cell, there are three statuses in the evaluation: no buffer, waiting due to LBT and transmission. Before UE arrival, the cell stays in no buffer status. After UE arrival, the cell tries to seize the channel for transmission by performing LBT. Its status would switch between waiting and transmission corresponding to LBT and data transmission procedure. The waiting and transmission time ratio observation in Fig.5 could help to analyze the throughput tendencies in Fig.4.

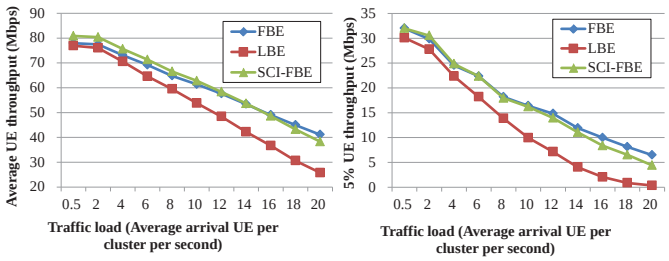
There are several observations on the throughput results in Fig.4. Firstly, average UE throughput is decreased with the increasing of traffic load, since averaged scheduling probability of each UE is low and interference is severe in high traffic load scenario. Secondly, FBE and SCI-FBE based LAA achieves higher average UE throughput than LBE-based LAA. As we discussed in section III, owing to unaligned CCA timing and data transmission in LBE-based LAA, LAA cells within one operator will block each other. Hence, significant higher waiting time ratio of LBE than other LBT schemes is observed in Fig.5 (a). Thus UE throughput of LBE-based LAA is relatively small. Thirdly, by comparing FBE and SCI-FBE, SCI-FBE based LAA has larger throughput in low traffic load and smaller throughput in high traffic load, in terms of averaged and 95% UE throughput. It is because that SCI-FBE could seize channel immediately by executing CCA in each subframe when new packet arrives, thus less waiting time compared to FBE especially in low traffic load. On the other hand, SCI-FBE achieves lower frequency reuse compared FBE due to CCA of SCI-FBE is not fully aligned among cells of one operator. Then waiting time ratio of SCI-FBE is relative high especially in high traffic load.

In summary of intra-operator co-existence, it is observed that SCI-FBE could achieve comparable performance and similar frequency reuse as FBE for LAA cells of the same operator.

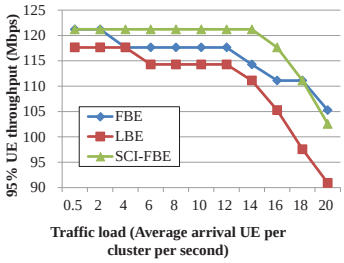
2) Wi-Fi-LAA co-existence

There are two operators deployed within a clustered area in Wi-Fi-LAA co-existence. LBT mechanism for LAA should firstly ensure that LAA is a good neighbor for Wi-Fi. It means that the Wi-Fi performance in Wi-Fi-LAA co-existence should be equal or better than the performance of the same Wi-Fi operator in Wi-Fi-Wi-Fi co-existence. Second, the LBT mechanism of LAA should ensure the high efficient LAA transmission when LAA co-exist with another system.

Fig. 6 shows the average UE throughput performance of Wi-Fi-LAA co-existence by considering the maximum burst length for LAA of 4ms. The baseline is the Wi-Fi throughput in Wi-Fi-Wi-Fi co-existence. From Wi-Fi throughput in Fig. 6(a), it is found that Wi-Fi could achieve higher throughput if it co-exists with LAA instead of another Wi-Fi, thanks to more efficient transmission of LAA due to some advanced technologies such as close-loop link adaptation (CLLA) and HARQ. From LAA

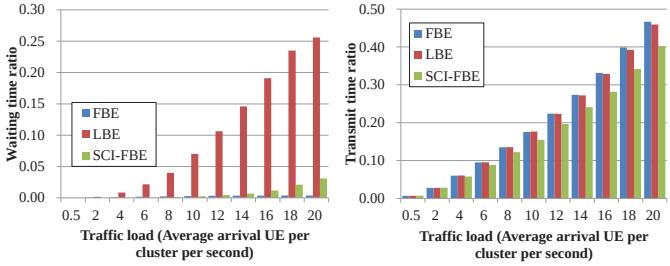


(a) Average UE throughput of LAA (b) 5% UE throughput of LAA



(c) 95% UE throughput of LAA

Fig.4 Average, 5% and 95% UE throughput of LAA in different traffic load in scenario of intra-operator LAA co-existence

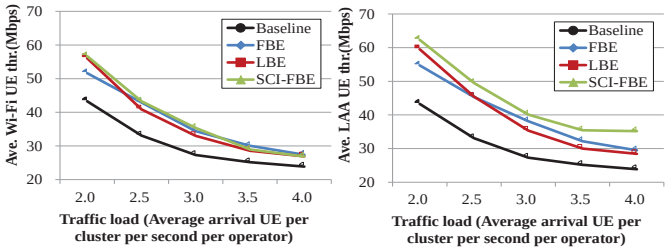


(a) Waiting time ratio of LAA (b) Transmit time ratio of LAA

Fig.5 Waiting and transmit time ratio of LAA in different traffic load in scenario of intra-operator LAA co-existence

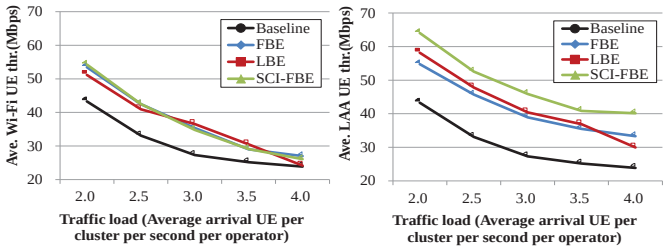
throughput in Fig.6 (b), several points are further observed. First, FBE achieves lower performance in low traffic load and higher performance in high traffic load than LBE. As it is already observed in evaluations of intra-operator co-existence, benefits from frequency reuse by applying FBE are obvious in high load scenario but negligible in low load scenario. Thus FBE has higher performance than LBE in high traffic load. When co-existing with Wi-Fi, LBE-based LAA has higher channel access probability than FBE-based LAA, it helps LBE achieve higher throughput than FBE in low load case. The other observation is that SCI-FBE achieves higher throughput than FBE and LBE in both low and high traffic load. This is because that both intra-operator frequency reuse and higher carrier seizing ratio could be achieved by fixed and more frequent CCA timing design of SCI-FBE, respectively.

Fig.7 shows performance of Wi-Fi-LAA co-existence with maximum 10ms burst length for LAA. The LAA performance is improved comparing to 4ms burst length in Fig.6, since it allows longer continuous transmission time transmission without LBT after single CCA procedure. SCI-FBE still achieves higher throughput than FBE and LBE.



(a) Average UE throughput of Wi-Fi (b) Average UE throughput of LAA

Fig.6 Throughput of Wi-Fi-LAA co-exitence, 4ms max. burst length for LAAs



(a) Average UE throughput of Wi-Fi (b) Average UE throughput of LAA

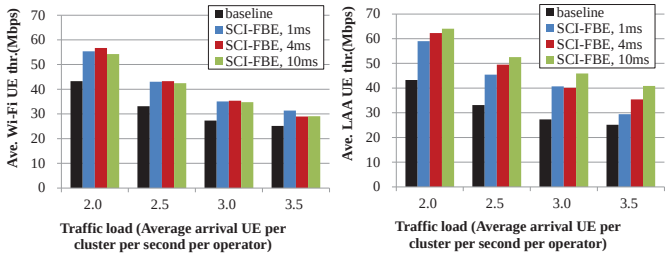
Fig.7 Throughput of Wi-Fi-LAA co-exitence, 10ms max. burst length for LAAs

Fig.8 shows performance of SCI-FBE based LAA with maximum burst length of 1, 4 and 10ms co-existed with Wi-Fi. It is found that LAA throughput is increased with the increasing of maximum burst length. Since the longer burst length allows longer continuous transmission time without LBT after single CCA procedure. Then the waiting time of LBT needed for LAA is shorter, which is also showed in Fig.9 (a), and throughput performance is larger. For Wi-Fi, it is observed that waiting time ratio is decreased with the increasing of LAA maximum burst length. While the throughput performance difference between burst length of 1ms and 10ms is relative smaller than that of LAA. Although longer waiting time will degrade the Wi-Fi throughput, fast LAA transmission would benefits Wi-Fi.

VI. Conclusion

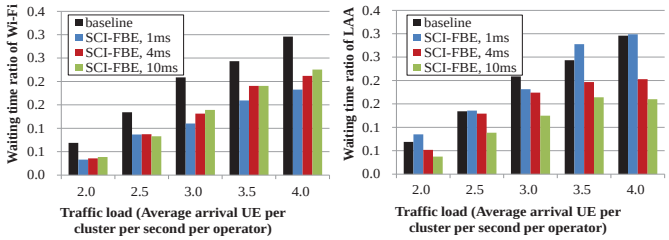
LBT mechanism is regarded as an essential technology for LAA to fairly access the unlicensed carrier when co-exist with other systems. In this paper, we analyze and figure out the problem of conventional LBT mechanisms of FBE and LBE. The proposed SCI-FBE mechanism absorbs the advantages from FBE and LBE, where frequency reuse and fair channel access with coexistence system such as Wi-Fi could be achieved at the same time.

System level evaluations are performed to investigate the throughput performance of FBE, LBE and SCI-FBE mechanisms used for LAA in both intra-LAA operator co-existence and Wi-Fi-LAA co-existence. Throughput results show that the proposed SCI-FBE mechanism achieves comparable performance as FBE by achieving frequency reuse in intra-LAA operator co-existence. More important observation is that SCI-FBE could provide better throughput



(a) Average UE throughput of Wi-Fi (b) Average UE throughput of LAA

Fig.8 Throughput of Wi-Fi-LAA (SCI-FBE) co-exitence with 1, 4, 10ms burst length



(a) Waiting time ratio of Wi-Fi (b) Waiting time ratio of LAA

Fig.9 Waiting time ratio of Wi-Fi-LAA (SCI-FBE) co-exitence with 1, 4, 10ms burst length

performance of Wi-Fi and LAA than mechanisms of FBE and LBE in Wi-Fi-LAA co-existence due to high efficiency of LAA and comparable channel access capability as Wi-Fi. Furthermore, longer burst length of SCI-FBE, such as 10ms, could improve the throughput of LAA significantly while introduce negligible degradation on Wi-Fi.

***Abstract*—Compared to the cyclic prefix orthogonal frequency division multiplexing (CP-OFDM), filter bank based multi-carrier with offset quadrature amplitude modulation (FBMC/OQAM) is more suitable for asynchronous access applications and cognitive radio scenarios in the fifth generation (5G) communication by using synthesis and analysis filter banks composed of well time-frequency locationed (TFL) prototype filters. However, real orthogonality instead of complex orthogonality makes the channel estimation in FBMC/OQAM system challenging. In this paper, an effective and low complexity compressive sensing based channel estimation method via Generalized Approximate Message Passing (GAMP) algorithm was proposed, when it was compared with several other popular methods presented for FBMC/OQAM in the literatures, analysis and simulation results demonstrate this method is more robust to channel frequency selectivity and always works well even in underdetermined cases, in virtue of utilization of the prior probability and the sparsity property of the channel impulsive response (CIR) coefficients.**

I. Introduction

In the future 5G wireless communication, asynchronous access [1] will be an important scenario because machine-to-machine communication needs relaxed synchronization to reduce constant exchange of control signaling. Furthermore, massive machines will aggravate fragmentation of spectrum. Physical layer scheme with confined waveform and relaxed synchronization is needed to satisfy the asynchronous access and cognitive radio communications [2]. FBMC/OQAM [3] has been regarded as a candidate alternative multicarrier scheme to CP-OFDM, because of its lower sidelobe leakage, higher spectral efficiency without CP and the insensitivity to the synchronization errors. But Balian-Low theory [4] tells us, the complex orthogonality, well time-frequency locationed prototype filters and the maximal spectral efficiency cannot achieve simultaneously, and then real orthogonality instead of complex orthogonality makes the channel estimation of the FBMC/OQAM system challenging.

Organizations such as Mobile and wireless communications Enablers for the Twenty-twenty Information Society (METIS) [5] and 5th Generation Non-Orthogonal Waveforms for Asynchronous Signalling (5GNOW) [6] under European Framework 7 has been devoted to the key techniques of the FBMC/OQAM. [7] and [8] use an auxiliary pilot to cancel the interference coming from the imaginary term. [9] proposed Pairs of Pilots method (POP) and Interference Approximation Method (IAM), the latter frequency domain estimation method regards the desired time-frequency grid plus the pure imaginary interferences coming from the neighborhood grids as a pseudo pilot, but it is under the assumption that symbol interval is much longer than the maximum channel delay spread, which leads to an error floor of performance when the channel frequency selectivity increases. [10] and [11] developed a time domain channel estimation method in terms of the channel impulse response (CIR), but it is not spectral efficient to transmit all the frequency domain pilots for the sparse channel estimation, and linear estimation methods have higher complexity. In recent years, applications of compressive sensing [12] to sparse channel estimation have saved the spectral sources and increased the performance. [13] demonstrated a greedy algorithm called Orthogonal Matching Pursuit (OMP), [14] proposed a compressive sensing method based on Basis Pursuit (BP). GAMP [15] was presented that not only provides the low complexity of iterative threshold algorithm but also the strong reconstruction ability of BP. [16] and [17] applied GAMP into multiuser detection for uplink massive MIMO and massive spatial modulation MIMO. In this paper, considering the special time-frequency structure in FBMC/OQAM system, we proposed a compressive sensing based channel estimation method using GAMP algorithm.

This paper first analyzed the time domain channel estimation model and the input-output expression of FBMC/OQAM system explicitly. To further improve the performance and decrease the computation complexity of the estimation method, a GAMP based method was proposed, the prior probability and sparsity of the channel impulse response coefficients were also utilized to achieve a better performance.

The rest of this paper is organized as follows. Section II depicted the FBMC/OQAM system model. Section III described the problems of channel estimation exist in the FBMC/OQAM system, followed by the detailed design procedure of compressive sensing based channel estimation via GAMP in Section IV. The simulation results are given in Section V. Finally, Section VI concludes the whole paper.

II. System model

In FBMC/OQAM system [18], a set of parallel data symbols are transmitted through a bank of synthesis and analysis filters. The selection of prototype filters decides the localization in spectrum of the generated waveform [19]. OQAM modulation combined with Nyquist constraints on the transmit and receive prototype filter is used to guarantee real orthogonality between adjacent symbols and adjacent carriers. Meanwhile,

no use of CP provides maximum spectral efficiency. In order to decrease the processing complexity of this system, a feasible and efficient implementation of FBMC/OQAM transmit and receive processing is obtained using the Fast Fourier Transform (FFT) and Polyphase Network (PPN) in [20] and is used in this paper. The output vector of transmit synthesis filter bank $s[n]$ is given by

$$s[n] = \sum_{k=-\infty}^{\infty} \sum_{m=0}^{M-1} d_m[k]\theta_m[k]p[n-k\frac{M}{2}]e^{j\frac{2\pi}{M}m(n-k\frac{M}{2}-D)} \tag{1}$$

where $d_m[k]$ are the real transmit data extracted from the complex QAM symbols, $\theta_m[k] = j^{m+l}$ is used to keep the real orthogonality between adjacent grids, $p[n]$ is the prototype filter [21] used in the synthesis filter bank, such as (physical layer for dynamic spectrum access and cognitive radio) PHYDYAS [22], half cosine, root raised cosine (RRC), Isotropic Orthogonal Transfer Algorithm (IOTA) and Extended Gaussian Functions (EGF), all of the prototype filters have well time-frequency location (TFL) properties and guarantee the confined spectrum of the FBMC/OQAM. Delay term $D = \frac{L_g-1}{2}$, L_g is the length of prototype filter.

The output vector of transmit synthesis filter bank $s[n]$ is first affected by the CIR $h[l]$, whose length is L_h, K is the number of non-zero taps. When $K \ll L_h$, the channel can be recognized as sparse channel.

The input vector of receive analysis filter bank

$$r[n] = h[l] * s[n] + w[n] \tag{2}$$

where $w[n]$ is Gaussian white noise with variance σ^2.

On the receiver side, take a desired time-frequency grid into account, the decoded signal at the qth subcarrier and kth time instance is

$$y_q[k] = \sum_{l=0}^{L_h-1} h[l] * A_{m,l} + W_q[k] \tag{3}$$

$$A_{m,l} = \sum_{m=0}^{M-1} \sum_{n=0}^{L_g-1} d_m[k]\theta_m[k]p[n-l]*p[n]e^{j\frac{2\pi}{M}m[(n-D)(m-q)-l]} \tag{4}$$

$$W_q[k] = \sum_{n=k\frac{M}{2}}^{L_g-1+k\frac{M}{2}} w[n]p[n-k\frac{M}{2}]e^{-j\frac{2\pi}{M}q(n-k\frac{M}{2}-D)} \tag{5}$$

III. Problem description

The key issue of our paper is to estimate the channel coefficients, we use time domain model which is more robust to channel frequency selectivity and then channel impulse response coefficients will be estimated. In order to compare our proposal with other estimation methods, we also use frequency domain pilots, which is the same with IAM method. Three symbol are used as the frequency domain pilot with the first and the third is all zero, the pilot in the subcarriers of the middle symbol is repeated as 1,1,-1,-1.

A. IAM method

As mentioned in the FBMC/OQAM system before, the channel frequency response $H_{q,k}^{(c)}$ is complex but the transmit data $d_{q,k}$ is real, so IAM take the non-zero pilot and the pure imaginary interference $d_{q,k} + j \sum_{(q_0,k_0)\neq(0,0)} (d_{q+q_0,k+k_0} < g >_{q+q_0,k+k_0}^{q,k})$ as a complex pseudo pilot based on the assumption of $H_{m_0+p,n_0+q}^{(c)} \approx H_{m_0,n_0}^{(c)}$. The estimated channel frequency response is

$$H_{q,k}^{(c)} = y_{q,k}^{(c)}/d_{q,k} + j \sum_{(q_0,k_0)\neq(0,0)} d_{q+q_0,k+k_0} < g >_{q+q_0,k+k_0}^{q,k} \tag{6}$$

B. Time domain estimation method

When channel frequency selectivity increases and the symbol duration is not much longer than the maximum channel delay excess, IAM will suffer from severe performance degradations. Similar as [10] and [11], we consider our method in time domain to improve robustness of our method. We put equation (3) into the matrix form

$$Y = A * h + W \tag{7}$$

Y is the received signals of the middle non-zero pilots, A is a matrix with dimension $M * L_h$, the elements of A is decided by the pilot and mutual ambiguity function of the prototype filters. $h = [h_0 h_1 ... h_{L_h}]^T$ is the unknown parameters to be estimated.

Particularly, W is color noise filtered by the analysis filter bank and therefore the elements of it are not independent any more. Considering the whiten of noise, we firstly obtain the covariance coefficient of the color noise

$$\mathrm{cov}[w_{q_1} w_{q_2}] = \sigma^2 \alpha_{q_1,1}^{q_2,1} \tag{8}$$

where $\alpha_{q_1,1}^{q_2,1}$ means coherence degree between two subcarriers q_1 and q_2 on the middle pilot time instance. The $\alpha_{q_1,1}^{q_2,1}$ can be simplified to be

$$\alpha_{q_1,1}^{q_2,1} = \begin{bmatrix} 1 & \mathrm{j}\beta & 0 & ... & 0 & \mathrm{j}\beta \\ -\mathrm{j}\beta & 1 & \mathrm{j}\beta & ... & 0 & 0 \\ & & & ... & & \\ \mathrm{j}\beta & 0 & 0 & ... & -\mathrm{j}\beta & 1 \end{bmatrix} \tag{9}$$

then (7) is changed to be

$$Y' = A' * h + W' \tag{10}$$

after the whiten process, where

$$W' = (\alpha_{q_1,1}^{q_2,1})^{-1/2}/\sigma) * W \tag{11}$$

and the elements of it follow independent Gaussian white noise with variance σ^2. The key issue is to estimate the CIR h from the observation Y'.

IV. Compressive sensing based channel estimation via GAMP

In this paper, GAMP based compressive sensing channel estimation is used in the FBMC/OQAM system. Firstly, in order to model the sparsity of the channel, the CIR coefficients $\{h_l\}$ are regarded as random variables with independent Bernoulli-Gaussian prior distribution, the probability density function

$$p_{h_l}(h) = \frac{K}{L_h} CN(h; \mu_l, \sigma_l) + (1 - \frac{K}{L_h})\delta(h) \tag{12}$$

where $\frac{K}{L_h}$ is the sparsity rate which means the non-zero probability of the CIR coefficients.

$$CN(h; \mu_l, \sigma_l) \triangleq (\pi\sigma_l)^{-1} \exp(-{\sigma_l}^{-1}|h - \mu_l|^2) \tag{13}$$

means complex Gaussian probability density function.

Considering the sparsity property of CIR coefficients, it is not spectral efficient to using all subcarriers for transmit pilots, so we pick P pilot observations from N subcarriers. Equation(10) is further changed to be

$${Y_p}' = {A_p}' * h + {W_p}' \tag{14}$$

where ${Y_p}' = Y'(1 : I : M)$, we assume the pilot observations follow uniform distribution and I is the distance between neighbor observations. ${A_p}'$ is a matrix with dimensions $P * L_h$, whose elements are a_{ij}, $i \in [P]$, $j \in [L_h]$.

Our goal is estimating CIR coefficients $\{h_l\}$ from P pilot observations, the estimated values of elements is

$$\{\hat{h}_j = \sum_{h_j} h_j p(h_j|Y_p)\}_{j \in [L_h]} \tag{15}$$

where $p(h_j|Y_p)$ is the posterior probability density function of $\{h_l\}$.

By the literature[15], it can be known that Loopy Belief Propagation [23] can be used to compute $p(h_j|Y_p)$ approximatively, but the computation complexity is very high because it involves high dimensional integral and should maintain a large number of messages. GAMP algorithm proposed in [15] is a simplified algorithm based on the Central limit theorem (CLT) and Taylor expansion. The channel estimation is computed as follows,

A. Initialization

Let the initial iterative number $t = 0$, with $i \in [P]$ and $j \in [L_h]$, the initial mean and variance of $\{h_l\}$ is $\hat{h}_j(0) = 0$ and $\tau_j^h(0) = 1$, and set $\hat{s}(-1) = 0$.

B. Output linear step

For each i, compute:

$$\tau_i^p(t) = \sum_j |a_{ij}|^2 \tau_j^h(t) \tag{16}$$

$$\hat{p}_i(t) = \sum_j a_{ij} \hat{h}_j(t) - \tau_i^p(t) \hat{s}_i(t-1) \tag{17}$$

C. Output nonlinear step

For each i, compute:

$$\hat{s}_i(t) = (Y_i - \hat{p}_i(t))/(\tau_i^p(t) + \sigma^2) \tag{18}$$

$$\tau_i^s(t) = 1/(\tau_i^p(t) + \sigma^2) \tag{19}$$

D. Input linear step

For each j, compute:

$$\tau_j^r(t) = 1/\sum_i |a_{ij}|^2 \tau_i^s(t) \tag{20}$$

$$\hat{r}_i(t) = \hat{h}_j(t) + \tau_j^r(t) \sum_i a_{ij} \hat{s}_i(t) \tag{21}$$

E. Input nonlinear step

For each j, compute:

$$\hat{h}_j(t+1) = E(h_j|\hat{r}_j(t), \tau_j^r(t)) \tag{22}$$

$$\tau_j^h(t+1) = var(h_j|\hat{r}_j(t), \tau_j^r(t)) \tag{23}$$

F. Decision

Increment $t = t + 1$ and return to step 2 until a sufficient number of iterations have been performed, or

$$\frac{||\hat{h}_j(t+1) - \hat{h}_j(t)||_2^2}{||\hat{h}_j(t+1)||_2^2} < tol \tag{24}$$

is satisfied.

Equation (22),(23) are the expectation and variance of $\{h_l\}$ at the $(t+1)th$ iteration which are evaluated with respect to $CN(h_j; \hat{r}_i(t), \tau_j^r(t))p(h_j)$, where $p(h_j)$ is the Bernoulli-Gaussian probability distribution function.

The result is

$$\hat{h}_j(t+1) = \sum_{l \in [K]} b_l p_l \tag{25}$$

and

$$\tau_j^h(t+1) = \sum_{l \in [K]} |b_l|^2 p_l - |\hat{h}_j(t+1)|^2 \tag{26}$$

where b_l is the non-zero coefficients,

$$p_l = \phi(b_l; \hat{r}_j(t), \tau_j^r(t))/KP \tag{27}$$

$$P = (1 - \frac{K}{L_h})\phi(0; \hat{r}_j(t), \tau_j^r(t)) + \frac{1}{K} \sum_{l \in [K]} \phi(b_l; \hat{r}_j(t), \tau_j^r(t)) \tag{28}$$

$$\phi(u; \hat{r}_j(t), \tau_j^r(t)) = exp(-|u - \hat{r}_j(t)|^2/\hat{r}_j(t)) \tag{29}$$

Through the iterative computation above, the ultimate result $\hat{h}_j(t+1)$ is the estimated values of CIR coefficients.

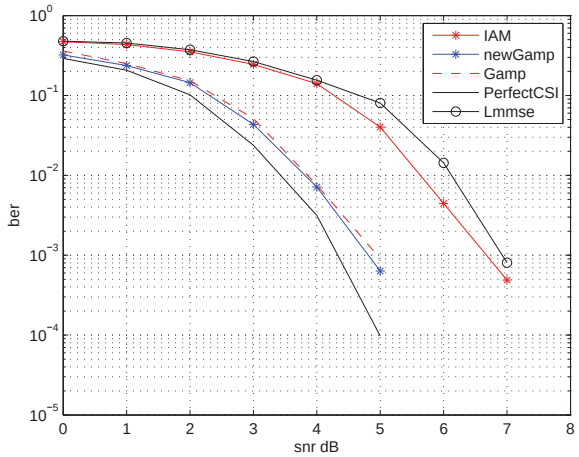

Fig. 2. BER performance of different channel estimation methods in FBMC/OQAM under less pilot observations

V. Simulation Results

In this section, we compared the proposed GAMP based channel estimation with several other methods under different number of pilot observations. To make comparisons, we use the same frequency domain pilot of three time instance, and PHYDYAS prototype filter with the overlapping factor 4 is employed. We use IEEE802.22 standard channel model which aims at constructing Wireless Regional Area Network (WRAN) utilizing free TV bands. The main channel parameters of the system used are given below: Sampling frequency is 9.14 MHz, CIR length is $L_h = 129$, Number of paths is 6, Power profile (in dB) of the 6 paths are -6.0, 0.0, -7.0, -22.0, -16.0, -20.0 and Delay profile (μs) of the 6 paths are -3, 0, 2, 4, 7, 11 respectively. QPSK modulation and convolutional channel coding (K =7 with generation polynomial (171, 133) and code rate 1/2) are used, Frame length is 41 symbols.

In the simulations, we compared four different methods, which are 'Gamp' (without noise whiten), 'newGamp' (with noise whiten), 'IAM' and 'Linear minimum mean square error (Lmmse)', the BER curve of 'PerfectCSI' assumption is also ploted to be a performance limitation reference. Firstly, We set number of subcarriers in FBMC/OQAM system to be 256, pilot observations is also 256, which means complete use of frequency domain pilots. In Fig.1, we can see the 'newGamp' method is the best and approach the performance under 'PerfectCSI'. At the position of $BER = 10^{-2}$, the newGamp is about 2.3db better than IAM, 1.5db better than Lmmse, and 0.5db better than the Gamp method. This coincides with our analysis above, GAMP based methods utilized the sparsity of CIR coefficients. When pilot observations on all subcarriers are used to construct the CIR coefficients, subcarriers are relevant because of FBMC/OQAM system's characteristic. Therefore newGamp can improve estimation performance through whitening the color noise.

Secondly, we set the number of subcarriers to be 512, pilot observations interval is 4 and the number of pilot observations is 128, which is smaller than the CIR length. In Fig.2, we can see Lmmse method rapidly deteriorates, however GAMP based methods is only about 0.4dB worse than the PerfectCSI

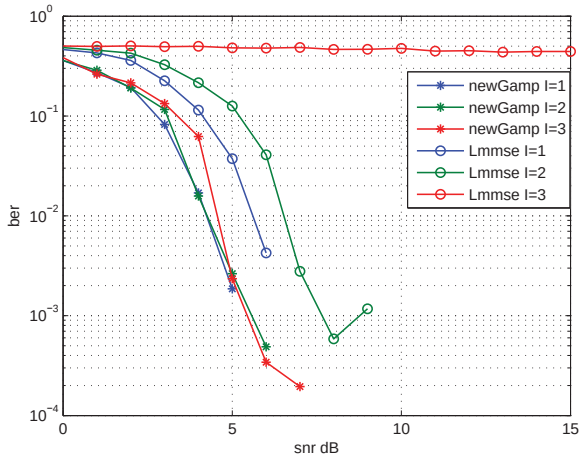

Fig. 3. BER performance comparison between GAMP and Lmmse under different cases

case at the position of $BER = 10^{-2}$. There is an interesting phenomenon that 'Gamp' and 'newGamp' method are almost the same in this situation, this is because the well time-frequency location of the prototype filters in FBMC/OQAM system. When the pilot observations are picked up apart, the pilot observation subcarriers are approximatively independent.

Thirdly, we compare the GAMP and Lmmse based methods under different number selections of picked pilot observations. We set number of subcarriers to be 256, and picked pilot interval $I = 1, 2, 3$ respectively, which means pilot observations are 256, 128 and 85 respectively, responding to using larger, equal and less number of observations to reconstruct the variables to be estimated. Fig.3 tells us, with the decrease of observations, GAMP based methods varies slowly, however, Lmmse based method deteriorates quickly. GAMP based method remains well even in underdetermined case because it utilizes the sparsity of the variables to be estimated, however, linear estimator cannot tackle the underdetermined problem because a prior probability and sparsity of the variables are not been

utilized.

VI. Conclusions

In this paper, several popular channel estimation methods used in the FBMC/OQAM system are reviewed and compared, a compressive sensing based channel estimation method via GAMP algorithm was proposed, simulation results reveal that GAMP based method is better than Lmmse method and IAM method no matter how much pilot observations are selected to reconstruct the CIR coefficients, which saved the pilot overhead and is important for asynchronous multiuser access applications in FBMC/OQAM. Secondly, GAMP based method reduces the computational complexity due to avoidance of matrix inversions of the linear estimations. Furthermore, benefiting by the time-frequency location of prototype filters in the FBMC/OQAM, when pilot observations are selected with interval larger than one, the subcarriers can be regarded as approximately independent and noise whiten process can be omitted for further lower complexity. In a word, the compressive sensing based channel estimation method via GAMP is proved to be an effective and low complexity method to tackle the channel estimation difficulties in FBMC/OQAM system.

***Abstract*—We consider the problem of distributed indoor target tracking using a wireless sensor network (WSN) based on received signal strength indicator (RSSI) values. To facilitate distributed tracking of targets by various nodes we consider an approach based on *random linear network coding (RLNC)* for dissemination of quantized RSSI values. Our simulation results show that the root mean square (RMS) tracking error obtained with the approach based on RLNC is strictly lower than that of the competing scheme owing to its rapid dissemination capability. Finally we observe that with the RLNC based scheme, RMS value of tracking error in a strongly connected network grows much slowly with noise variance in comparison with that of a weakly connected one.**

I. Introduction

Target tracking using wireless sensor networks (WSNs) is one of the important applications both on the domestic and defence fronts. Indoor target tracking based on WSNs is found to be a viable alternative to the global positioning system (GPS) based target tracking system, since the latter lacks desired accuracy in indoor environments [1]. Among various metrics used for tracking, RSSI is the most preferred for building a simple and inexpensive tracking system, since unlike other metrics it does not require synchronization among various network nodes [2] [3]. The target tracking system based on WSNs has to be distributed in which the sensor nodes run the tracking algorithm without help from any centralized entity like a base station. This requirement warrants the nodes to exchange their respective observations with minimal transmissions and latency.

Network coding (NC) has been shown to maximize throughput and/or minimize latency (or delay) for many different network topologies, especially for broadcast and multicast transmissions [4]. We refer interested readers to [5] for a survey on NC and its applications in internet and wireless networks. A specific instance of NC known as random linear NC (RLNC) has been found to be suitable for implementation in networks where computation across various network nodes happens in a distributed fashion. Implementation of a distributed target tracking algorithm at a given node of a WSN requires access to observations made at the other nodes [1]. It is highly desirable to ensure that the communication complexity scale linearly with the number of nodes in the network. To this end the authors in [3] propose a mechanism in which the leader node for a given target collects observations from its localized neighborhood, which is determined by an aggregation radius. It was shown using simulations that for a sufficiently large aggregation radius the performance of such a scheme comes close to the scheme in which observations from all the sensor nodes are used for target tracking. In this paper we evaluate tracking performance of the particle filter bank based tracking algorithm with RLNC mechanism as a means for information dissemination among various nodes.

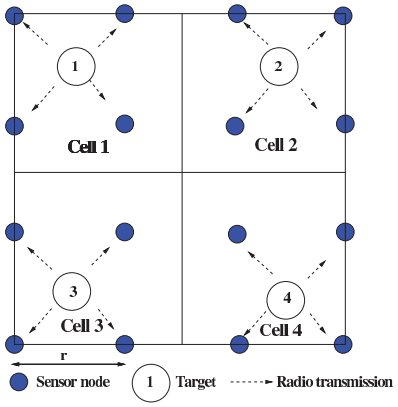

Fig. 1. The figure shows a WSN deployed on a uniform square grid for indoor target tracking.

II. Topology of WSNs, Targets' Maneuver Model and RSSI Observation Model

A. System Model

Consider a two dimensional uniform square grid of side S metres shown in Fig. 1 that is deployed with N number of nodes to track M targets moving inside it. Let r denote the common spacing between adjacent nodes. We assume each node makes RSSI measurements based on the periodic beacon frames sent by active RFID tags mounted on targets. The measured RSSI value is quantized, converted into message and encoded with messages of *same generation* received from other nodes to produce a NC packet. The RLNC mechanism used to produce the NC packet is described in Section III. The NC packet is then transmitted by each node by observing the CSMA protocol mechanism. We assume that all the nodes are synchronized to the same clock and the network to be slotted such that in a given slot only one NC packet is transmitted by a node.

B. Targets' Maneuver Model and RSSI Observation Model

Denote $X^t_{m,d}$ and $V^t_{m,d}$ as the position and velocity of m^{th} target in d^{th} dimension at time instant t. The total state of the m^{th} target at time instant t, comprising of position and velocity in each of the D dimensions, is given by $\mathbf{z}^t_m = \left[X^t_{m,1}, V^t_{m,1} \cdots, X^t_{m,D}, V^t_{m,D}\right]'$ (the operator $'$ denotes matrix transpose). We denote the total system state comprising of positions and velocities of M targets in D dimensions at time instant t as $\mathbf{z}^t$. If we assume the total system state to evolve according to a first order Markov chain, then the total system state at time instant $(t+1)$ in terms of total system state at time instant t can be written as

$$\mathbf{z}^{t+1} = A\mathbf{z}^t + B\mathbf{u}^t \ , \tag{1}$$

where A is a block diagonal matrix of size $2MD \times 2MD$ with the sub-matrix $\begin{bmatrix} 1 & T \\ 0 & 1 \end{bmatrix}$ repeated along the diagonal (T denotes the maneuver interval). The matrix B of size $2MD \times MD$ is another block diagonal matrix with $[\frac{T^2}{2}, T]'$ repeated along the diagonal. The vector $\mathbf{u}^t$ of size $MD \times 1$ represents the random acceleration that the M targets are subjected to in D dimensions. It is assumed to be Gaussian distributed of mean vector $\mathbf{0}$ and covariance matrix $\sigma^2_S I_{MD}$.

The RSSI value recorded at the n^{th} sensor node located at $\mathbf{r}_n$ corresponding to the m^{th} target whose true location is $\mathbf{x}^t_m$ at time instant t, is given by the following equation [3]

$$Y^t_{m,n} = \Phi^t_m + \Gamma^t_{f(\mathbf{x}^t_m).n} - \rho 10 \log\left(||\mathbf{x}^t_m - \mathbf{r}_n||\right) + W^t_{m,n} \ , \tag{2}$$

where Φ^t_m denotes transmission power of the target m at time instant t, Γ denotes gain of the channel from target m to the node n at time instant t, $f(.) : \mathbb{R}^D \rightarrow \{1, 2, \cdots, L\}$ denotes the cell location quantization function which maps a given location in the tracking region to one of the L possible cell values and $W^t_{m,n}$ denotes the measurement noise that is assumed to be both *spatially* and *temporally* independent across the various sensor nodes and time instants. It is assumed to be Gaussian distributed of zero mean and variance σ^2_W.

At every observation time instant t each sensor node $n\ (= 1, 2, \cdots, N)$ quantizes the observation $Y^t_{m,n}$ made about every target using a uniform quantizer. Let Y_{max} and Y_{min} denote the upper and lower limits of the quantizer. In uniform quantization the entire range of $(Y_{max} - Y_{min})$ is broken down into q equal quantization levels of width $\Delta \triangleq \frac{Y_{max} - Y_{min}}{q}$. The resulting quantization noise variance is given by $\sigma^2_q = \frac{\Delta^2}{12}$. The quantized observation is then sent using the RLNC described in next Section.

III. Random Linear Network Coding (RLNC) for Information Dissemination in WSNs

The quantized RSSI value (which is encoded over a binary alphabet) at a given observation time instant t available at a given node is converted into a packet suitable for dissemination the various fields of which are described subsequently. The following fields namely node ID and target ID are self explanatory. The field *NC coefficient* contains the encoding vector used for producing the data that goes into the *NC message* field. The NC message at a given node is generated using its quantized RSSI value for that target and NC messages for the corresponding target received from all the other nodes. The field *generation id* helps in combining of NC messages belonging to the same generation. Packets with same generation IDs essentially contain encoded quantized RSSI values for the same observation time instant t. We shall next describe as how NC messages can be produced by various nodes in the network.

Let $G(V, E)$ denote the network graph with $|V| = N$ nodes and links $E \subset V \times V$. Let $\{\mathbf{q}_n\}_{n=1}^N$ denote the set of quantized RSSI values at the N network nodes for a given observation instant corresponding to a given target (for convenience we suppress the target index m and the observation instant t). Note that each $\mathbf{q}_n$ is a binary encoded vector of length l for each node $n \in V$. For convenience we assume the field size k divides l the length of quantized RSSI value, otherwise zero padding is applied to ensure the same. At the beginning of some transmission time slot τ, an arbitrary node $n \in V$ contains a set of coded messages (as exchange of quantized RSSI values happens among various nodes):

$$Q_n(\tau) = \left\{\mathbf{u}_1, \mathbf{u}_2, \cdots, \mathbf{u}_{|Q_n(\tau)|}\right\} \ . \tag{3}$$

Each message $\mathbf{u}_i$ is generated as a linear combination of the underlying quantized RSSI values $\{\mathbf{q}_n\}_{n=1}^N$. Thus,

$$\mathbf{u}_i = \sum_{n=1}^{N} c_{i,n}\mathbf{q}_n, \ \text{(for } i = 1, \cdots, |Q_n(\tau)|) \ , \tag{4}$$

where $c_{i,n} \in \mathbb{F}_{2^k}$ denote NC coefficients which are made available using the packet header. Note that if $\mathbf{q}_n$ for a given n is not available then the corresponding $c_{i,n}$ is set to zero. The arithmetic operations involved in computation of $\mathbf{u}_i$ are performed over $\mathbb{F}_{2^k}$.

Let $\mathbf{c}_i \triangleq [c_{i,1}, \cdots c_{i,N}]^T \ (i = 1, \cdots, |Q_n(\tau)|)$, $\mathbf{q} \triangleq \left[\mathbf{q}_1^T, \cdots, \mathbf{q}_N^T\right]^T$, then one can write

$$\begin{bmatrix} \mathbf{u}_1^T \\ \vdots \\ \mathbf{u}^T_{|Q_n(\tau)|} \end{bmatrix} = \underbrace{\begin{bmatrix} \mathbf{c}_1^T \\ \vdots \\ \mathbf{c}^T_{|Q_n(\tau)|} \end{bmatrix}}_{\triangleq C_n(\tau)} \mathbf{q} \ . \tag{5}$$

From the encoded messages $\{\mathbf{u}_i\}_{i=1}^{|Q_n(\tau)|}$ the node n will be able to recover $\mathbf{q}_1, \cdots, \mathbf{q}_N$ when the rank of $C_n(\tau)$ equals N with the knowledge of NC coefficients vector $\{\mathbf{c}_i\}_{i=1}^{|Q_n(\tau)|}$.

The node n if it captures the channel at transmission time slot τ creates a vector $\mathbf{s}_n(\tau)$ by linearly combining the messages in the set $Q_n(\tau)$ (defined in Eq. (3)) with the encoding coefficients $b_i \in \mathbb{F}_{2^k}$ $(i = 1, \cdots, |Q_n(\tau)|)$. Thus

$$\mathbf{s}_n(\tau) = \sum_{i=1}^{|Q_n(\tau)|} b_i \mathbf{u}_i \ . \tag{6}$$

Note that the node n inserts the quantity $\sum_{i=1}^{|Q_n(\tau)|} b_i \mathbf{c}_i^T$ in the NC coefficient field of the transmitted packet (it just does not put $\sum_{i=1}^{|Q_n(\tau)|} b_i \mathbf{1}^T$).

IV. Particle filter based distributed target tracking

A. Target Tracking using Particle Filters

Each node once in possession of the quantized RSSI values (corresponding to M targets) from the remaining $(N-1)$ nodes computes position estimates for the underlying targets. We use a sampling importance resampling (SIR) based particle filter bank for tracking the M targets. The superior performance of particle filters for non-Gaussian and non-linear state space models over other approaches like extended Kalman filter is well known and we refer interested readers to [6] for a detailed exposition on particle filters. The SIR particle filter based tracking algorithm is given in Algorithm 1. Unlike the algorithm used in [3], in the Algorithm 1 we do not allow any interaction between the various sub-filters used for tracking of individual targets. This is because we assume the targets move independently which is unlike what was assumed in [3], where the authors assumed targets to move in a correlated fashion. In Algorithm 1 the estimates $\hat{\Phi}_m(t)$ and $\hat{\Gamma}_{l,n}(t)$ are computed incrementally using the approach given in next sub-section. Note that we have approximated the noise, introduced due to quantization of observations, to be Gaussian. Consequently, in the Step 5 of Algorithm 1, the measurement noise variance σ_W^2 is indeed augmented by the quantization noise variance σ_q^2.

B. Radio Environment Estimation

The incremental estimator is based on stochastic expectation and maximization (EM) algorithm. EM algorithm is used to compute ML estimates of unknown parameters [7]. The EM algorithm comprises of two main steps namely the E-step which involves computation of the *auxiliary likelihood function* and the M-step which involves maximization of the auxiliary likelihood function. It is used extensively in models where the observations depend on hidden or unknown random variables. In the current case the quantized observations $\left\{\left\{S_{m,n}^t\right\}_{m=1}^M\right\}_{n=1}^N$ depend on the unknown total state vector $\mathbf{z}^t$. To derive EM algorithm in the current case we introduce $\Theta^t \triangleq \left[\left\{\Phi_m^t\right\}_{m=1}^M, \left\{\left\{\Gamma_{l,n}^t\right\}_{l=1}^L\right\}_{n=1}^N\right]$. The quantized observation vector at any arbitrary time instant $t^{'}$ is denoted as $\mathbf{s}^{t^{'}} \triangleq \left[\mathbf{s}_1^{t^{'}}, \cdots \mathbf{s}_M^{t^{'}}\right]$ where $\mathbf{s}_m^{t^{'}} \triangleq [S_{m,1}^{t^{'}} \cdots S_{m,N}^{t^{'}}]$ $(m = 1, \cdots, M)$. We denote $p(\mathbf{y}_{1:t}, \mathbf{z}_{1:t}|\Theta)$ as the joint PDF of observations and total state until time t given the unknown parameter Θ. Using the fact that observations across different time instants are independent given $\mathbf{z}^t$ and Θ one can compute the auxiliary likelihood function $\mathbb{E}\left[\ln\left(p\left(\mathbf{s}_{1:t}, \mathbf{z}_{1:t}|\Theta\right)\right)\right]$ (where $\mathbb{E}(.)$ is with respect to the filtered PDF $p\left(\mathbf{z}_{1:t}|\mathbf{s}_{1:t}\right)$) and maximize it using the following recursion to compute estimate for $\Theta^{t^{'}+1}$ given the past estimate $\widehat{\Theta}^{t^{'}}$: $\widehat{\Theta}^{t^{'}+1} = \widehat{\Theta}^{t^{'}} + \epsilon \mathbf{f}\left(\widehat{\Theta}^{t^{'}}; \mathbf{s}^{t^{'}}\right)$, where $\epsilon \ll 1$ denotes a constant step size (constant step size would help us track slow time variations in parameter values), $\mathbf{y}^{t^{'}}$ as defined before denotes the vector of all observations at time instant $t^{'}$ and $\mathbf{f}\left(\widehat{\Theta}^{t^{'}}; \mathbf{s}^{t^{'}}\right) \triangleq \nabla_\Theta \sum_{m=1}^M \int_{\mathbb{R}^{2D}} \ln p\left(\mathbf{s}_m^{t^{'}}|\mathbf{z}_m^{t^{'}}, \Theta\right) p\left(\mathbf{z}_m^{t^{'}}|\widehat{\Theta}^{t^{'}}, \left\{\mathbf{s}_m^l\right\}_{l=1}^{t^{'}}\right) d\mathbf{z}_m^{t^{'}}$ ($\nabla_\Theta(.)$ denotes the gradient operator with respect to Θ).

Algorithm 1 : SIR based Particle Filter for Target Tracking

1: For each $m = 1, \cdots, M$ do steps 2 through 6:
2: **Particle Initialization:** Initialize $\left\{\tilde{\mathbf{z}}_{m,i}^t, i = 1, 2, \cdots, \Pi\right\}$ using a uniform distribution over the finite tracking area of interest. Then for each $t = 1, 2, \cdots$ execute the following steps:
3: **Creation of full-state particles:** Using the Π sub-state particles of all M targets corresponding to time instant $t-1$ i.e. $\left\{\tilde{\mathbf{z}}_{m,i}^{t-1}, i = 1, 2, \cdots, \Pi\right\}$, create Π full-state particles $\left\{\tilde{\mathbf{z}}_i^{t-1} = \left[\tilde{\mathbf{z}}_{1,i}^{t-1}, \tilde{\mathbf{z}}_{2,i}^{t-1}, \cdots, \tilde{\mathbf{z}}_{M,i}^{t-1}\right], i = 1, \cdots, \Pi\right\}$.
4: **Importance Sampling from Transitional Prior:** Generate samples for the current time instant t (i.e. $\tilde{\mathbf{z}}_i^t$) by sampling from the (sub-optimal) transitional prior $p(\mathbf{z}^t|\mathbf{z}^{t-1})$ which is done as follows: $\tilde{\mathbf{z}}_i^t = A\tilde{\mathbf{z}}_i^{t-1} + B\mathbf{u}^t$.
5: **Computation of particle weights corresponding to each target and their normalization:** (a)$w_{m,i}^t = \exp\left(-\frac{1}{2\left(\sigma_W^2+\sigma_q^2\right)} \sum_{n=1}^N term\ 1(n)\right)$, where $term\ 1(n) = (S_{m,n}^t - \hat{\Phi}_m^t - \hat{\Gamma}_{f(\tilde{\mathbf{z}}_{m,i}^t),n}^t + \rho 10\log_{10}||\tilde{\mathbf{z}}_{m,i}^t - \mathbf{r}_n||)^2$ (where $S_{m,n}^t$ denotes the quantized version of $Y_{m,n}^t$). (b)**Normalization of weights:** $\tilde{w}_{m,i}^t = \frac{w_{m,i}^t}{\sum_{i=1}^\Pi w_{m,i}^t}$, $i = 1, \cdots, \Pi$.
6: **Resampling step:** Draw Π numbers from 1 to Π with replacement using the distribution $\left\{\tilde{w}_{m,i}^t, i = 1, \cdots, \Pi\right\}$. Use these indices to select Π particles from the pool $\left\{\tilde{\mathbf{z}}_i^t, i = 1, \cdots, \Pi\right\}$. Denote these resampled particles as $\left\{\tilde{\mathbf{p}}_i^t\ i = 1, \cdots, \Pi\right\}$.
7: **Extraction of sub-state particles:** The sub-state particles $\left\{\tilde{\mathbf{z}}_{m,i}^t\ i = 1, \cdots, \Pi\right\}$ can be extracted from $\left\{\tilde{\mathbf{p}}_i^t\ i = 1, \cdots, \Pi\right\}$ by discarding all the components other than those that of m.
8: **Computation of state estimate of target** m**:** $\hat{\mathbf{z}}_m^t = \frac{1}{\Pi}\sum_{i=1}^\Pi \tilde{\mathbf{z}}_{m,i}^t$.

The various components of $\mathbf{f}\left(\widehat{\Theta}^{t^{'}}; \mathbf{s}^{t^{'}}\right)$ can be computed for $m = 1 \cdots, M)$ and $(l = 1, \cdots, L), (n = 1, \cdots, N)$ as follows:

$$f_{\Phi_m}\left(\widehat{\Theta}^{t^{'}}; \mathbf{s}_m^{t^{'}}\right) \approx \sum_{n=1}^N \frac{1}{\Pi} \sum_{p=1}^\Pi (term\ 2(n,p)) \tag{7}$$

$$f_{\Gamma_{l,n}}\left(\widehat{\Theta}^{t^{'}}; \mathbf{s}^{t^{'}}\right) \approx \sum_{m=1}^M \sum_{n=1}^N \frac{1}{\Pi} \sum_{p=1}^\Pi term\ 3(m,n,p) \tag{8}$$

where $term\ 2(n,p) = \frac{S_{m,n}^{t^{'}} - \widehat{\Phi}_m^{t^{'}} - \widehat{\Gamma}_{f(\tilde{\mathbf{z}}_{m,p}^{t^{'}}),n}^{t^{'}} + \rho 10\log\left(\left\|\tilde{\mathbf{z}}_{m,p}^{t^{'}} - r_n\right\|\right)}{\sigma_W^2+\sigma_q^2}$ and

$term\ 3(m,n,p) = \frac{\left(S^{t^{'}}_{m,n} - \widehat{\Phi}^{t^{'}}_{m} - \widehat{\Gamma}^{t^{'}}_{f(\tilde{\mathbf{z}}^{t^{'}}_{m,p}),n} + \rho 10\log\left(\|\tilde{\mathbf{z}}^{t^{'}}_{m,p} - r_n\|\right)\right)}{\sigma^2_W + \sigma^2_q}$
$\mathbb{I}_l\left[f(\tilde{\mathbf{z}}^{t^{'}}_{m,p})\right]$.

Notice the difference between expressions given in Eq. (7) and Eq. (8) to similar expressions in [3]. This can be attributed to the fact that in [3] the authors compute estimates so that the likelihood function is maximized, while in our case we maximize the auxiliary likelihood function as usually done in the EM algorithm. We believe our approach has the advantage of computing the estimates of parameters contained in the state transition equation given in Eq. (1)

V. Simulation Study of Indoor Target Tracking using WSNs with RLNC

A. Simulation scenario and Localized Aggregation Method

We simulate movement of $M = 8$ targets in a uniform square grid of side 30 metres thereby implying a total target area of 900 square metres. We assume the spacing $r = 10$ metres between adjacent nodes. Thus we have deployed around 16 targets to track the 8 targets of interest. The entire tracking area is assumed to be divided into $L = 4$ cells. The time-invariant transmit power values $\{\Phi^t_m\}^8_{m=1}$ of the 8 targets are set to random values as $\Phi_m = \phi_{nominal} + 3 \times \mathcal{N}(0,1)\ \ (m = 1, \cdots, 8)$, where we have set $\phi_{nominal} = 5$. The time-invariant gain(s) experienced by a transmission from cell l to node n, denoted as $\Gamma_{l,n}$, are set as $\Gamma_{l,n} = \lambda_{wall} d_{l,n} + \alpha_{l,n}\left(1 - \mathbb{I}_l(r_n)\right)$, where $d_{l,n}$ denote the number of walls crossed by a transmitted signal in straight line path from cell l to node n, $\alpha_{l,n}$ denote random values generated from the $\mathcal{N}(0,3)$ distribution and $\mathbb{I}_l(x)$ denotes an indicator function which is equal to 1 only when $x \in l$ and 0 otherwise. The parameters set as per the above procedure are kept constant for throughout the simulation. As in [3] one may consider varying the parameters slowly and the parameter estimation recursion should still be able to track the changes. For the purpose of particle filtering we assume the number of particles $\Pi = 128$. We measure the tracking performance in terms of root mean square error (RMSE) which is given by $\text{RMSE} = \frac{1}{M}\sum_{m=1}^{M} \mathbb{E}\left[||\mathbf{x}^t_m - \hat{\mathbf{x}}^t_m||^2\right]$ (where $\hat{\mathbf{x}}^t_m$ denotes the position estimate of the target m). In practice since it is not possible to compute the ensembled mean therefore we replace it by the corresponding time average. For the RLNC part we assume the observations are quantized by using a uniform quantizer with $q = 256$ levels and Y_{max} and Y_{min} are set to be 10 and -20 respectively (the upper and lower limits of uniform quantizer used at various nodes). The size of the finite field k is set equal to 8 i.e. the NC coefficients are generated over the finite field $\mathbb{F}_{2^8}$. We performed the simulation in MATLAB (for target tracking and generation of finite field) and JProwler an open source network simulator (for RLNC and CSMA mechanism).

In the localized aggregation method (against which we shall compare the proposed approach based on RLNC) every target that is to be tracked is associated with an owner node [3]. The node that is closest to a given target is chosen as the owner node. Once target owner is selected then all the nodes within a given aggregation radius of say $r^{'}$ meters will send their RSSI value to the owner node. Using the observations sent by nodes in the neighbourhood the target tracking algorithm given in Algorithm 1 is run.

B. Results and Discussion

The Fig. 2 shows plots of RMSE versus the noise variance for the cases of local aggregation scheme with radii 10 and 20 metres respectively and the scheme based on RLNC. As can be seen from the figure the RMSE obtained with RLNC scheme is strictly below that of the RMSE obtained with the aggregation scheme. From the Fig. 2 it can also be noted that the rate at which RMSE grows with noise variance is much slower than what can be seen for the localized aggregation scheme (for lower values of measurement noise variance). This can be attributed to two reasons: firstly the dissemination is much faster with RLNC a fact corroborated by the results in Fig. 3. Secondly each node in RLNC has access to a greater number of observations in comparison with the localized aggregation scheme.

The Fig. 3 shows the plot of RMSE versus the total number of transmission time slots taken for information dissemination in the localized aggregation scheme and RLNC. We assume the measurement noise variance to be fixed and equal to 1 dB. The RMSE achieved by the scheme based on RLNC is much lower than for the localized aggregation scheme. From this we can conclude that for a given RMSE the RLNC scheme would require lower number of transmission time slots than the localized aggregation scheme.

Finally in Fig. 4 we compare the tracking performance of RLNC scheme for two cases. In the first case connectivity among nodes is very strong and in the second case the connectivity is much weaker than the first. In the former case less number of time slots are required for dissemination than the latter one to achieve the same amount of RMSE. In general as measurement noise variance increases RMSE increases. However in the strongly connected case the observations from other nodes reach much faster than in the weakly connected case thereby causing the RMSE to grow much slower with the measurement noise variance compared to the weakly connected case.

VI. Conclusion

We considered distributed indoor target tracking using WSNs based on RSSI measurements. RLNC is used by various network nodes for dissemination of their respective quantized RSSI values to each other. We compared the tracking performance of the distributed target tracking algorithm with RLNC based dissemination against the scheme that aggregates observations only from the a given target neighborhood. The distributed tracking algorithm based on RLNC based information dissemination resulted in a lower RMS value of the tracking error compared to the localized aggregation scheme. This can be attributed to the rapid dissemination capability of the RLNC scheme. Our simulation results also showed that

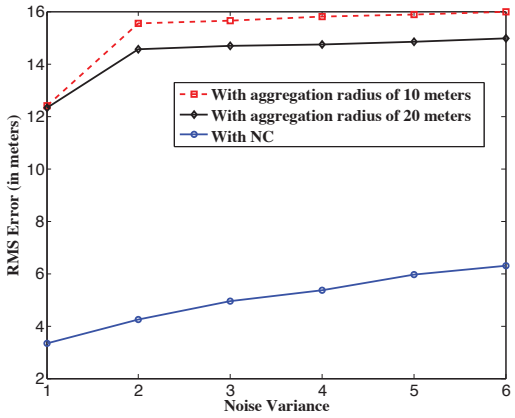

Fig. 2. The figure shows plots of RMS versus the noise variance in dB for RLNC and localized aggregation schemes.

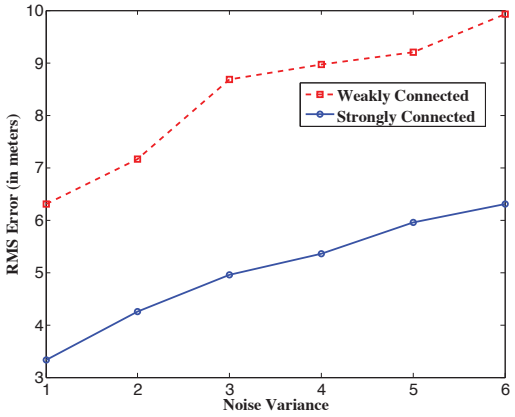

Fig. 4. The figure compares the plot of RMS versus the noise variance in dB for two contrasting network scenarios in which information is disseminated using RLNC.

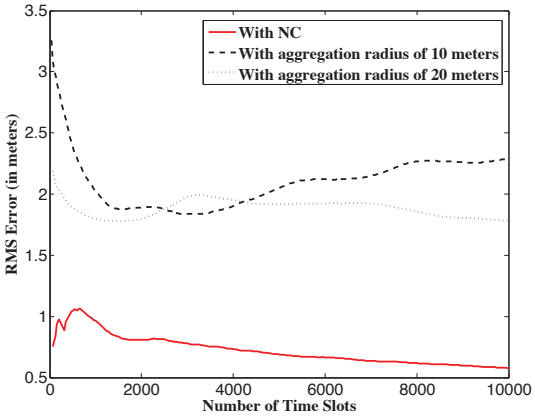

Fig. 3. The figure shows plots of RMS versus the total number of time slots used in information dissemination for the cases of RLNC and localized aggregation scheme.

in strongly connected networks the growth of RMS value of tracking error with measurement noise variance is much slower in comparison with the weakly connected case.

***Abstract*—In this work, a harmonic rejection mixer with Local Oscillator (LO) frequency programming facility is proposed. The virtual LO frequency programming facility in this mixer enables it to cover VHF III, UHF and L bands of mobile TV communication with very relaxed master LO frequency requirement. This also uses simple frequency divider circuit to generate multi phase LO signals from master LO wave, unlike other universal mobile TV receiver front ends. The proposed circuit has other advantages like current reusing single MOS pole-zero filtering, which reduces the power consumption and offers faster roll offs, noise cancellation facility and virtual RF filtering provided by passive mixer feedback. The frequency programming facility achieves virtual LO frequencies of $2f_{LO}$, $3f_{LO}$ and $4f_{LO}$ from an actual frequency of f_{LO}. The simulation studies show a peak gain of 10.51dB, an IIP2 of 63.47dBm, IIP3 of 2.44dBm and a NF of 18.4dB. The circuit consumes 7.5mW power when operated with a supply voltage of 2.5V.**

I. Introduction

Mobile television integrates two of the most popular customer products ever: television and mobile phone. The co-existence of numerous standards defined for mobile TV transmission demands the integration of hardwares supporting multiple standards and multiple frequency bands. Mobile TV bands reside in 3 frequency bands, VHF-III (174 to 248 MHz), UHF (470 to 862 MHz) and L (1.4 to 1.7 GHz) [1]. The function of a mixer is to down-convert the desired RF input to an IF output, but, in this wide range of operating frequencies, the mixer down converts blockers around LO harmonics to required IF frequency band. Hence the receiver requires bulky external Surface Acoustic Wave (SAW) filters to eliminate the blockers. To avoid down-conversion of blockers around harmonics to baseband, wideband receivers often use a poly-phase down-converter. The use of poly-phase (N-Phase) mixers for harmonic rejection demands N poly-phase LO signals of frequency f_{LO}, phase shifted to each other by (360/N) degrees. If a simple frequency divider circuit is used to generate these N number of LO waves, then a master LO frequency of Nf_{LO} is required to drive it. This high frequency operation of master local oscillator consumes high energy and demands complex Phase Locked Loop (PLL) and Voltage Controlled Oscillator (VCO) designs.

Fujian et al [2], realized mobile TV receiver front end covering from 0.15GHz to 0.85GHz without any off chip SAW filters or separate internal RF filter. This circuit has an 8-path active mixer in the forward path with passive mixers as feedback. The mixer is stacked with a current mode single-MOS pole-zero LPF. The fed back passive mixers frequency translate the low pass ($Z_{in}(\Delta\omega)$ LPF input impedance to

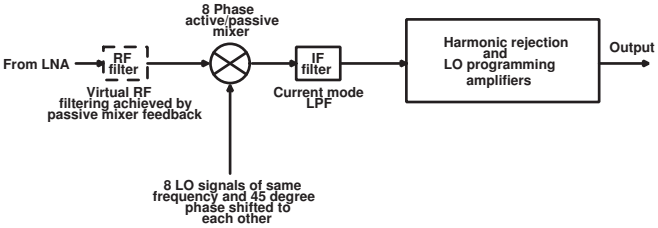

Fig. 1: Block diagram of the proposed system

$Z_{in}(n\omega_{LO} + \Delta\omega)$) at the RF input port. This LO defined input matching helps in stop-band rejection right at the mixer input. This extra filtering feature helps in avoiding the need or in relaxing the properties of external SAW filters. This circuit also has a noise cancellation property because of the feedback included. This system uses a digital divided-by-8 circuit to generate the 8-phase clock required for the 8-phase mixer. A master LO frequency of $8f_{LO}$ is required at the frequency divider circuit's clock to generate 8-phase LO waves of frequency f_{LO}. For achieving effective f_{LO} of more than 1.7GHz in 8-phase mixer case, one need to generate a master LO frequency greater than 13.6GHz. This much high frequency requirement in master local oscillator makes the VCO and PLL designs complex [3]. These drawbacks makes the system unable to cover the L (1.4-1.7GHz) band of mobile TV [1].

Pui et al [1], developed a unified receiver front end covering all 3 specified TV bands. It uses a complex direct injection-locking 4/8 phase LO generator instead of a much simpler frequency divider circuit. Direct injection circuit needs a master LO which is equal to the f_{LO} required for the multi-phase mixer. This relaxation in master LO frequency requirement enables it to cover the higher L band frequencies unlike the receiver in [2]. But this direct injection circuit, which is used to generate poly-phase LO waves, consumes larger power and area, and is complex as compared to much simpler and better, frequency divider circuit used in [2]. This receiver also needs 3 separate bulky external SAW filters unlike [2] since it lacks any passive mixer feedback, for frequency translation of base band LPF impedance to RF input.

In this work, a mixer covering all the mobile TV bands is developed by using LO programming cum Harmonic rejection circuits based on modified version of the architecture put forwarded by Travis et al [4]. This new LO programming cum HR circuit can replace the normal harmonic rejection circuits in [2] and makes it able to operate in higher L band mobile

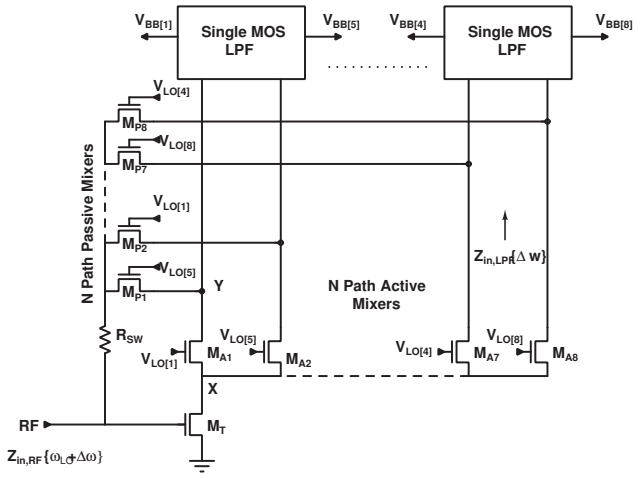

Fig. 2: 8-phase mixer with current mode LPF [2]

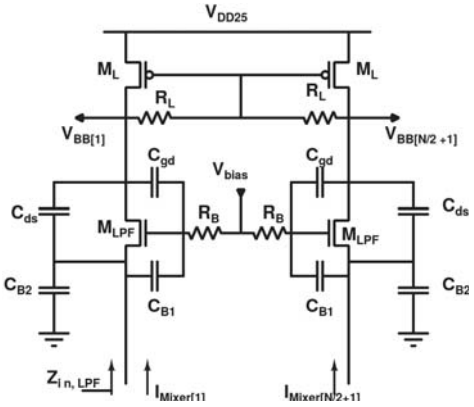

Fig. 3: Current mode single-MOS LPF[2]

TV spectrum. The tunable LO facility is able to produce the effect of 2LO, 3LO, 4LO frequencies from an 8-phase LO frequency fed 8-path mixer. This enables it to cover all the mobile TV band with a much lower maximum 8-phase f_{LO} of 850 MHz. This frequency requirement is same as that of [2], which can cover frequencies up to UHF band only. The simpler frequency divider circuit can be employed to generate these 8-phase waveforms from a master frequency of 6.8GHz. This master frequency is not a big challenge as far as the VCO and PLL designs are concerned. Additionally, this architecture needs no external SAW filters unlike [1].

II. Blocks and circuits

The block level architecture of the work is shown in the Figure 1. The mixer used here is based on the parallel 8 path active passive mixer from [2]. The 8 outputs from mixer are given to the proposed harmonic rejection cum LO programming amplifiers. Different sets of amplifiers are used for different modes of operation. The 8-phase active/passive mixer is driven by 8, LO signals with 12.5% duty cycle and 45 degree phase difference to each other. These eight LO signals can be obtained from a frequency divider circuit, which is driven by a frequency 8 times the frequency of LO signals,$8f_{LO}$. The mixer is stacked with a current mode LPF to eliminate the unwanted frequencies. The combined harmonic rejection and LO frequency mode selection circuit allow the system to obtain effective local oscillator frequencies of $f_{LO}, 2f_{LO}, 3f_{LO}, 4f_{LO}$, from an actual LO frequency of f_{LO}. This is achieved by employing different set of gains for different phase outputs of 8 phase mixer [4].

The passive mixer feedback in this circuit helps in noise cancellation and LO based frequency translation of low pass LPF input impedance to RF input node. This frequency translation effect results in a virtual RF filtering at the input of the mixer. This feature can also be used in the higher modes of operation which are obtaining the effective frequencies equal to the harmonics of the LO wave. This observation proves that the HR cum LO programming architecture proposed by Travis et al [4] can be used in [2] as well. A simple set of amplifier circuit with current mode signal summing is proposed, which can be attached to [2] to realize the architecture proposed in [4].

A. Mixer and LO defined LPF base band impedance translation to RF input[2]

The 8 path mixer circuit is shown in Figure 2. The transconductor MOS M_T convert the RF voltage at V_{in} to current. The switching action of M_A transistors down convert the V_{in} at node Y. The passive mixer switches (M_P transistors) up-convert the voltage at Y to the input RF node by same amount. In effect this loop act like a positive feedback. The equivalent input impedance from RF input of this N-path mixer can be proved as expression (1), from theory suggested by [5].

$$Z_{in}(\omega) = \frac{R_{\mathrm{SW}} + N\sum_{n=-\infty}^{+\infty} |k_n|^2 Z_{\mathrm{BB}}(\omega - n\omega_{\mathrm{LO}})}{1 - G_{\mathrm{loop}}}. \quad (1)$$

Where G_{loop} is the loop gain is

$$G_{\mathrm{loop}} = \frac{1}{N} \cdot g_{\mathrm{m,CS}} \cdot Z_{\mathrm{in,LPF}}\{\Delta\omega\}, \quad (2)$$

According to (1), the input impedance seen from the RF input is the frequency translated value of low pass input impedance of current mode LPF, shifted to the integer harmonics of the f_{LO} along with a scaling factor of $N|k_n|^2 = 1/Nsinc^2(n/N)$ at $n\omega_{LO}$. So at the RF input node, frequencies around f_{LO} and its harmonics experience a high impedance, while all other frequencies experience low impedances. This achieves a filtering at the RF input node itself for all modes of operation since the virtual LO frequencies achieved at higher modes are the harmonics of the fundamental LO frequency f_{LO}. Since $k_1 > k_2 > k_3 > k_4$, gains will be lesser for higher modes of operation.

B. Proposed replacement of the normal Harmonic Rejection (HR) in [2] with HR and LO programming circuit

1) Concept: In this work, new harmonic rejection (HR) cum LO programming circuits are proposed using the architectural idea put forwarded by Travis et al [4]. In N path HR mixers, as in [2] the out put is generated by scaling and

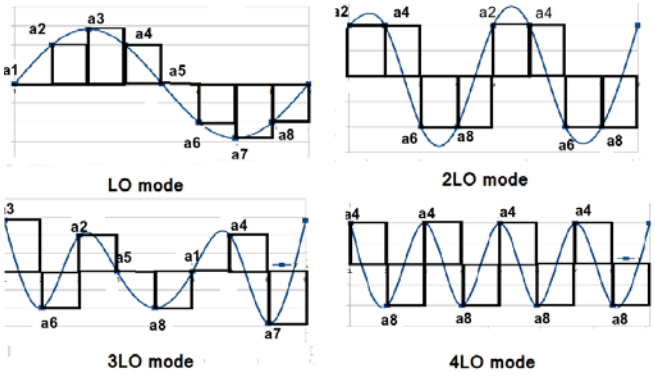

Fig. 4: Effective sinusoid LO achievement in different modes of operation

combining each of N equally phase shifted and (1/N) duty cycle LO waves. The scaling coefficients are scaled versions of samples of a sine wave of frequency f_{LO} with a sampling frequency of Nf_{LO}. These samples are given by,

$$a_k = G \sin\left\{\frac{2\pi k}{N}\right\} \tag{3}$$

where $0 \leq k \leq N$, and G is a scaling factor. In an 8 path mixer, these scaling coefficients ratios $a_1 : a_2 : a_3 : a_4 : a_5 : a_6 : a_7 : a_8$ are equal to $0 : 1 : \sqrt{2} : 1 : 0 : -1 : -\sqrt{2} : -1$.

It can be mathematically proven that, the sampling of a sinusoid of frequency nf_{LO} results in the same sampling values as obtained from a sine wave of frequency f_{LO}, where n is an integer. If the sampled values of $\sin(2\pi f_{LO}t)$ are represented as $[a_k]$ and sampled values of $\sin(2\pi n f_{LO}t)$ is represented by $[a_k^n]$, then $[a_k^n]$ will be a subset of $[a_k]$ if n is even and $[a_k^n]$ will be a permutation of $[a_k]$ if n is odd. So by rearranging the scaling coefficients in normal N path harmonic rejection mixer, the virtual effect of integral multiples of LO frequency, nf_{LO} can be obtained. The frequency spectrum of effective nf_{LO} obtained is given by

$$X(f) = \frac{1}{2} \sum_{m=-\infty}^{\infty} \delta(f - (mN \pm n) f_{\mathrm{LO}}) \mathrm{sinc}\left(\frac{n\pi}{N}\right) \tag{4}$$

It is evident from equation (4) that, while achieving virtual frequency of nf_{LO} from an actual frequency of f_{LO} using an N path mixer outputs, the first unattenuated harmonic appears at (N-n)f_{LO}. This limits the number of modes that can be achieved. If $n > N/2$ the first unattenuated harmonics will be higher in magnitude than that of required frequency. So maximum number of modes possible with 8 path mixer is 4. The pictorial representation of effective LO wave achievement in different modes is shown in Figure 4.

2) Circuit Implementation: In the current mode filter in Figure 3, which is a stacked above all the 8 branches of the mixer, the transistor M_L is diode connected. So the outputs from the 8 paths $V_{BB[1]}$ to $V_{BB[8]}$ can be used to mirror the current flowing through each of these signal paths. For achieving different modes of operation i.e. different effective LO frequencies, each of these outputs should be amplified with different amplification factors and then combined to form an approximate sinusoidal wave. Here the amplification and addition is done in current mode since the outputs from mixer can be used easily to mirror the current. The amplification is achieved by varying the width of the mirroring transistor. Separate set of amplifiers are used for different modes of operation. If the receiver is working in one mode of operation, power to all other amplifiers can be cut-off to reduce power conception.

TABLE I: Harmonic Rejection of Different Modes

Mode	HRR2 (dB)	HRR3 (dB)	HRR4 (dB)	HRR5 (dB)	HRR6 (dB)
LO	39	44	66	55	61
2LO	38	21	90	29	56
3LO	24	41	22	49	39
4LO	95	18	98	24	106

The amplifying circuits used for the four modes of circuit operation is shown in Figure 5. Here PMOS transistors preferred to have thicker gate oxide as is the case of transistor M_L used in LPF. It can be observed that the scaling factor i.e. size of mirroring transistor for each mixer output is different for different mode.

III. SIMULATIONS AND RESULTS

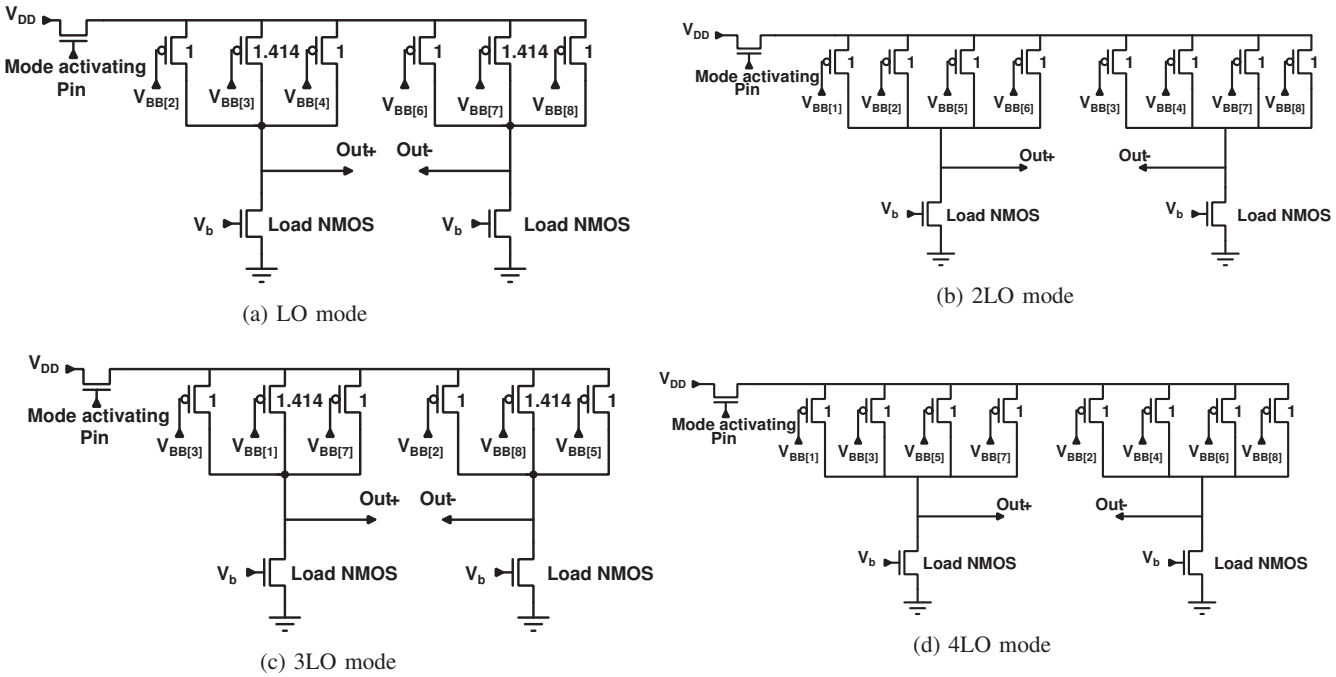
The harmonic rejection mixer (HRM) is tested for all the 4 modes of operation. All these results are subsequently compared with similar works reported in the literature.

A. Harmonic Rejection (HR)

The harmonic rejection for different modes of operation is listed in the Table I. In Figure 4, it can be observed that in LO mode, the equivalent LO signal is approximately a sine wave. Thereby, high rejection for both even and odd harmonics are obtained in this mode. In 2LO and 4LO modes, the equivalent LO signals are perfect square waves. This makes these modes to have no odd harmonic rejection and it is reflected in the measurements. A 16-phase mixer based HR and frequency programming can avoid this problem. In 3LO mode the imperfect shape of the effective LO wave is causing lower values of even HRRs, but the absence of DC value enables it to have a higher values of odd HRR. Low HRR does not cause much problems in 2LO, 4LO and 3LO modes, since the higher order harmonics are away from the frequency of interest.

B. Gain and NF

Maximum gains obtained in different modes are given in the Table II. As can be seen in Figure 4, the effective LO in modes 2LO and 4LO are not good sinusoidal waves and this cause the fundamental component to have lesser gain. This can also be observed from Table II. Figure 6 shows the gain variation with frequency in LO mode. The reduction in gain with frequency is due to action of the current mode LPF. Noise figure obtained is slightly worser in the higher modes of operation. This is mainly because of the reduction in gain of mixer LPF combination.



(a) LO mode

(b) 2LO mode

(c) 3LO mode

(d) 4LO mode

Fig. 5: HR and LO programming circuits for different modes of operation

TABLE II: Gain and NF in Different Modes

Mode	Gain(dB)	NF(dB)
LO	10.51	18.03
2LO	9.27	20
3LO	8.34	22.3
4LO	9.3	20.6

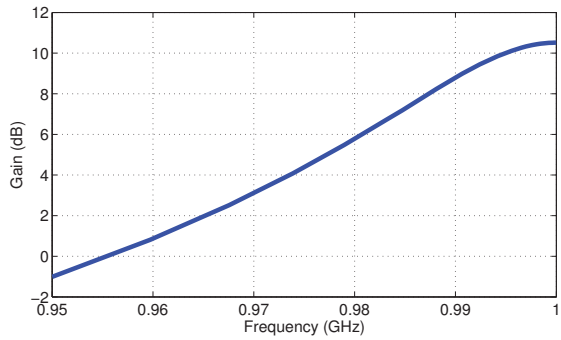


Fig. 6: Gain variation with input RF frequency(LO mode), f_{LO}= 1GHz

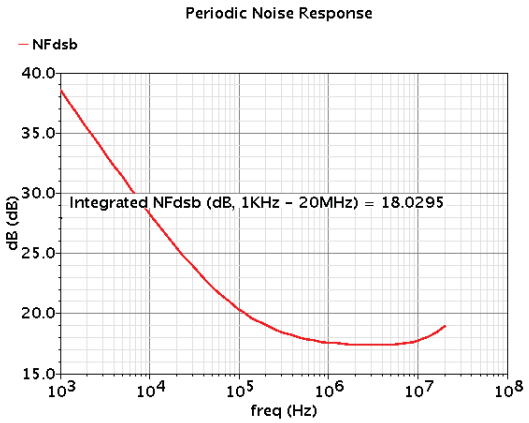

Fig. 7: NF variation with output BB frequency(LO mode)

TABLE III: IIP2 and IIP3 in Different Modes

Mode	IIP2(dBm)	IIP3(dBm)
LO	63.47	2.44
2LO	67.77	2.04
3LO	27.71	-0.78
4LO	63.64	-0.74

C. IIP2 and IIP3

The IIP2 and IIP3 values obtained for different modes of operations are summarized in Table III. With a worst case NF of 22dB and worst case IIP3 of -0.78dBm for the mixer, the LNA which is to be used prior to the mixer stage, demands a gain of 15dB to 20dB, NF less than 3dB and an IIP3 more than 3dBm. These are easily achievable with a standard LNA. So mobile TV receiver front end requirements are easily achievable with this work.

TABLE IV: Comparison with Recent Works

Feature	This work	[1]	[2]	[4]	[7]	[8]	[9]
Implementation	Mixer	Receiver	Receiver	Mixer	Receiver	Receiver	Receiver
Down conversion	Active/Passive	Passive or Active	Active/Passive	Passive	Passive	Passive	Passive
RF input style	Single ended	Single ended	Single ended	Single ended	Single ended	Differential	Single ended
RF range(GHz)	0.174-1.7	0.174-1.7	0-0.85	0.05-0.83	0.7-1.6	0.48-.86	0.04-1
Power(mW)	7.5	55	16.2	-	12	144	440
DSB NF(dB)	18.43	4	4.6	11	10.5	6	3
IIP3(dBm)	2.44	-3.4	-12	5.4	10	-13	-15
IIP2(dBm)	63.47	32	61	54	26.6	51	20
External Parts	nil	3SAWs	nil	SAW	nil	nil	inductor
HRR 3,5(dB)	44,55	35,39	53,51	72,71	34,34	70,70	65,65
RF-IF Gain(dB)	10.51	35	51	12	37	42	40
Supply(V)	2.5	1.2,2.5	1.2,2.5	1.2	1.3	1.8	1.8
CMOS Technology	65nm	65nm	65nm	130nm	65nm	180nm	80nm

D. Power

The maximum power consumption is approximately 7.5mW among all the modes of operation. This is very low in comparison with reported mobile TV receiver front ends. The gain and NF are traded-off to attain such a low power operation. Since mobile phones and portable electronic equipments have a very stringent requirement of battery backup, the proposed circuit has potential to be employed in mobile TV applications.

E. Comparison

Table IV tabulates a comparison of this work with recent works. As expected only [1] and [7] can cover all the mobile TV bands like this work, but those have complex circuits. In addition to this, circuit in [1] demands three external SAWs for blocker rejection at input. The LO programming facility employed in our work affected the harmonic rejection slightly, but when compared with others, only [4], [8] and [9] has a better HR than this work in LO mode of operation. This work is carried in 65nm technology as opposed to the 130nm, 180nm and 80nm in [4], [8] and [9] respectively.

IV. Conclusion and future scope

A wideband mobile-TV mixer, which covers all the mobile TV bands are designed. This work contains an 8-path active/passive mixer stacked with current mode LPF and a harmonic rejection cum LO programming facility. The LO programming facility of the circuit allows the system to cover a wide range of frequency using a comparatively low master LO frequency. This makes the use of simple PLL, VCO and frequency division based 8-phase LO generator possible. In this work a single stage harmonic rejection amplifier circuit is used instead of two stage circuits as in [2], to make the hardware simple, but the system becomes more prone to the bad effects of device mismatches [6]. As different circuits are employed for current mode scaling and summing for different modes of operation, they can be isolated from power supply for saving power, when not in use. A more advanced digitally assisted circuit which performs all the modes of operation with single set of amplifiers is possible. This digital circuit can direct the 8 path mixer outputs to different transistors in different modes. If a 16-phase multi-path harmonic rejection mixer is used, modes of operation up to 8LO will be possible. This higher number of paths in mixer can be utilized to make more harmonic rejection in higher modes of operation.

Abstract— **The current networking methodologies need a change because the users are being compromised with the already defined networking features. The flexibility in extending the network nodes simplifies the network management, thereby facilitating network evolution. Recently, introduced Software Defined Networking (SDN) concept facilitates the intelligent decision-making, flexibility, operational simplicity, and improved security across a defined infrastructure. The objective of this paper is to analyze the networking management by the software defined controller, which provides the flexibility and agility of data transmission in the data plane according to the user's requirements at any instant. The controller is informed about the transmission discrepancies, like a failure or malfunctioning in the transmitting nodes. The controller can redefine the data transmission path during such unexpected networking situations automatically, according to the predefined Open Flow table rules in the controller. Else, the authenticated user can change the data path between the other existing nodes and continue the data transmission through the controller depending upon the permitted access. Also, the performance of the implemented SDN model is analyzed by increasing the number of switches and the corresponding nodes. The paper highlights the idea of implementing the firewall in the controller over the simple topology. The firewall implemented in the test scenario will analyze and permit the data packets through the controller with respect to their arrival time. The comparative analysis of applying the firewall in the controller and the switches is done in terms of latency and throughput of data transmission.**

Keywords—***Data transmission; firewall, latency; Open-Flow table; Software defined controller; throughput***

Introduction

Today, Software Defined Networking (SDN) [1], [2] has paved a way towards the next-generation networking. It is spawning an innovative research and promoting advances in networking scalability, flexibility, performance of data communicating devices and architectures, for dependability and security in data transmission [3]. SDN blends the historical and real-time network state with performance data, to decouple the network control from the forwarding functions in a data transmission. This initiates the centralized control over the data transmission in the network [4], [5].

Current networking applications implicitly and indirectly describe their network requirements, involving a number of user processing steps, like, to negotiate if there are any sufficient resources and policy controls to support the particular application [4], [5]. So these networks do not inculcate the capability of expressing the full range of user requirements, such as throughput, delay variation or network availability in dynamic runtime [4], [5]. Some networks try to infer the user's requirements on their own, which incurs additional setup cost and sometimes leads to misclassification. Besides, these networks do not expose the information of network state to the applications using them at any point of time [6].

Network misconfigurations and related errors are extremely common in traditional networks. A single misconfigured device can be a big issue for the network operators and may have extremely severe consequences [1], [7]. To alleviate the lack of in-path functionalities within the network, a myriad of middle-boxes, which are special components like deep packet inspection, firewalls and intrusion detection systems, proliferate the current traditional networks [7]. Though the middle-boxes support the in-path functionalities, the complexity in network design and its operations have increased considerably.

SDN is a network architecture where the control plane manages the data forwarding operations in the data plane [6]. This characteristic feature enables the flexibility in implementing and customizing the networking policies in the controller. The topology for the data transmission can be decided upon in the data plane according to the user's convenience. Thus, the software defined controller acts as the networking brain of the constructed architecture [3].

The functions such as topology, statistics, notifications, transmission management, shortest data path forwarding and security mechanisms, are essential networking control functionalities, which are possible through the controller [1], [2], [3]. As the networks undergo the customization for evolutionary technologies, securing the data transmission becomes the top-most priority and a must. There are many related works [8], [9], [10], which focus on securing the data plane by implementing firewalls in the switches. It was found that firewall implementation in the data plane switches, increases the communication overhead, thus reducing the overall efficiency of the software defined data transmission Moreover, securing the controller is considered as utmost

importance because of its intelligence for controlling the data plane [11]. Hence, in this paper, a novel approach to analyze the data traffic by the transmission nodes through the controller is done. Also, a single firewall is implemented in the control plane, to reduce the communication overhead of the entire networking infrastructure.

The organization of the paper is as follows. Section II defines the emergence of Software Defined Networks. Section III describes the functional layers of SDN topology considered for the test scenario. Section IV illustrates the SDN data transmission management done through the software defined POX controller, over a simple networking topology. The section also deals with the Open-Flow table showing the failure of data transmission node over the constructed topology. It illustrates the idea of implementing the firewall in the controller instead of the switches over the default topology. Section V concludes the paper with the ideas, to enhance the implementation of the same in different scenarios in the near future

I. How Software Defined The Networks?

Emerging technologies in the field of networks have led to the creation of a digital society, where everything is connected and is accessible from everywhere. Their widespread implementation is on traditional IP networks, which involves complexity in their network management [2].

In the current dormant IP networks, a new routing protocol takes 5 to 10 years to get fully designed, tested and deployed [12]. Likewise, a clean-slate approach to change the Internet architecture (e.g., replacing IP), is regarded as a tantalizing task. Ultimately, this situation has inflated the capital and operational expenses of running an IP network [12], [13]. This growing complexity further demands novel approaches to future computer networks in which the complexity can be managed [13].

Conventional routers and switches embody a strong integration between the control and the data planes. This coupling made various network-management tasks, such as, debugging configuration, predicting or controlling routing behavior, to be extremely challenging. To address these challenges, various efforts to separate the data and control planes began to emerge [4], [5].

The 1990s saw the evolution of Internet to diverse the applications usage through active networks. The researchers developed capsule and programmable router/switch models to standardize their protocol implementation in these networks. The DARPA (Defense Advanced Research Projects Agency) stimulated these active networking concepts enforcing the ‘technology push and use pull’. The technology introduced concepts like the programmable functions in a network, virtualization, demultiplexing software programs based on packet headers and a vision for middle-box orchestration for unified network architecture. Though, innovative concepts were introduced in active networks, their practical performance upgradation in the routers, configuration management, definite routing path deployment, and network security remained unaddressed.

The early 2000s focused on the idea of widespread networks deployment, by separating the functional (data) and the management (control) planes. The ForCES (Forwarding and Control Element Separation) [3] working group, proposed a standard, open interface to the data plane to enable innovation in control-plane software. The SoftRouter [14] used the ForCES API, to allow a separate controller to install forwarding-table entries in the data plane, enabling the complete removal of control functionality from the routers. Unfortunately, ForCES was not adopted by the major router vendors, which hampered incremental deployment. Instead, the vendors started to use an existing standard control-plane protocol (Border Gateway Protocol) to install forwarding-table entries in legacy routers, enabling immediate deployment [5], [15].

In mid 2000s, the ideas pertaining SDN faced a tensed environment between the vision of fully programmable networks and pragmatism that would enable the real-world networking deployment. The Open Flow concept enabled more functions to be implemented than the earlier route controllers, which were built on-existing switch hardware [13], [16]. But, relying on existing switch hardware, has limited the flexibility of network extensibility. The development of the Open-Flow API [17], [18] was followed quickly by the design of controller platforms like NOX [19] that enabled the creation of many new controller applications.

NOX was the first controller implemented in the SDN based on OpenFlow environment [19]. Sooner, with the fast growing user requirements and the idea of network expandability, has led to the introduction of controllers like POX, OpenDaylight, Floodlight, Ryu and so on [3], [4], [5].

Then, focus shifted to the need of identifying and controlling the data attacks in the network architecture. Algorithms for performing the change-impact analysis of firewall policies, highlighted that a firewall administrator can verify a proposed change on the network before committing it [20]. The proposed algorithms can be practically used in the iterative process of firewall policy design and data packets maintenance.

A firewall application was developed over an Open-Flow based SDN controller to show that most of the firewall functionalities are able to be built on software, without the aid of a dedicated hardware [21].

Using POX controller, implementation of the firewall was tried over the default topology of the Mininet. The firewall implementation was done in OpenvSwitches in the data plane. The presence of firewall using the metrics - latency and throughput was analyzed. [9].

In this work, the concept of managing the data transmission over the simple topology is highlighted. The novel idea is to prove the flexibility of customizing the data transmission through the software defined controller, according to the users’ needs. The network performance is analyzed using throughput and latency, by customizing the network topology and with firewall in the controller. It is implied that, implementing the firewall, in the controller,

improves the communication efficiency, compared to the firewall implementation in the data plane switches.

II. SDN ARCHITECTURE

Current networking concept does not satisfy the user's day-to-day requirements completely because of their rigid networking policies. Complexity is increased, by trying to reconfigure the network according to the predefined policies, and their response to faults, load, and changes. The SDN enables the users to incorporate abstractions in the networking policies, to ease the network management [3]. Fig.1 depicts the simple default topology to describe the SDN based architectural model layers. It consists of a single POX controller. The POX controller is made to interface with transmitting nodes, which are being operated through corresponding OpenvSwitches for data transmission. The SDN architecture contains the basic functional planes- Control (Management) Plane and Data (Functional) Plane.

A. Data Plane (Infrastructure Layer)

The transmitting nodes are connected to the controller through a compatible version of Linux OS based open-source OpenVSwitch software. The forwarding devices are the transmitting nodes (h_1-h_{125}) as represented in fig.1. This occupies the bottom most infrastructure layer i.e., the Data plane. The choice of OpenvSwitch is for the extensibility into network virtualization in n for the adoption of a SDN based Open-Flow Protocol [17].

B. Control Plane

The control plane is a software stack, which consists of SDN based controller POX/Floodlight/Ryu/ OpenDaylight (open source). The controller is to monitor the data transmission and to enforce policies like control flow, infrastructure security, authenticated access control or firewalling for securing the data transmission over the implemented set of networks.

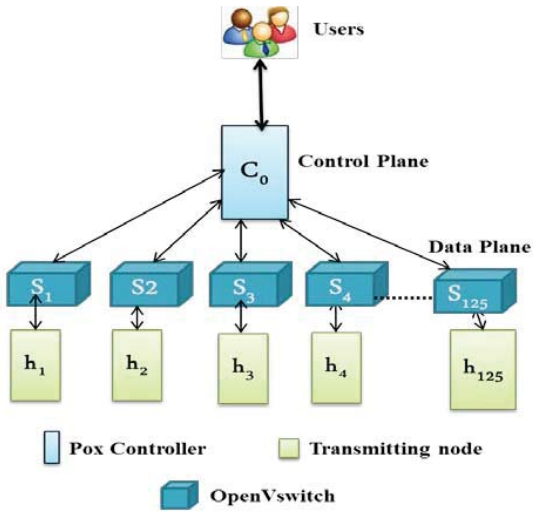

Fig. 1. SDN Architecture

The controller plane configures the data plane to respond autonomously to events such as network failures. The controller will do the maintenance of the data nodes at the data level according to the rules implemented in the open flow table tables The secured sub-policies can be implemented using open flow standard programming languages such as FLOG, Merlin [20].

The authenticated users can enforce the networking policies in the controller for the data transmission management like topology decision, en-routing data transmission path in case of any failure transmission node and firewall policies.

C. Open-Flow Standard

Vendors offer varying degrees of user programmability on their routers and switches, can lead to limited functionality for traffic engineering and management. Open-Flow design [16] is to provide consistency in network management and engineering by making it control-function independent of the hardware. Open-Flow based SDN technologies enable the users to address the high-bandwidth; dynamic nature of applications, adaptation of the network to the ever-changing business needs, and significantly reduce the operations and management complexities [17].

Controllers communicate to the switches via the Open-Flow protocol and impose policies on the flows. The controller could set up paths through the network, optimized for specific characteristics, such as speed, fewest number of hops or reduced latency [18].

III. ANALYSIS OF SOFTWARE DEFINED DATA TRANSMISSION

A. Data Transmission Management

The data transmission nodes in the data plane can be organized into different topologies like the simple, single, tree, bus, mesh, and hybrid**.** The topology selection is flexible unlike the traditional networking where only fixed topologies can be opted. The Fig.1 topology is a basic topology available in the Mininet, which has each node connected to a single switch. The switches will communicate to the single POX controller.

The topology is flexible for customization according to the users' requirements. Here, the architecture is customized by increasing the number of transmitting nodes and the corresponding switches. In this test scenario, the simulation trials for 10, 25, 50, 75 and 100 switches are considered for the performance analysis.

It is inferred from the Fig. 2, that, as the numbers of switches are increasing in the topology, there is no much difference in the throughput. This suggests that the number of forwarding devices can be increased according to the network implementation and the user needs. Simultaneously, latency for the same simulations is calculated. From Fig. 3, it is deduced that there are increasing variations in the latency as the number of data packets are increased, during the transmission for each simulation.

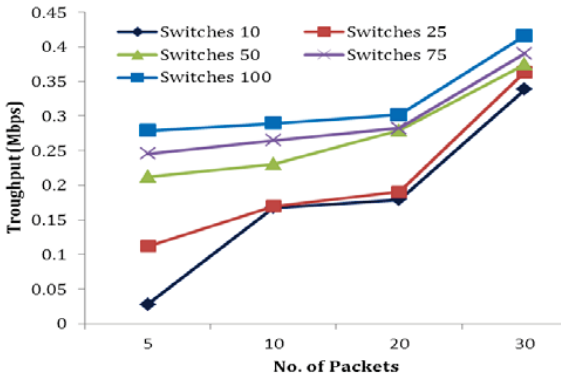

Fig. 2. Throughput vs. No. of Packets Transmitted

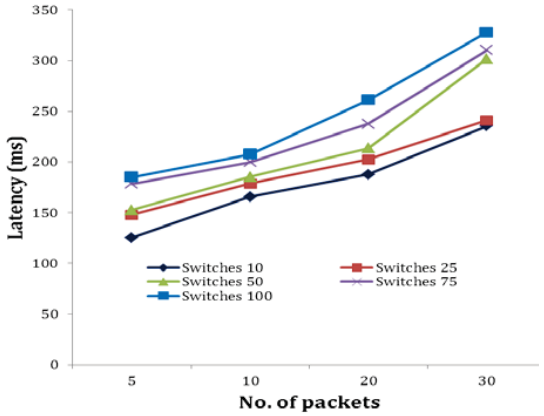

Fig. 3. Latency vs. No. of Packets Transmitted

Also, the latency rate increases, as the number of switches increases. It is estimated that, there is a difference of approximately 60ms between the simulations of 10 and 100 switches. The fig.2 & 3 analyses show that there is flexibility in scaling the network infrastructure i.e. the data transmitting nodes through software defined networking concepts.

B. Failure Node Detection

Fig. 4 shows that, if any networking node is not transmitting data packets at that point of instance, it will be communicated to its immediate SDN controller. The communication will be done, if there is any packet delay between the transmitting nodes as shown in Table II. Here, the packet delay is identified through a mismatch in the predefined priority column of the Open-Flow table.

In Table II, the priority field has null values because; the particular node is not transmitting any data packets. This is contradictory to the Table I priority column, where there is no match to the predefined Openflow rules. The priority column will be incremented only, if there is a data transmission between the nodes and the controller without any hindrance. Tables I & II analysis signify that the software defined concept eases the node failure detection and management in a network.

TABLE I. OPENFLOW TABLE FOR DATA TRANSMISSION THROUGH THE CONTROLLER

Match Field	Priority	Counter	Ins	Timer	Cookie	Delay (ms)
00	00	01	00	00	01	10.71
00	01	01	00	00	01	09.14
00	02	01	00	00	01	08.43
00	03	01	00	00	01	10.33
00	04	01	00	00	01	07.67

TABLE II. OPENFLOW TABLE FOR FAILURE NODE DETECTION

Match Field	Priority	Counter	Ins	Timer	Cookie	Delay (ms)
00	00	01	00	00	01.0	377
00	00	01	00	00	01.2	268
00	00	01	00	00	01.3	160
00	00	01	00	00	01.1	84.6
00	00	01	00	00	01.2	85.2

C. Firewall Implementation Analysis

Though the SDN concept provides the flexibility of changing the topology of a networking infrastructure, network node failure detection and management, the efficiency of the network lies in securing the controller. Firewall is always the first tool to be considered for securing a data transmission against any data attacks. SDN provides the liberty of formulating rules in the default controller firewall.

Initially, the firewall was implemented in the data plane switches. Each packet will be filtered by the firewall during the transmission between the switches and the controller [9]. This was increasing the communication overhead, while processing and transmitting large number of data packets. In order to reduce the transmission overhead, a single firewall was implemented in the controller, instead of implementing the firewall in each switch. Fig.5 shows the firewall implementation in the controller is more efficient than the switches, as the data packets filtering is done only once during the controller-switch communication.

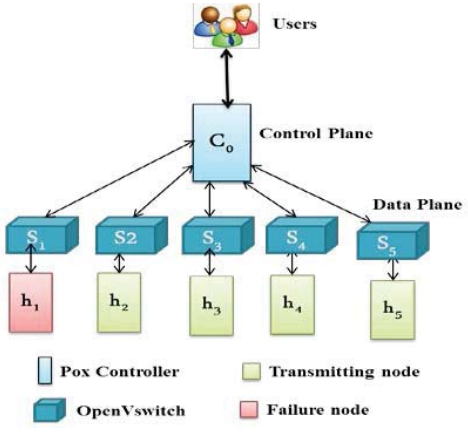

Fig.4. Failure node detection

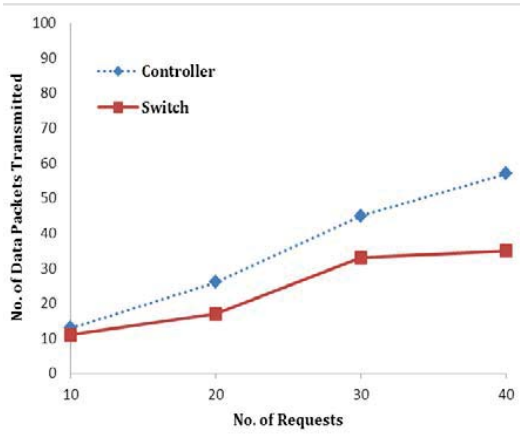

Fig. 5. Firewall Implementation Efficiency in Controller and Switches

IV. Conclusion & Future Work

The telecommunication world is witnessing new heights in data transmission technologies. There is a growing demand for personalized data transmission between the users irrespective of the application usage. The Software Defined Networking innovates the network infrastructure according to the user needs. This paper shows the data transmission management by the Software defined controller on the simple available topology in the Mininet. Also highlighted is the implementation of firewall in the controller. The presence of firewall secures the architecture from any malicious attacks causing the delayed data transmission. The same analysis can be experimented in other customized topologies like the Single-switch, tree, bus, mesh and hybrid. The Software Defined controller implementation can be extended to heterogeneous networks instead of homogeneous networks. Networking polices can be customized for improving the scalability and security of the network. The topology customization can be done by connecting more than one controller, to set up distributed or logically centralized controller in distributed environment. This can be efficiently possible by implementing Floodlight controller instead of POX controller in the proposed networking architecture.

***Abstract*—We develop an efficient general-purpose blind image quality assessment (IQA) algorithm. It utilizes curvelet domain features of phase congruency (PC) values, local spatial entropy values and local spectral entropy values of distorted images as quality relevant features for quality prediction. A 2-stage framework including classification of distortion types and distortion specific quality assessment is utilized for mapping the quality relevant features to predictive scores. The classifier is implemented by a support vector machine (SVM) and the regression model is implemented by a support vector regression (SVR) model. The proposed approach which is named Phase Congruency and Spatial-Spectral Entropy based Quality (PCSSEQ) index can assess image quality blindly with out knowing the distorted type of the testing image and the predictive results of the proposed approach correlates well with human subjective scores. The performance of PCSSEQ on LIVE database is competitive with some state-of-the-art general-purpose blind image quality assessment (BIQA) approaches and some full-reference (FR) image quality assessment (IQA) approaches. We also prove that PCSSEQ has a good database independence characteristics.**

I. Introduction

Blind image quality assessment (BIQA) aims to build computational models that can evaluate image quality consistently with human perception without the undistorted version of the testing image. With the easier availability of digital images from the internet and the popularization of digital imaging devices such as smart phones with big screens and digital cameras, digital images have been becoming one of the most important way of representing and transmitting information in our everyday life. However, the perceptual quality of digital images may be declined by the process of acquisition, transmission, compression, restoration, etc. And in most cases the undistorted version of the observed image is not available, thus assessing image quality blindly has becoming increasingly important [1].

In terms of whether specifying the distortion types of testing images, the current BIQA methods can be classified as distortion specific methods [2], [3] or general purpose methods [4], [5], [6], [7], [8]. The application of distortion specific BIQA methods is limited by the necessity of knowing distortion types of testing images before quality assessment while the general-purpose BIQA approaches aim to predict quality of an image without any prior knowledge of the distortion type. Most general-purpose BIQA approaches proposed are based on training and learning. Moorthy and Bovik proposed a two-stage framework for BIQA [7] which first compute the probability of occurrence of each distortion type and then compute quality score on each distortion type, the two-stage framework performs well. They later proposed the DIIVINE index [6] which is also based on the two-stage framework and achieves better performance by utilizing natural scene statistics (NSS) features from wavelet domain. The BRISQUE index proposed by Mittal *et al.* extracts NSS features from the spatial domain which results in very low time complexity and superior performance [4]. L.Liu *et al.* proposed SSEQ [9] which applies curvelet domain statistical features, i.e. mean values and skew values of histograms of block-based spatial entropy and spectral entropy, as features. The 2-stage framework is also used for mapping features to quality scores, the performance of SSEQ is comparable to state-of-the-art BIQA methods.

However, the spatial entropy features (mean values and skew values of histograms of block-based spatial entropy) used in SSEQ performs poorly when utilized to the two-stage framework [7], [6]. In our work, we propose some new curvelet domain statistical features that performs significantly better for BIQA than spatial entropy features used in SSEQ. The new features are the mean values and the skew values of phase congruency (PC) histogram of an image. Although PC has already been applied for image quality assessment (IQA) in the literature [10], [11], [12], few of them utilize the curvelet domain statistical features of PC. Adding the proposed features to SSEQ framework results in a new BIQA which we call phase congruency and spatial-spectral entropy based quality (PCSSEQ) index. We thoroughly evaluated PCSSEQ on LIVE IQA database [13] and proved that PCSSEQ performs significantly better than SSEQ and its performance is comparable to several top-performing BIQA methods such as DIIVINE and BRISQUE, it also outperforms the two classical full reference (FR) IQA method PSNR [14] and SSIM [15] on LIVE database.

The rest of the paper is organized as follows. Section 2 describes details about the framework of PCSSEQ. In Section 3, we analyzed the power of quality prediction of each feature

This work is supported by the National Science Foundation of China (61271190).

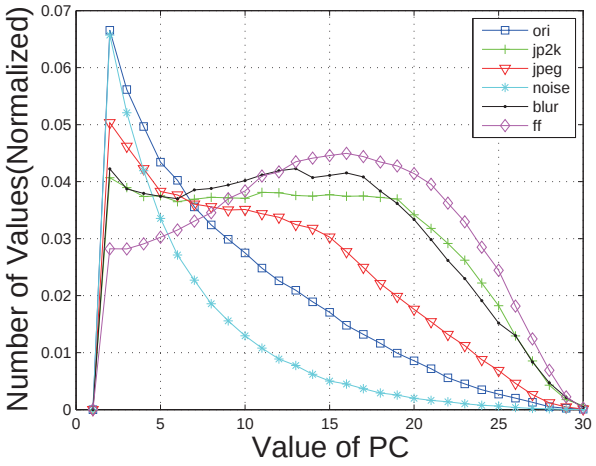

Fig. 1. Histograms of PC for different distortion types. The 6 curves correspond to the image "sailing4.bmp" and its distorted counterparts. "ori" (DMOS = 0), "jp2k" (DMOS = 64.7259), "jpeg" (DMOS = 64.6264), "noise" (DMOS = 63.7033), "blur" (DMOS = 53.3056), "ff" (DMOS = 71.6422).

subset used in PCSSEQ and evaluated the performance of PCSSEQ by several experiments. Finally, Section 4 concludes with a summary of our work.

II. BIQA BASED ON PHASE CONGRUENCY AND SPATIAL-SPECTRAL ENTROPIES

A. Phase congruency features

The physiological and psychophysical evidences had proved that visually discernable features coincide with points where the Fourier waves have congruent phases at different frequencies [16], [17], i.e., at points of high PC values. Besides, PC also have the characteristic of contrast invariance. Thus, the PC theory provides a simple but biologically plausible model of how mammalian visual systems detect and identify features in an image.

In this paper, we adopt the method of computing PC developed by Kovesi [17], which is widely used in literature. We adopt logarithmic Gabor filters [18] for wavelet transform and adopt Gaussian function as the spreading function for the log-Gabor filters to extend to 2D ones. The 2-D log-Gabor filters extended by Gaussian function have the following transfer function:

$$G_2(\omega,\theta_j)=\exp\left(-\frac{\left(\log(\frac{\omega}{\omega_0})\right)^2}{2\sigma_r^2}\right)\cdot\exp\left(-\frac{(\theta-\theta_j)^2}{2\sigma_\theta^2}\right), \tag{1}$$

where ω_0 is the filter's center frequency, and σ_r controls the filters bandwidth, $\theta_j = j\pi/J$, $j=\{0,1,...,J-1\}$ is the orientation angle of the filter, J is the number of orientations, and σ_θ determines the filter's angular bandwidth.

Denoted by M^e_{n,θ_j} and M^o_{n,θ_j} the even- and odd-symmetric filters of the 2-D log-Gabor filters on scale n and orientation θ_j, and they form a quadrature pair. By modulating ω_0 and θ_j and convolving G_2 with an image, we get a set of responses at each point x as $\lfloor e_{n,\theta_j}(x), o_{n,\theta_j}(x)\rfloor$, where $e_{n,\theta_j}(x)$ and $o_{n,\theta_j}(x)$ are responses of the quadrature pair on scale n and orientation θ_j at location x. The local amplitude on scale n and orientation θ_j is $A_{n,\theta_j}(x)=\sqrt{e_{n,\theta_j}(x)^2+o_{n,\theta_j}(x)^2}$, and the local energy along orientation θ_j is $E_{\theta_j}(x)=\sqrt{F_{\theta_j}(x)^2+H_{\theta_j}(x)^2}$, where $F_{\theta_j}(x)=\sum_n e_{n,\theta_j}(x)$ and $H_{\theta_j}(x)=\sum_n o_{n,\theta_j}(x)$. The 2-D PC at x is defined as follows:

$$PC(x)=\frac{\sum_j E_{\theta_j}(x)}{\lambda+\sum_n\sum_j A_{n,\theta_j}(x)} \tag{2}$$

where λ is a small positive constant to keep the fraction stable when all the Fourier amplitudes are very small. $PC(x)$ is a real number within $0-1$.

B. Phase congruency and spatial-spectral entropy based quality index

One reference image in LIVE database and its five distorted counterparts of different distorted types are chosen for showing their histograms. The histograms are shown in Fig. 1, numbers of zeros of histograms are excluded. We can see that the mean and skew values of PC histograms change with different distorted types and distorted extents. From the experiments in section III, we can prove that mean and skew values of PC histograms are strong features for BIQA.

The mean and skew values of spatial entropy histogram and spectral entropy histogram of a natural image would also change with different distorted types and distorted extents in a similar way. The process of computing spatial and spectral entropies are as follows.

The spatial entropy is

$$S=-\sum_x p(x)\log_2 p(x), \tag{3}$$

where x are the pixel luminance values, $p(x)$ is the empirical probability density of x.

The spectral entropy is

$$F=-\sum_i\sum_j P(i,j)\log_2 P(i,j), \tag{4}$$

where

$$P(i,j)=\frac{C(i,j)^2}{\sum_i\sum_j C(i,j)^2}, \tag{5}$$

where $P(i,j)$ is the spectral probability of normalized DCT coefficients $C(i,j)^2$,$i\neq 1$,$j\neq 1$ (DC is excluded).

We extracted mean and skew values of histograms of pixel based PC values, mean and skew values of histograms of block based spatial entropy values and mean and skew values of histograms of block based spectral entropy values as the feature vector of an image for quality assessment, the 2-stage framework proposed in [7], [6] is utilized to map feature vectors to predictive scores. The proposed BIQA method is

named Phase Congruency and Spatial-Spectral Entropy based Quality (PCSSEQ) index.

The proposed PCSSEQ can be divided into four steps:

1) Down sampling. Each incoming distorted image is down sampled twice with a factor of 2 yielding 3 scales of the incoming image, in our experiments we found that this multi scale strategy can enhance the overall performance.

2) Feature computing. PC values PC on pixels, spatial entropy values S and spectral entropy values F on 8×8 nonoverlapping neighboring blocks are computed for each scale.

3) Feature pooling. For each scale, by sorting PC, S and F values of an image in ascending order, the ordered sets $PC = (pc_1, pc_2, ..., pc_m)$, $S = (se_1, se_2, ..., se_n)$ and $F = (fe_1, fe_2, ..., fe_n)$ are yielded. Here pc_i, se_j and fe_k are PC values, local spatial entropies and local spectral entropies, m and n are the number of pixels and blocks respectively within each scale. Then percentile pooling is applied to PC, S and F based on the assumption that distortions only occur in a subset of pixels or blocks. Extracting the central 60% elements from PC, S and F yields $PCp = (pc_{\lfloor 0.2m \rfloor}, pc_{\lfloor 0.2m \rfloor+1}, ..., pc_{\lfloor 0.8m \rfloor})$, $Sp = (se_{\lfloor 0.2n \rfloor}, se_{\lfloor 0.2n \rfloor+1}, ..., se_{\lfloor 0.8n \rfloor})$ and $Fp = (fe_{\lfloor 0.2n \rfloor}, fe_{\lfloor 0.2n \rfloor+1}, ..., fe_{\lfloor 0.8n \rfloor})$. The mean values of PCp, Sp, Fp and the skew values of PC, S, F make up the final features of each scale:

$$f = (mean(PCp), skew(PC), mean(Sp), skew(S), mean(Fp), skew(F)). \quad (6)$$

4) Prediction. Each distorted image has a feature vector of $3 \times 6 = 18$ dimensions. A two-stage framework for BIQA is utilized to map the feature vector to the final image quality score. The two-stage framework used here is the same as that in [7], [6]. The first stage of the framework is to compute the probability of occurrence of each distorted type of the testing image. The second stage is to map feature vector to a quality score on each distorted type. Then the the dot product between the vector of the probability of occurrence of each distorted type and the vector of quality score on each distorted type is the final predictive score. We use a support vector machine (SVM) for classification and support vector regression (SVR) for regression [19], [20]. The SVM and SVR are implemented by the LIBSVM package [21] and the radial basis function (RBF) is used in both implementations.

III. Experiments and results

We tested the performance of PCSSEQ on the LIVE database [13], which consists of 29 reference images and their distorted versions. The database offers five different types of distortion, i.e., JPEG2k (JP2K), JPEG, white noise (WN), Gaussian blur (BLUR) and fast fading (FF). For each distortion type, distorted images of 5 to 6 different distorted levels of each reference image are offered. Difference Mean Opinion Score (DMOS) values of those images are available.

Two evaluation indexes are used to evaluate the performance of our model. The first one is the Spearman Rank Order Correlation Coefficient (SROCC) which is related to prediction monotonicity of a model. The second one is the Linear Correlation Coefficient (LCC) after non-linear mapping. LCC is considered as a measure of prediction accuracy of a model. The non-linear mapping function used in our experiments is the same as the one in [22]. A value close to 1 for SROCC and LCC indicates good performance.

	JP2K	JPEG	WN	BLUR	FF
f1	0.8638	0.7190	0.9510	0.9183	0.8104
f7	0.9052	0.9432	0.9462	0.9408	0.8323
f13	0.1081	0.6914	0.6392	0.4832	0.3234
f4	0.8720	0.7061	0.7970	0.9132	0.8244
f10	0.8405	0.8429	0.3768	0.8405	0.7671
f16	0.0630	0.6129	0.1453	0.3138	0.1807

A. Comparison of feature prediction power

We conducted two experiments to investigate the prediction power of the three feature subsets, i.e. phase congruency feature subset, the spectral entropy feature subset and the spatial entropy feature subset. The first experiment is to investigate the correlation between each feature subset and DMOS on LIVE database. The meaning of features are shown in Table I. The absolute values of SROCC between those feature values and the DMOS for distorted images in LIVE database are shown in Table II. We only computed the SROCC between DOMS and the features extracted from the original scale of images ($f1$,$f7$,$f13$,$f4$,$f10$ and $f16$) since the SROCC on other two scales shows similar regularity.

For mean values (f_1, f_7 and f_{13}), the mean value of spectral entropy of images (f_7) correlates best except on "WN" while the mean value of spatial entropy of images (f_{13}) correlates worst on each distorted type and the mean value of PC of images (f_1) correlates much better than mean value of spatial entropy (f_{13}). For skew values (f_4, f_{10} and f_{16}), the skew value of PC of images (f_4) correlates best except on "JPEG" distorted type while the spatial one (f_{16}) correlates worst on each distorted type. We can conclude that PC features (f_1, f_4) correlate much better than spatial entropy features (f_{13}, f_{16}) and is competitive with spectral entropy features (f_7, f_{10}).

We also applied each feature subset, i.e. phase congruency feature subset, the spectral entropy feature subset and the

TABLE III
MEDIAN SROCC AND LCC ACROSS 1000 TRAIN-TEST TRIALS FOR EACH FEATURE SUBSET.

	SROCC	LCC
f1-f6	0.7644	0.7770
f7-f12	0.8763	0.8757
f13-f18	0.7205	0.7211

spatial entropy feature subset, to the 2-stage framework respectively. 80% of the reference images and their distorted counterparts were randomly selected as the training set and the remaining 20% of the reference images and their distorted counterparts were used as the testing set, the median experimental results over 1000 iterations across all distortion types are shown in the first two columns of Table III. We use the realigned DMOS scores [22] of the LIVE database.

From Table III, we can observe that the spectral entropy features ($f_7 - f_{12}$) perform best while the spatial entropy features ($f_{13} - f_{18}$) perform worst and the PC features ($f_1 - f_6$) perform significantly better than the spatial entropy features ($f_{13} - f_{18}$).

B. Comparison with other IQA approaches

PCSSEQ utilizes all three feature subsets which are phase congruency features, spectral entropy features and spatial entropy features. We tested PCSSEQ on LIVE database and compared the performance of PCSSEQ with three FR IQA methods (PSNR[14], SSIM[15] and FSIM[11]) and three other BIQA methods (SSEQ[9], DIIVINE[6], and BRISQUE[4]). The SSEQ [9] compared here only utilize the spatial entropy feature subset and the spectral entropy feature subset to the 2-stage framework. For BIQA methods in our experiments, median results of 1000 train-test trails by randomly selecting 80% of reference images and their corresponding distorted versions as the training set and the rest images in the database as the testing set. For FR IQA methods, a random 20% test set selection for 1000 times is also performed for a fair comparison, and the median results of 1000 trials are reported. Only the distorted images in the database are used for training and testing in our experiments. The results are shown in Table IV. The top three values of SROCC and LCC across all distortion types ("ALL") are shown in boldface.

The SROCC and LCC of PCSSEQ are higher than that of SSEQ on each distortion type and across all distortion types ("ALL") except the LCC value on "JPEG". The SROCC values in the column indexed by "ALL" are higher than that of FR IQA methods PSNR and SSIM and higher than that of BIQA method DIIVINE. But it is lower than that of FSIM and BRISQUE noting that FSIM is a full-reference approach and BRISQUE is one of the state-of-the-art blind IQA approaches. The LCC values in the column indexed by "ALL" shows consistent results. Although the overall performance of the proposed PCSSEQ is slightly inferior than that of BRISQUE, it is significantly better than that of SSEQ because of utilizing extra PC features. The results also demonstrate that PC map of an image has great potential for blind IQA while most extant literatures only focus on its application for FR IQA.

TABLE V
RESULTS OF THE PAIRWISE T-TEST CONDUCTED BETWEEN SROCC VALUES OF 1000 TRAIN-TEST TRAILS OF DIFFERENT METHODS.

	PSNR	SSIM	FSIM	DIIVINE	BRISQUE	SSEQ	PCSSEQ
PSNR	0	-1	-1	-1	-1	-1	-1
SSIM	1	0	-1	1	-1	1	-1
FSIM	1	1	0	1	1	1	1
DIIVINE	1	-1	-1	0	-1	-1	-1
BRISQUE	1	1	-1	1	0	1	1
SSEQ	1	-1	-1	1	-1	0	-1
PCSSEQ	1	1	-1	1	-1	1	0

TABLE VI
MEDIAN CLASSIFICATION ACCURACY ACROSS 1000 TRAIN-TEST TRIALS.

	JP2K	JPEG	WN	BLUR	FF	**ALL**
SSEQ	65.7	86.5	100.0	66.7	46.7	72.8
PCSSEQ	71.4	91.9	100.0	66.7	43.3	74.7

C. Statistical significance and hypothesis testing

The student t-test results between compared BIQA methods for SROCC values of 1000 iterations are listed in Table V. A value of "1" in the table means that the mean value of SROCC of row method is statically higher to the column method, while a "-1" means that the mean value of SROCC of row method is statistically lower than the one in the column. A value of "0" means that the mean values of SROCC of row and column are statistically equivalent.

D. Classification accuracy

The median classification accuracy of 1000 train-test trails of SSEQ and PCSSEQ are listed in Table VI. From the table we can see that introduction of PC features slightly enhances the overall classification accuracy.

E. Database independence

TABLE VII
SROCC OBTAINED BY TRAINING ON THE LIVE IQA DATABASE AND TESTING ON THE TID2008 DATABASE.

	JP2K	JPEG	Noise	Blur	**ALL**
PSNR	0.7848	0.8585	0.9147	0.8914	0.7527
SSIM(SS)	0.9603	0.9354	0.8168	0.9598	0.9016
BRISQUE	0.9037	0.9102	0.8227	0.8742	0.8977
SSEQ	0.9112	0.8629	0.7986	0.8531	0.8501
PCSSEQ	0.9418	0.9168	0.8001	0.9106	0.9112

In order to demonstrate the degree of database independence of PCSSEQ, we trained it on the entire LIVE database and applied it to the TID2008 database [23]. The TID2008 database consists of 25 reference images and 1700 distorted images over 17 distortion categories. Of the 25 reference images only 24 are natural images, we test PCSSEQ on the 24 natural reference images only on distortions that are shared by the two

TABLE IV
MEDIAN SROCC AND LCC ACROSS 1000 TRAIN-TEST TRIALS ON THE LIVE IQA DATABASE. THE TOP THREE VALUES OF SROCC AND LCC ACROSS ALL DISTORTION TYPES ("ALL") ARE SHOWN IN BOLDFACE.

	SROCC						LCC					
	JP2K	JPEG	Noise	Blur	FF	**ALL**	JP2K	JPEG	Noise	Blur	FF	**ALL**
PSNR	0.8673	0.8843	0.9428	0.7575	0.8721	0.8633	0.8657	0.8866	0.8963	0.7855	0.8616	0.8568
SSIM(SS)	0.9395	0.9480	0.9644	0.9083	0.9413	0.9129	0.9513	0.9605	0.9828	0.9033	0.9569	0.9057
FSIM	0.9700	0.9807	0.9662	0.9711	0.9511	**0.9636**	0.9139	0.9833	0.9751	0.9681	0.9465	**0.9581**
DIIVINE	0.8907	0.8960	0.9826	0.9335	0.8396	0.9057	0.8961	0.9074	0.9765	0.9270	0.8541	0.8990
BRISQUE	0.9095	0.9647	0.9778	0.9511	0.8759	**0.9364**	0.9122	0.9735	0.9848	0.9456	0.9013	**0.9386**
SSEQ	0.8994	0.9420	0.9591	0.9172	0.8565	0.9122	0.9033	0.9609	0.9642	0.9286	0.8746	0.9158
PCSSEQ	0.9132	0.9461	0.9675	0.9246	0.8652	**0.9259**	0.9110	0.9477	0.9744	0.9377	0.8867	**0.9258**

databases: JP2K, JPEG, Gaussian noise (Noise), and Gaussian blur (Blur). The results are shown in Table VII. The SROCC between DMOS and the predictive scores of PCSSEQ is the highest compared with PSNR, SSIM, BRISQUE and SSEQ and it is even higher than that of BRISQUE. The results means that PCSSEQ has excellent database independence characteristic. The reason for the excellent database independence characteristic is probabily that the features of PCSSEQ are statistical features of histograms of an entire image, those features are not easily affected by the sizes and the contents of the distorted images.

IV. CONCLUSION

We proposed a general-purpose BIQA approach called Phase Congruency and Spatial-Spectral Entropy based Quality (PCSSEQ) index. The curvelet domain statistical PC features proposed in our work shows strong predictive ability for BIQA. The proposed approach performs significantly better than another curvelet statistical feature based BIQA method SSEQ on LIVE database. The performance of PCSSEQ is also competitive with some state-of-the-art BIQA methods such as BRISQUE, DIIVINE and some FR IQA methods such as PSNR and SSIM. PCSSEQ also has a good database independence characteristic. Moreover, our work indicate that PC map of an image has great potential for BIQA while most extant literatures only focus on its application for FR IQA.

***Abstract*— Virtual classroom is an online learning environment which is similar to the real world classroom, where the students and professors are at different location and they interact with each other through internet with the help of audio and video data. So the students in the remote location will get the same experiences as if they are in the same classroom and there will be a full interactivity between the students and teachers. Under high bandwidth congestion, for the continuous delivery of video data between the main class room and virtual classroom, an optimized way of video streaming is required. This optimization can be achieved by dynamically changing the frame rate, bit rate, resolution and quantization parameter. During the time of congestion, streaming the same quality video across all the classrooms will result in poor end user experience. Overall experience of the classroom can be improved by dynamically changing the priority of the various video feeds in the system. The proposed system will help us to continuously deliver the optimized video stream between the classrooms based on the priority level.**

Keywords—Remote Classroom; Local Classroom; Quantization Parameter; Peak Signal to Noise Ratio

I. INTRODUCTION

Transmission of video packets through internet exposes the media packets to variable bandwidth, loss of packets and delay as they are travelling through the network. Due to the variation in the bandwidth and less reliability of wireless medium the transmission of video over the internet is a very difficult task. Wireless transmission will always have variable bandwidth. Also the wireless medium is very prone to interferences.

Video streaming is important in all aspect of life like education, work, entertainment etc. The main requirement of streaming a video are, it should have enough quality, quick response to users and continuity. Late arrival of video packets causes poor end user experience and early arrival of video packets also doesn't help. Live streaming is always very risky. As the number of users who try to watch an online video at the same time increases, there will be a great problem in the quality of the stream. A fixed bandwidth should be available for the reliable delivery of video. So we want to accurately measure the available bandwidth. Adjusting the quality is one of the optimum solutions to deliver the audio and video during the time of network congestion. But it should be smooth enough; sudden fluctuations in video quality should be avoided. Human vision will get adapt to a specific quality after a few second. So care should be taken to avoid rapid fluctuation since it is too annoying to the users.

The rest of the paper has been structured as follows. Section II introduces the related work. Section III details the system architecture. In Section IV we present the software implementation and the result obtained. Finally we present our conclusion and future work in section V.

II. RELATED WORK

The paper of Vamseedhar R. Reddyvari et. al. [2] provides a method to enhance the end user experience by means of a video scheduling policy. This will ultimately help to solve the troubles related with scalable H.264 video scheduling.H.264 will improve the video quality by utilizing the video scalabilities like temporal video scalability, quality video scalability and space based scalability. Temporal scalability adjusts the GOP size by the creation or deletion of video layers. In quality video scalability, different quantization parameters are given to different video layers.

Yen-Fu Ou et.al. [3] explains a method to find out the effect of frame rate and quantization step size on quality. The work provides an idea of reduction in quality with the

decrease in frame rate . Quality of a video can be expressed with two factors for a given frame rate and quantization step size. They are the temporal quality factor and spatial quality factor. Temporal quality factor describes how the quality reduces as the frame rate decreases with fixed quantization step size. Spatial quality factor describes how the quality reduces as quantization step size increases. Also large frame rate variation induces noticeable jitter.

Arpad Huszak and Sandor Imre, [4] deals with a scheme that provides a correlation between GOP size (Group of pictures), packet loss and video quality. Group of successive pictures within a coded stream of video is called as GOP.A GOP can contain the intra coded frames, predictive coded frames and bipredictive coded frames. The length of a GOP is its GOP size. In this work the main goal is to find an optimal GOP structure. They came up with the findings that the coding efficiency and propagation distortion is highest with larger GOP size. Under high packet loss ratio, it is better to have a small GOP size to achieve better quality. The video quality increases with increase in GOP size, but after reaching the highest peak signal to noise ratio (PSNR), it starts to decrease. They found out that the optimal GOP size is not more than 10.

Yao Wang et.al, [5] explains a method to find out the effect of frame rate and quantization step size on the bit rate and quality. They have proposed a quality model and rate model. Quality model relates the quality with quantization step size and frame rate. Quality model is derived as the product of PSNR of the decoded frame and by means of a temporal correction factor for quality. Rate model predicts the rate from quantization step size and frame rate. Model is derived as the product of a metric (describes how rate changes with quantization step size) and a temporal correction factor for rate. Relative reduction in either rate or quality with the reduction in frame rate is quite independent of the quantization step size.

S.Sowmyayani and P.Arockia Jansi Rani [6] explains a method to achieve better quality and to reduce bit rate by means of adaptive GOP structure using frame comparison. If GOP size is large, quality of the video after decoding is low which would reduces the bit rate. The quality and bit rate increases with small GOP size. They have proposed an adaptive GOP algorithm which sends side information to the decoder which contains the GOP size for the entire video. Proposed method achieves high PSNR and small bit rate than with fixed GOP structure. Video quality can be optimized by adjusting the parameters like changing the GOP size, frame rate, bit rate and quantization step size. In addition to these parameters to adjust the video quality we can change the resolution. Our proposed system is a solution to optimize the video content with all the video parameters, and to stream this optimized video content based on priority under high bandwidth congestion.

III. SYSTEM ARCHITECTURE

As we have stated in our previous work [7], the system model will provide an optimal solution of multimedia content transmission in a virtual class room environment under high bandwidth congestion. In response to network condition the quality of the video stream is adjusted so as to ensure graceful and smooth continuous play out. Consider a simplistic virtual class room environment of three class rooms, consisting of a local class room and two remote class rooms as in Fig 1. Local class room is the class room in which the professor is taking the class. Local class room also consists of local class room students. Remote class room is in a different geographical location where remote students are present. In this system model we will adjust the quality of the different video streams which are going in and out from the different classrooms based on the priority. Quality adjustment is done by changing the parameters like resolution, bit rate, quantization step size and frame rate. Following are the different video streams for a 3-classroom scenario which are going in and out from different classrooms

1. Lecturing video of the professor to remote classroom-1(outgoing)
2. Lecturing video of the professor to remote classroom-2(outgoing)
3. Local classroom students video to remote classroom-1(outgoing)
4. Local classroom students video to remote classroom-2(outgoing)
5. Remote classroom-1 students video to local classroom-(incoming)
6. Remote classroom-2 students video to local class room-(incoming)

In addition to this two more video streams are there which is streaming between the remote classrooms.

1. Video stream of remote classroom-1 students to remote class room-2.
2. Video stream of remote classroom-2 students to remote class room-1

The priority making system should have the knowledge about all of the video streams. Normally when there is no bandwidth congestion all the videos will be streamed in high quality between the classrooms. Whenever network congestion happens, the priority making system will check the current priority of each of the video. For example, consider the scenario in which the professor is taking the lecture and remote students are just listening to the lecture. In this case the video feed which needs high priority is the lecturing of the professor. So to cope up with the bandwidth congestion, the priority making system will take a decision to adjust the quality of the video streams. A feedback is provided to each of the classroom. According to the decision from the priority making system one with high priority is streamed in the higher quality and video streams with least priority are streamed in a lower quality than that of the high priority video.

IV. SOFTWARE IMPLEMENTATION AND RESULTS

The system is implemented with five machines. Among that two will act as the server, which is attached to the camera. Another two will act as clients, that will perform as the display machine and the last machine will act as the central controller. The server will capture the videos of different classrooms. This raw video data will be encoded using FFmpeg (fast forward moving picture expert group) [8] which is a solution to stream audio and video data. Under normal condition, this streamed video

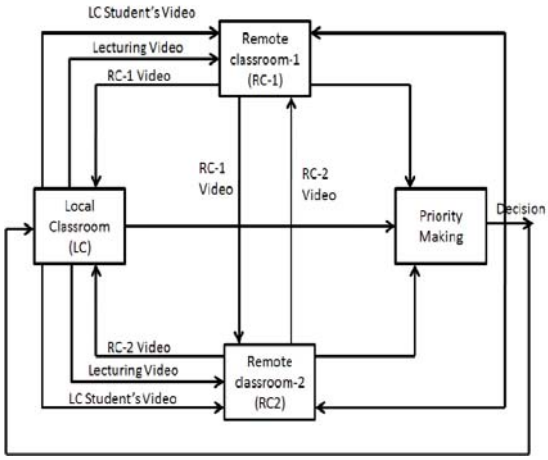

Fig 1. System Architecture

will be forwarded to the client in high quality. The client will respond with a congestion report to the central controller if there is a discontinuity in video delivery due to congestion. The congestion report carries the information to reduce the quality by adjusting the video parameters like frame rate, resolution, bit rate and quantization step size. Socket programming is used for this exchange of information between the client and the central controller. Whenever the central controller finds congestion, it will check the priority as in Fig 2. A rule based prioritization is implemented by means of keyboard input. If we pressed the keyboard input 'p' the first video stream from server-1 has treated with more importance and it will be streamed in a high quality. At the same time we will reduce the quality of the video stream from server-2. If the keyboard input is 'q' second video stream will get more importance and that is streamed in higher quality than the first. After taking the priority decision by central controller, it will request the server to adjust the quality accordingly. As a result the two servers will stream the video by adjusting the video parameters, so that the participants do not feel any perceivable change in the quality of the multimedia content presented to them. The experimentation is done with an assumption that the decoding errors are occurring only because of congestion even though interference may also lead to errors in the network. The packet drop is introduced manually using iptables[9] for creating the network congestion and Peak signal to noise ratio (PSNR) is taken into account in evaluating the quality of video in the model. Following are the result obtained for different scenarios with the system implementation.

Scenario 1: Without introducing packet drop

In the first scenario the test is conducted by not introducing any packet drop using iptable ie, the packet loss is 0%.Then the two clients will request for video files and the servers will stream a high resolution video towards the client with a bit rate of 200kb/s and a frame rate of 25fps.704*576 is taken as the high resolution value for streaming as in Table 1, beyond that the quality of the video decreases.704*576 resolution video will have a PSNR value of 30,which is of fair video quality in figure 3,4

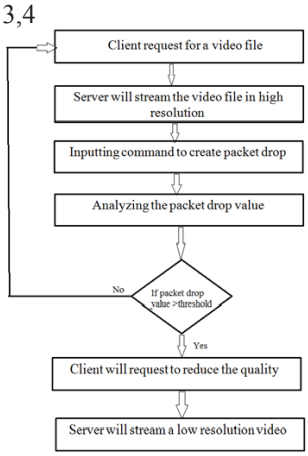

Fig 2. Flow chart of the system

Resolution	Bit rate(kb/s)	Frame rate(fps)	PSNR(dB)	Quality of Video
Sqcif,128*96	200	25	40	Excellent
Qcif,176*144	200	25	35	Good
Cif,352*288	200	25	32	Good
4cif,704*576	200	25	30	Fair

. Table 1: Parameters used for video streaming

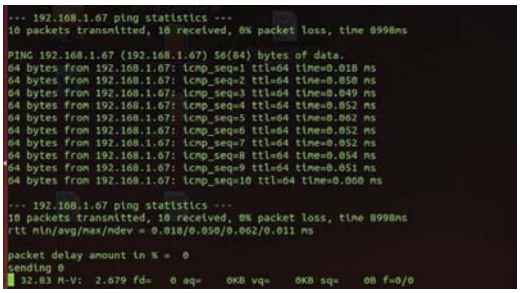

Fig 3. Packet drop is 0%

Fig.4 Video streamed without any packet drop

Scenario 2: With the introduction of packet drop

In the second scenario the test is conducted by introducing random packet drop using iptable. Then we analyze the value of packet drop. If it is less than the threshold value, the servers will stream the high resolution videos towards the clients as in fig. For the analysis purpose the threshold value of packet drop is taken as 25%.Here also a fair quality video can be streamed with a resolution of 704*576 as in Table 1.The video is streamed using a bit rate of 200kb/s and a frame rate of 25fps as in Fig 5,6.

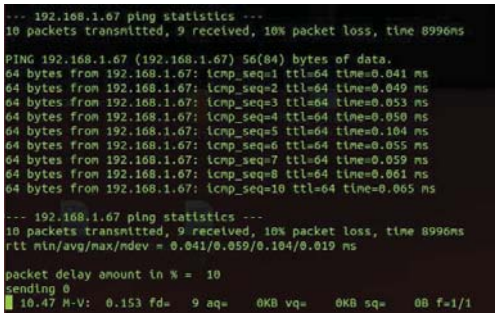

Fig.5 Packet drop is 10%

Fig.6 Video streamed at 10% packet drop

If the packet drop is greater than the threshold value the client will notify that to the central controller. Central controller will check the priority. In the priority decision, if the server 1 gets higher priority than server-2.The video from server-1 will stream in a higher resolution with fair quality. At the same time the central controller will request the server-2 to adjust the quality to have a continuous video delivery. So the video from server-2 will be streamed in a lower resolution to adjust with the packet drop introduced in the network.352*288,cif resolution can maintain a PSNR value of 32 with a bit rate of 200kb/s and a frame rate of 25fps which will help to deliver a good quality video as in fig 7,8.

If the server-2 gets higher priority than server 1, then we will stream a high resolution video to server-2 and a low resolution video to server-1 as in fig 9

If we send a video of 40 % packet drop without reducing the resolution, then the video which is delivering at the client side will be of poor quality as shown in Fig.10. In this time the video would be blocky causing irritation to the end users.

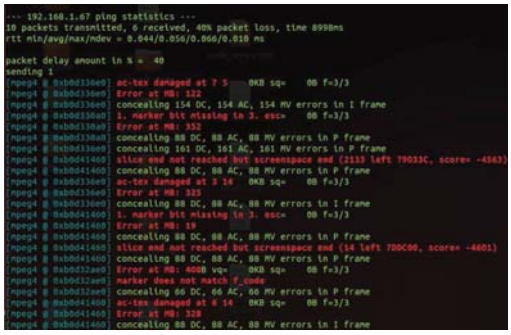

Fig.7 40% packet drop

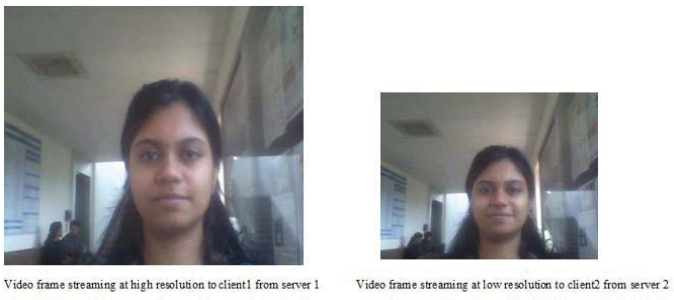

Fig.8 Video streamed when server-1 gets more priority

Fig.9 Video streamed when server-2 gets more priority

Fig.10. Video streamed without introducing our system at 40% packet drop

V. Conclusion And Futurework

A novel solution is proposed to improve the end user experience for a virtual classroom environment during congestion periods. A quality optimization and prioritization approach is introduced based on the available bandwidth by adjusting the resolution. Results indicate that the students in the main class room and remote class room will never face any noticeable change in the quality of video even in the time of congestion. Proposed system will deliver the video contents to the end-users for a virtual classroom system without any discontinuity.

In future research, the influence of decoding errors can be examined to reduce the amount of flickering. Also it is possible to implement the system with n-number of servers and n-number of clients.

ACKNOWLEDGEMENT

We would like to express our sincere gratitude to our beloved Chancellor Sri. Mata Amritanandamayi Devi (AMMA) for the immeasurable motivation and guidance for doing this work.

***Abstract*—In order to minimize the energy consumption of the user terminal with guaranteeing the delay performance, a novel energy efficient (EE) scheduling algorithm for the real-time multicast and unicast services is proposed. According to the demand relations between the users and the services in the multicast broadcast single frequency network (MBSFN) area, the system model of the energy consumption for the user terminal is established, and the upper bound and the lower bound of the terminal energy consumption are analyzed. It adopts the idea of centralized burst transmission to realize the joint scheduling for the combination with various services, so as to achieve the minimum energy consumption of the user terminal. The simulation results show that the proposed algorithm can greatly save the energy of the user terminal by ensuring the delay performance for the real-time multicast and unicast services.**

Keywords—multicast broadcast single frequency network; energy efficient scheduling; delay; energy consumption

I. INTRODUCTION

In the LTE networks, more and more real-time multimedia services are provided for people. The single frequency network (SFN) is introduced to be a transmission mode for multicast and broadcast in the multiple cells [1]. A multicast broadcast single frequency network (MBSFN) area is a region within which all the time-synchronized base stations (BSs) send the same multicast services in a SFN fashion. On the one hand, it must satisfy the delay requirements of the real-time services. On the other hand, the energy saving of the user terminal is important for the multimedia services. The services scheduling by the centralized burst transmission is usually adopted for power saving, but it maybe leads to the delay for the real-time multimedia services. Therefore, the conflict between time delay and energy consumption is the key to the real-time multimedia services. It is essential for minimizing the energy consumption of the user terminal with guaranteeing the delay performance.

The work on energy efficient scheduling in wireless system is inherited from the burst scheduling [2] and the energy efficiency [3]. Joint packet scheduling for both multicast and unicast [4] is proposed in MAN networks. Furthermore, the energy-efficient multicast scheduling [5] is associated with the burst transmission for WiMAX networks. The problem of the battery-constrained mobile devices is focused in the wireless communication, and it takes into account energy savings for uplink cellular OFDMA transmission with low complexity [6]. Another energy-efficient scheduling in uplink OFDMA systems considers the fairness with resource allocation [7]. To guarantee the required QoS provisioning, the minimizing power consumption is adopted for the multicell cooperation networks [8]. The energy-delay trade-off for energy saving [9] is proposed in the wireless communication systems and it adopts the energy-efficient scheduling with individual packet delay constraints. The limited feedback for the delay constrained traffic [10] is introduced in the energy-efficient transmission strategies. However, to our best knowledge, there is no energy efficient scheduling for the real-time multicast and unicast services in MBSFN.

In order to minimize energy consumption of the user terminal, a novel energy efficient (EE) scheduling based on the centralized burst transmission is proposed for the real-time multicast and unicast services in MBSFN. With assuring the delay performance, the system model of the energy consumption for the user terminal is formulated. The proposed algorithm adopts the joint scheduling by the services combination, and then it achieves the minimum energy consumption of the user terminal for the real-time multicast and unicast services.

The remainder of this paper is organized as follows: the system model is introduced in Section II; the proposed energy efficient scheduling algorithm is given in Section III; Section IV provides the simulation results; and Section V concludes with the paper.

II. SYSTEM MODEL

According to the transmission energy consumption and the conversion energy consumption of the user terminal, the total energy consumption of the terminal is almost determined. Let P_{T} be the transmission energy consumption per unit time of the user terminal, and P_{S} be the conversion energy consumption of each state change between work and sleep. It is assumed that K, J and I are the number of the users per cell, the number of the multicast services and the number of

the unicast services in the MBSFN area, respectively. Let t_k denote the services delivery time of the user terminal k, and n_k denote the number of state transition in the services delivery. Then the energy consumption P_k of the user terminal k can be expressed as:

$$P_k = P_T \cdot t_k + P_S \cdot n_k \quad (1)$$

Furthermore, a set K_i denotes the users which need unicast service i in MBSFN, and d_{ki} is defined for the demand relation between user k ($1 \le k \le K$) and unicast service i （$1 \le i \le I$） as:

$$d_{ki} = \begin{cases} 1 & k \in K_i \\ 0 & k \notin K_i \end{cases} \quad (2)$$

Since the demand relationship between the users and the unicast services is not the one-to-one mapping, each user can transmit multiple unicast services, but each unicast service can be only provided for one user. The expression is given by:

$$\sum_{k=1}^{K} d_{ki} = 1 \quad (3)$$

Let T_{mj} represent the delivery time of the multicast service j, and t_{mj} is the ending time of its transmission. Then the transmission time interval of the multicast service j is $m_j = (t_{mj} - T_{mj}, t_{mj})$. Similarly, T_{ui} and t_{ui} represent the delivery time and the ending time of the unicast service i, respectively. $u_i = (t_{ui} - T_{ui}, t_{ui})$ is the transmission time interval of the unicast service i. The multicast transmission is all the same time for every user. That is, the transmission time interval of the multicast service j for each user is $m_j = (t_{mj} - T_{mj}, t_{mj})$. Because the transmission time of the multicast and unicast services can not be conflict, $m_j \bigcap u_i = 0$ is given. Additionally, there is no conflict between the transmission time of unicast services each other, $u_i \bigcap u_{i+1} = 0$ is formalized.

Furthermore, the real-time multicast and unicast services have the delay requirements. Let D_{mj} and D_{ui} be the delivery deadline of the multicast service j and the unicast service i, respectively. The expression is given by $0 < T_{mj} \le t_{mj} \le D_{mj}$ and $0 < T_{ui} \le t_{ui} \le D_{ui}$.

According to the demand relationship between the user k and the multicast and unicast services, t_k can be expressed as:

$$t_k = \sum_{j=1}^{J} T_{mj} + \sum_{i=1}^{I} d_{ki} T_{ui} \quad (4)$$

Since n_k is the number of state transition in the multicast and unicast services delivery for the user k, P_k can be also formalized as:

$$P_k = P_T \cdot (\sum_{j=1}^{J} T_{mj} + \sum_{i=1}^{I} d_{ki} T_{ui}) + P_S \cdot n_k \quad (5)$$

where $P_T \cdot (\sum_{j=1}^{J} T_{mj} + \sum_{i=1}^{I} d_{ki} T_{ui})$ and $P_S \cdot n_k$ denote the transmission energy consumption and the conversion energy consumption of the user terminal k, respectively.

III. Energy Efficient Scheduling Algorithm

A. Optimization Problem

To achieve the optimization goal of minimizing the energy consumption of the user terminal, the EE scheduling algorithm is proposed for the effective energy saving. The average energy consumption of all users can be expressed as the target function, which can also provide the real-time multicast and unicast services with the delay requirements. Therefore, from Eq. (5), the object function is formulated as:

$$\min \ \frac{1}{K} \sum_{k=1}^{K} P_k \quad (6)$$

For the user k, the value of P_k is determined by the number of the state transitions n_k after it is associated with the demand for the multicast and unicast services. The case of the upper bound is that the transmission time of all the services for the user k is not adjacent to each other. Namely, there are seconds between the transmission time interval of various services and it leads to the conversion energy consumption of the state transition between work and sleep. So the value of the upper bound can be expressed as:

$$P_k = P_T \cdot (\sum_{j=1}^{J} T_{mj} + \sum_{i=1}^{I} d_{ki} T_{ui}) + P_S \cdot (J + \sum_{i=1}^{I} d_{ki}) \quad (7)$$

However, the case of the lower bound is that the transmission time of all the services for the user k is adjacent. The transmission time interval of each service is continuous and it needs the conversion energy consumption of the only one state transition between work and sleep at the beginning of service transmission. Therefore, the value of the lower bound is given by:

$$P_k = P_T \cdot (\sum_{j=1}^{J} T_{mj} + \sum_{i=1}^{I} d_{ki} T_{ui}) + P_S \quad (8)$$

Due to the delay constraints of the real-time multicast and unicast services, the scheduling for all the users needs to be coordinated with each other, which can not guarantee that every user may get the lower bound. However, in order to

minimize the energy consumption of the user terminal, P_k can be achieved as the value of the lower bound as possible with the delay requirements of the real-time services.

B. Optimization Solution

Let P be the average energy consumption of all users in MBSFN area, and it can be expressed as follows:

$$P = \frac{1}{K}\sum_{k=1}^{K} P_k \tag{9}$$

Considering the delay constraints of the real-time multimedia services, $\min P$ is expressed as the optimization objective function. Through the comparison of the average energy consumption of user terminals to choose the minimum value with the corresponding services combination, it obtains the minimum energy consumption and determines the joint scheduling for the corresponding real-time multicast and unicast services.

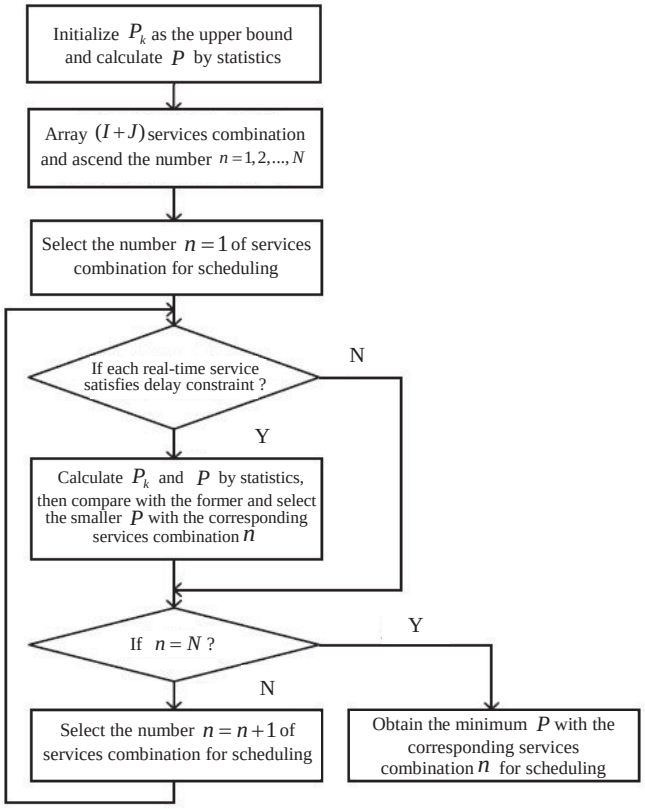

Figure 1. Minimizing energy consumption of the user terminal

As illustrated in Fig. 1, the flow of the minimizing energy consumption of the user terminal is proposed as:

Step 1: initialize the value of P_k for each user as the upper bound, and P is carried out by statistics;

Step 2: order the real-time multicast and unicast services by a full array of $(I+J)$ services combination, and code the number $n=1,2,...,N$ according to the ascending order;

Step 3: select the number $n=1$ of services combination for scheduling;

Step 4: if each real-time service satisfies the delay constraint, calculate P_k of each user at the current services combination, and then obtain P by statistics. Compare with the previous value of P and select the smaller one with the corresponding services combination n, then go into step 5; otherwise directly execute step 5;

Step 5: if $n=N$, the current value of P is the minimum average energy consumption for the user terminals. Schedule according to the corresponding services combination n, and then the algorithm is over; otherwise, turn into the implementation of step 6;

Step 6: define $n=n+1$ and select the next number of services combination for scheduling, then repeat step 4 until the ending $n=N$ of the algorithm.

IV. Performance Evaluation

To evaluate the energy saving performance of the proposed EE scheduling algorithm, the P of EE is compared with that of the upper bound and the lower bound in the different scenarios of K, J and I. As the mentioned above, K is the number of the users per cell, J is the number of the multicast services and I is the number of the unicast services in the MBSFN area, respectively. The demand relations of the user k and the unicast service i is random. However, each unicast service can be provided for only one user and each user may share different unicast services. Furthermore, the ending time of each multicast and unicast service can not beyond its deadline, which may assure the delay performance of the real-time services.

Let P_{ee} be the average energy consumption of the user terminals for the real-time multicast and unicast services in the EE scheduling algorithm. $P_{\max}$ and $P_{\min}$ denote the upper bound and the lower bound of the average energy consumption of the user terminals, respectively. The greater the difference of P between P_{ee} and $P_{\max}$ is, the higher the energy saving performance of the P in EE is.

A. Analysis of Different Number of Multicast Services

To evaluate the impact of J on $P_{\max}$, $P_{\min}$ and P_{ee}, the P of the different J with the fixed K = 30, I = 10, 30 or 60 is depicted in Fig. 2. For the same I and K, the larger J is, the more P is given by $P_{\max}$, $P_{\min}$ and P_{ee}. But the difference of P between P_{ee} and $P_{\max}$ becomes greater with the increasing J. Thus the more energy saving of the user terminals can be achieved in EE. Because the lager J leads to the less times of

the state conversion between work and sleep, the conversion energy consumption becomes smaller with the less P .

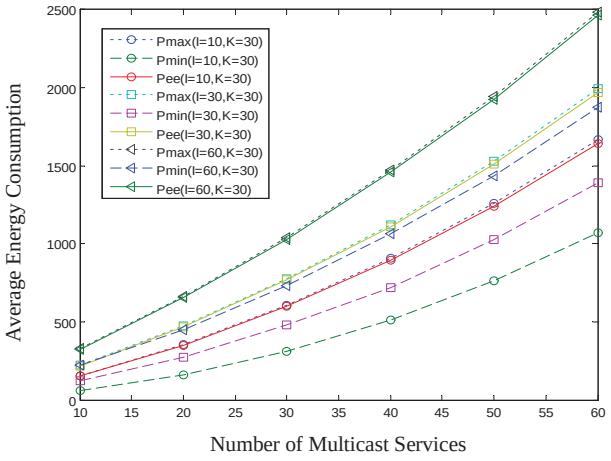

Figure 2. Impact of J on P of $P_{\max}$, $P_{\min}$ and P_{ee} (K=30)

B. *Analysis of Different Number of Unicast Services*

With the fixed K = 30, J = 10, 30 or 60, $P_{\max}$, $P_{\min}$ and P_{ee} are simulated and the impact of the different I on the P is analyzed. As shown in Fig. 3, the P of $P_{\max}$, $P_{\min}$ and P_{ee} all become more and more with the increasing I . For the fixed J = 30 and K = 30, the difference between P_{ee} and $P_{\max}$ is almost the same with the different I . However, P_{ee} can cut down the conversion energy consumption by the idea of centralized burst transmission in the EE scheduling, which may provide more energy saving for the user terminals.

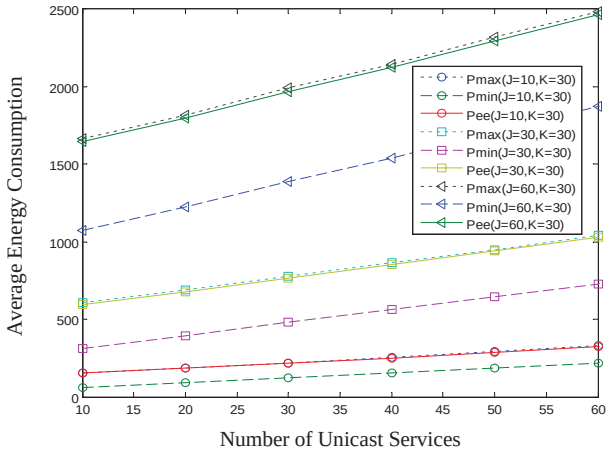

Figure 3. Impact of I on P of $P_{\max}$, $P_{\min}$ and P_{ee} (K=30)

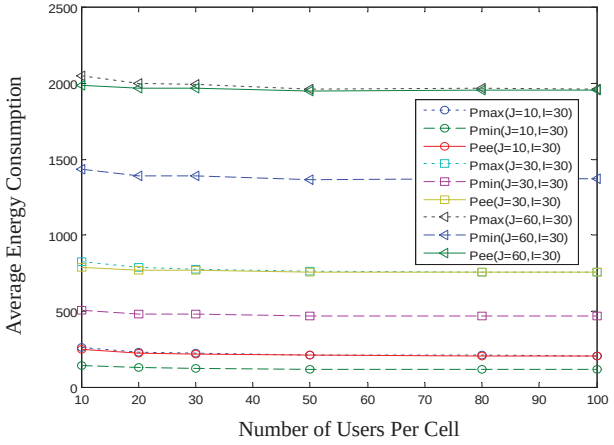
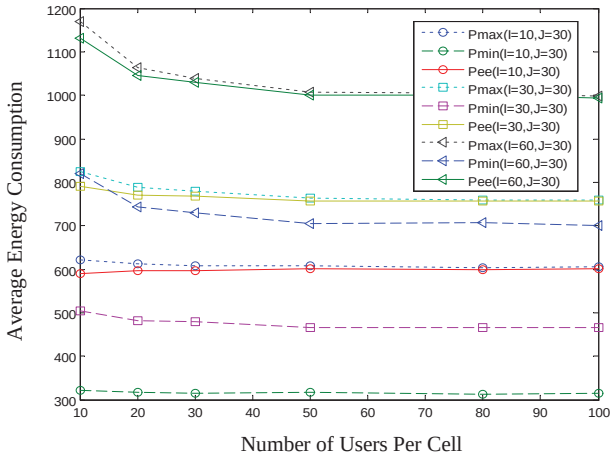
C. *Analysis of Different Number of Users Per Cell*

To analyze the influence of K on P , P_{ee} is compared via simulation with $P_{\max}$ and $P_{\min}$ in the different K . As indicated in Fig. 4, it can be seen that P_{ee} is less than $P_{\max}$ in the different K with the fixed $I = 30$ or $J = 30$ .With the increasing K , the difference of P between P_{ee} and $P_{\max}$ becomes smaller and smaller. Thus the lager K is, the less energy saving of the user terminals is achieved in EE scheduling. Due to the increasing K , the chance to the centralized burst transmission of the real-time services becomes less and less. Therefore, it seems that there are more and more times of the state conversion between work and sleep in the EE scheduling. Then the conversion energy consumption becomes more with the less energy saving impact on the user terminals.



(a) Fixed $I = 30$



(b) Fixed $J = 30$

Figure 4. Impact of K on P of $P_{\max}$, $P_{\min}$ and P_{ee}

V. CONCLUSION

In this paper, a novel EE scheduling algorithm based on the centralized burst transmission is proposed for the real-time multicast and unicast services in the MBSFN area. It formulates the system model of the energy consumption for the user terminal and minimizes the average energy consumption for all the user terminals by joint scheduling in the services

combination. The simulation results show that the energy consumption of EE is less than that of the upper bound in the different number of multicast services, unicast services and users per cell in MBSFN.

Performance Analysis of Energy Detector in Correlated Log-normal Fading Channels for IR-UWB Systems

Josephine. S *Member, IEEE*, A. Mahanta *Member, IEEE* and P. R. Sahu *Member, IEEE*

***Abstract*—This work presents an analysis of the performance of an energy detector, which has the lowest hardware complexity among the suboptimal noncoherent receivers for Ultrawideband (UWB) communication. One of the major requirements among the many applications where UWB systems are used, is low complex receivers. In this communication we present a derivation of the probability density function (PDF) of the signal-to-noise ratio (SNR) at the output of the energy detector. The probability of error is numerically evaluated and plotted with respect to the number of multipath components (MPCs) and the correlation between them. The results of the paper show that a larger integration width increases the performance as the receiver input has more signal energy. In a correlated log-normal channel the correlation between the bins also affect the performance of the detector.**

***Index Terms*—Energy Detector (ED), Ultrawideband (UWB), Log normal channel.**

I. Introduction

Ultrawideband (UWB) technology, operating in the frequency range 3.1-10.6 GHz at very low power levels (-41.3dBm/MHz) is characterized by its huge achievable data rates for short range communication, using simple receiver structures [1]. UWB technology is employed in technology areas like Wireless Personal Area Networks (WPAN) and the recently standardized Wireless Body Area Networks (WBAN) for both low rate and high rate applications. In UWB communication, implementation of conventional optimum (coherent) receivers is relatively complex. Therefore, non-coherent receiver is an attractive option especially if simple and robust implementations with low power consumption is required. However, this comes at the expense of increased sensitivity to noise. Among the noncoherent receivers, energy detector (ED) is the most attractive solution for applications where low complexity is the primary motivation.

Energy detector measures the energy in the received waveform over an observation window. A typical energy detector requires a bandpass filter, a square-law device, an integrator and a decision device [2] as shown in Fig.1. The UWB ED receiver has the advantage of requiring only coarse synchronization which makes the system robust against clock jitter and triggering inaccuracy [3]. ED does not require any prior knowledge of the transmitted signal and the fading channel. However, low power design goal is challenging for UWB systems when a large number of multipath components (MPCs) have to be collected and combined at the receiver to improve the detection performance. The performance enhancement methods for energy detectors in a UWB receiver is therefor an important research topic.

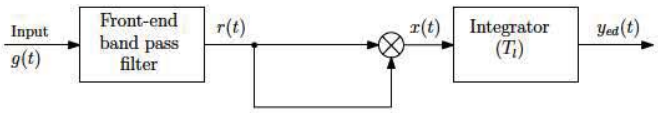

Fig. 1. Energy Detector Receiver Structure.

In this paper, an analysis of the performance of an ED in UWB communication in correlated log-normal channel, in particular, is carried out. In a UWB channel, MPCs that make up one resolvable MPC is much smaller due to the fine time delay resolution and it can change noticeably on a much shorter time scale. Due to this, it has been empirically determined that in many environments, alternative amplitude distributions are more suitable to represent the channel [4] such as Nakagami, Rice, Log-normal etc. It was suggested in [5] that the small scale fading in indoor environment follows log-normal distribution. Further, the IEEE 802.4a WPAN report on channel model for body area network in the frequency range of 2-6 GHz suggests that the best fit for the amplitude distribution measured near the body is a log-normal distribution. Thus the expressions derived in this study can be used to evaluate the performance of UWB systems over log-normal channel. Traditionally, in wireless communication, the log-normal distribution has been used to model the shadowing effect of the signal due to large obstacles. This has been studied quite extensively in the literature [6]. In this paper, we consider the small scale fading as log-normal.

The probability of detection of a deterministic signal in presence of band-limited Gaussian noise for an ED has been discussed in [7]. In [8], the probability of detection of a narrow band communication signal with random amplitudes has been presented [9] gives the performance when the detection capability is boosted by some diversity schemes. All these studies pertain to narrow-band communication. However, the propagation in UWB channel is very different from that in a narrow band channel. Several studies are also reported for the case of wideband communications using RAKE receivers [10], [12]. In the majority of the analysis of the ED, the probability of detection in an AWGN channel presented in [7] is considered, where the statistical distribution of the energy detector output is taken as a non-central chi-square random

variable. In addition to these studies, some results have been reported in the area of improving the performance of energy detector without adding much complexity to the basic structure [13]. Some results are reported describing the factors affecting the performance [14].

The goal of our work is to provide a statistical description of the performance of an ED in a UWB receiver in a correlated log-normal channel using an On-Off-Keying (OOK) modulated signal. We present the bit error rate (BER) performance of energy detector along with an exact expression for the probability density function (PDF) of the output SNR. The PDF derivation is based on the basic expression for the instantaneous output SNR. Further the bit error rate (BER) is numerically evaluated using the Gaussian approximation methods as in the case of an ED in AWGN channel presented in [15]. Eventhough this approximation is not valid for UWB environments, where the number of MPCs having significant energy is less for this approximation, we have nevertheless considered this in order to gain some knowledge as to how the error probability varies in a correlated log-normal channel.

The rest of the paper is organized as follows. The system model and the channel model are presented in Section II. We derive the exact expression for the pdf of the output SNR. In the same section, an approximate average bit error probability equation is also derived. Section III describes the Numerical results and observations and Section IV gives the conclusion.

II. System Model and Channel

The IR-UWB (Impulse Radio UWB) communication transmits information by very short pulses with durations in the range of nano seconds. For purpose of analysis, we focus on baseband UWB signals with OOK (on-off keying) modulation. In OOK UWB signaling, the binary symbols $x[n] = \{0, 1\}$ are transmitted using a train of short pulses. The pulse waveform $p(t)$ represents a single pulse of duration T_p. There are N_f frames, each of duration T_f, per symbol period with one pulse per frame. The transmitted symbol waveform is given by $x(t) = \Sigma_{j=0}^{N_f-1} p(t - jT_f)$ and has a symbol duration of $T_s = N_f T_f$ with energy normalized to unity. Thus the transmitted UWB OOK signal with energy E_w per symbol is given by

$$\mathrm{x}(t) = \sqrt{Ew} \sum_{n=0}^{\infty} x[n] p(t - nTs) \tag{1}$$

The function $p(t)$ represents the transmitted signal waveform which includes the effects of transmitting and the receiving antennas.

The impulse response $h(t)$ of a UWB channel may be expressed as [16]

$$h(t) = \sum_{i=1}^{N} \alpha_i \chi_i(t) * \delta(t - t_i), \tag{2}$$

where N is the number of MPCs that can be resolved at the receiver, α_i is the gain of the i^{th} path where $i = 1, 2, 3, .., N$. Further, t_i is the delay of the i^{th} path and χ_i(t) models the frequency selective distortion experienced by the multipath components due to its interaction with the propagation environment between the transmitter and the receiver. This is due to the variations of the averaged transfer functions caused by the different attenuations that the different frequency components of the UWB signal encounter because of its high relative bandwidth [17].

Studies on channel modeling investigations [4] reveal that the MPCs arrive in clusters and this is mathematically represented as Saleh-Valenzuela (SV) model. In specific environments where not every resolvable bin contains energy, ie., for sparse channels, the arrival times are modeled as a continuous-time stochastic point process. We consider such a sparse channel. Based on extensive channel measurements, the channel modeling subgroup of IEEE 802.15.4a proposed a modified SV model, where the number of cluster is assumed to be Poisson-distributed, while the ray arrival times are modeled as a mixture of two Poisson processes [18]. Here, the arrival times t_i has two components, T_l and $\tau_{k,l}$. T_l is the delay of the l^{th} cluster and $\tau_{k,l}$ is the delay of the k^{th} multipath component in the l^{th} cluster. The continuous-time process is converted into a tapped delay line model to simplify the analytical studies. With this simplification, the channel response $g(t)$ to the UWB pulse $x(t)$ can be obtained as [16]

$$g(t) = x(t) * h(t) = \sum_{i=1}^{N} \alpha_i p_i w(t - t_i), \tag{3}$$

where $w(t) = p(t) * \chi_i(t)$, '*' is the convolution operator and p_i is the probability whether or not the i^{th} bin is occupied with an arrival. $p_i = 1$ if there is an arrival otherwise $p_i = 0$. If the maximum excess delay of the channel is T_h and W is the channel bandwidth, then $N = T_h W$.

In this paper, we consider a base band representation of the signals. Therefore, the channel $h(t)$ and the gain are real quantities. Further, the α_i are lognormally distributed random variables and their probability density function is given as [10]

$$f_x(\alpha; \mu, \sigma) = \frac{1}{\sqrt{2\pi}\sigma\alpha} e^{\frac{-(\ln \alpha - \mu)^2}{2\sigma^2}}, \alpha > 0, \tag{4}$$

where the parameters μ and σ are the mean and the standard deviation respectively of $ln(\alpha)$. Some of the channel measurements show high correlation coefficients between adjacent bins [19].

For simplicity we assume that through proper synchronization and control methods, the integration window of the integrator collects only the energies of the different clusters, without accumulating the noise energy from the noise-only region between the clusters.

A. Energy Detector Input and Output SNR

At the input of the ED, the received waveform $g(t)$ is passed through a bandpass filter of a bandwidth W. The band limited signal after squaring, is integrated over a time window T_l. For our analysis, we have considered the received signal of one symbol duration to be consisting of only one pulse. Thus, the received signal at the ED input can be written as

$$r(t) = \sqrt{E_w} g(t) + n(t), \tag{5}$$

where E_w represents the average received energy per pulse, and $n(t)$ is the filtered noise, modeled as an additive Gaussian process with power spectral density $N_0/2$ within the double sided bandwidth W. Assuming a multipath resolvable channel, L can be written as $L = T_l W$ which represents the number of bins of width $1/W$ within the observation window. The signal at the output of the energy detector is given by

$$\begin{aligned} y_{ed} &= \int_0^{T_l} \left(\sqrt{E_w} g(t) + n(t)\right)^2 dt \\ &= x_1 + x_2 + x_3, \end{aligned} \tag{6}$$

where $x_1 = E_w \int_0^{T_l} g^2(t)dt$, $x_2 = \int_0^{T_l} n^2(t)dt$ and $x_3 = 2\sqrt{E_w}\int_0^{T_l} g(t)n(t)dt$.

The term x_1 in (6) is the 'desired signal', while x_2 and x_3 are the 'noise' and the 'signal multiplied by noise' components respectively. From the energy of the signal and the noise at the output of the receiver, the instantaneous SNR at the output (Γ_{out}) can be expressed mathematically. Noise energy can be calculated from the mean and the variance of x_2 and x_3. From (6), the signal component at the output of the energy detector is

$$x_1 = E_w \int_0^{T_l} g^2(t)dt = E_w \sum_{i=1}^{L} \alpha_i^2, \tag{7}$$

under the assumption of dense resolvable multipath channel. The various steps involved in finding the mean and the variance of noise components are shown in Appendix in detail. The mean and the variance of x_2 can be derived from the characteristic function (C.F) of the sum of the squares of $2L$ Gaussian random variables with zero mean and is given as [20, (6.24)] as

$$\Psi_x(\omega) = \left[\frac{1}{1 - 2j\omega\sigma^2}\right]^L \tag{8}$$

where σ^2 is the variance of $n(t)$. From (8), the mean of x_2 is $N_0 T_l W$ and the variance is $N_0^2 T_l W$. Similarly, the mean and the variance of x_3 is calculated from the basic definitions and are derived as zero and $(N_0/2)4x_1$ respectively [2]. Thus, the instantaneous SNR at the input of the ED is

$$\Gamma_{in} = \frac{2E_w}{N_0} \sum_{i=1}^{L} \alpha_i^2 \tag{9}$$

and the SNR at its output is

$$\Gamma_{out} = \frac{x_1^2}{2N_0 x_1 + N_0^2 T_l W + (N_0 T_l W)^2} \tag{10}$$

From (7) and (10), we can express Γ_{out} in terms of Γ_{in} as

$$\Gamma_{out} = \frac{1}{4} \frac{\Gamma_{in}^2}{\Gamma_{in} + T_l W + (T_l W)^2}. \tag{11}$$

B. Input and Output SNR Distributions

From (9), the distribution of Γ_{in} can be obtained by finding the distribution of the sum of L lognormal RVs[1]. The distribution of $Y = \sum_{i=1}^{L} \alpha^2$ is also lognormal as per the results in [21]- [23]. Several methods have been proposed for computing the parameters of the resulting log normal distribution. Among these, the method proposed by Schwartz and Yeh gives accurate estimates more accurately for the case of correlated signals with different mean and standard deviation [22]. Further,this case is more applicable for the UWB environment which we consider. Thus, applying this method the PDF of Γ_{in} can be written as

$$f_{\Gamma_{in}}(\gamma_{in}) = \frac{1}{\sqrt{2\pi}\sigma_L \gamma_{in}} e^{\frac{-\left(\ln \frac{N_0}{2E_w}\gamma_{in} - m_L\right)^2}{2\sigma_L^2}}, \gamma_{in} > 0 \tag{12}$$

where the parameters, m_L and σ_L are the mean and the standard deviation of the sum lognormal.

Thus from (11), the Cumulative Distribution Function (CDF) of Γ_{out} can be written as

$$\begin{aligned} F_{\Gamma_{out}}(\gamma_{out}) &= \Pr\left\{\frac{\frac{\Gamma_{in}^2}{4}}{\Gamma_{in} + T_l W + (T_l W)^2} \le \gamma_{out}\right\} \\ &= \Pr\left\{\Gamma_{in1} \le \Gamma_{in} \le \Gamma_{in2}\right\}, \end{aligned} \tag{13}$$

where $\Gamma_{in1}, \Gamma_{in2} = 2\gamma_{out} \pm 2\sqrt{\gamma_{out}^2 + \gamma_{out}(T_l W + T_l^2 W^2)}$ are the roots of the argument. Eliminating Γ_{in1}, which is negative, we can rewrite (13) as

$$\begin{aligned} F_{\Gamma_{out}}(\gamma_{out}) &= \Pr\left\{\Gamma_{in} \le \Gamma_{in2}\right\} = F_{\Gamma_{in}}(\varphi(\gamma_{out})) \\ &= \int_0^{\varphi(\gamma_{out})} f_{\Gamma_{in}}(\gamma_{in}) d\gamma_{in}. \end{aligned} \tag{14}$$

Then, the PDF of Γ_{out} can be derived by using the formula in [11, (3.56)]. Therefore,

$$f_{\Gamma_{out}}(y) = \frac{dF_{\Gamma_{out}}(y)}{dy} = f_{\Gamma_{out}}\left[\varphi(y)\right] \frac{d\varphi(y)}{dy}. \tag{15}$$

Thus, substituting $y = \gamma_{out}$ in (15), an expression for the PDF of Γ_{out} can be obtained as

$$f_{\Gamma_{out}}(\gamma_{out}) = e^{\frac{-(\ln(2\gamma_{out}+2K) - m_L)^2}{2\sigma_L^2}} \frac{(2K + 2\gamma_{out} + T_l W + T_l^2 W^2)}{K\sqrt{2\pi}\sigma_L(2\gamma_{out} + K)}, \tag{16}$$

where $K \triangleq \gamma_{out} + \sqrt{\gamma_{out}^2 + \gamma_{out}(T_l W + T_l^2 W^2)}$. The PDF expression given in (16) has been verified by integrating it w.r.t γ_{out} by numerical evaluation using Mathematica and has been found to be unity, i.e, $\int_0^{\infty} f_{\Gamma_{out}}(\gamma_{out}) d\gamma_{out} = 1$. For the purpose of illustration, the numerical values of integration are tabulated in Table I as a function of parameters σ, L and m. To the best of our knowledge (16) is a new expression.

C. Bit Error Rate

The bit error rate (BER) is one of the most important performance characteristic of a communication system. The detection probability of energy detector in the case of narrow-band channels as well as in the case of RAKE receivers in wideband channels has been studied extensively in literature.

[1]Since α is lognormal distributed, α^2 is also lognormally distributed [23]

Moreover, some specific cases like the bit error performance of UWB systems with RAKE receiver for a hybrid pulse amplitude and pulse position modulation scheme over an indoor lognormal fading channel using a RAKE receiver has been numerically evaluated in [10]. In [24] an analytical expression for optimum receiver bandwidth is derived and the effect of bandwidth on the bit-error-rate (BER) is quantified.

In the work presented here, the BER of energy detector in IR-UWB channel is derived by applying the approach for optical signals [15]. This method has been used in communication systems extensively [14], [24]. After filtering, the input signal to the ED can be considered to be a finite sum of L random variables, which can be gathered together in an integration window T_l. This assumption is applied to IR-UWB channel model, where a sequence of distinct pulses are received as in a tapped delay line and L is the number of MPCs which can be gathered together in the integration window. It was shown in [9] that the statistics of the ED output in an AWGN is non-central chi-square distributed.

When the receiver compares the output from the integrator with a threshold ρ, the average BER for equiprobable 0/1 can be calculated as [15]

$$P_{e|\gamma_{in}} = \frac{1}{2}\left[1 - Q_M\left(\sqrt{2\gamma_{in}}, \sqrt{\frac{2\rho}{N_0}}\right) + e^{-\frac{\rho}{N_0}} \sum_{i=1}^{M} \frac{1}{i!}\left(\frac{\rho}{N_0}\right)^i\right] \tag{17}$$

where Q_M is the generalized Marcum-Q function.

Therefore, the average error probability for an IR-UWB systems in a correlated log-normal channel can be written as

$$\overline{P_e} = \frac{1}{2} + \frac{e^{-\frac{\rho}{N_0}}}{2} \sum_{k=0}^{M-1} \frac{1}{i!}\left(\frac{\rho}{N_0}\right)^i + \int_0^\infty Q_M(\sqrt{4\gamma_{in}}, 2\frac{\rho}{N_0}) \frac{1}{\sqrt{2\pi}\sigma_L\gamma_{in}} e^{\frac{-(\ln\gamma_{in}\frac{N_0}{2E_w} - m_L)^2}{2\sigma_L^2}} d\gamma_{in} \tag{18}$$

However, as L increases, the PDF of the output of the ED can be approximated by a Gaussian PDF. With this assumption, which is called the gaussian approximation of an ED, the average BER can be written as

$$\overline{P_e} = \int_0^\infty Q\left(\frac{\gamma_{in}}{\sqrt{L} + \sqrt{L + 2\gamma_{in}}}\right) f_{\Gamma_{in}}(\gamma_{in}) d\gamma_{in}, \tag{19}$$

where $f_{\Gamma_{in}}$ is the PDF of the input SNR and

$$\overline{P_e} = \int_0^\infty \frac{1}{\sqrt{2\pi}\sigma_L\gamma_{in}} e^{-\frac{(\ln(\gamma_{in}\frac{\Omega_L}{\gamma_{in}}) - m_L}{2\sigma_L}} erfc\left(\frac{\sqrt{L+2\gamma_{in}} - m_L}{2\sqrt{2}}\right) d\gamma_{in} \tag{20}$$

III. Numerical Results

Fig. 2 shows the PDF of the SNR at the output of the energy detector for varying number of multipath components as a function of output SNR. As the number of branches increases, the pdf of output SNR increases. Further, the increment is larger in low SNR region compared to the increment in high SNR region. Also, it is observed that when the instantaneous input and output SNRs (9) and (11) are compared, the ratio is found to be very low. This is due to the multiplication of noise

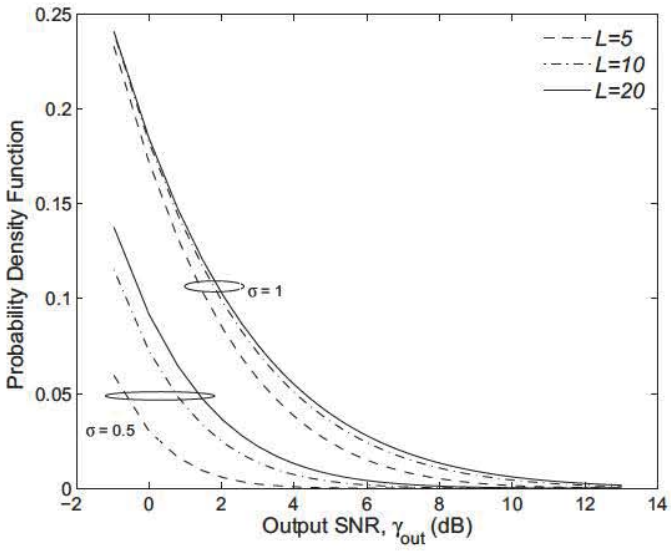

Fig. 2. PDF of output SNR.

energy. In order to capture the maximum amount of signal energy, the integration window must be kept longer than the delay spread. In the case of Wireless Body Area Networks, measurements reveal that a maximum of $L = 6$ is sufficient on all sides of the body, since in the worst cse, the average bin energy will decay by more than 20 dB after 6 bins [25].

Fig. 3 shows the gaussian approximated average probability of error for OOK modulation (20) in correlated log-normal channels. The number of MPCs are taken as $L = 4$ and $L = 6$ for a correlation of $\rho = 0.1$ and $\rho = 0.2$. From the figure, it is observed that more the integration time, lesser is the BER. As regards correlation, it is observed that as the correlation between the bins increases, the BER increases for a given L. This is due to the decrease in mean value and the increase in the variance of the sum of the log-normal components. Typical parameters for the correlated log-normal components are taken from the curves of [23]. Larger number of MPCs implies a larger integration window and thus more signal energy can be captured for conventional energy detectors without added complexity. However, in practice, the complexity will increase due to the additional synchronization circuits to receive the exact multi path energy.

IV. Conclusions

In this paper, we present a theoretical analysis of an energy detector in correlated lognormal channel, which is the best fit for some of the UWB indoor environments. Mathematical expressions for the PDF of the output SNR is derived and plotted. The numerically integrated curves for the gaussian approximated PDF are also plotted for different values of correlation among the MPCs. From these results, we conclude that L, which decides the integration time window is the most significant parameter. While implementing the energy detector in UWB, it is important to gather the MPCs that have significant energy. It is also observed that the performance improves if the bins are not correlated.

APPENDIX A
MEAN AND VARIANCE OF x_2 AND x_3

A. Mean and Variance of x_2

The energy in the finite duration sample of $n(t)$ is the sum of $2L$ squares of zero mean gaussian variates all having the same variance. To find the mean and variance, the characteristic function of the product of the sum of the squres of $2L$ Gaussian random variables is taken as follows

$$\Psi_x(\omega) = \left[\frac{1}{1-2j\omega\sigma^2}\right]^L, \quad (21)$$

where σ^2 is the variance of $n(t)$. Therefore the mean of x_2 is

$$E[x_2] = \frac{d[\varphi_x(w)]}{dw}/w = 0 \quad (22)$$

and the variance can be calculated by $Var[x_2] = E[x_2^2] - E[x_2]^2$ where $E[x_2^2] = \frac{d^2[\varphi_x(w)]}{dw^2}/w = 0$. Thus, the variance of $x_2 = N_0^2 T_l W$.

B. Mean and Variance of x_3 in (6)

Mean of x_3 is $E[x_3] = E\left[\int_0^{T_l} 2\sqrt{E_w} g(t) n(t) dt\right] = 0$, since $E[n(t)] = 0$. The variance of x_3 can be derived as

$$\begin{aligned} Var[x_3] &= E\left[\int_0^{T_l} 2\sqrt{E_w} g(t) n(t) dt\right]^2 \\ &= \frac{N_0}{2} 4E_w \int_0^{T_l} g^2(t) dt = \frac{N_0}{2}(4x_1) \end{aligned} \quad (23)$$

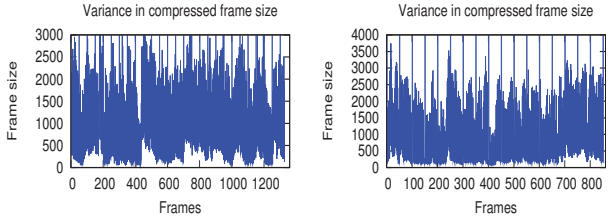
***Abstract*—In this paper, we proposed a generic Time Division Multiple Access (TDMA) based Medium Access Control (MAC) for transmitting multimedia traffic in Ad hoc Wireless Networks (AWNs). We studied the complete system with integrated services such as data, voice, audio and video flows by providing the Quality of Service (QoS) for real time traffic. The core idea behind the protocol is a novel slot distribution for different kind of flows (particularly video flows due to their huge bandwidth requirement) based on the dynamic requirement of bandwidth. We first present the slot distribution for different flows and then explain the algorithm to further optimize the slots usage with adaptive reservation based on the video compression analysis. Since the End to End (E-to-E) delay in a multi hop network is a critical factor in guaranteeing QoS for multimedia traffic, we considered the slots distribution most favourable to real time media transport over AWNs. The simulations were conducted for investigating the performance of the protocol such as E-to-E delay, packet loss ratio (PLR) and throughput by varying different types of services. The adaptive reservation of slots based on the analysis of the bit rate generated by video codec, highlights the work in evaluating the performance of the system.**

***Index Terms*—Slot Distribution, Multi-hop, Multimedia, QoS, TDMA, MAC, AWNs.**

I. Introduction

TDMA based MAC protocols are well known for providing deterministic service in AWNs. Providing the wireless communication using single Radio Frequency (RF) for control as well as actual data transfer in a multi-hop topology, leads to a challenging work. With the increasing enormous technologies such as smart phones, tablets and other mobile technologies, it requires the network to support all kinds of traffic such as data, voice, audio and video on demand, which has made the slot distribution in AWNs, much more interesting research area. Hence, we perform the application specific slot distribution by classifying the real time traffic to provide the QoS guarantee. The traffic is classified based on the bit rate generated by the application, such as Available Bit Rate (ABR), Constant Bit Rate (CBR) and Variable Bit Rate (VBR). This again divided into real time and non real time services such as CBR, rt-VBR, nrt-VBR, rt-data and nrt-data traffic as classified in [1].

In our Adaptive Slot Reservation for Integrated Media Access (ASRIMA) protocol, we considered the design of MAC system for an AWN by providing the QoS for different types of traffic. We first present TDMA slot distribution mechanism



(a) (b)

Fig. 1: **Histogram for compressed bit stream variance (I, P and B frames): (a). High motion and (b). Low motion**

for different flows and then specifically talk about the real time multimedia transport over AWNs. Tremendous research has been going on in supporting data and voice traffic over an AWN. But, providing video over AWNs, is a complex problem due to its VBR nature and QoS needs. Considering High Efficiency Video Coding(HEVC) video compression known as ISO/IEC 23008-2 MPEG-H Part 2 and ITU-T H.265 [2], the frame size after compression, is highly non deterministic as shown in Fig. 1. The reason behind such phenomena is, the Group of Pictures (GOP) structure, for instance IPBPPBBBP...(where, the frames of the video are classified as I, P and B) and scene cut or high variance in motion of video. Therefore, for such kind of VBR sources, the appropriate slot distribution and frame structure is a crucial design decision for a TDMA based MAC to get the effective utilization of bandwidth. In this paper, we show the effect of VBR traffic due to its huge bandwidth requirement that effects flows with low bit rate requirements. The remaining of this paper is organized as follows: Section II presents an overview of literature in this work. In Section III, the traffic is examined for effective distribution of slots for different flows. Section IV explains the proposed TDMA MAC system particularly by studying the video transport. The simulation studies and corresponding results are evaluated in Sections V. At last, the concluding remarks are presented in Section VI.

II. Related Work

The media access protocols such as in [3][4] are not suitable for all kinds of real time traffic due to the VBR nature of video flows. These protocols works well with low bit rate CBR flows with end to end reservation of resources along the multi

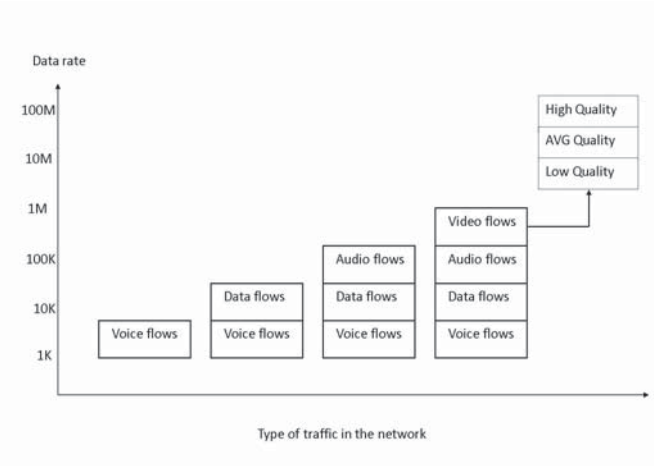


Fig. 2: **Bit rate requirement for different types of flows**

hop path. Reddy, T.B et.al [5] proposed multimedia support MAC protocol in AWNs by providing QoS. The work has well examined the VBR traffic, however it does not speak about the TDMA Frame Structure (TFS) and the slot distribution with respect to application. This also is not suitable for video flows that have high variance in the motion content. In [6][7], a cross layer approach is proposed to provide QoS for real time service. The authors have studied about the E-to-E by providing a minimal length TDMA schedule, however the video transport over AWNs and CAR performance is not well investigated. In [8], the authors have proposed the work to enhance the flow capacity of the system but were not considering the effect of TFS and VBR traffic. Many protocols were proposed as presented in [9], a comparative study of well known TDMA protocols for MAC level optimization of traffic. However, most of the protocols are not providing the full MAC layer functionality as a system with application specific slot distribution. Here, we are going to present a TDMA based MAC protocol with different kind of flows and effect of TFS on such flows.

III. Traffic Analysis

The slot distribution for different type of flows is carried out by identifying type of traffic from application, typically with Type of Service (TOS) field of Internet Protocol (IP) header. A new flow along E-to-E path, is identified with the Equation (1). The TOS field is used to detect the type of application such as voice, data, audio and video. And, the dst_id and src_id are the node identifiers of the network and dst_port is port number on the destined node, to which the application is sending data. Hence, together with TOS and, source and destination address and port number a new type of flow is identified and handled indepenent of other ongoing applications.

$$newFlow = f(TOS) \odot g(dst_port, dst_id, src_id) \quad (1)$$

First, considering the huge bandwidth requirement of video flows, the slot distribution for each video flow is handled by taking different parameters of video codecs into consideration. For instance, in HEVC video compression, Sequence Parameter Set (SPS) and Picture Parameter Set (PPS) were studied carefully to adapt the allocated slots during the session, across the E-to-E path. Second, considering low bandwidth requirement and CBR nature of voice flows as an advantage, the slot distribution for different voice flows is done in a simple approach. At the time of voice flow establishment itself, a virtual circuit for each flow is established by reserving the slots over end to end path. Suppose, for voice codec G.729 with 40ms periodic time frame and 6kbps bit rate, the size of the voice packet generated at the application is 80 Bytes per 40ms. For channel with 1Mbps data rate and slot duration 625us, one slot for each hop along the E-to-E path is enough for 40ms TDMA frame. Finally, data flows with ABR slot distribution, are established without any bandwidth reservation along the E-to-E path. Since the data traffic has high tolerance towards E-to-E delay, such flows are established with Best Effort (BE) service. Here, the queue length is analyzed for each TDMA frame and VBR extraneous slots can be used when the VBR flows are in Low Bandwidth Requirement (LBR) mode. Hence, the data traffic may also have the chance to reduce its queuing delay which is an essential requirement for data traffic such as E-mail delivery delay, text message delivery time.

IV. Proposed Work

The slot distribution for a voice traffic is illustrated in section III. We consider SDS for data and video traffic as it is a crucial factor in the effective utilization of bandwidth due to their VBR nature. First, considering the slot distribution for video calls, the design decisions are greatly dependent on the video coding algorithm. The codec parameters such as

      return $peakSlotsReq \in \Phi_{idle}$; /* *i.e, packets are coming towards* ($\lambda_{mean} + \sigma_{var}$) *or* Γ_{peak} */
    else
      Use reserved slots;
      return $Null$;
    end if
  end if
end if

mean (λ_{mean}), variance (σ_{var}), peak bit rate (Γ_{peak}) and the periodicity of I, P and B frames are considered in SDS, for each video call at the time of call establishment. For each video call, the slots required (Υ_{slots}) $\in N_{ds}$ for its λ_{mean}, are reserved along the E-to-E path. The importance of E-to-E delay analysis is detailed in [10], which is a precious factor for every packet in ensuring the QoS guarantee of an E-to-E video call. Also, from the Fig. 1, it is clearly appearing that the frame size of an I frame is very high compared to the other video frames, which however can lead to improper distribution of slots for a typical video call. As the slots allotted are based on the λ_{mean}, whenever an I frame is to be sent over the network, the allotted slots for that particular call are not enough for sending the whole I frame. This leads to an improper delay of an I frame at the receiver and may degrade the quality of the video, as the I frames are sent to provide the reliable reference for other frames. Since an I frame generates the Γ_{peak} bit rate, we model the problem as an I frame Peak bit Rate (IPR) problem. Also, we may face the IPR problem in the case of very high motion which gives very few matching macro blocks which in turn produces huge bit rate.

$$peakSlotsReq = (\Gamma_{peak} * F_d)/S_d \quad (2)$$

Therefore, we considered the periodicity of an I frame known as GOP, as an important factor in eliminating the IPR problem. Additionally, the motion (T_{mcwf}) present in the video, classified based on the DSAVC algorithm presented in [11], is also considered as a second parameter in controlling the Γ_{peak} bit rate. Allotting suitable slots for Γ_{peak} bit rate at the GOP interval or based on the motion present in the video achieves a good quality and also effective utilization of bandwidth. From the Equation (2), the slots required for sending Γ_{peak} bit rate, namely, $peakSlotsReq$ $\in N_{vpeak}$, is calculated. These $peakSlotsReq$ are used for every interval of $peakSlotPeriodicity$ which is determined based on the GOP and T_{mcwf} as shown in Equation (3). The weights $1/2 \leq \xi_1 \leq 1$ (ξ_1=1/2: if the motion is very less which does not require much bandwidth and ξ_1=1: if the motion in the video is peak stage, where the quality is highly dependent on the I frame) and ξ_2 are calculated using the motion present in the video, using DSAVC [11] algorithm.

$$peakSlotPeriodicity = \Phi(\xi_1.f(GOP), \xi_2.g(T_{mcwf})) \quad (3)$$

Initially, the $peakSlotsReq$ are used for every GOP. However, if the motion content is very less, the video call does not need much bandwidth and the Υ_{slots} goes underutilized. In this case, the reserved slots which are not used for transmission, called as $silenceSlots \in \Upsilon_{slots}$, are used for compensating the Γ_{peak} bit rate. Hence, the low motion video content eliminates the usage of $peakSlotsReq$. Further, these $silenceSlots$ are used to send the VBR data traffic (if the packets are experiencing more queuing delay i.e, $\delta_{Ql} > \delta_{dth}$). The data traffic is handled using the Best Effort (BE) service with idle slots from N_{ds} as shown in Fig. 3, without any slot reservation along the E-to-E path.

Fig. 4: **PLR and E-to-E delay variation of ASRIMA protocol with respect to Load (Average hop count of a flow is 6)**

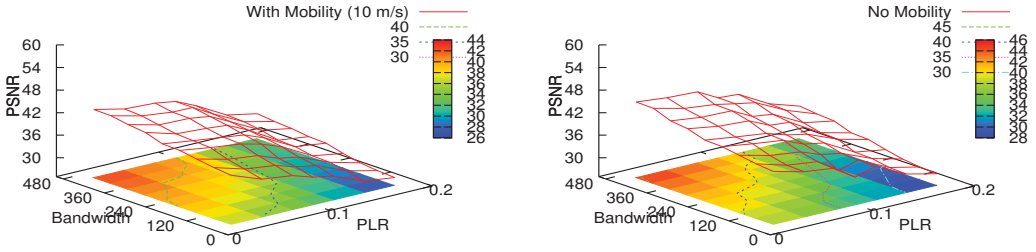
V. Experimental Results

The performance of the protocol is investigated using Network Simulator-3 (NS-3) [12]. We customized NS-3 framework to support TDMA based MAC protocol. The simulation is performed by considering voice, data and video traffic in multiple scenarios. The voice source is considered as a CBR source, video source is considered as rt-VBR source and data traffic is considered as nrt-VBR source, and the slot distribution is performed according to the bit rate of the respective codecs. For transmitting the real time multimedia traffic over the network on NS-3, we used EvalVid, a framework for video transmission and quality evaluation, proposed in [13]. EvalVid evaluates the performance metrics of a video flow such as PSNR, PLR and E-to-E delay. The performance of the proposed protocol is studied by varying the GOP value of x264 video codec with respect to the PLR and the quality of the video. Also, as the performance of the protocols improves greatly with lower values of GOP, in the case of video flows, we experimented the protocol with different values of GOP for each video flow. Additionally, PLR, the E-to-E delay, CAR and throughput of the system for different types of flows, is also studied by varying the load and number of nodes. For all the experiments, we considered a $1Mbps$ link with parameters shown in Table I and 10x10 grid topology, later, we introduced mobility to investigate the performance of the protocol with respect to PLR and quality metric of video flows. For all the flows in the network, we considered the average hop count as 5 and with a hop count variance of 3.

We considered varied number of VBR video flows (10, 20 and 30) for evaluating the performance of the system combined with ABR or CBR flows. As shown in Fig. 4, as expected, the PLR and E-to-E delay changes according to GOP values and hop count respectively. From Fig. 4(a-c), it is observed that the packet loss is increasing with load as well as increase in the number of VBR video flows. The curve with GOP value 128, has higher average PLR values because of its frequent insertion of huge I frame bit rate, when compared to GOP value of 256. Also, from Fig. 4(d-f), as expected, the E-to-E delay is increasing gradually with respect to load as well as number of VBR video flows, and the average E-to-E delay with hop count (H_c) as 6, is always higher when compared to hop count as 4. The throughput of the ASRIMA protocol, as shown in Fig. 6, lies above the curve with IPR problem at almost every time frame. Here, due to the VBR traffic

TABLE I: **Simulation Parameters**

Slot information	Quantity
Number of Nodes	100
Number of Open slots	1
Number of Control slots	24
Number of Data slots	60
Open slot	100 μs
Control slot	100 μs
Data slot	625 μs
Frame duration	40 ms



(a) No Mobility

(b) Mobility with 10m/s

Fig. 5: **VBR video flows performance: Average PSNR versus PLR and bandwidth**

induced by I frame packets, slot usage of the flow is varying over the time. By solving the IPR problem, ASRIMA protocol achieves deterministic throughput values. Additionally, we experimented the VBR video flows for evaluating the PSNR values with respect to PLR and bandwidth available at each node. In Fig. 5(a), the average PSNR values are more in the case of high bandwidth and low PLR values. The PSNR values falls below $30dB$, as the PLR value increases and bandwidth reduces. Further, as the PLR is more in the case of mobility, from Fig. 5(b), a greater fall of PSNR values is observed when compared with no mobility environment.

VI. Conclusion and Future Work

A cross layer traffic analysis should be considered as a crucial factor for QoS guarantees in TDMA based AWNs. In this paper, we studied integrated traffic support by solving the IPR problem in slot distribution of a TDMA protocol towards effective utilization of bandwidth. We experimented the system with flows such as ABR, CBR and VBR flows. From the experimental results, it is observed that the E-to-E delay is reduced marginally compared to previous algorithms. However, the PLR values and PSNR of the video flows are significantly improved. Further, the mobility environment gives poor results compared to static network, hence, the work could be extended for solving huge PLR due to mobile nodes in the network.

Abstract- **Ever going need of data rate and coverage can be achieved by mitigating the impairment of wireless communication system. Interference is most challenging impairment of wireless. Multi cell cooperation (MCC) is one the technique to mitigate the inter cell interference. In this paper, stochastic geometry approach is used to analyse cooperation between MCC. The positions of Base Stations (BSs) follow Matérn Hardcore Point Process (MHCP) distribution. Specifically, we derive upper and lower bounds expressions of the CCDF of SIR for MHCP distribution of base station over Chi square fading following stochastic geometry approach. To validate our model, we compare the CCDF of SIR of the Matérn hardcore topology with [6] where, a Poisson Point Process (PPP) distribution is taken in place of MHCP.**

***Key words*: MHCP, channel state information, beam forming**

I. INTRODUCTION

Base station (BS) coordination allows the cooperation among neighboring cells to improve coverage, cell-edge capacity, and/or spectral efficiency [1].The most popular approach used in modeling the BSs topology is the hexagonal grid model however these models do not accurately captures the real BSs topology and also they are not friendly to analysis. The most common information theoretic downlink model for cellular networks is the Wyner Model [2] due to its mathematical manageability. However, it is a simplified one dimensional model that sets the Signal-to-Interference ratio (SIR) as a constant. The recent witnessed evolution of cellular networks from a carefully planned deployment to more irregular, heterogeneous deployments of Macro, Pico and Femto-BSs makes the hexagonal and regular deployment models of limited utility. Which, in turn, motivates recent studies, tools and results inspired by stochastic geometry to capture the real deployment as accurately as possible. There has been growing recent interest in the use of stochastic geometry [3] to describe wireless networks. In the past ten years, stochastic geometry and related techniques have been applied and adapted to cellular systems, cognitive radio, relay networks, and many other types of wireless systems since classical methods of communication theory are generally insufficient to analyze these new types of networks. We consider the downlink of a network whose topology is modeled through stochastic geometry. For downlink topology, there are two different approaches namely, joint processing (JP) and coordinated beam forming (CB) [4]. In CB, user scheduling and beam forming are dynamically coordinated among neighboring BSs, which reduces the interference among different transmissions as well as increases the desired signal strength. Most of the stochastic geometry work on cellular networks concentrate on the case where the BS deployment follows a Poisson point process (PPP) in which the points are independent which considerably simplifies the analysis [5]. However, this is not the reality since the BSs locations are not totally independent in real cellular networks. We simplify the independent PPP analytical framework in [6] to a Matérn Hardcore Point Process (MHCP) [7], [8] which retains a minimum distance between BSs in an attempt to capture real deployments.

The remainder of the paper is organized as follows. Section II describes the proposed model for the considered MHCP scheme. The expressions are derived for the CCDF of SIR in Section III. In Section IV, we provide our numerical results. Finally, in Section V conclusions are drawn.

II.SYSTEM MODEL

We model the BS locations of a cellular network as a MHCP which is a variation of the independent PPP. A MHCP guarantees minimum distance r between BS deployment locations. In this paper, we consider a mathematically tractable type of the point processes, namely the MHCP ϕ_m of intensity λ_m and a minimum distance r between BSs. An MHCP process is generated by a dependent thinning of a stationary Poisson point process as follows:

1) A PPP ϕ_P is generated with density λ_P.

2) For each point $x \in \phi_P$ associate a mark $m_x \sim U[0,1]$ independent of any other point.

3) A point x is retained in ϕ_m if it has the lowest mark compared to all points in B(x,r) i.e. a circle centered at x with radius r.
The probability of an arbitrary point x is retained in ϕ_m is given by:

$$p = \frac{1-\exp\left(-\lambda_p \pi r^2\right)}{\lambda_p \pi r^2} \quad (1)$$

The density of the MHCP ϕ_m is $\lambda_m = p\lambda_p$, i.e.

$$\lambda_m = \frac{1-\exp\left(-\lambda_p \pi r^2\right)}{\pi r^2} \quad (2)$$

We assume that the mobile users' spatial distribution follows an independent homogeneous PPP and is connected to the nearest BS. Hence, the base stations downlink coverage areas are Voronoi tessellations. We assume the standard path loss propagation model with path loss exponent β and assume that the channel between the mobile user and the attached BS fading distribution varies according to Chi square. Moreover, since the MHCP is a stationary PP we can assume without loss of generality that the user is located at the origin.

We consider a cellular network consisting of K BSs, each equipped with N_t antennas. In dynamic clustering technique each user communicates with the K nearest BS and the set of users' locations that can be served by their K nearest BS is defined by the notion of the Kth-order Voronoi tessellation denoted by v_k. To guarantee separate encoding at each BS, an information symbol s_k (intended for the kth user) is transmitted by the kth BS through a linear beamforming vector $v_k = [v_k^1, v_k^2, \ldots, v_k^{Nt}]^T$ with unit norm $\| v_k \|$.

Our system model is illustrated in Fig.1, where r is the minimum distance between the mobile user and the serving BS at point y, v is the distance between the serving BS and any interfering BS at point x on the plane, R is the distance between the mobile user and any interfering BS at point x. Thus, the received power for a typical mobile user 1 at a distance r from the attached BS is

$$|h_{1,1}\, v_1|^2 \, \|r\|^{-\beta}$$

Where $[h^2_{1,k}, h^2_{1,k}, \ldots h^N_{1,k}] \in C^{1 \times Nt}$ represents the downlink channel between the kth BS and the user with entries that are independent and identically distributed (IID) with complex Gaussian random variables having zero mean and unit variance. The transmit power at each BS satisfies

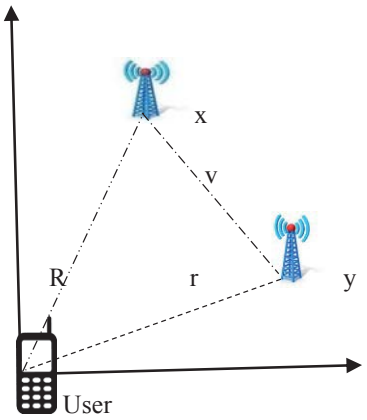

Fig.1 System Model

$E[|s_k|^2] \leq P$. Now the interference power I_k is defined as the sum of received powers from the interfering BSs which is given by

$$\mathrm{I_k} = \sum_{k=K+1}^{\infty} \left| h_{1,k} v_k \right|^2 \|R\|^{-\beta} \quad (3)$$

Hence, the corresponding SIR for the user 1 at origin is

$$SIR(K, N_t, \beta) = \frac{\left| h_{1,1} v_1 \right|^2 \|r\|^{-\beta}}{I_K} \quad (4)$$

The outage probability is defined as the probability that a typical mobile user is able to achieve some threshold SIR, denoted by γ. Hence, outage probability is the CCDF of the SIR for a typical mobile user i.e.

$$F_{SIR}(K, N_t, \beta; \gamma) = P\left[SIR(K, N_t, \beta) \geq \gamma\right] \quad (5)$$

$$P\left[SIR(K, N_t, \beta) \geq \gamma\right] = E\left[P\left[\frac{\left| h_{1,1} v_1 \right|^2 \|r\|^{-\beta}}{I_K} \geq \gamma \;\middle|\; \|r\|, I_K \right] \right] \quad (6)$$

Our aim is to characterize the outage probability under a MHCP process for which we have to derive the MHCP distance distribution.

MHCP Distance Distribution

In our model, we assume that a mobile user connects to the nearest BS. Thus, if a mobile user is at a distance r from the attached BS, then there is no interfering BS that is closer than r to the mobile user. The probability density function (PDF) of r is the distance distribution of underlying MHCP

with intensity λ_m is given by

$$f(r) = 2\pi r\lambda_m\left(\exp\left(-\lambda_m\pi r^2\right)\right) \quad (7)$$

Now to calculate this we have to derive the pdf of *r* which is given by

P [No BS is closer than *r*] = P [$N_m(B(0,r))=0$]

Here, $N_m(B(0,r))$ is the no. of points in a circle B(0,r) centered at the user at origin with radius *r* in a MHCP. Therefore,

$$P[N_m(B(0,r))=0]=\sum_{K=0}^{\infty} P[N_p(B(0,r))=K]\times$$
P [K points are eliminated in MHCP]

Where, $N_p(B(0,r))$= no. of points in B(0,r) in PPP.
Now,

$$P[N_p(B(0,r))] = \sum_{K=0}^{\infty}\frac{e^{-\lambda_p\pi r^2}(\lambda_p\pi r^2)^K}{K!}$$

P [K points are eliminated] $\approx (1-p\ )^K$

$$=\left(1-\left(\frac{\lambda_m}{\lambda_p}\right)\right)^K$$

$$P[N_m(B(0,r))] = \sum_{K=0}^{\infty}\frac{e^{-\lambda_p\pi r^2}((\lambda_p-\lambda_m)\pi r^2)^K}{K!}$$

$$P[N_m(B(0,r))] \approx e^{-\lambda_m\pi r^2}$$

Now pdf of *r* is given by

$$f(r) = \frac{d}{dr}\left(1-P\left(N_m\left(B(0,r)\right)\right)=0\right)$$

$$f(r) = 2\lambda_m\pi r\left(\exp\left(-\lambda_m\pi r^2\right)\right) \quad (8)$$

III.CCDF OF SIR

To characterize the coverage probability in terms of *K*, N_t and β we utilize a general characterization in integral form given by [6, Theorem 1]. The CCDF of the SIR can be written as

$$P\left[\frac{H_1 r^{-\beta}}{I_r}\geq\gamma \mid R\right] = P\left[H_1\geq r^{\beta}\gamma I_r \mid R\right] \quad (9)$$

Using [6, lemma 4] and applying binomial expansion we get

$$P[H_1 > x] = 1-P[H_1\leq x]$$

$$P[H_1 > x] = 1-(1-e^{-lx})^M$$

$$P[H_1 > x] = \left[\sum_{m=1}^{M}\binom{M}{m}(-1)^{m+1}(e^{-lxm})\right] \quad (10)$$

Putting (10) in (9) the conditional CCDF is upper bounded by

$$P\left[H_1\geq r^{\beta}\gamma I_r \mid R\right]\leq\sum_{m=1}^{M}\binom{M}{m}(-1)^{m+1}E\left[e^{-mlr^{\beta}I_r} \mid R\right] \quad (11)$$

Where, M =N_t-K+1 and l= $(M!)^{-1/M}$, and the expectation is over the distribution of I_r. Now CCDF can be written as

$$F_{SIR}^{c}(K,N_t,\beta;\gamma) = E\left[P\left[SIR(K,N_t,\beta)\geq\gamma \mid R\right]\right]$$

$$F_{SIR}^{c}(K,N_t,\beta;\gamma) \leq \sum_{m=1}^{M}\binom{M}{m}(-1)^{m+1}E\left[E\left[e^{-lmr^{\beta}\gamma I_r} \mid R\right]\right] \quad (12)$$

With inner and outer expectations over the distributions of I_r and R respectively. We first calculate the conditional Laplace transform of I_r to evaluate these expectations,

$$L_{I_r}(s) = E\left[e^{-sI_r} \mid R\right] \quad (13)$$

$$L_{I_r}(s) = E\left[\prod_{R\in\phi/B(0,r)} e^{-sH_k\|R\|^{-\beta}} \mid R\right] \quad (14)$$

$$L_{I_r}(s) = E\left[\prod_{R\in\phi}\frac{1}{1+s\|R\|^{-\beta}} \mid R\right] \quad (15)$$

$$L_{I_r}(s) = \exp\left(-\lambda_m\int_{R^2}\frac{1}{1+s^{-1}\|R\|^{\beta}}dR\right) \quad (16)$$

$$L_{I_r}(s) = \exp\left(-2\pi\lambda_m\int_{r}^{\infty}\frac{R}{1+s^{-1}R^{\beta}}dR\right) \quad (17)$$

Where (14) follows from the independence of R and H_k, (15) holds because H_k is exponentially distributed and unit mean, and (16) follows from the probability generating functional of the PPP [9].

Evaluating (17) at s=mlγr^{β} we will get

$$L_{I_r}\left(ml\gamma r^{\beta}\right)=\exp\left(-2\pi\lambda_m\int_r^{\infty}\frac{R}{1+(ml\gamma)^{-1}(R/r)^{\beta}}dR\right) \quad (18)$$

$$L_{I_r}\left(ml\gamma r^{\beta}\right)=\exp\left(-\pi\lambda_m r^2(ml\gamma)^{2/\beta}\int_{(ml\gamma)^{-2/\beta}}^{\infty}\left(\frac{dv}{1+v^{\beta/2}}\right)\right) \quad (19)$$

$$L_{I_r}\left(ml\gamma r^{\beta}\right)=\exp\left(-\pi\lambda_m r^2 D(ml\gamma,\beta)\right) \quad (20)$$

Where (19) follows from change of variable $v=\left[\left(\frac{1}{ml\gamma}\right)^{1/\beta}\frac{R}{r}\right]^2$ and (20) follows because of

$$D(ml\gamma,\beta)=(ml\gamma)^{2/\beta}\int_{(ml\gamma)}^{\infty}\frac{1}{1+v^{\beta/2}}dv \quad (21)$$

$$D(ml\gamma,\beta)=\frac{2}{\beta-2}(ml\gamma)\,{}_2F_1\left(1,\frac{\beta-2}{\beta},2-\frac{2}{\beta},-ml\gamma\right) \quad (22)$$

Where (22) follows by using [5] which is gauss hypergeometric function.

Now to evaluate the outer expectation of (12)

$$E\left[L_{I_r}\left(mlr^{\beta}\gamma\right)\right]=\int_{r>0}L_{I_r}\left(ml\gamma r^{\beta}\right)f(r) \quad (23)$$

$$E\left[L_{I_r}\left(mlr^{\beta}\gamma\right)\right]=\int_{r>0}\exp\left[-\pi\lambda_m r^2(D(ml\gamma,\beta)+1)\right](2\lambda_m\pi r)dr \quad (24)$$

$$E\left[L_{I_r}\left(mlr^{\beta}\gamma\right)\right]=\int_0^{\infty}\frac{e^{-x}dx}{2\pi\lambda_m r}\left(\frac{2\pi\lambda_m r}{[1+D(ml\gamma,\beta)]}\right) \quad (25)$$

$$E\left[L_{I_r}\left(mlr^{\beta}\gamma\right)\right]=\frac{1}{[1+D(ml\gamma,\beta)]} \quad (26)$$

Here (24) will be obtained by putting (7) and (20) in (23), where (25) follows from variable change $x=\pi\lambda_m r^2[1+C(ml\gamma,\beta)]$. If K=1 and N_t=1 then the above equation reduces to the case of PPP where there is no coordinated beamforming. By putting (26) into (12) we finally obtain the upper bound

$$F_{SIR}^{c,U}(K,N_t,\beta;\gamma)\le\left[\sum_{m=1}^{M}\binom{M}{m}\frac{1}{[1+D(ml\gamma,\beta)]}\right] \quad (27)$$

and by putting l=1 in this equation the lower bound of the CCDF of SIR will be obtained.

When N_t=K then the upper and lower bound will coincide, from which we obtain the exact CCDF.

$$F_{SIR}^{c}(K,K\ ,\beta;\gamma)=\left[\frac{1}{[1+D(\gamma,\beta)]}\right] \quad (28)$$

IV.NUMERICAL RESULTS

In this section numerical analysis of different closed form expressions are presented. In Fig. 2, when both no. of transmit antennas and no. of base stations is equal to 1 (i.e. N_t =K=1) then PPP and MHCP overlap with each other. After that we have compared proposed CCDF of SIR of equation (28) for different values of K and path loss exponent β=4, which is a standard value in terrestrial outdoor wireless systems, for this case $D(\cdot,\cdot)$ reduces to

$$D(\zeta,4)=\sqrt{\zeta}\,arc\cot\left(\frac{1}{\sqrt{\zeta}}\right)$$

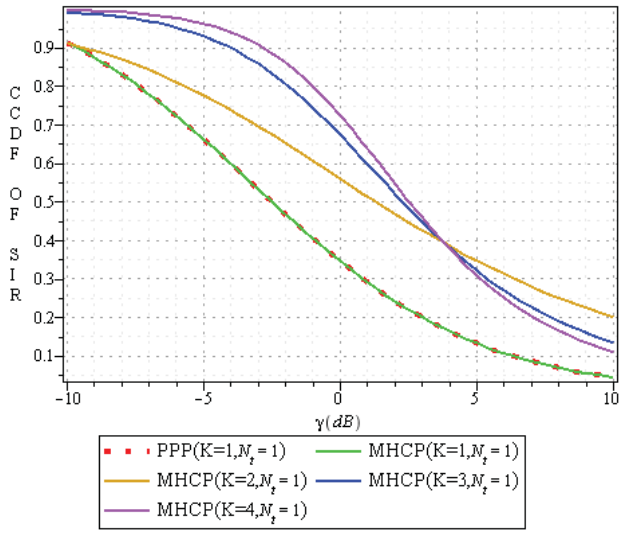

Fig. 2. CCDF of SIR of β=4 and different no. of BS

It can be noticed from Fig. 2 that as the value of *K* increases SIR of MHCP process improves.

In Fig. 3 the equation (27) for different values of transmit antennas exactly matches the exact CCDF over the entire range of SIRs of interest which clearly shows the benefits of having N_t antennas.

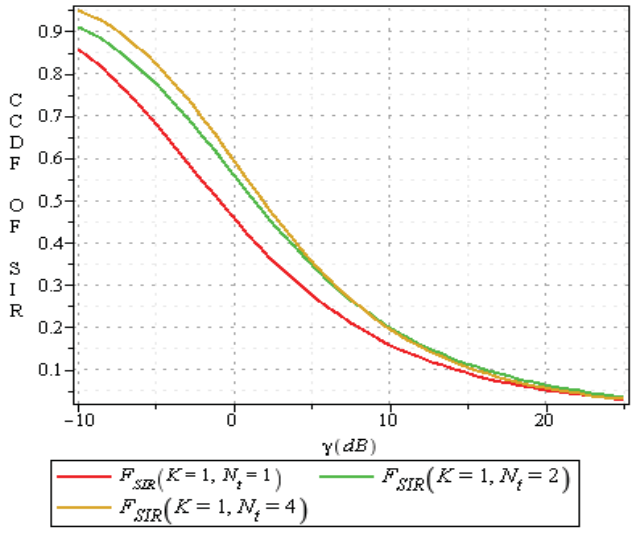

Fig. 3. CCDF of SIR of proposed model, β=4 and different number of transmit antennas

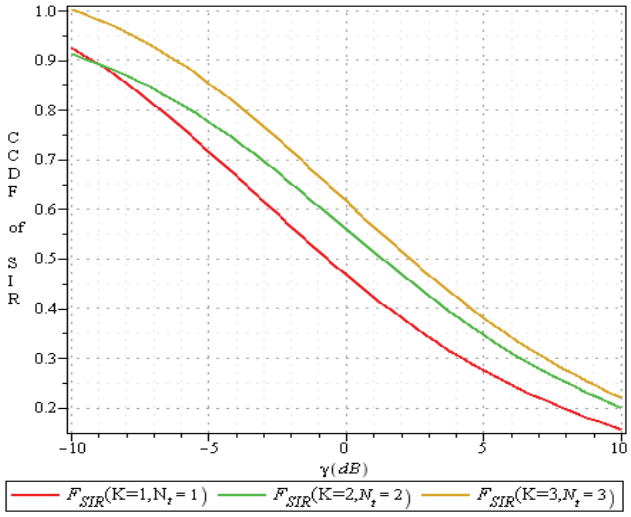

Fig. 4: CCDF of SIR of proposed model for β=4 and N_t =K

In Fig. 4 with coordinated beamforming and N_t =K the performance is simply characterized by the expression in (28), when N_t=K=2 and β=4, the SIR of MHCP improves upto γ=10dB

V.CONCLUSIONS

We presented a stochastic geometry formulation using the Matérn hardcore spatial point process to model the MCC in cellular networks. Basically, we novel closed form expression for CCDF is derived for MCC using stochastic geometry approach. In [6, 8 and 9] PPP distribution for BS distribution is assumed. However, in this paper MHCP is used in place of PPP. Also, expressions for upper and lower bounds for CCDF of SIR are presented. The results are compare with available literature; showing perfect agreement. Further, work may be extended to derive closed form expressions of the coverage probability and Ergodic capacity.

***Abstract*—Routing protocol of MANET works with the presumption that nodes will transmit the data in collaboration. This presumption is a limitation of routing protocol which gives an occasion to attackers to hinder the security of the device and data in the network. Therefore, it becomes vital to develop methods and systems which will ensure the safety, integrity and confidentiality of data in such devices and systems. Although, existing IDS are able to detect various types of attack but some misbehaviour goes undetected which potentially damage the network. Collusion attack is one such misbehaviour where nodes perform maliciously in collaboration with neighbouring nodes without being detected. In this work, Intrusion detection algorithm has been proposed that can effectively detect and isolate colluding nodes from the network so that these malicious nodes do not affect the performance of the network. Proposed detection algorithm uses in-out traffic information and overhearing statistics of nodes to identify colluding attackers. Detection algorithm works successfully for DSR routing protocol. Experimental results on NS-2 show that the proposed algorithm is capable of reducing the packet drops consequently improving the throughput of the network in presence of collusion attack.**

***Index Terms*—Mobile Ad hoc Network (MANET), Intrusion Detection System (IDS), Collusion, Misbehaviour.**

I. Introduction

A Mobile Ad hoc Network (MANET) is a self-coordinating, self-designing wireless network, where the nodes are responsible for creation, operation and maintenance of the network. Mobile system or nodes or device in the mobile ad-hoc network has a freedom for entry or exit from the network as discussed in review [1]. Trusted and co-operative behaviour of mobile nodes helps in the communication of mobile nodes in the MANET. Establishment and maintenance of connections between mobile nodes can be done with the help of existing routing protocol which have not been designed keeping security issues in mind.

The charactestics of mobile ad hoc networks raises many challenges to the security design. The main problem that hinders the security of MANET is that, it is easy for malicious attackers to reach the ad-hoc network. This is possible because of no physical protection to mobile nodes, also packets are forwarded with the assumption that nodes in the network are cooperative. This facilititate attackers to capture and compromise nodes to spoil the network security. With the increase of vulnerabilities in MANETs, raise the need of efficient and effective intrusion detection system (IDS) that indentify as well as neutralize the attacks. B. Sun [2] has demonstrated that Intrusion detection in mobile ad hoc networks is a difficult and complicated task due to the very nature of MANETs. Many IDSs are designed especially for MANETs to find out selfish or malicious nodes in the network.

In this paper, a security threat where neighbouring nodes perform malicious activity in collaboration is analyzed. Based on analysis an intrusion detection algorithm is proposed which can detect misbehaviour carried out by the collaborating neighbouring nodes.

The rest of the paper is organised as follows. Section II discusses about existing acknowledgement based IDS that how they perform against malicious activity. Section III describes collusion attack. In Section IV Intrusion detection algorithm have been proposed for detecting colluding nodes. Section V shows performance analyses of proposed detection algorithm. Finally the paper is concluded in Section VI.

II. Related Work

Transmission in MANET take place with the supposition that nodes in the network always collaborate with each other to transmit the data. This supposition makes an easy way for attackers to cause potential damages in the network by compromising one or two nodes. In order to conquer over this damage IDS is designed to intensify the safety of MANETs. Marti et al. [3] have proposed Watchdog and Pathrater techniques for mitigating the routing misbehaviour in MANETs. A Watchdog keeps an eye on the transmission of the next hop for identifying misbehaving nodes. A Pathrater then calculates the routes which avoids the misbehaving nodes. Watchdog technique is used to detect misbehaviour at the forwarding level. But this scheme fails to detect misbehaving nodes in the presence of 1) ambiguous collision, 2) receiver collisions, 3) limited transmission power, 4) false misbehaviour, 5) collusion, and 6) partial dropping.

TWOACK proposed by Liu et al. [4] is one of the approach in order to solve issues of Watchdog technique. Balakrishnan et al. [6] given a function of TWOACK to detect misbehaving links by sending a TWOACK packet for every data packet transmitted over every three consecutive nodes along the path from the source to the destination. The TWOACK scheme is able to solve the receiver collision and limited transmission power problem of Watchdog but with the disadvantage of increase in network overhead. Also there will not be any missed detections in the TWOACK scheme unless collusions between two neighbouring misbehaving nodes exist.

Pragya Mishra is M.Tech student at ABV-IIITM Gwalior, India and Dr. K V Arya is Associate Professor at ABV-IIITM Gwalior, India.

Sheltami et al. [5] proposed a hybrid scheme of TACK similar to TWOACK and end-to-end acknowledgement (ACK) scheme called AACK. AACK scheme has reduced network overhead than in TWOACK because of employing ACK scheme. As it employs TWOACK scheme so it can resolve limited transmission and receiver collision problem. AACK is able to detect misbehaving nodes but misbehaviour due to colluding attack described by Kannhavong et al. [12] is not taken into account. TWOACK and AACK suffer with the problem of false misbehaviour report.

Shakshuki et al. [7] designed EAACK to tackle false misbehaviour, limited transmission power and receiver collision problem of Watchdog scheme. It is comprised of mainly three schemes, namely, ACK, secure ACK (S-ACK), and misbehaviour report authentication (MRA). EAACK is an acknowledgement-based IDS which trust acknowledgement packets to detect malicious activity in the network. Digital signature approach is adopted to fortify integrity of IDS by sending out digitally signed acknowledgement packet. With the help of digital signature EAACK is able to authenticate false misbehaviour report. However, EAACK still suffers with the problem of collusion and partial droping.

Ghosh et al.[11] has given a mechanism to isolate malicious nodes trying to misbehave in collusion with other malicious nodes and presented a mechanism which successfully works for AODV protocol in MANET. Kannhavong et al.[12] has presented a model of collusion attack against Optimized link state routing protocol (OLSR). Simple detection mechanism has been demonstrated to detect attack but results contradicts due to frequent change in network topology. So, these techniques are not able to profitably works for existing acknowledgement based IDSs agsinst collusion. Since, these IDSs are designed over dynamic source routing (DSR) protocol. In this paper, we are designing detection algorithm against collusion attack which auspiciously works for dynamic source routing (DSR) protocol.

III. Problem Definition

The problem with existing acknowledgement based IDS like watchdog, TWOACK, AACK and EAACK is that they lack to perform well if attack occurs due to collaborative malicious nodes. Although, these IDS contributes to increase the network performance by detecting and isolating malicious nodes but fails to detect misbehaviour which occurs in collaboration of neighbouring nodes.

Consider a scenario presented in Fig. 1. Source node S sends a Packet1 to node n1 then n1 forwards this packet to n2. Since, n2 is two hop away from S it redirects S-ACK packet to S following the reverse path and forwards Packet1 to n3. By receiving S-ACK from n2, S is ensured that till node n2 there is no misbehaviour. Now, n3 is two hops away from n1 so it has to redirect S-ACK packet to n1. Node n1 is assured that there is no misbehaviour till now. But n3 instead of forwarding Packet1 further it drops the packet which n2 knows but it hides the misbehaviour of n3 and does not generate any misbehaviour report. So it is found that n2 and n3 performs malicious activity in collusion. But this goes undetected by node S. So, this how neighbouring nodes help each other in hiding their illegal actions and hamper the security of the network.

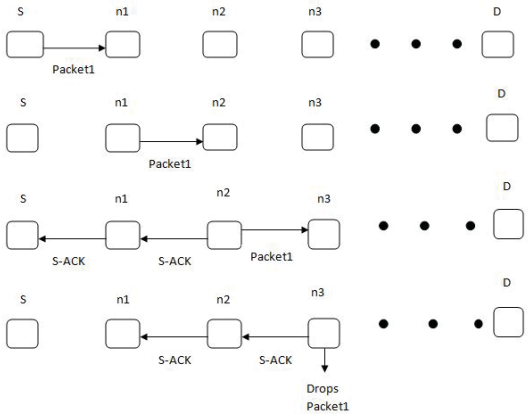

Fig. 1. Scenario presenting misbehaviour in collusion

IV. Proposed Scheme

The proposed scheme consist of two phases namely attack model and detection of attack which are described below.

Attack Model - In our system, threat occurs only when two or more nodes trying to collude with each other to simply drop the packets. These colluding nodes cooperate in the DSR Route Discovery and Route Maintenance phases, but decline to relay data packets further in the network. For example, In Fig. 2, misbehaving node n3 drops the packet rather than forwarding it to next hop with the help of node n2. Node n2 hides the misbehavior of node n3 by not reporting the misbehaviour of n3 to source node S . Node n3 upon receiving packet sends S-ACK packet to n1 through n2. Receipt of S-ACK from n3 makes n1 assured that there is no misbehaviour. This is how n2 and n3 misbehaves in collaboration.

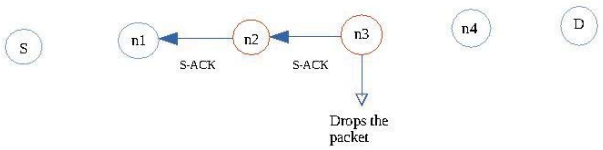

Fig. 2. Attack Model

It is required for the nodes to be in transmission range of one another in oder to collude, otherwise they have to collude through a third party. Generally, compromised neighbouring nodes are responsible to occur collusion. A node is said to be compromised when it is captured and manipulated by an attackers. Thus, when two nodes in the same neighborhood are compromised, they may be manipulated to collude. As a result of collusion, colluding misbehaving nodes hide illegal actions of each other and hamper the security of the network. A colluding attack occurs when two or more selfish or malicious nodes collaborate and gain access to certain information that

they are not authorized to have by secretly sharing their knowledge to simply destroy the secure connection in the network.

Detection of attack - In DSR protocol, source node S has information of all the routes hop-by-hop to the destination. An arrangement of continuos nodes n_i, n_{i+1}, n_{i+2},....n_k on the path from source to destination D are acting as colluding adversaries. Here promiscuous listening mode is utilized which obliges that every node keeps up the details of the sending conduct of its neighbouring nodes. Every node keeps up the data about the packets which it gets notification from its neighbour by incorporating the id of the neighbour node furthermore the timestamp at which the packet was overheard. Procedure DETECT_COLL_ATCK describes the details of the procedure adopted for identifying the colluding nodes.

Algorithm 1 DETECT_COLL_ATCK(Source S, Destination D)

Step 1: S sends random audit packet to random selected node n_i
Step 2: Node n_i sends in-out traffic T_i to S
Step 3: S sends the same audit packet to the successor node n_{i+1}
Step 4: Node n_{i+1} sends in-out traffic T_{i+1} to S
Step 5: S checks T_i and T_{i+1} and calculate threshold value

Th_i = [(no. of pkt send by S - no.of pkt received by n_i)/ no.of pkt send by S]*100

Th_{i+1} = [(no. of pkt send by S - no.of pkt received by n_{i+1})/ no.of pkt send by S] *100
Step 6: If ($Th_{i+1} >= 30\%$), is true then check threshold value of node n_i
Step 7: If ($Th_i >= 30\%$), is true then recurse the algorithm beacuse colluding adversaries present downstream ni

DETECT_COLL_ATCK(S, n_{i-1})
Step 8: Check n_{i-1} and n_i overhearing statistics If no packet is overheard at both n_{i-1} and n_i then n_i and n_{i-1} suspected.
Step 9: Else if ($Th_{i+1} < 30\%$), is true then recurse the algorithm because colluding adversaries present upstream n_i

DETECT_COLL_ATCK(n_{i+1}, D)
Step 10: Else, No colluding adversaries found

Algorithm finds out colluding adversaries if any in path segment from source to destination by checking in-out traffic of nodes and their overhearing statistics. As soon as colluding attackers detected these nodes are kept in isolation from the network so that they further not effect. The proposed intrusion detection algorithm is able to acheive network security through identifying and removing colluding attackers from the network. When colluding attackers are removed from the network the packet loss will be reduced and destination nodes will be able receive packets successfully.

V. Performance Evaluation

A. Simulation Configuration

Simulation has been done to test the performance of a network in the presence of colluding adversaries on NS-2.35 simulator. In Table I, simulation parameters are given on which simulation is performed for network size of 50, 100, 150 nodes with variable number of colluding nodes. In the simulations, a colluding node is the one that agrees to participate in forwarding packets but then indiscriminately drops all data packets that are routed through it. The percentage of the network comprised of colluding nodes is varied from 0% to 40% in step of 10%.

TABLE I
Simulation Parameters

Parameter	Values
Simulator	NS-2.35
Processor	CORE i3
RAM	4 GB

Traffic type	CBR
Data payload	512 bytes

B. Experimental Results

Simulation has been done for two scenarios of collusion attack in presence and absence of detection algorithm for four performance parameters packet delivery ratio, routing overhead, throughput and average end-to-end delay described in [7] against different percentage of colluding nodes for 50, 100 and 150 nodes in NS-2.35 network simulator. By evaluating the packet delivery ratio from Fig. 3, Fig. 4 and Fig. 5 for 50, 100 and 150 nodes respectively in absence and presence of detection algorithm against 10% to 40% colluding nodes; PDR in presence of detection algorithm is higher than the PDR in absence of detection algorithm, because as soon as detection algorithm encounters the nodes misbehaving in collaboration, it report such nodes as malicious. With the increase in percentage of colluding attackers in the network, PDR acheived with detection algorithm is decreasing but with lesser rate than that of PDR acheived without detection algorithm. As the size (number of nodes) of the network is increasing, packet delivery ratio are not as much expected for both scenarios of collaborative attack but scenario in which detection algorithm is present to detect colluding nodes PDR acheived is better than the scenario in which algorithm is not present.

Similarly, By evaluating routing overhead from Fig. 6, Fig. 7 and Fig. 8 for 50, 100 and 150 nodes respectively in absence and presence of detection algorithm against 10% to 40% colluding nodes; routing overhead in presence of detection algorithm is higher than the routing overhead without detection algorithm against collaborative attack, because in detection algorithm node sends audit packet to randomly selected node and its successor node in the route, these nodes have to reply

back with their in-out traffic, so it require little more number of control packets. As the size (number of nodes) of the network is increasing, routing overhead are also increasing because more number of nodes participating in communication.

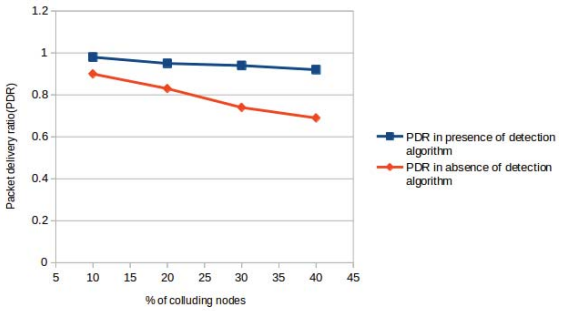

Fig. 3. PDR vs colluding nodes for 50 nodes

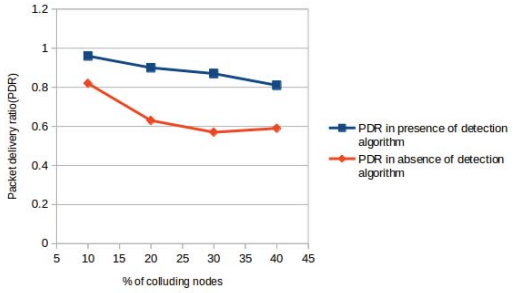

Fig. 4. PDR vs colluding nodes for 100 nodes

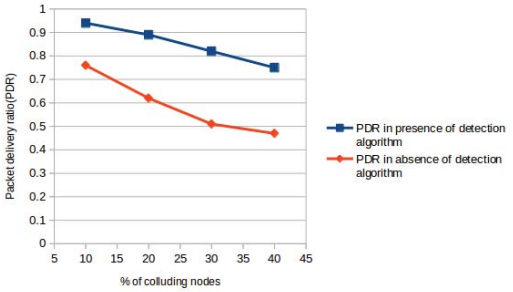

Fig. 5. PDR vs colluding nodes for 150 nodes

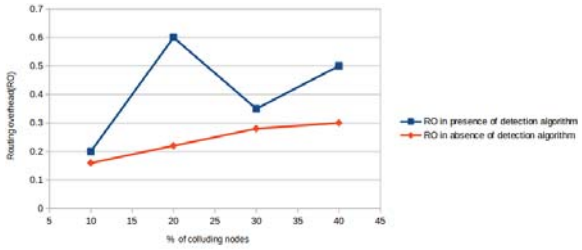

Fig. 6. RO vs colluding nodes for 50 nodes

By evaluating throughput from Fig. 9, Fig. 10 and Fig. 11 for 50, 100 and 150 nodes respectively in absence and

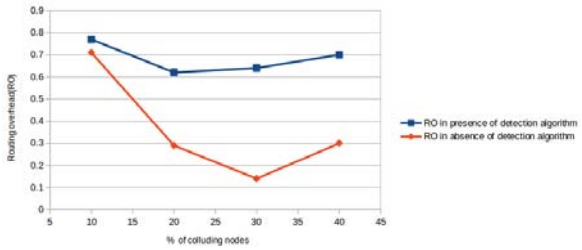

Fig. 7. RO vs colluding nodes for 100 nodes

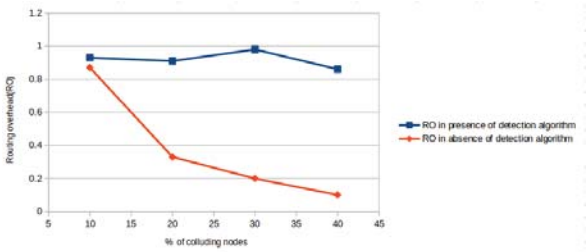

Fig. 8. RO vs colluding nodes for 150 nodes

presence of detection algorithm against 10% to 40% colluding nodes; throughput in presence of detection algorithm is higher than the throughput in absence of detection algorithm, because as soon as colluding attackers get detected that nodes kept isolated and further packet loss is controlled. We are not getting the expected throughput for both the scenarios of collaborative attack when percentage of colluding nodes is increasing. Throughput in both presence and absence of detection algorithm are slightly decreasing with the increment of colluding nodes. As the size (number of nodes) of the network is increasing, throughput are not as much expected for both the scenarios. It is decreasing with the increase in size of network.

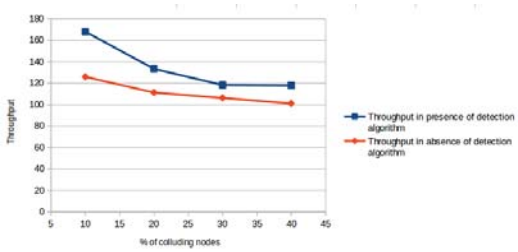

Fig. 9. Throughput vs colluding nodes for 50 nodes

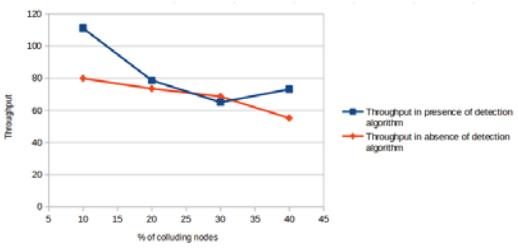

Fig. 10. Throughput vs colluding nodes for 100 nodes

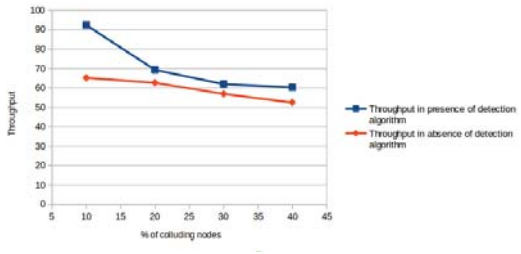

Fig. 11. Throughput vs colluding nodes for 150 nodes

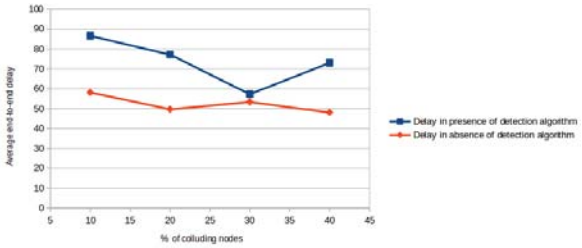

Fig. 12. Average end-to-end dealy vs colluding nodes for 50 nodes

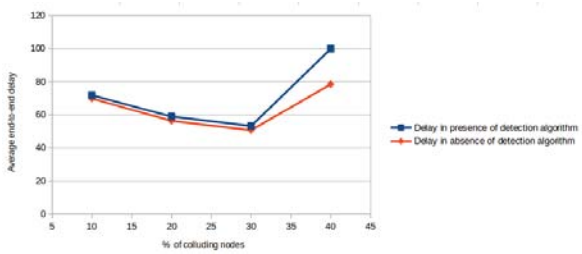

Fig. 13. Average end-to-end dealy vs colluding nodes for 100 nodes

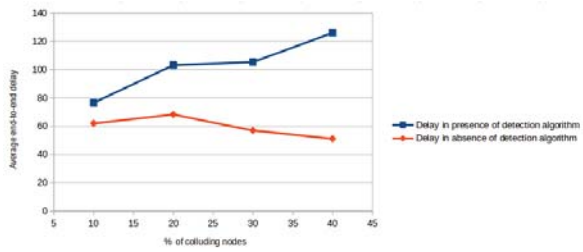

Fig. 14. Average end-to-end dealy vs colluding nodes for 150 nodes

Similarly, By evaluating average end-to-end delay from Fig. 12, Fig. 13 and Fig. 14 for 50, 100 and 150 nodes respectively in absence and presence of detection algorithm against 10% to 40% colluding nodes; average end-to-end delay in presence of detection algorithm is higher than the average end-to-end delay in absence of detection algorithm, because time taken by algorithm to detect colluding nodes adds up in time of transmitting packets to nodes. As the size (number of nodes) of the network is increasing, average end- to-end delay for both scenarios of collaborative attack are slightly increasing.

VI. Conclusion

Intrusion detection algorithm has been proposed and simulated for varying number of colluding nodes and for different sizes of network. Detetcion algorithm checks in-out traffic of selected nodes alongwith keeping an eye on the activity of neighbouring nodes. From simulation results it is observed that an improvement is visible in packet delivery ratio and throughput of the network in presence of the proposed detection algorithm which led to improved security level. Therefore, it is concluded that detection algorithm performs effectively in detecting and isolating colluding nodes from the network so that these malicious nodes do not further participate in routing consequently improves performance of the network. Although, with the increase in network size performance was not remarkable but still algorithm maintains the good network performance.

Abstract*— E-learning technology helps both students and teachers, to access the remote classroom and the professor in that classroom can interact with them efficiently. In the current scenario, the professor will view the remote classrooms in multiple screens which failed in realistic interaction. But still there are some improvements that can be done. This paper proposes a system which will help the professor to recognize the remote student who is trying to interact and thus allow him to change the flow of lecture with respect to the student interaction. Here we implement audio detection to identify the classroom and also we used a gesture recognition algorithm to switch between remote classrooms, so that the professor could access the students and continue helping the student based on the student's subject base knowledge. This will allow a more realistic feel to the virtual classroom, allowing both the student and professor to interact with ease. We can also allow this design for the interaction between students for discussions during lectures or presentations.

Keywords—E-learning; Remote classroom; Remote student; Audio detection; Gesture recognition; Virtual classroom

I. INTRODUCTION

There has been a rapid growth in the use of internet over several years. According to a recent survey, the number of Internet users worldwide reached about 2.27 billion, almost exactly twice what it was in 5 years ago which also increases the Data traffic [1]. Multimedia plays a vital role among various classes of traffic on the internet. Live video telecast, video conferencing, etc. are some of the most common applications that deliver video content over the internet. With the advancement in the internet technologies lot of applications demands interactive responses, VOIP, video streaming, etc. became our part of life.

Virtual classroom, it is one of the prominent features of the E-learning platform. As the name implies, the classes are conducted virtually, which means the students and the professors attend the class from their respective remote locations as in Figure 1.1. It is an online, web-based tool, which creates a virtual classroom environment similar to traditional classroom [2]. It is considered as an alternative to traditional, location-based classroom, as it saves the expenses of physical infrastructure [3].

Usually, professor's interaction with the local classroom-students will be more causing lack of attention and interaction with the remote classroom students. Hence, the professor fails to understand the effectiveness of his/her lectures. The proposed system focuses on improving the interaction between the professor and the students who are in different locations by adding the features like audio detection and gesture recognition

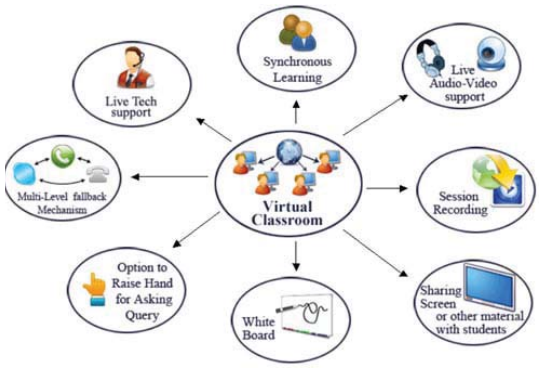

Fig. 1.1 Virtual Classroom technology [2]

The main challenge of the work is to reduce the misidentification of murmuring sound as a real sound and less audible voice as noise. The proper identification of the sound variations in the different categories like murmuring, less audible sound, surrounding noise, etc.

Hence, we propose a system which will enable an effective interaction between the professor and the students in remote classroom in multi classroom scenario. Our system will be useful in virtual classroom scenario ensuring the evident speaker detection and gesture recognition. The system filters the unwanted sounds and properly identifies the classroom in all interactive and non-interactive sessions. The professor could switch the classroom with distinct gestures without any fail.

The paper is organized as follows: Chapter 2 provides a comprehensive study and background information on existing studies. The detailed system architecture is discussed in Chapter 3, followed by Simulation Results in Chapter 4. Conclusion and future work of the presented work has been given in Chapter 5.

II. Related Work

The gesture recognition system using Kinect is described in [2]. In this system, when a student in a remote location, raises his/her hand to talk to a professor, the Kinect camera detects the student, identifies the gesture of the remote student, after identifying the gesture of the student, the student gets zoomed in with the PTZ HD camera. To zoom in the student the authors used AXIS M5014 PTZ Dome Series network cameras, i.e. the camera are accessed through its IP address. The PTZ camera, does not know to whom it has to zoom and at what angle it has to rotate to focus on the student with the raised hand. In order to solve this issue, it is imperative to map the images between both the cameras by using Homography Estimation and SIFT algorithm. From the SIFT algorithm, key points are collected and the key points are matched to estimate the Homography. The Homography Estimation determines how much the camera has to rotate and to whom the camera has to zoom.

A method to find the hand gesture by using Kinect is discussed in [4]. Initially, a gesture set is created and is compared with the hand gesture which is detected by the Kinect and, displays its meaning and the corresponding picture on the screen. The system consists of 3 phases. First phase, Hand Detection, which will detect the hand and separate it from the background. The Second phase is Finger Identification, which uses a three point alignment algorithm to detect hand contours and finger identification algorithm to identify fingers. The Last phase is Gesture recognition, where gestures are identified by passing it through some classifiers, namely finger counting classifier, finger name collecting classifier and vector matching classifier.

The detection of hand raising gestures in a meeting room and classroom environment is discussed in [5]. From the video frame the student's face is detected and the region of interest is defined. The system The system proposes a hand raising gesture in images. The hand raising gesture is identified by considering the edges of the raised arm that are parallel and close to the face that are of the same height which will determine whether the student raises the hand or not. Here, they consider the meeting room set-up in which two people face each other and the third sits in such a way that only the left side of the person is visible in the video. This type of gesture detection does not work in a messy environment.

A method for gesture recognition using depth data obtained by the Kinect sensor is discussed in [6]. Here, the proposed Gesture Recognition System consists of four steps. The Initial step is to obtain the depth map and the 3D coordinates of six joints and by using the hand coordinates the hand region is cropped. The second step is to extract the hand shape features based on the cropped hand regions gradient value. The third step is to calculate the arm movement features based on the six joint values. Finally the gesture is identified using a Hidden Markov Model. The method used in this system requires background modelling and is expensive.

III. System Architecture

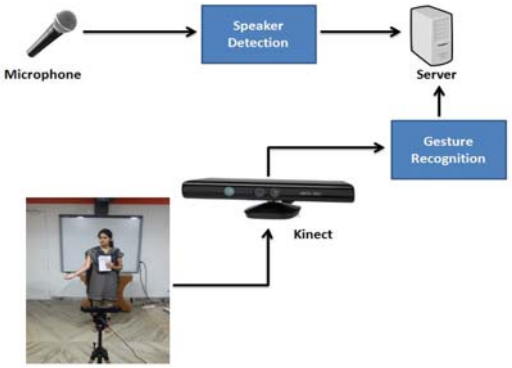

Fig. 3.1 An Overview of System Architecture

An Overview of the entire system is shown in the Figure 3.1. The system consists of microphone which capture student's interaction, and cameras for real time video streaming and a Kinect camera which identifies the gesture of the professor to switch the classroom. In our system, it consists of two main modules, speaker detection module and gesture recognition module. In speaker detection module, when a student asks doubt from any of the remote classrooms the system will capture that sound, and the input will be processed in speaker detection module and finally the system will find out the classroom from which the student asks doubts. Next is the gesture recognition module. Here, whenever the professor identifies the classroom from where the student ask doubt, the professor will give a particular gesture for that respective classroom so as to switch the classroom which is displayed on the professor side display.

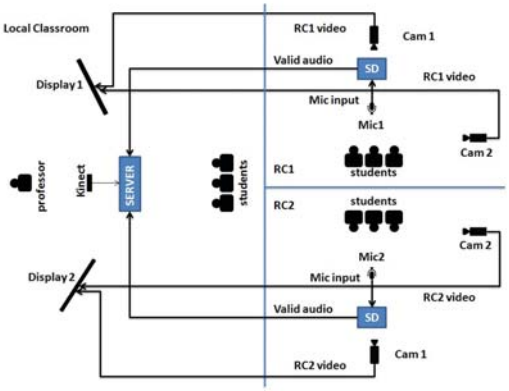

Fig. 3.2 Proposed System Architecture

The proposed system is implemented using five machines in three classrooms, i.e one local classroom and two remote classrooms. In the proposed system architecture shown in Figure 3.2 the block diagram 3.3, Among the five machines, two will act as the speaker detection (SD) module in remote classrooms, to determine whether the student's sound is valid or not. Another one will act as a server, which is attached to the Kinect camera and the rest two i.e display 1 and display 2 will act as the professor side display screens for switching the

remote classroom perspectives. From both the remote classrooms, real time videos are streamed to the professor side screens. In the remote classroom, the speaker detection module will capture the student's interaction and determines whether it is valid or not. This is performed using a speaker detection algorithm. We know that when we consider a classroom environment, it may change dynamically. So that it is a real challenge to determine whether the sound is valid or not. Initially, we will analyze the classroom for some time and at the same time we will find out the RMS (Root Mean Square) of each sample and the average of these RMS values will be set as the threshold for the remaining time. The threshold will be dynamically changed, with the variation in time. After the initial time, the calculated RMS values are compared with the threshold which is dynamically changing and whenever the RMS value is greater than the threshold the system will determine whether the sound is valid or not.

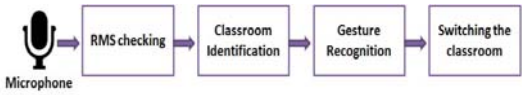

Fig. 3.3 diagram of the System

After the detection of the valid input, it is forwarded to the server. A Kinect camera is connected to the server for the gesture recognition module. In the gesture recognition module, whenever the professor identifies the classroom from which the student asks doubt by viewing the screens placed on both sides of the professor, he/she will show a particular gesture to the Kinect =camera for that respective classroom. The Kinect camera will identify the gesture and by analyzing both the inputs from the Kinect camera and the speaker detection module, i.e. valid input, the system will switch the classroom perspective displayed on the screens placed on both sides of the professor.

The flow chart of the system is shown in Fig. 3.4.

IV. Simulation Results

- Speaker Detection

The figure 4.1 shows the output of the speaker detection module in remote classroom 1 (RC1) and remote classroom 2 (RC2). The speaker detection module detects whether the captured student's voice is a valid input or not and this information is forwarded to the server.

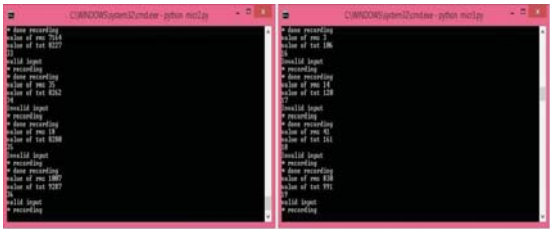

Fig. 4.1 Output of the speaker detection module in RC1 and RC2

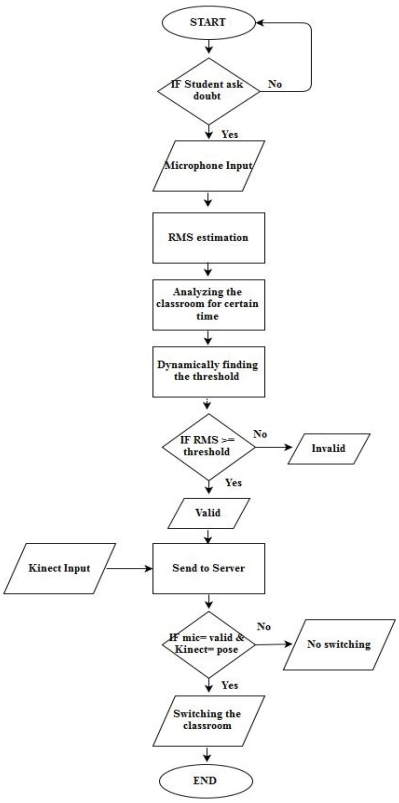

Fig. 3.4 Flow chart

- Gesture Recognition

When the professor enters the range of the Kinect camera, it will identify the professor who is in front of the camera. Initially, the calibration process has not started and it can track multiple people simultaneously and all the users have a unique ID. After that it will check to see whether the professor is in the calibration pose or not as shown in figure 4.2. If the professor has assumed to be in the calibration pose, then the skeleton detection and the skeleton drawing are initiated. The calibration process is not always successful. The skeletal drawing is initiated whenever the calibration process is successful. If the calibration process is not successful, then again the process has to be restarted to detect the calibration pose.

Fig. 4.2 Calibration of the professor when he/she is in calibration pose.

Whenever the professor identifies the classroom from which the student asks doubt by viewing the screens placed on both sides of the professor, he/she will show a particular gesture (poses) to the Kinect camera in that respective classroom. Here, we are using three different poses for each classroom. When the professor identifies the sound from the remote classroom 2 (RC2), he/she will show pose 3 as shown in figure 4.3 so as to switch to that classroom see figure 4.4.

Fig. 4.3 Pose 3 for remote classroom (RC2).

Fig. 4.4 Classroom switching after pose 3 initiated.

Similarly, pose 1 as shown in figure 4.5 will switch to remote classroom 1 (RC1) see figure 4.6.

Fig. 4.5 Pose 1 for remote classroom (RC1).

Fig. 4.6 Classroom switching after pose 1 initiated.

After the interaction from the remote classrooms, the professor will show pose 2 as shown in figure 4.7 to continue the normal classroom scenario see figure 4.8.

Fig. 4.7 Pose 2 to continue the normal classroom scenario

Fig. 4.8 Classroom switching after pose 2 initiated.

V. Conclusion and Future Work

We proposed an innovative approach to improve the interaction between the professor and the students in remote classroom in a multi classroom scenario. One of the major problems in a virtual classroom is that the remote students will not get much attention of the professor. This problem is avoided by using speaker detection and gesture recognition modules which will do the filtering of unnecessary sounds and switching of the classrooms respectively. A reliable and efficient interactive environment between teacher and student irrespective of the locations is ensured by the proposed system. As future work, we can enhance the proposed system with an added advantage of face detection and student hand raise gesture recognition modules. Whenever a student raises his/her hand, using Kinect and PTZ camera we can find that particular student and identify him/her. Details of that student can be displayed on the bottom of the screen so that the professor can vary his/her way of teaching according to the student's knowledge. Thus, the interaction of the professor and the students can be improved and some of the disadvantages in the present E-learning scenario can be solved by using this technique.

ACKNOWLEDGMENT

This project is partly funded by a grant from MPEC, National Knowledge Network (NKN), Department of Electronics and Information Technology (DeitY), Govt. Of India. We would also like to express our gratitude for the immeasurable motivation and guidance provided by Sri. Mata Amritanandamayi Devi (AMMA), Chancellor of Amrita University for doing this work. I would also like to express my sincere gratitude to Mr. Ram Kumar for the time he dedicated to help us in solving doubts at various stages of this research.

The Impact of Network Neutrality on the OTT Service of 5G WISDOM

Yapeng WANG, Ramjee Prasad
Center of TeleInFrastrukur, Aalborg University
Aalborg, Denmark
yapeng@es.aau.dk, Prasad@es.aau.dk

***Abstract*—This paper presents the influence that the Network Neutrality (NN) policy may bring to the Over the top (OTT) service and 5G Wireless Innovation System for Dynamically Operating Mega Communications (WISDOM) era. It reviews the evolution of Network Neutrality, figures out the main theme of Network Neutrality and its impact to OTT services. The paper collects and analysis the opinions from different sides, including the network providers, the OTT companies, governments and researchers and points out that there are still not enough evidence to prove the long term benefit of NN policy. Let the market decide maybe a better solution.**

Keywords—Network Neutrality, Over the Top Services, 5G WISDOM, regulation, impact, long term benefit

I. INTRODUCTION

With the internet service and application develops, the debates of the "network neutrality" has continued over 'one decade. The phrase of "network neutrality" is first used in a law review article [1] by Tim WU in 2003, welcomed by those who advocate freedom, competition and innovation. Originally "Network Neutrality" was only a concept suggesting that each network protocol layer should be independent and perform their duties. With the expansion of the internet commercial-scale, the focus of the competition switch from the connection and network layer to the application and content layer which make the debate of Network Neutrality switch from technological field to commercial field. And now it is a fight among telecom operators, Internet companies and regulators, especially after the OTT services appear.

OTT implies communications carried over the physical network infrastructure using an IP protocol to reach services available on the internet. An OTT application is any app or service that provides a product over the Internet and bypasses traditional distribution. Services that come over the top are most typically related to media and communication and are generally, if not always, cheaper than the traditional method of delivery [2].

WISDOM was first proposed in February 2008[3, 4]. It is a novel concept and the evolution to 5G era. WISDOM with 4G will lead to 5G realization. WISDOM can provide the wireless link rates in short-distance burst-mode at up to1T bit/s or up to 1Tbit/s of system aggregated traffic with sustainable symmetric link rates of larger than 250 Mbps to mobile terminal at high speed.

In terms of WISDOM research, 5G will provide services and applications offered by GIMCV (Global Information Multimedia Communication Village) as shown in Figure 1 shows. National and international zones constitute the Global information village which can be divided into macro cells including suburban, regional and national network, meanwhile, micro cells which includes city centers and highway networks constitute Macro cells which further contains small pico-cell (in-house network) where there are many small personal area networks (PAN). It gives scope of WISDOM application which varies from person in home to globe from where they belong to [3, 4]. In 5G WISDOM Era, OTT will play a very important role.

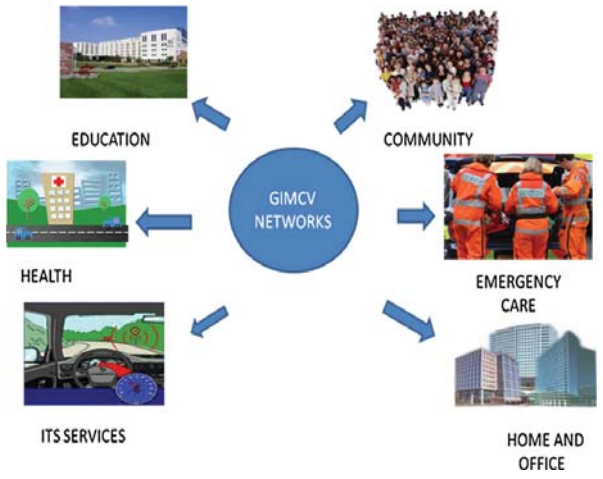

Fig 1: WISDOM in GIMCV applications

This article describes the evolution of Network Neutrality, main points of Network Neutrality, OTT services and the 5G WISDOM system. It also introduces the state of the art of OTT services, why OTT services become a focus. The article collects and analysis the opinions from different sides, including the network providers, the OTT companies, governments and researchers. Points out that at least for the long term, NN may be dangerous for the OTT Industry, 5G

WISDOM system and whole economy. The article considers that leaving the issue to market maybe a better solution.

II. NETWORK NEUTRALITY

Network Neutrality has been regarded as a hot topic for over one decade. The proponents think Network Neutrality will benefit the whole telecom market and industry, and encourage the service providers to innovate and become motivation of the society development. But the opponents think it will harm the whole telecom industry because it will aggravate the pressure on the network providers who is already in a difficult position.

A. The evolution of Network Neutrality

TABLE I

The evolution of Network Neutrality [5, 6]

Date	The evolution of Network Neutrality
February 2004	FCC called for Network Neutrality should encompass four Internet freedoms
August 2005	The FCC commanded the incumbent telecommunications carriers should share their DSL broadband connections with competitors, and approved an Internet policy statement reflecting Powell's four freedoms.
Decembe r 2010	the FCC approved three items Network Neutrality regulations including transparency, no illegal closure and no unreasonable discrimination. (mobile operator is not applicable)
January 2011	Verizon challenged to the net-neutrality rules, with the reason that the FCC did not have the authority to enforce them.
Early 2011	U.S. House of Representatives Republicans tried to overturn the FCC's net-neutrality rules without success.
Septembe r 2011	The FCC's new network neutrality rules was published in the Federal Register and originally taken effect on November 2011
Septembe r 30,2011	Verizon appeals the Open Internet Order to the D.C. Circuit challenging the FCC's authority to impose the Open Internet rules.
January 2014	The D.C. Circuit overturns the Open Internet rules, reaffirming the FCC's authority to promote the growth of the internet but telling the FCC that if it wants to treat internet access like a telecommunications service it cannot classify it as an information service.
May 2014	The FCC's proposal still tentatively concluded that it will allow fast lanes and slow lanes online, but also includes questions about Title II reclassification.
Novembe r 2014	President Obama reiterates his support for strong open internet rules and for the first time explicitly calls for those rules to be grounded in Title II authority.
February 2015	he FCC's new net neutrality rules was approved at 3-2according President Obama's recommendation
April 2015	The FCC's new net neutrality rules have been published in the Federal Register. As per normal process the rules are now scheduled to formally go into effect sixty days after publication, or June 12 of this year.
June 12 2015	The network Neutrality take effect

B. The key points of new Net Neutrality rules[7]

By the end of February 2015, the FCC approved new network neutrality rules and in mid-March has released the detailed rules and regulations. The new rule is the strongest one in the history. With that, FCC urged the network provider to treat all Internet traffic fairly. The new rule is approved at 3: 2 with three affirmative votes from Democrats and two negative votes from the Republicans.

The new network neutrality rules fold three key points, which are No Blocking, No Throttling and No Paid Prioritization and they are in detail as below:

- "No Blocking: prohibiting broadband providers from blocking lawful content, applications, services, or non-harmful devices.
- No Throttling: prohibiting broadband providers from impairing or degrading lawful Internet traffic on the basis of content, application, service, or use of non-harmful device. (including content, applications, services, or sound equipment);
- No Paid Prioritization: Prohibiting broadband provider from providing the differentiation services when they accepts payment (monetary or otherwise) to manage its network in a way that benefits particular content, applications, services, or devices and protect against "fast lanes" ."

In addition, FCC also proposed network providers " no-unreasonable interference/disadvantage" which means under which the Commission can prohibit practices that unreasonably interfere with the ability of consumers or edge providers to select, access, and use broadband Internet access service to reach one another, thus causing harm to the open Internet. This no-unreasonable interference/disadvantage standard will operate on a case-by-case basis and is designed to evaluate other current or future broadband Internet access provider policies or practices—not covered by the bright-line rules—and prohibit those that harm the open Internet. FCC claims that small operators who have less than 10 million users can exempt from these requirements.

C. The debate focus of new Network Neutrality

From the evolution of Network Neutrality, we can realize the difficulty of the approval of the Network Neutrality. And the debate focus of Network Neutrality is different at different phases of the internet development. Initially the network neutrality concerns the openness of internet and citizens' right to connect the network. The second phase is the reasonable needs of the Internet business model. By now, the focus switches to the legitimacy of the operators' network management strategy especially on OTT services management.

In recent years, Internet services develop very rapidly, especially with the emergence of OTT services, traditional

telecom services including the voice service and text message are being replaced by the OTT services. OTT services have become not only the focus of the competition between network providers and internet companies but also the debate focus of the network neutrality issue.

At this stage, the two points of "no blocking" and "no throttling" of network neutrality have reached the consensus in telecom industries. And the main debate focus is "No Paid Prioritization" which means the network providers should **not** provide differentiated services based on charges of QoS (here

the difference service means the different service qualities provided by network providers to internet companies). That is, the network providers should not charge the internet companies more money for the higher quality of broadband services, especially the OTT services such as Voice over Internet Protocol (VoIP) and video services. This paradox exist in other industry for example the highway operating. Governments charge the highway fee to construct and maintain the highway and most countries authorities charge according the size of the vehicle and the quantity of good they ferry. The current discussion is actually whether the Internet companies should pay for the high quality service and the large bandwidth consumption.

III. NN POLICY'S IMPACT ON OTT SERVICES

With the continuous emergence of the OTT services and the explosive growth of the traffic, network providers face threaten from internet companies. The industrial value is gradually transferring from pipe to content, from traditional communication network to internet and from voice services to information services. As a result, the dominate position of network providers is challenged and the traditional communication network is becoming the dumb pipe. According to the GSMA forecast, the data traffic will grow rapidly with more than 10 times than 2012 and the internet revenue will get to 290 million dollars till 2020 [8]. As an example of video services like Youtube which will occupy from 66% to 75% of the traffic on 4G network and 33% for video services and 34% for clear video. By 2020, it is estimated that the mobile volume will reach up to 2.1billion connections. [9]

But from the technical aspects, the current mobile communication cannot match OTT technology well. OTT services on the current internet not only occupy the network sources but also harm the network stability. As an example of the OTT communications services, in order to ensure instant online users, the OTT mechanism is to ask the communication system send signal frequently which make the signaling resources of the network operators been occupied constantly. Both in iOS and Android system, when the application is moved to the background, even though the user does not send any message, the signaling resource are being occupied till the application closed.

In the short term run, Network Neutrality will give the OTT services big development space, encourage more innovative applications and increase the efficiency of the society. But in the long term run, Network Neutrality will harm the enthusiasm of the investment on the network construction, make the quality of network worse gradually and weaken the connectivity of WISDOM paradigm, which also harm OTT service in the end. The reasons are as follow:

1) In technical aspect, NN will impact the quality of the OTT service because NN limits the ability to supply QoS of the network. Usually network providers guarantee the QoS of network in two ways, one is Resource Reservation Protocol (RSVP) and the second way is differentiated service (diffserv). RSVP is a signaling mechanism, which uses Integrated services (Intserv) semantics to invoke per-conversation traffic handling. RSVP simply provides a lot of resources with rich and secure equipment and it aims to cope with the expected margin in the "peak" demand. But it is expensive, and cannot cope with the scenario when peak demand is unexpected. Meanwhile, the deployment of additional resources is also time-consuming. Diffserv is an aggregate traffic handling mechanism to address scalability concerns associated with earlier approaches. The Integrated Services over Specific Link Layers (ISSLL) working group of the IETF has made a RSVP signaling model used with diffserv traffic handling to enable QoS in a scalable manner. In addition, by listening to RSVP signaling, network devices are more readily able to identify and classify traffic in order to determine the appropriate traffic handling mechanism [10]. But with NN, differentiated service is banned in public network.

2) In the original Internet, the network's objective is to provide a simple, but the best service. That is, the network makes the best-effort to deliver data packets without any guarantees for delay, bandwidth or losses. So the network operates like the default service offered by the postal service, which does not guarantee the arrival of a letter. But different applications do have different requests. Some services are very sensitive to delay, but not the packet loss and some services are sensitive to packet loss but not the delay. It is very necessary for a network to treat packets belonging to different applications differently in terms of their different requests. For instance, a network should give low-delay service to VoIP packets, but best-efforts service to e-mail packets [11]. Different OTT services also need different QoS.

3) QoS will play a very important role in 5G WISDOM network. 5G WISDOM will give us more bandwidth but QoS is also needed. As the OTT application development, the demand of the data resources will grow in geometrical progression. Over a period of time, the bandwidth demand of the network will be constantly higher than the capacity of network can provide. The network will always be a kind of scare resource. So QoS mechanism must be applied. In 5G Wisdom network, network provider should provide prioritization service to guarantee the services' quality. As we

know, video service is traffic-consuming and sensitive to delay. Packet Delay Budget(PDB), an important parameter of QoS will treat the delay with a confidence level of 98%. For example a test on requirement for delay in 3G, 4G and 5G network, if there is no quality assurance the packet delay budget of 3G, 4G and 5G are respectively undetermined, 100-300 and undetermined, but under the condition of quality assurance, the parameters change to 100-280, 50-300 and 1 respectively[9]. QoS is the guarantee of the new technology.

4) In social and economy aspect, NN may make network operators give up the investment plan on the network construction. The network cannot provide the qualified service when OTT companies overuse the network. The end result is a completely damaged network. It will reduce access to quality of services for everyone. Like the high-speed road free in holiday, it would absolutely cause congestion. Unsufficient investment on new network capacity with the increasing demand for bandwidth will result in network congestion. In order to maintain the steady operation of the network, Carriers will strictly manage the network. For example, AT&T had once blocked video applications.

5) Internet companies will also lose the incentive to improve the efficiency of content services transmission, because NN will limit the cost on content distribution on telecom Network. That easily lead to unreasonable overuse of the network resources and network operator can do little. Traffic congestion and bad QoS will be the result. China's mobile Internet, especially OTT services developed quickly in the past two years, the radio network signaling storm. It has also caused operators and Internet companies of saliva war.

6) FCC's final purpose should be prosperity and Internet innovation, not the death of traditional telecom operators. As we know, the funds usually float to the market with big profits, so it is obvious that when NN was enacted, less investments will go to the network operators and thus lead to loss of the investment incentives for the telecommunications industry, which will be a serious challenge to those traditional network constructors. That will also force those large scale internet companies construct their own networks, like Google is doing. It may be of some benefits, at least make them understand more of each other.

IV. CONCLUSIONS

The emergence of "net neutrality" debate accompanied with the new challenge and demand to traditional telecom network, business model and operation method was made by the internet economy. The attitude to NN of most regulators in worldwide except US is cautious, because NN will influence not only the internet investment, innovation and vitality but also the telecom infrastructure construction and upgradation. On the one hand, considering the rate of return on investment (ROI), in capital market, Internet applications and content services (such as OTT) attracts more funds which is significantly higher than the network infrastructure construction and maintenance. As the main role of the telecom industry chain, the ROI of the network providers is not high and the paradox of traffic growth without revenue growth becomes more and more severe. But the benefits of the network providers and investors should also be protected because the network infrastructure construction and upgradation are the basis of the healthy development of the whole telecom and Internet industry. On the other hand, we should also protect the internet companies who provide the OTT services because they are the motivation of the innovation, the source of the revenue and benefit the whole society. How to balance the interests of the two sides is a big challenge and problem to the telecom regulators. NN by now should not be considered as a final solution. It will be much better for the paradox be solved by the market and competitions, all the stake holders can find a way to ensure the prosperous development of the industry in the market on their own, especially in 5G WISDOM era.

***Abstract*— Wireless Sensor Network (WSN) is quickly emergent research field. The sensor is a fundamental part of WSN. IT has the bulk amount of sensor nodes which is arbitrarily deployed in given sensor field that collects, processes and sends the data back to the base station. It has the quality of service (QoS) parameters such as Congestion, energy, throughput, reliability and so on. Reliability is uniformity in calculating results. A system is said to be reliable if and only if it gives equal results constantly. To increase the reliability of a particular system, we introduce a new method called, "Adaptive Sectoring Scheme for Reliability" (ASSR). In this method, the given sensor field is divided into some sectors and at a time we activate current sector only in which an event happens. To minimize the congestion as well as increasing throughput with maximum packet delivery ratio, we ought to adjust sector dynamically to perform data transmission process effectively and efficiently. In this paper, different parameters are used for calculating reliability that gives better results in terms of packet delivery ratio, packet loss ratio, control overhead, throughput, and energy consumed.**

Keywords— Energy; QoS; Reliability; Sectoring; WSN

I. INTRODUCTION

Wireless Sensor Network consists of sink node called as a base station with unlimited energy and multiple sensor nodes with limited energy. Out of this sink, the node is secured but sensor nodes are unsecured. In WSN, sensors nodes are randomly distributed in given environment to collect the information about the changes occurred in the atmosphere of temperature, pressure, humidity, soil content, etc. and sent these noted readings back to the base station [1].WSN is most widely used in real world applications such as weather forecasting, tsunami detection, volcano sensing, and earthquake predictions and so on. It is an easy and good solution for the various applications. Since it is used to a great extent from last few years, it will be useful for future works also. It introduced a new way to perform our jobs within specific time durations. It can establish a connection between different sensor nodes across the given network [2]. The fig. 1 shows wireless sensor network. Different sensor nodes are placed in the sensor field. These sensor nodes are densely deployed in a given network. Source node collects the information from the area and sends it to sink node. The path followed by them is also shown in fig. 1

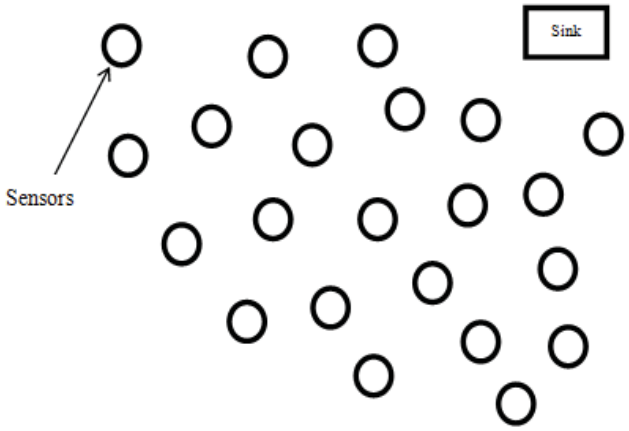

Fig. 1. Wireless Sensor Networks.

A cooperative effort of sensor nodes is one of the unique features of sensor networks. Sensor nodes use limited power and memory, and it uses broadcast communication. There are various types of sensors as seismic, magnetic, thermal, infrared, acoustic, and radar. Wireless sensor network costs efficient than wired sensor network. However, it is difficult and time-consuming in the case of the wired sensor network. As the nodes are widely distributed, it collects the respective information from surroundings and will forward this information finally to sink through the routing nodes. There may be the possibility of packets loss during transmission; hence we need to resend the packets to the destination. It creates multiple copies of single packets that result in the increase of reliability of the system [3].WSN is cost efficient than wired network because wired sensor networks are more costly to implement across the network. It is beneficial for many users to used WSN which minimizes the establishments cost of the network[3]. However, in the case of the node failure, we can replace nodes easily and quickly. However, it is difficult in the case of a wired network. As the sensor nodes are widely distributed in a given surrounding, noted down the readings and sent them back to the sink node. There may be possibilities of packet loss during this data transmission process hence we need to resend the

packets to the destination that may result in multiple copies of the single packet. It may increase the reliability of packet data[4].

Reliability is the consistency in measuring the results of any test. A test is said to be reliable if and only if it produces same results repeatedly. It is the most challenging task to send the packets with high speed and more reliability. As the number of packets reaching the destination increases, the reliability of system also increases. However, it also creates traffic or congestions in the traversed path and puts an extra load on one hop away node from the sink. It also minimizes the life of nodes. We must replace them after regular interval of times. Hence, it is a major challenge to find a way that reaches the position, where we can achieve more reliability by controlling congestion, and other parameters in wireless sensor networks like, Energy, Delay, Congestions, Throughput, and so on [3].

II. Related Work

Dukhyun Chang et al. [5] states that flooding is the mechanism in which a message sent by source node propagates throughout the complete network. The fundamental aim of flooding mechanism is to ensure that all the nodes present in given network must take delivery of that same message. This paper proposed a probabilistic and opportunistic flooding algorithm (POFA) which is used to control, rebroadcast and retransmission of data packets to attain superior target reliability. In this method, a given node will select only the subsets of its one-hop neighboring nodes called as multipoint relays (MPR) to rebroadcast the same message. While selecting the eligible neighbors to consider the link error rate. The number of retransmissions is be controlled by the sender by knowing the present states of message reception at its neighbors. Let R be network wide reliability of node, the node that received the message will forward that message, to its one-hop as well as two hop neighboring nodes for which nodes will select Reliability-aware Multipoint Relays (RA-MPR) nodes. Suppose that all of the one-hop neighbors are elect as RA-MPRs in this subsection. The first sender who is to broadcast a message will calculate an expected delivery probability (EDP). The EDP is the ratio of the expected number of close neighbors that will receive the message probabilistically to the number of all close neighbors.

Hong Luo et. al. [6] States that in wireless sensor network reliable and energy efficient data transmission process is necessary. For this data fusion process is used, in this the combination of data packets into large packet takes place that contains more correct and abundant information than individual packets. In fusion data tree, each node fuses all its incoming packets into a single packet by its own and then forwards it to its parent node. Here we use different topologies of data packets such as star, tree, chain, etc. If the packet size of the fused packet is either smaller or larger than the size of the original data packet, then this type of fusion is called as partial fusion. If the packet size of fused data is equal to the original data packet, then this type of fusion is called as full fusion. Information weight of a fusion node is the sum of all information weights of received packets including its weight. The author studied the difficulty of minimum energy reliable information gathering (MERIG) with unreliable data fusion structure. The basic idea is to allocate dissimilar transmission reliability to the packets having different information weight. They used multiple transmissions without acknowledgments that minimize latency of data packet delivery and promise the desired transmission reliability

Tien wen sung et. al. [7] states that in directional wireless sensor networks sensing angle and directionality of sensors are the two significant characteristics to calculate sensing coverage area. To study properties of Voronoi cell diagram and direction, adjustable sensing angle are used. The Voronoi cell is a geometrical structure having special properties. These Voronoi cells can be constructed by drawing a perpendicular bisector of a line that joins each sensor pair. These bisector lines form Voronoi cells boundaries called as Voronoi edges and endpoints of these edges are called Voronoi vertices. The author studied the distributed greedy algorithm to find near optimal solution. The directionality of sensors is selected and adjusted based on three criteria as firstly, to increase the area inside the Voronoi cell. Secondly, to minimize the overlapped coverage area between the sensor and its neighboring cells and finally, to reduce the sensing coverage area outside the sensing field.

Reliability is the most important factor of wireless sensor networking. The data transmitted from the source must be completely received before destination end with or without a minimum packet loss then the transmission is said to be reliable [8, 9].

III. Proposed Work

In proposed algorithm, the aim is to achieve desired reliability by using Adaptive sectoring method. In this method, the given networks are divided into N number of sectors and at a time keep current only one sector activate which helps to avoid congestion and consume less energy. After an event occurs, all data packets will send their data to their respective sector head and ultimately it is forwarded to destination sink node.

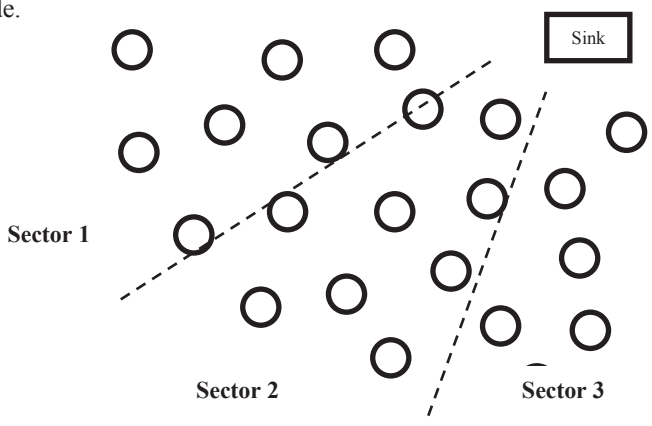

Fig. 2. Proposed Sectoring Scheme

Fig. 2 shows after sectoring method where the given sensor field is divided into three different sectors. If an event occurs in any one of these sectors, then only the current sector is activated which belongs to that event, and all other remaining nodes remains in idle conditions i.e. they do not take part in the data transmission process. Here we get better data reliability and less energy consumption in after sectoring method than before sectoring method.

As shown in the figure, after using sectoring method we divide the sensor networks in n number of sectors logically. Wherever the event occurs, the only current sector is activated, other sectors nodes are in sleep mode. Nodes, which belong to the sector in which the event occurred, transfer the packets to their respective SH within the event sector only. Finally, transfer the packets to sink.

Algorithm: Adaptive Sectoring Scheme

1. Divide given sensor node area into N number of sectors.
2. A node that is closer to sink declared as Sector Head (SH).
3. Let θ will be the angle of one sector; such that
   θ = TotalAngle / N
4. Let Δθ will be maximum angle of θ; such as max(Δθ) = θ
5. If an event occurs then, current sector nodes are activated.
6. Let dθ will be the incremental angle of the current sector.
7. Calculate Δθ = θ ± dθ
8. To find Observed reliability (Ro) and Desired Reliability (Rd) such that Ro = No. of packets received / No. of packets send.
   Rd = No. of packets received / (PD)*100.
9. (If Ro < Rd) then
   Calculate New angle of sector (θ(n) = θ(c) + dθ(n)); where θ(c) is the current angle of the sector. Adjust the sector dynamically by θ(n)
   Data packets are transferred to the sink via their receptive SH
10. End if
11. Go to statement 8.

These algorithms mainly run on each node including Source and Sink of the network with minimal functionality at the source nodes. More precisely, sensor nodes only need the following functionality.

Considering Sink node as Corner, divide given area into n number of sectors. A node that is close to sinking is declared as Sector Head (SH). If an event occurs then activated nodes present in current sectors only. Remaining sector nodes keep in the idle condition that is they neither transfer packets nor receives them. Rotate the sector dynamically accordingly to find the shortest path and avoid congestion. Data packets are transferred to the sink via their receptive sector head (SH). Firstly divide the given network area into N number of sectors by taking sink node as at a center position. Secondly, Find the node that is close to the sink node then assign it as a Sector Head (SH). Then start the data transmission process so that an event occurs in a given network area. During the data transmission process, the source node will transmit data packets to the destination. It may lead to the congestion in a given network that results in packets loss. Hence, we need to retransmit the lost data packets to the destination node.

When an event occurs, then activate nodes that are present in a given sector only. The rest of all nodes automatically goes into starvation mode means they neither transmit the packets nor receives them. The path taken by packets for data transmission process is the shortest path among all available paths. If necessary, rotate the given sector dynamically so as to transmit data packets faster. Due to the specified path, the congestion is avoided which ultimately helps us in minimizing energy consumption by nodes present in the network. Data collected by the nodes will be collected at their respective sector head and from sector head it is forwarded to sink node. AODV works within the sector. It doesn't choose the path outside of the sector. Hence within sector only shortest path is found. Route request & route reply messages are interchanged in given sector.The single hop node from the sink will be chosen as sector head. This persists as long as N/W exists. SH is rich device & has higher resources than other nodes. There is no computation performed as it is there in clustering approach; every packet must be trace passed through SH to reach to the sink. Reliability can be calculated in terms of PDR at N/W level rather than at particular Node.

IV. RESULT ANALYSIS

The testing scenario for the analysis uses Tool NS-2(Network Simulator-2). The topology used is Uniform Random. The Area of Sensor Field will be 1000*1000 m. The MAC Protocol used is IEEE 802.11 and Routing Protocol is AODV(Ad-hoc On Demand Distance Vector) used. Number of Nodes are 30 within the given field. Packet Size is 50 bytes and Reporting Rates varied from 10 to 50 packets / sec with the step of 10 packets per sec.

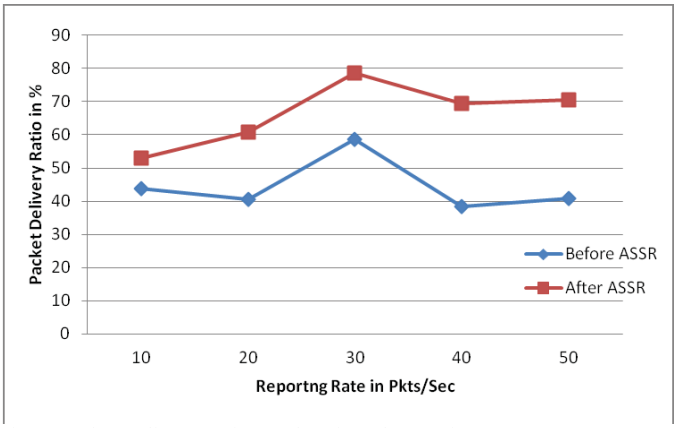

Fig. 3: Packet Delivery Ratio as a function of Reporting Rate

Fig. 3 shows the packet delivery ratio as a function of reporting rate. As the reporting rate is increasing the packet

delivery is decreasing. This is because as the reporting rate is increasing the numbers of packets in the networks are also increasing. However, the processing speed and the storage capacity of the nodes are constant. They are not increasing with respect to the reporting rate. So the packet drop also increases as we increase the reporting rate. The packet delivery ratio of After ASSR is approximately 30 percent greater for reporting rate 40 pkt/sec before ASSR was applied. The other quality of service parameter like packet loss ratio, throughput, and controls-overhead shows better performance than the Before ASM.

Fig. 4 shows the packet loss ratio as a function of reporting rate in packets/sec. As the reporting rate is increasing the packet loss ratio is decreasing. Firstly when the reporting rate is ten, then packet loss ratio is high. However, as reporting rate increases, packet loss ratio decreases. However, it is up to certain threshold point 30, after which as reporting rate increases, there is a respective increase in packet loss ratio. The packet loss ratio of After ASSR is approximately 50 percent greater for reporting rate equal to 30 packets/sec than the case for Before ASSR.

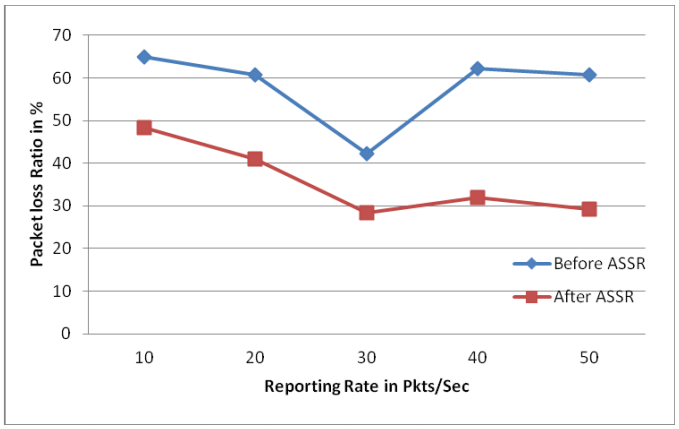

Fig. 4. Packet Loss Ratio as a function of Reporting Rate

The graph is shown in Fig. 5 is the Control Overhead variation for reporting rate. As the reporting, rate increases the Control Overhead increases. Firstly when the reporting rate is ten, then Control Overhead is small. However, as reporting rate increases, Control Overhead remains nearly constant. The packet loss ratio of After ASM is approximately constant than the Before ASSR. Control overheads can be measured at MAC as well as routing layer. RTS/CTS & other handshaking signal or messages are a part of MAC layer control overhead. Route request/route reply will be contributed as N/W layer control overhead. After sectoring scheme implementation, overall control overhead will be drastically reduced.

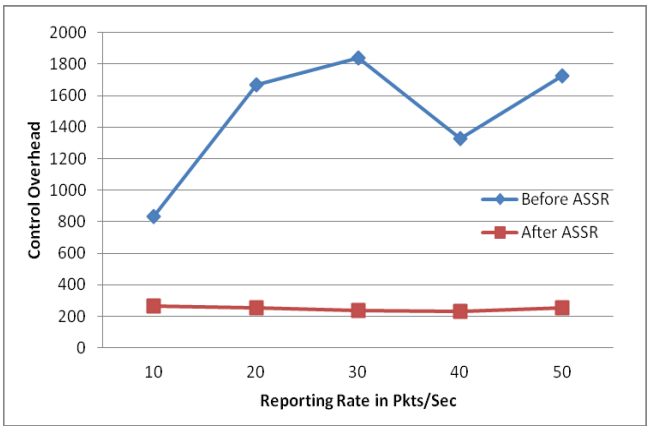

Fig. 5. Control overheads as a function of Reporting Rate

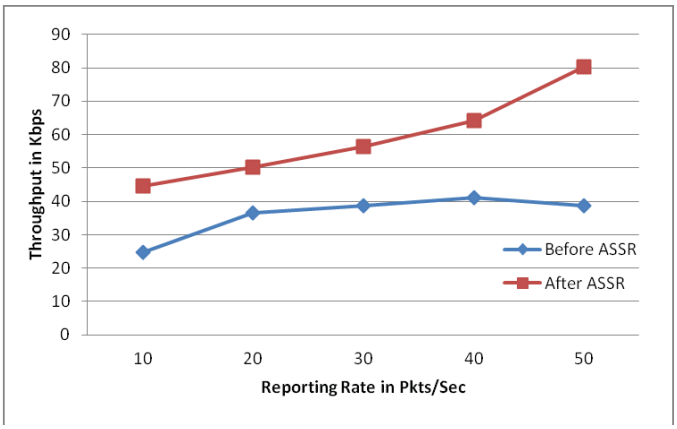

Fig. 6. Throughput as a function of Reporting Rate

The graph is shown in Fig. 6 shows the Throughput in kbps as a function of reporting rate in pkts/sec. As the reporting, rate increases the throughput increases. Firstly when reporting rate is ten then throughput is low. However, as reporting rate increases, throughput increases drastically. The throughput of After ASSR is approximately 50% greater for reporting rate 50 pkts/sec than reading before ASSR.

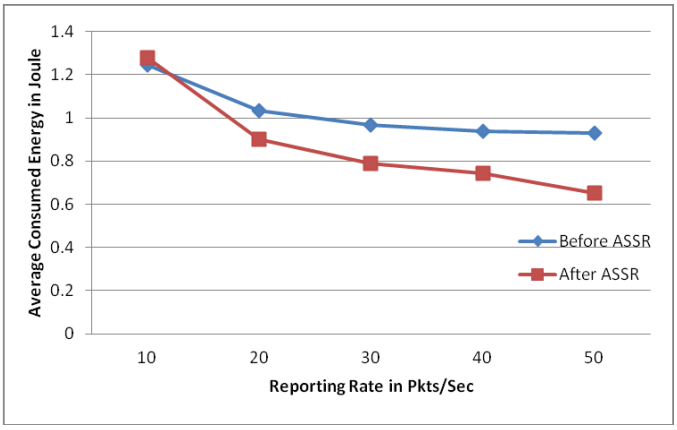

Fig. 7. Consumed Energy as a function of Reporting Rate

The graph is shown in Fig. 7 shows the Energy consumed in joule as a function of reporting rate in pkts/sec. As the reporting, rate increases the energy decreases. The energy

consumed after ASSR is approximately 30% greater for reporting rate 50 pkts/sec than before ASSR.

V. CONCLUSION

Reliability of sensor network can significantly be enlarged through the use of adaptive sectoring Scheme for Reliability (ASSR). By using Adaptive Sectoring Scheme Algorithm one can increase packet delivery ratio, minimize packet loss ratio and energy consumption, also we are successful in lowering control overhead. The proposed Adaptive Sectoring scheme gives more reliability, i.e. packet delivery ratio increase by 63.33%, packet loss ratio is minimize to 25%, throughput increases by 75% with less control overhead, and energy consumption is minimized to 20 percent when a number of nodes are 30.

***Abstract*— Quality of Service (QoS) assurance in Wireless Sensor Network (WSN) is a tough task, and it is more exciting due to the scarcity of resources. The requirement of different WSN applications running over has different constraints. In QoS, routing protocol the network has to balance the traffic. This paper presents a novel heuristic routing algorithm known as QoS Assured Multi-Objective Hybrid Routing Algorithm (Q-MOHRA) for Heterogeneous WSN. Q-MOHRA takes into account the link (energy, hop count, link quality indicator etc.) and path (jitter) metrics for optimal path selection. The performance of Q-MOHRA is evaluated through intensive simulation and equated with Simple Hybrid Routing Protocol (SHRP) and Dynamic Multi-objective Routing Algorithm (DyMORA). The metrics such as Average Energy Consumption, Residual Energy, Packet Delivery Ratio, Jitter, and Normalized Routing Load are used for comparison. The performance of Q-MOHRA has been observed to outclass SHRP and DyMORA. It improves the Packet Delivery Ratio (PDR) by 13.72% as compared to SHRP and 28 % as compared to DyMORA. Q-MOHRA outperforms SHRP and DyMORA in terms of Average Energy Consumption (AEC) by a factor of 4.2 % and 2.3 %.**

Keywords—WSN; Routing; Hybrid Routing; Multi-Objective; Cluster; Energy Efficiency; Quality of Service

I. INTRODUCTION

The significant and express advancements in the field of wireless technologies and particularly rapid growth in the area of Micro-Electro-Mechanical-Systems (MEMS) have made Wireless Sensor Networks (WSNs) part of pervasive communications for conveying, accessing and storing information across different platforms. In WSNs, huge no of sensor nodes are placed in remote target areas for collecting, processing and transmitting data to the Base Station (BS) [1]. The sensor nodes mainly characterize WSNs. The different attributes of the sensor nodes include small size, limited battery, inadequate processing capability, restricted memory and range of communication, mobility of sensor nodes, etc. [2]. WSNs have gained remarkable consideration from most of the researchers in the field of wireless due to their widespread applications. WSNs have many diversified applications such as monitoring physical or environmental conditions (vibration, pressure, temperature, sound etc.), battlefield monitoring, civilian and military applications, habitat monitoring, home automation, healthcare applications, asset tracking etc. Increasing the life of sensor node and making the WSNs energy efficient is the prime goal in all the WSNs applications due to scarcity of resources [1, 2].

Due to the shortage of energy of wireless sensor nodes in almost all applications, lot of research work has been done in the routing protocols. The requirement of all the routing protocols differs from application to application. In spite of that, the prime goal of all the routing protocols is to conserve the energy and increase the life of the network and the time of partition. The routing protocol will select the route from source to destination in the finest effort delivery manner [3].

In many traditional routing protocols, only limited number of nodes is involved in sending data packets from source to the destination while other nodes stay practically idle. The energy of the nodes those engage in the communication process depleted at a very fast rate. These nodes will quickly die out when the energy is completely drained. The dead nodes may cause partition of the network or disconnection of the link. This paper has made an effort to evade this. The prime goal of this paper is to distribute the energy uniformly across the network and to increase the network lifetime. Traditional routing algorithms use few parameters and put some conditions or threshold value for routing procedure [4, 5]. The contribution of this paper is a novel heuristic multi-objective hybrid routing with QoS assurance for heterogeneous WSNs. This protocol uses a novel weighted sum method to obtain optimal solution in order to resolve the multi-objective routing problems of existing protocols. Q-MOHRA applies multiple measures for the selection of the best route from source to destination. The various measures are (i) Reaction Time (ii) Control Overhead (iii) Average Energy consumption (iv) HOP Count (v) Link Quality Indicator. Q-MOHRA selects the energy efficient route. Packet Delivery Ratio (PDR), Average Energy Consumption (AEC), Jitter, Normalized Routing Load (NRL), etc. are the few QoS parameters used to compare the performance of Q-MOHRA. The performance of Q-MOHRA is superior compared with the state of the art solutions.

The remainder of the paper organized as follows. Section II summarizes the different multi-objective decision-making protocols. Q-MOHRA explained in section III. Section IV describes the simulation details and analysis of results. Section V concludes the work.

II. RELATED WORK

Many researchers based on various, criteria, design issues and applications in order to increase energy efficiency have proposed several multi-objective routing protocols [6].

Nevertheless, no routing protocol is ideal, which can be used for different applications and for different purposes.

The main purpose of Multi-Objective Swarm Optimization (2LB-MOPSO) [9] algorithm is to detect permanent and intermittent faults based on the multi-objective approach. It tries to find out the balance between detection accuracy and detection latency. This algorithm identifies defective sensor nodes based on the comparison of sensed data between one-hop neighboring nodes. It uses time redundancy to detect intermittent faults. This paper has demonstrated the effectiveness of the algorithm by using the multi-objective QoS parameters. The authors of the paper recommended using the parameters such as are Detection Accuracy (DA), False Detection Rate (FDR), diagnosis latency, network lifetime, and packet delivery ratio. The authors have also suggested a multi-objective optimization technique to identify an intermittent fault.

The authors in [10] proposed an innovative multi-objective routing optimization approach using evolutionary algorithms. This evolutionary algorithm tries to find out the trade-off between minimum lifetime and the average lifetime of nodes in the network. The authors have proposed a novel approach known as "k-shortest paths based search space pruning in conjunction with a new edge metric" in order to achieve faster optimization and to allow dynamic optimization. Due to scarcity of computing resources this evolutionary algorithms uses a centralized approach. The evolutionary algorithm tries to maximize the minimum lifetime of any node in the network together with the average life of all nodes in the network. The evolutionary algorithms use packet- loss ratio and QoS performance indicators as a feedback mechanism to upgrade the overall performance of the system when it declines.

Multi-Objective QoS Routing (MQoSR) [11] uses an empirical neighbor selection mechanism. It combines the geographic routing mechanism and QoS routing. MQoSR takes into account the quality of service parameters such as reliability, delay, distance to sink, energy, end-to-end delay, reliability and network lifetime. MQoSR builds multiple disjoint paths. MQoSR divides these QoS parameters into link QoS parameters and path QoS parameters. Link QoS parameters enable MQoSR to select the next hop and path QoS parameters allow to reduce the overall network resource consumption.

Multi-Objective Evolutionary Algorithm based on Decomposition (MOEA/D) [12] is designed to solve the energy conservation problem in WSN. MOEA/D solves the Multi-Objective Problem (MOP) by using problem-specific knowledge. MOEA/D divides the MOP into many sub-problems those can be optimized concurrently by using the local problem specific knowledge. MOEA/D alleviates the problem of unnecessary searches and harsh coupling, negatively affecting their overall performance. Functioning of MOEA/D solely depends on randomly generated internal population and calculation of the Euclidean distances between the weight vectors for generating more quality solutions. In MOEA/D, the optimization depends on sensors clustering with the choice of appropriate cluster-heads (CHs) and the active or inactive status of sensor nodes.

AACOCM [13] proposes a multi-objective model based on bandwidth constrained. AACOCM optimizes the route up to the destination based on multi-objective function. The multi-objective function tries to optimize multiple metrics such as energy consumption, network delay, and packet loss rate simultaneously. Each metric is associated with a weight. The algorithm adjusts well to several services by adjusting the weights. The prime goal of AACOCM is to reduce energy cost, delay, and packet loss ratio. AACOCM, defines three categories of they are, ordinary ants, greedy ants, unusual ants. In this algorithm, the progression of any ant from the source node to the destination node is a process of building a routing tree. Once the routing tree is constructed, the data is transmitted to the destination along the tree. The move probability of ordinary ant depends on the pheromone intensity trajectory and heuristic factor. Greedy ants pick the node having greatest probability as the next hop node. AACOCM uses adding positive and negative feedback mechanisms and depends on a cloud. . AACOCM is suitable for the large-scale network. The convergence rate is high in AACOCM.

For routing in WSN, the authors of [15] have proposed a framework. IT is adaptive, constraint-based, and multi-objective, and it is solely dependent on localized knowledge of each node. The authors have defined a routing task for each message m. The routing function depends on source id, single destination or a group of destination, local route constraints (LRC) and routing objective (RO). LRC applied to the current node's neighbors attribute. LRC could be avoided low-energy, hazardous areas, etc. RO depends on multiple attributes for optimizing the route. The various attributes are minimizing hop count, using the maximum energy level route, reducing hazard on the route.

Simple Hybrid Routing Protocol (SHRP) [16] is one of the energy saving protocol in WSN. SHRP selects the optimal route based on the hop count, link quality, and battery life. SHRP forwards the data only if there is a change compared with last sensed data. Among the multiple available paths, SHRP picks a route that has lesser hop count and larger available energy. If the sensed data remains unchanged during a prescribed period, SHRP forwards the data periodically to the BS. SHRP tackles the bad connection and dead neighboring problem with the help of minimum threshold.

DyMORA [16] uses the concept of Hybrid Routing Algorithm (HRP) from SHRP but it alters the mechanism with which the optimal route is selected. DyMORA is comparable with Hierarchical Routing Algorithm (HRA) that is an original version of SHRP. In terms of consistency, and time convergence DyMORA uses less energy level, but it needs more processing time. DyMORA uses multiple metrics simultaneously in order to select the best route up to the BS in critical situations or during energy crises

III. QoS Assured Multi-Objective Hybrid Routing Algorithm (Q-MOHRA)

Many everyday optimization problems have more than one trait to be considered at the same time, i.e., multiple objectives to be minimized or maximized. In multi-objective optimization domain, the researchers have identified different approaches. In scalarization approach, the multiple objective problems are

combined into a single function by using weighted sum approach. In the second approach, the domain expert might rank the objectives according to some order of preference. In this case, the domain expert access the objectives based on some predefined order. The second approach is known as lexicographical approach. In most of the real life problems, the multiple objectives are conflicting with each other. The above methods are not suitable to provide full set of optimized solutions as they introduce some prejudice. They offer few solutions, which will not often cover the entire set of objective space [8]. Unlike the scalarization and lexicographical approaches, Multi-Objective Hybrid Evolutionary Algorithms consider that all the objectives of a problem should be considered simultaneously. In order to tackle the complexity in a situation when multiple objectives are conflicting with each other, the algorithm should provide Pareto optimal solution such that the objective functions cannot be further optimized.

A. Assumptions to implement Q-MOHRA:

The entire target area is divided into small clusters. Each cluster has Cluster Heads (CH) and Cluster Member (CM). The sensor nodes are haphazardly placed in the target area and they are stationary. All the sensor nodes are heterogeneous in terms of initial energy. The CMs are liable for sensing the events in the nearby area. All the CMs harmonize themselves for selecting the CH. The CMs communicate only with the CH of that cluster or the CMs of the same cluster. They are not allowed to talk to CMs or even CH of the other cluster directly. The CHs have a second level of hierarchy. The CHs can communicate with the CHs of another cluster. The Base Station (BS) is a high-energy node situated away from the target area. The BS can communicate to any CH or CM directly. The Cluster Member (CM), Cluster Heads (CHs) and the sink node are stationary. The sensor nodes are not GPS enabled. At the outset, the density of sensor nodes in the target area very high as it helps for the cluster based routing.

B. Network model of Q-MOHRA:

As shown in Fig. 1 illustrates the WSN modeled as a graph G. Here, the vertices of the graph are nothing but sensor nodes of WSN. The graph G= (V, E) where V= {v1…..v2} is set of vertices, and E {(ni, nj) V x V | i ≠ j} is a set of edges between vi and vj. The graph G is modeled as a set of small clusters. The communication within the cluster (i.e. between the CMs and CMs or CHs) and the communication among the cluster (i.e. between the CHs and CHs is categorized into different levels of hierarchy. At the first level in the hierarchy, CMs within the cluster elect a CH based on a weighted average of multiple criteria (metrics) as mentioned in section III. The CMs will forward the data to the CH using multihop communication. The CMs will organize themselves like a pyramid. As we move, up in the pyramid the weighted average of multiple metrics increases. It is a rational organization and not physical arrangement. The node having greatest weighted average is CH. After successive rounds of communication, the role of CH is switched among the different CMs. This rotation of the role of CH among different CMs will balances the energy in the entire network. At the second layer of the hierarchy, all the CHs will organize themselves like a pyramid and the communication procedure is same as that of intra-cluster communication. The CH is elected in each round at each level. The elected CH will forward the accumulated data to the BS after applying some aggregation function to the accumulated data.

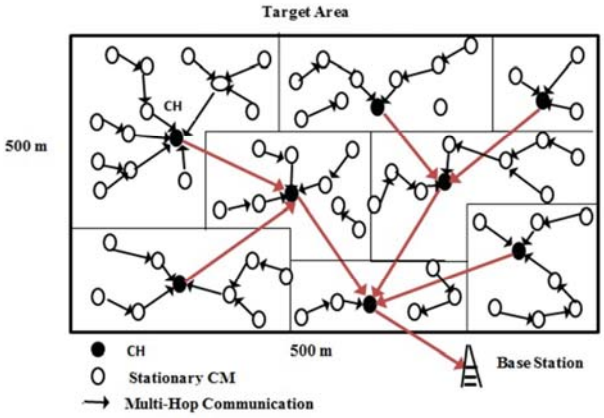

Fig. 1. A Clustered Wireless Sensor Network

C. Q-MOHRA Algorithm

Q-MOHRA is a multi-objective hybrid routing protocol based Weighted Average Method (WAM). At a high level, Q-MOHRA operations are forked into three phases.

- Establishing Neighborhood Relationships
- Routing
- Data Forwarding

1) Establishing Neighborhood Relationships

In Q-MOHRA, the routing scheme starts with Building Neighborhood Relationship. Each node has a routing table and it maintains a list called as neighborhood information. The routing table has following information for each neighbor

Neighbor ID	energy	LQI	Overhead	rtime	hops

The procedure for Building Neighborhood Relationship is as follows

- After power on a node-N in the network will broadcast a Hello Packet out to discover 1–hop neighbors.
- If a 1-hop neighbor is available then in response to the Hello packet the nodes will send a reply message.
- The reply message will contain the information about Neighbor ID, energy, LQI, Overhead, rtime and hops.
- On receipt of the reply message, the node-N will attempt to establish a neighborhood relationship with new nodes.
- Node-N will add the information about the new nodes directly into the routing table.
- All these steps are repeated periodically or whenever there is a change in the network.

2) Routing

The optimized route is calculated based on the routing table. Each node will calculate a weighted average of multiple metrics (score) as mentioned in TABLE I for each neighbor available. The score is calculated based on WAM. The CH election is based on a global parameter [7] as

$$f(n_{ij}) = \alpha.m_{energy}(n_{ij}) + (1-\alpha).\Big[\beta.m_{overhead}(n_{ij}) + (1-\beta)\Big[\gamma.m_{rtime}(n_{ij}) + (1-\gamma)\Big[\delta.m_{lqi}(n_{ij}) + (1-\delta)[\eta.m_{hops}(n_{ij})]\Big]\Big]\Big] \quad (1)$$

Where $0 \leq \alpha, \beta, \gamma, \delta, \eta \leq 1$ and $\alpha + \beta + \gamma + \delta + \eta = 1$ are weighing factors. All CM will evaluate the cost function according to the updated values in the routing table. CMs will form a pyramid (logical) and the CM with largest weighted average becomes the CH for the next iteration.

3) Data Forwarding

The data packet is forwarded up in the pyramid (forwarded to parent node in multi hop communication). The information about whom to forward is available from the routing table. The packet will get propagated up in the hierarchy. This is continued until the data packet reaches the sink node.

IV. Simulation and Result Analysis

The simulation is carried out using Network Simulator (ns2.34). The aim of the simulation is to annotate the QoS parameters and compare the Average Energy Consumption (AEC), Jitter, Normalized Routing Load (NRL) and Packet Delivery Ratio (PDR) in Q-MOHRA, SHRP, and DyMORA. To authenticate the performance of Q-MOHRA, following simulation parameters mentioned in Table II are used

TABLE I. Simulation Parameters

Parameter	Q-MOHRA	SHRP	DyMORA
Area (m)	500 * 500	500 * 500	500 * 500
Simulation time (s)	200	200	200
Initial Energy (J)	10	10	10
Rate :	0.2	0.2	0.2
Packet size (bytes)	512	512	512
Simulation Time	200 s	200 s	200 s
Number of nodes	50 -100 in step of 10		
Radio Model	TR3000		
Transmission power	24.75mW		
Receiving power	13.5mW		
Idle Power	13.5mW		
Sleep Power	15µW		

A. Packet Delivery Ratio (PDR)

PDR gives the liaison between the total number of packets received by the destination and overall packets produced by all the nodes. Fig. 2 demonstrates the packet delivery ratio of Q-MOHRA, SHRP, and DyMORA. Due to the multi-criteria mechanism, Q-MOHRA has PDR higher than DyMORA by a factor of 28.63 % and a factor of 13.8% than SHRP in various circumstances due to routing of the packets on an optimized route. The PDR confirms that the sensor nodes are used efficiently for advancing data packets. This results into increase of network life. In Q-MOHRA, PDR is higher because each node selects the optimal path based on multi-objective metrics .

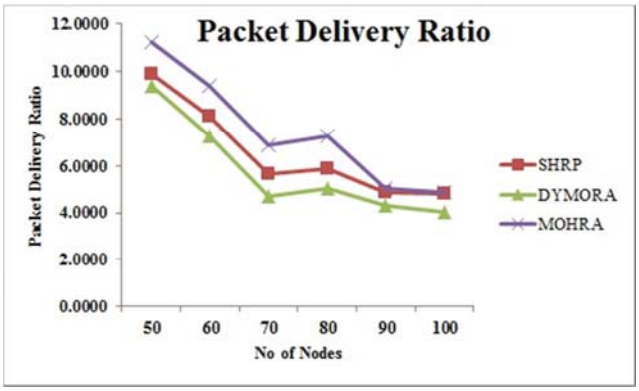

Fig. 2. Packet Delivery Ratio.

B. Average Energy Consumption (AEC)

AEC is a ratio of sum of the energy consumption of different nodes to the sum of total number of nodes. Fig. 3 shows the average energy consumption. AEC of Q-MOHRA is lesser than DyMORA and SHRP in several circumstances due to hierarchical clustering. Q-MOHRA outperforms SHRP by a factor of 2.3 % and DyMORA by 4.2 % in terms of AEC. This saving of energy extends the life of the overall system and illustrates the effectiveness of Q-MOHRA.

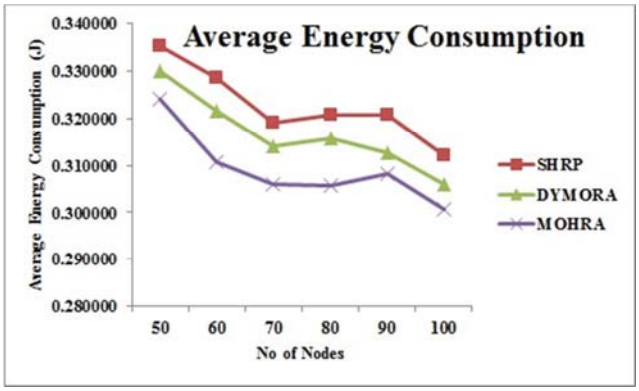

Fig. 3. Average Energy Consumption.

C. Normalized Routing Load (NRL)

Normalized Routing Load is calculated as a ratio of total number of routing packet transmitted including total no of forwarded routing packets per data packet. Q-MOHRA is a multi-objective hybrid routing protocol and it addresses QoS parameters from different layers in the WSN architecture. Q-MOHRA uses weighted average of Control Overhead, HOP Count LQI, and Average Energy consumption Reaction Time, for selecting the best path from source to sink. Routing overhead is less in Q-MOHRA by 18 % than DyMORA and 5% than SHRP. Fig. 4 gives a comparison of NRL between SHRP and DyMORA.

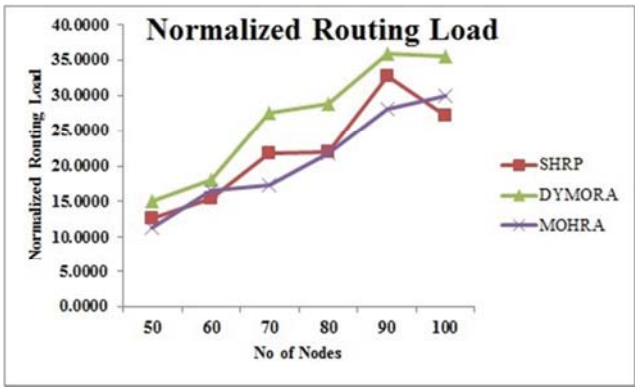

Fig. 4. Normalized Routing Load

D. Jitter

Fig. 5 illustrate the comparison of jitter. Q-MOHRA has lower jitter than SHRP and DyMORA. In WSN, the endwise one-way difference in delay between packets arrivals at destination is called as Jitter. Q-MOHRA is more efficient in routing the packets from source to destination as compared to SHRP and DyMORA. Q-MOHRA improves jitter by a factor of 19.1% and 14.7% as compared to DyMORA and SHRP respectively.

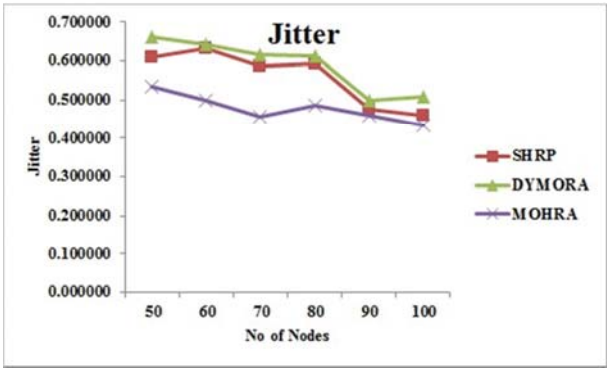

Fig. 5. Jitter

V. CONCLUSIONS AND FUTURE WORK

This paper proposes an innovative QoS assured Multi-Objective Hybrid Routing Algorithm called Q-MOHRA for WSNs. The main goal of Q-MOHRA is to assure QoS while selecting an optimal route up to sink based on multi-objective criteria. The performance of Q-MOHRA is evaluated and equated with two multi-objective hybrid routing algorithms, SHRP, and DyMORA. Q-MOHRA is energy efficient as comparing to SHRP and DyMORA. Q-MOHRA outperforms SHRP and DyMORA in terms of average energy consumption, jitter, Normalized Routing Load, and packet delivery ratio. The routing protocol can be extended taking into consideration the parameters such as heterogeneity and mobility of both sensor nodes and sink.

***Abstract*— The nodes of the Mobile Ad Hoc Network (MANET) are movable. This leads to unpredictable nature of node mobility and continuously changing topology there by difficulty in maintaining central control over the nodes of MANET. Secondly, the essential requirement of most of the cryptographic techniques is to share a key between the two end parties of the communication. To address the above two issues and to implement security in MANET environment, there is a basic need of sharing a key between the two communicating parties without the help of central management like Certification Authority CA or Key Generation Centre KCG or Key Distribution Centre KDC. This problem is addressed here with the help of verifiable secret sharing and bilinear pairing concepts. A verifiable secret sharing (VSS) scheme is an extension of standard secret sharing scheme with the additional property that every participant is able to validate whether the share distributed to him by a dealer is accurate. This additional property is ensured with the help of commitments created for the coefficients of a polynomial commonly used in the standard secret sharing schemes like Shamir's secret sharing. Pairings on elliptic curves initially are used as cryptanalysis tool but since 2000 they are also used to construct cryptographic systems.**

Keywords*— *Verifiable Secret Sharing, Bilinear maps, Pairings, Key Distribution protocol, Key Agreement protocol, Mobile Ad Hoc Networks.

I. INTRODUCTION

Key establishment [15] is the mechanism of sharing a secret key between two or more users. There by this secret key can be used to realize some cryptographic services like confidentiality or data integrity. Key establishment protocols are of two types namely key transport protocols and key agreement protocols. In key transport protocols, any user can choose the key and securely transmit it to the other user. In key agreement protocols both the users contribute information required to generate the shared secret key. Our key establishment protocol is especially key agreement protocol based on verifiable secret sharing scheme and bilinear pairings and very much suitable for MANETs environment due to non requirement of central authority.

A standard secret sharing scheme [2] is the process of dividing a secret into n number of shares and distributing each share to each participant of a set of n participants in such a manner that only qualified subsets of t participants can collude to construct the secret from their shares. In standard secret sharing schemes [2], the dealer and participants are believed to be honest. But dealer or participants may misbehave in real world practices i.e., dealer [3] may transmit incorrect shares to some or all of the participants during distribution phase or participants may submit incorrect shares during the reconstruction phase or the shares may be modified by the adversary during transmission of secret shares. To address all these issues, integrity service must be provided to the secret shares in the form of commitments. Such solution is provided by Verifiable secret sharing schemes. A verifiable secret sharing (VSS) [2][3] scheme is a secret sharing scheme with an extra property that every participant is capable to verify whether the share received by him from a dealer is accurate. VSS is an elementary tool of threshold cryptography and decentralized computing. VSS is a useful tool for protecting threshold cryptography schemes from malicious attackers.

A Mobile Ad Hoc Network (MANET) [4] consists of a huge number of mobile devices, moving within an unpredictable (or sometimes well specified) area, using wireless transmission channels in a hop-by-hop mode, without the help of any fixed infrastructure or centralized administration. The basic inherent characteristics [4] of Mobile Ad Hoc Networks (MANETs) are dynamic topology, absence of infrastructure and hence difficult to setup a traditional central authority for central control, limited bandwidth, limited power supply and hence the nodes may present selfishness behavior, node cooperation, self configuration etc. Such characteristics cause them to be more exposed to attacks than other types of networks. These characteristics also cause the traditional security mechanisms unsuitable for them. However, in MANETs, key distribution process is challenging as a consequence of its non-centralized structure. Obviously no user is always available; consequently no user alone can be used as a central authority. Hence we present a two-party key distribution protocol without the need of central administration and that consumes fewer resources and increases the level of security. This model makes use of pairing based cryptography and verifiable secret sharing VSS schemes. If we choose pairing friendly elliptic curves [1], the computational cost reduces to much extent and as elliptic curve cryptography is involved, it improves the intensity of security. VSS scheme avoids the attacks on integrity of the

secret shares performed either by the dealer, or participants, or attacker.

Lack of Infrastructure and dynamic topology nature of MANETs causes difficulty in establishment of Central Administrator; and key sharing between the source and destination is needed by most of the cryptographic mechanisms. So in MANET environment to provide security, certainly there is a necessity of a key distribution protocol without central administration. Our previous paper [5] proposed a model to address this requirement, but suffers from the problem of lack of integrity to the secret shares. So here we are appending the concept of verifiable secret sharing to make our previous work a complete solution. Along with the secret shares the source will also send the commitments to the destination so that the integrity of secret shares is ensured.

The paper organization is as follows. Section II briefly describes the background essentials required for understanding the proposed protocol. Section III elaborates the two major building blocks of the proposed model namely Joux's protocol and Jie and Futai's Verifiable Secret Sharing scheme. Section IV gives the detailed procedure of the proposed model. Section V gives the conclusion for the paper.

II. BACKGROUND ESSENTIALS

The proposed model uses the concepts of Pairings or Bilinear maps and Verifiable secret sharing, a specialization of threshold cryptography. So we elaborate these concepts in this section.

A. *Bilinear Pairing or Bilinear Map*

Let D_1, D_2 and D_3 be three abelian groups of the same order q, a prime. Consider D_1, D_2 as additive groups and D_3 as a multiplicative group. Assume that discrete logarithm problem (DLP) is hard in D_1, D_2 and D_3. A mapping $f : D_1 \times D_2 \rightarrow D_3$ satisfying the following properties is called a cryptographic bilinear map or bilinear pairing [7].

Bilinearity For $X_1, X_2 \in D_1$ and $Y_1, Y_2 \in D_2$

$$f(X_1+X_2, Y_1) = f(X_1, Y_1)f(X_2, Y_1)$$

$$f(X_1, Y_1+Y_2) = f(X_1, Y_1)f(X_1, Y_2)$$

Mathematically it is equivalent to $f([a]X_1, [b]Y_1) = f(X_1, Y_1)^{ab}$ for all a; b $\in \mathbb{Z}_q^*$. [a]P denotes P added to itself a times.

Non-degeneracy For all $X \in D_1\backslash\{0\}$ exists $Y \in D_2$ with $f(X, Y) \neq 1$.

For all $Y \in D_2\backslash\{0\}$ exists $X \in D_1$ with $f(X, Y) \neq 1$.

Computable There exists an efficient polynomial time computable algorithm to compute f(X, Y) for all $X \in D_1$, $Y \in D_2$.

Pairings on elliptic curves initially are used as cryptanalysis tool to attack Discrete Logarithm DL-based elliptic curve cryptography problems. Since 2000 they are also used to construct cryptographic systems. Some of them are one round tripartite key agreement [8], Identity based key agreement [9], Identity Based Encryption (IBE) [10], Hierarchical IBE [11], Short signatures [12] etc.

B. *Verifiable Secret Sharing*

The idea of verifiable secret sharing (VSS) [2] was first initiated in 1985 by Benny Chor et. al. The users that are part of VSS protocol are a dealer and set of participants; dealer is not part of the set of participants. Dealer wants to share the secret among the set of n participants by dividing the secret into n shares with each share distributed to each participant. The standard secret sharing scheme consists of two phases [3]: the distribution phase and reconstruction phase. As part of distribution phase the dealer divides the secret into n shares and distributes them to the set of n participants. As part of reconstruction phase a subset of at least t participants correlate all their shares and reconstruct the secret. Fewer than t participants can never reconstruct the key. So here the concept of threshold cryptography and especially Shamir secret sharing scheme [6] can be used for implementation. Unique to VSS, the dealer [2] broadcasts t commitments to the coefficients of the t-1 degree polynomial involved in the Shamir scheme. Once these commitments are received any party can verify their share so that the integrity of the shares can be ensured. This is called verification phase, additional phase in VSS.

The basic procedure of a VSS scheme is comparatively the same as standard secret sharing scheme expect an extra verification phase between the standard distribution phase and reconstruction phase, which can be easily implemented with the public commitments of some secret information during the distribution step. So VSS scheme consists of three different phases specifically the distribution or sharing phase, the verification or authentication phase and the reconstruction or restoration phase as shown in figure 1.

Fig. 1. Phases of Verifiable Secret Sharing Scheme

There are two types of VSS schemes: Interactive VSS and Non-interactive VSS. With Interactive VSS, interaction between dealer and participants is needed for verification. Goldwasser-Micali VSS [17], Benaloh VSS [18] are some of the interactive VSS schemes. With Non-interactive VSS, interaction between dealer and participants is not needed for verification. Feldman VSS [16], T Pedersen's VSS [19] are some of the Non-interactive VSS schemes. The proposed model is a non-interactive VSS as it is based on Jie and Futai's VSS which in turn is based on Feldman VSS.

III. BUILDING BLOCKS

The proposed model is based on Joux's protocol [8] and Jie and Futai's verifiable secret sharing scheme [13]; hence

these are the building blocks. In this section we brief the building blocks of the proposed model.

A. *Joux's Protocol*

Joux's protocol [5][8][14] is a very simple and well-designed tripartite one-round protocol. In other words it is used to establish a secret session key for three parties by just one broadcast per party. Assume A, B, and C want to share a secret key among them. Consider Symmetric pairing D1 x D1 → D3. Let P be the generator of D1. In this protocol, x, y, z ∈ Z_q^* are integers chosen at random by A, B and C respectively. The order of protocol communication messages is irrelevant and any of the three entities can initiate the protocol. In the protocol communication the symbol "→" indicates "Sends to".

Protocol Communication

A → B, C : [x]P

B → A, C : [y]P

C → A, B : [z]P

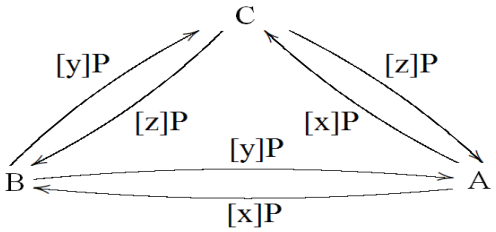

Fig. 2. Joux's Tripartite Key Agreement

Protocol Description

Once the communication is finished as shown above and in figure 2, A computes $K_A = f([y]P, [z]P)^x$, B computes $K_B = f([x]P, [z]P)^y$ and C computes $K_C = f([x]P, [y]P)^z$. From bi-linearity property of f, K_A, K_B, K_C are all equal to $K_{ABC} = f(P, P)^{xyz}$. This can act as the secret key shared by A, B and C. The security strength of Joux's protocol depends on the Bilinear Diffie-Hellman Assumption that is stated below.

Bilinear Diffie-Hellman Problem

There are several problems associated with pairings. Here we define only the BDH problem needed for our protocol. This problem is stated as follows:

Given P, uP, vP, wP with u, v and w chosen uniformly at random from Z_q^*, the computation of $f(P, P)^{uvw}$ is hard.

B. *Jie and Futai's VSS*

Jie and Futai's [13] scheme is a verifiable secret sharing scheme consisting of three phases the sharing or distribution phase, the verification phase and the reconstruction phase. This scheme considers a symmetric bilinear map $f : D_1 \times D_1 \rightarrow D_3$. Choose a random generator P from D_1. Suppose the number of participants is n and the threshold is t, the minimum number of participants that correlate to reconstruct the secret key such that $t \leq n$. The parameters in this scheme are $<D_1, D_3, f, P, f(P, P), t, n>$. The scheme functions as follows.

Distribution Phase

(1) Dealer chooses a secret K = [s]P to be distributed to n participants; s is the randomly chosen integer from Z_q^*.

(2) Dealer chooses a polynomial $p(x) = p_0 + p_1x + ... + p_{t-1}x_{t-1}$ where $p_0 = s$ and $p_1, p_2, ..., p_{t-1}$ are randomly selected from Z_q^*.

(3) Dealer calculates and broadcasts $Comm_i = f(P, P)^{p_i}$ for i = 0 to t-1 as the commitments of K and p(x).

(4) Dealer calculates the share $K_i = [p(i)]P$ mod q and sends each share secretly to participant R_i, for i = 1 to n.

Verification Phase

When participant R_i receives his share K_i from the dealer, he verifies if

$$f(K_i, P) = \prod_{j=0}^{t-1} Comm_j^{i^j}$$

If the verification is not successful, the share K_i received by R_i participant is invalid.

Reconstruction Phase

Suppose $R_1, R_2, ..., R_t$ be the t participants want to reconstruct the shared secret K. Each R_i broadcasts his share K_i to the remaining t-1 participants and every participant can check the validity of the received share using the above equation of verification phase. Once all the t shares K_i are confirmed to be legitimate, every participant can rebuild the secret K using the following equation.

$$K = \sum_{c=1}^{t} K_c \prod_{1 \leq d \leq t, d \neq c} \frac{d}{c - d}$$

IV. THE PROPOSED MODEL

The proposed model does not have dealer, and set of participants, but has only source and destination who wish to share a secret key between them because the aim of this model is to share a secret key between the two end parties of communication. Source plays the role of dealer and destination plays the role of set of participants. Source chooses the secret key to be shared with the destination, partitions the secret key into n shares using Shamir's secret sharing scheme [6], where n is the number of disjoint paths exist between source and destination. Source calculates the t commitments to the coefficients of t-1 degree polynomial and transmits the shares and commitments to the destination via n disjoint paths. Once the destination receives at least t shares and t commitments, it can verify the shares using commitments and if verification is successful, then reconstruct the secret key there by a secret key is established between the source and destination without the support of centralized trusted authority.

A. Protocol Description

If Joux's protocol is directly extended to two-party key agreement, the protocol works as below and shown in figure 3.

(1) $A \rightarrow B$: [x]P

(2) $B \rightarrow A$: [y]P

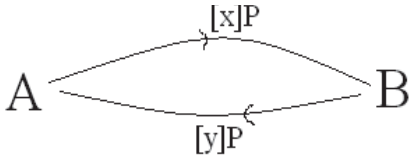

Fig. 3. Joux's protocol extension to two-party

Once [x]P and [y]P are received by B and A respectively, A calculates the key as $f(P, [y]P)^x$ and B calculates the key as $f([x]P, P)^y$ and both the calculations result in the same value $f(P, P)^{xy}$ according to the bilinear property of pairings.

But if adversary can intercept [x]P and [y]P during steps 1 and 2 above, he can also easily compute the key as f([x]P, [y]P) = $f(P, P)^{xy}$. So we cannot directly extend Joux's protocol to two-party key agreement. These issues are handled in our proposed model that is described below.

Consider the symmetric pairing $f : D_1 \times D_1 \rightarrow D_3$, where D_1 and D_3 are finite cyclic groups to same prime order q; D_1 is written additively and D_3 is written multiplicatively; $D_1 \subseteq E(Fp)$, $D_3 \subseteq (Fp\alpha)^*$ (embedding degree α = 1, 2, 3, 4, 6, 10, 12) [20]. This model can also be used with asymmetric pairing, but here we consider symmetric pairing for simplicity. Consider a random generator of D_1 as P. Let A and B wants to share a secret key K between them. The model functions as follows.

(1) A chooses $S_1 = [u]P$ where u is chosen at random from Z_q^*.

Similarly B chooses $S_2 = [v]P$ where v is chosen at random from Z_q^*.

(2) A selects a polynomial $p_1(x) = a_0 + a_1x + ... + a_{t-1}x_{t-1}$ where $a_0 = u$ and $a_1, a_2, ..., a_{t-1}$ are randomly selected from Z_q^*.

B selects a polynomial $p_2(x) = b_0 + b_1x + ... + b_{t-1}x_{t-1}$ where $b_0 = v$ and $b_1, b_2, ..., b_{t-1}$ are randomly selected from Z_q^*.

(3) A calculates $CA_i = f(P, P)^{a_i}$ for i = 0 to t-1 as the commitments of S_1 and $p_1(x)$. These values are transmitted to B via multiple paths so that they certainly reach B.

(4) B calculates $CB_i = f(P, P)^{b_i}$ for i = 0 to t-1 as the commitments of S_2 and $p_2(x)$. These values are transmitted to A via multiple paths so that they certainly reach A.

(5) A calculates the shares $U_i = [p_1(i)]P$ mod q for i = 1 to n and then sends the shares to B via n disjoint paths; one share thru each path.

B calculates the shares $V_i = [p_2(i)]P$ mod q for i = 1 to n and then sends the shares to A via n disjoint paths; one share thru each path.

(6) Once A receives at least t shares V_i and t commitment CB_i from B, he verifies the shares using the commitments as

$$f(V_i, P) = \prod_{j=0}^{t-1} CB_j^{ij}$$

Once B receives at least t shares U_i and t commitment CA_i from A, he verifies the shares using the commitments as

$$f(U_i, P) = \prod_{j=0}^{t-1} CA_j^{ij}$$

(7) Once the verification is successful, A reconstructs S_2 using the equation

$$S_2 = \sum_{i=1}^{t} V_i \prod_{1 \le j \le t, j=i} \frac{j}{j-i}$$

B reconstructs S_1 using the equation

$$S_1 = \sum_{i=1}^{t} U_i \prod_{1 \le j \le t, j=i} \frac{j}{j-i}$$

(8) A computes the secret key using the equation $f(P, S_2)^u$ and B computes the secret key using the equation $f(S_1, P)^v$. From the bi-linearity property of f, both the equations result in the same value $K = f(P,P)^{uv}$.

Among these 8 steps, steps 1-5 are part of Distribution phase, step 6 is the Verification phase and step 7 is the Reconstruction phase. By these seven steps S_1 and S_2 are exchanged between A and B, and these values are used in step8 to compute the secret key K. Hence secret key K is shared by A and B successfully.

If the shares of S1 and S2 are send via n independent paths between A and B without using commitment concept [5], the shares can be altered by the attacker during their transmission. There is no assurance to the receiver that the received shares are exact as sent by the sender. So, there is a need to provide integrity service to the shares and that is provided by the additional commitment concept of verifiable secret sharing compared to standard secret sharing schemes.

The above process for easy understanding can be simplified as follows:

(1) [u]P is transmitted from A to B by applying Jie and Futai's VSS technique on [u]P. Symbolically be represented as JF-VSS([u]P).
(2) [v]P is transmitted from B to A by applying Jie and Futai's VSS technique on [v]P. Symbolically be represented as JF-VSS([v]P).
(3) Once A receives [v]P successfully from B, computes the key $K = f(P, [v]P)^u$
(4) Once B receives [u]P successfully from A, computes the key $K = f([u]P, p)^v$. Hence key K is successfully shared between the two users A and B.

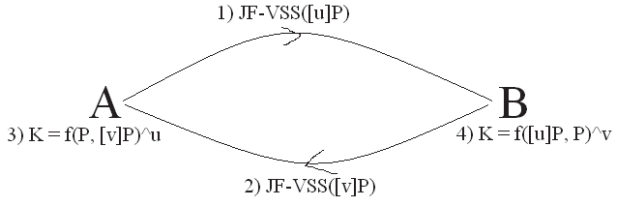

Fig. 4. Simplified Proposed Model

B. *Security Analysis*

Joux's protocol prevents the passive attacks but is vulnerable to man-in-the middle attack and active attacks. To counter these problems of Joux's protocol we appended the concept of verifiable secret sharing scheme. The man-in-the middle attack is prevented because [u]P and [v]P values are not send out directly, but are divided into shares using Jie and Futai's VSS technique. The active attacks are prevented by ensuring the integrity of secret shares using the commitments feature of verifiable secret sharing scheme. The deficiencies of Joux's protocol are addressed and also extended to two-party key agreement. As the n secret shares are transmitted via n independent or disjoint paths that exist between source and destination, the adversary or opponent [5] has to capture at least t shares by intercepting t paths at the same time, unless until he cannot recover the secret key. The cryptanalysis complexity has improved t times. As Jie and Futai's VSS is the major building block of the proposed model, the security analysis of proposed model can be inherited from Jie and Futai's VSS scheme [13].

V. Conclusion and Future Scope

We have proposed a simple and efficient model to share a secret key between the two end parties of communication without the support of central authority like certification authority, key generation centre or key distribution centre. This model is very much suitable to MANET environment due to MANET characteristics like lack of central administration and limited resources. Our model used the concepts of Joux's protocol and Jie & Futai's verifiable secret sharing. This secret that is shared between the two end-parties of communication can further be used as a secret key in Symmetric encryption algorithms. As key distribution along with encryption and signature algorithms provides a complete security solution for MANETs, we would plan to design encryption and signature pairing-based algorithms using this shared secret key.

Abstract— **Random mobility of a node in Wireless Sensor Networks (WSNs) causes the frequent changes in the network dynamics with increased cost in terms of energy and bandwidth. During data collections and transmission, they need the additional efforts to synchronize the activities of nodes. A key challenge in maintaining the effective data collection and transmission is to schedule and synchronize the activities of the nodes with the global clock. This paper proposes the Mobility-aware Hybrid Synchronization Algorithm (MHS) which works on the formation of cluster-based spanning tree mechanism (SPT). Nodes used for formation of the network have random mobility and are heterogeneous in terms of energy with static sink. The nodes in the cluster and cluster heads in the network are synchronized with the notion of the global time scale of the network. In the initial stage, the algorithm establishes the hierarchical structure of the network and then perform the pair-wise synchronization within the cluster and then in the network. With the random mobility of the node, the network structure frequently changes causing an increase in energy consumption. To mitigate this problem, MHS aggregate data with the notion of a global time scale throughout the network. In the second phase of MHS, the aggregated data packets are scheduled level by level using time-division multiple accesses (TDMA) techniques as MAC layer protocol to reduce the collision of packets. Simulation results show that MHS is energy efficient, with increased throughput, and has less delay as compared with state-of-the-art solutions.**

Keywords— Aggregation; Delay; Energy; random mobility; Scheduling; Synchronization; WSN.

I. INTRODUCTION

Time synchronization is an important service for the collaborative and coordinated operations in WSNs. For instance, network protocols such as time division multiple access (TDMA) strictly demands synchronization among sensor nodes. Time synchronization in the WSN is mainly affected by low-cost clocks, frequent topological changes, error sources during communication, node failures and the resource constraint nature of the nodes. These factors should be considered during the design and implementation of the synchronization protocols [1]. Synchronization algorithms are required to co-ordinate the time scale of node and network, and scheduling algorithms are required to allocate the collision-free time slots to reduce the energy consumptions in the WSN[2]. For instance, if the nodes used in the sensing and collection of data is not synchronized with the global clock, it takes more time to send the packet to sink and hence consumes more energy. Also, if the activities of the nodes are provided with different schedules according to the local clock and not synchronized with the global clock, then the result will be different and uneven with more energy consumption.

This paper proposes the hybrid approach which takes care of synchronizing a local clock of the node with the global clock of the network and schedules the activities based on the present and next state of the channel. With the random mobility of the node, it is difficult to integrate and interpret the information sensed by the nodes without synchronization. The unusable network conditions and scare resources of WSN make essential to develop a time synchronized protocols. Also, the random mobility of a node causes topological variations in the network architectures, and low bandwidth restricts the multi-hopping. Hence, to deal with these challenges hybrid protocol needs to be designed taking care of scheduling and clock synchronization. The improper scheduling and synchronization of the packets generated from the lower layer of the network to the upper layer causes more energy consumption. Also, retransmission delay is caused due to the improper balancing of slot allocation during scheduling and difference in the local clock of the node and global clock of the network. The retransmission delay can be minimized by use of an efficient scheduling MAC protocol, which manages the time slots of cluster head (CH) and nodes according to the global time sync. The data propagation from node to sink may be in one–hop or multi-hop, it depends on the depth of the spanning tree formed in intra and inter-cluster communication. The packet scheduling activities of the nodes are dependent on the availability of the channel, at least equal to the synchronization time. The neighboring node will synchronize their schedules periodically to prevent long term clock drift. Timing-Sync Protocol for Sensor Networks (TPSN) [3], considers the traditional approach of two-way message exchange between sender-receiver synchronization with an increase in sync errors and energy consumption. The traditional protocols are not energy efficient and difficult to implement for WSN.

The paper focuses on a hybrid approach to minimize the energy consumption with increased throughput, hence bandwidth utilization and reduced delay with the random mobility of nodes. The nodes used are heterogeneous in terms of energy which helps to increase the network lifetime. It considers clustered architecture with the spanning tree in the presence of non-ideal clocks. The result shows that application

of spanning tree algorithm for synchronization performs better than structured as compared to scheduled-based algorithms.

The remaining part of the paper progresses with different sections as; Section II focuses on the present work related to synchronization and scheduling algorithms. Section III presents the required assumptions and network model. Section IV briefs about the MHS, Section V discusses simulation setup and results, and Section VI conclusion along with the future scope.

II. Related Works

This section explores the idea how one can use TDMA technique for scheduling and synchronization technique to improve the QoS. [2] Considers the spanning tree mechanism to improve the energy consumption as compared with TPSN. It shows the reduced sync errors. [4] Defines a time synchronization protocol based on spanning tree. A spanning tree formed by the nodes is divided into multiple sub-trees. The sub-tree synchronization process helps to match the clock time within the level. It minimizes the clock adjustment time. In [5] Clustered Time Synchronization algorithm and energy model is presented, that conserves the energy beside accuracy while synchronizing the WSNs. Reference Broadcast Synchronization Protocol [6] (RBS) uses the synchronization between the two receivers by the intermediate node within the listening range of the sender and receiver. The intermediate node sends the message for recording the time hence saves the energy in clock updates. The major disadvantage of the protocol is that the energy is wasted to synchronize the reference sender. [7] Proposes the distributed clustering algorithm for grouping the mobile nodes into the clusters. The mobility of node frequently changes the structures and accordingly not suitable to use spanning tree. [8] Addresses the issue of adopting the mobility and space division multiple accesses techniques to collect the data. Author minimized the data gathering time by moving the mobile data collector through optimal route. The errors are increased due to the improper balancing of data flows. [9] Consider the effect of mobility of a node in real life example. The author presents the energy consumption as one of the performance measures. [10] Proposes the hybrid scheme to ensure the sync accuracy with minimum energy. It considers partial scheme to calculate the time offset of few child nodes. In [11] time synchronization of node and network is done at the time of cluster tree formation. Relative time drift and phase offset are the metrics of calculation. [12] Considers the delay-sensitive approach to achieve low packet delay and high throughput by considering cycle-based sync scheduling. The proposed hybrid approach helps in reducing the delay. It has a limitation of overhead with increased network size and synchronization error. [13] Proposes the hybrid approach for scheduling the activities of mobile nodes and slots are allocated using TDMA for improving energy consumption. The mobility of node restructures the cluster and increases the energy consumption. Hybrid Green Conflict Free (H-GCF) [14] algorithm uses the node mobility to reduce the conflict-free schedule for the three hop neighbors. It improves the minimum slot sharing for reducing the energy consumption and delay. In [15] clock skew is minimized by synchronizing the local clock of the node with reference to the global clock of the network. This process takes more time for synchronization of each node and hence increases the energy consumption. [16] Presents the scheme for data aggregation under distributed algorithms with an asynchronous and synchronous time model. The delay in the network is balanced by minimizing the small clock drifts occurring during synchronization. It uses competitive analysis to assess the quality of the algorithms. It lacks in the proper balance of data to be transmitted from nodes to sink with an increase in communication cost.

The different algorithms used in the section are either work on the scheduling or synchronization technique to improve the QoS parameters. During scheduling slot allocation is the major concern to avoid the collision, when the number of aggregated packets are increased. During synchronization, if the global clock of the network is not synchronized with the local clock of the node, it results in sync errors. To minimize the energy loss and errors, this paper proposes a technique by combining the two approaches (synchronization and scheduling) which works level by level.

III. Proposed Network Model

A. *Network Model*

Consider a network tree T (V, E), where ‘V’ denotes the set of ‘n’ wireless nodes and ‘E’ denotes the set of wireless links. The network T (V, E) is divided into many sub-trees of clusters T1, T2, T3,…,Tn. Every sub-tree has one CH, which acts as a root for each sub-tree. There is one base station (sink) in the network located at the root of the tree and collects data from all CHs. Each node uses its clock for maintaining the time stamp which is synchronized with the global clock of the network for collection and send data to CH. The received data is aggregated by min, max, and average functions. It reduces the transmission time per forwarding.

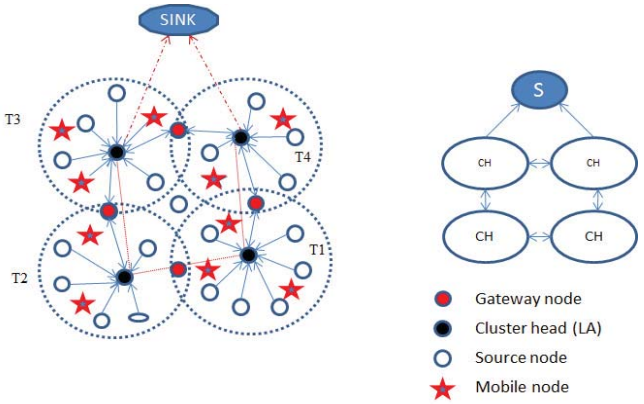

Figure 1. Cluster-based Network Model

In the first level (intra-cluster), the message ‘m’ generated by nodes within cluster, after forming tree is combined into a packet with a timestamp and forwarded to the parent node (CH). In the second level (inter-cluster), all the aggregated packets from CH are scheduled using time-slotted approach with error free channels. It benefits in achieving collision-free transmission of data packets to sink.

IV. PROPOSED MECHANISM

The main objective of proposed hybrid approach is to minimize the energy consumption with an increase in throughput. The steps in development of algorithm are as follows

- Form the cluster tree and perform level by level aggregation.
- Schedule the activities of the nodes according to free slots.
- Provide the network-wide synchronization to reduce the clock skew hence the energy consumption and increase the throughput.

A. Spanning tree formation (SPT)

In the present case WSN is considered as a connected, undirected graph G (V, E), the work considers the conversion of the graph into a minimum spanning tree. The Kruskal algorithm is used to form the minimum spanning tree of graph G (V, E). It considers the number of nodes in set A as a forest with the weight of each as one-hop.

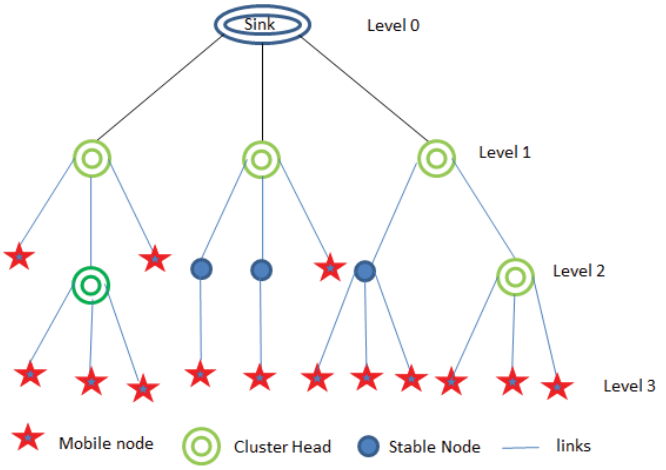

Figure 2. Structure of Proposed Spanning Tree Mechanism

In the initial stage of spanning tree as intra-cluster, nodes with random mobility are grouped into a cluster at time interval 't', a settling time, the cluster head is elected according to distributed clustering algorithms and CH is assumed to have level 0. To form a tree in the cluster, CH broadcast message and the neighbors receiving the message will be added to forest A, only the edges that are forming a loop will be discarded. The major constraint in the formation of the tree is the random mobility of node.

In the second level (inter-cluster), the CHs *v* at level 0 are grouped with a number of edges *l* connecting to CH and sink. Here, the same step like intra-cluster SPT formation is repeated; the only difference is that all the CH are static. The sink node will be assigned to level 0, and it will transfer the neighbor finding the message, the CH who will receive the message will form the spanning tree with sink node as a parent node. After connecting first level CH to sink node, the first level CH forwards the neighbor finding a message to a next CH and connect it to the spanning tree as shown in Figure 2.

B. Synchronization of nodes:

In the formation of spanning tree, different levels are maintained with sink node at level 0.The CH directly connected to sink are at level 1. The remaining CH and nodes will maintain the higher order according to the depth of spanning tree. All other nodes under CH will be assigned the next levels. The sink node, which is parent node, send clock estimation message to the direct child. The direct child is a child, who is one level distance from the parent as shown in Figure 2. The sink node maintains the global notion of time to synchronize the clocks of all nodes in the formation of spanning tree and communication of packets.

In TPSN mechanism, the global timescale is applied across the network at one time, and every node has to synchronize with global time, it introduces the clock drifts at different levels and performance decreases. It leads to increase in synchronization errors and also require more energy to keep it. But in MHS, the CH next to sink will take the global time scale from the sink while others will follow the level by level operation of synchronization with the parent node. The level by level synchronization of child and parent node reduces the clock drifts and overheads required to maintain equal time scale among all nodes at one time.

C. Energy and delay Model

In WSN, the potential source of energy consumption is in the process of communication. Typically, depending on the state of the nodes radio either in transmitting, in listing or sleep mode, energy consumption is decided. It also depends on the distance of the node to CH, CH to sink, and the number of packets transmitted by the nodes in the lower level to CH, and to 0 level by CH. According to the level of nodes in the spanning tree the energy consumption is

$$e(di) = k(e_t\, di^{\alpha} + e_0)\, t_{slots} \qquad \text{-- (1)}$$

α- path loss and depends on distance of node to CH and sink, k- number of packets, e_t- transmitter energy, e_0- initial energy. The main objective of the hybrid approach used in MHS is to increase the throughput of the network with minimum energy consumption. The radio states have different energy consumption as a transmitter (E_{tx}), receiver (E_{rcv}), listen (E_{lst}) and sleep (E_{slp}) respectively. The following assumption is made that the total time is logically divided into slots as t_{slot}, and these time slots are synchronized among nodes to avoid collision of packets. A scheduled period 'T' is composed of consecutive time slots as shown in Figure 3.

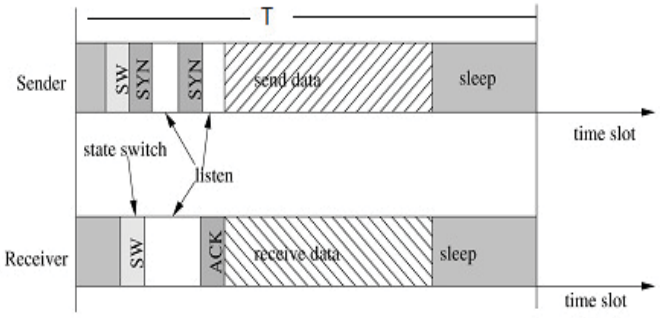

Figure 3. Structure of Synchronization Frame

Assume that a node n_i will produce r_i data packets per scheduling period T. Thus, in the one-time slot, a node can transmit multiple data packets under the ideal environment. When a node n_i is transmitting packets to a neighboring node n_j within intra-cluster, some other neighboring nodes that are in the listening state will also transmit its available data packet and consume energy. Therefore, the total energy consumption of node n_i that transmits the data packets in L slots listening to neighboring nodes is

$$\text{Energy consumption} = (E_{tx} + E_{rcv} + n * E_{lst})\ L * t_{slot}. \quad -- (2)$$

Also, the time required to schedule the 'k' packets at CH is calculated according to the number of forwardings and is

$$T_{ch} = ((N/k)-1)\ t_{slot} \quad -- (3)$$

The total time required to send the aggregated packets to sink is

$$T_{sink} = k.\ t_{slot} \quad -- (4)$$

Hence, total time required for packets to reach to sink is

$$T = [((N/K)-1) + K]\ t_{slot} \quad -- (5)$$

All the activities of each node are scheduled and synchronized in the time slot $1 \leq t_{slot} \leq T$

V. SIMULATION RESULTS

The simulation of the algorithm is performed using NS-2 (ns-2.34). The parameters considered for simulation of randomly placed mobile nodes are shown in Table I. The results are obtained by applying the spanning tree mechanism on mobile nodes. The performance of hybrid synchronization algorithm(MHS) is compared with SDA[2]using with static nodes and time synchronization (TPSN)[3], a network-wide time sync algorithm.

TABLE I. SIMULATION AND NODE PARAMETERS

Parameters	Value
Number of nodes	25,50,75 and 100
Number of sources	24, 49, 74 and 99
Number of Sinks	1
Placement of source and sink	Random and sink at center
Initial energy	100J
Idle power	14.4mW
Receive power	14.4mW
Transmit power	36.0mW
Runs of each simulation	20
Node mobility(random)	20 meters /sec

A. *Result and Discussion*

Figure. 4 represents the average energy consumption of three different synchronization mechanisms TPSN, SDA, and MHS. The average energy consumption by TPSN is more than that of MHS and SDA because TPSN tries to apply global timescale across the network at one time, while MHS uses the spanning tree based synchronization mechanism which works on level by level.

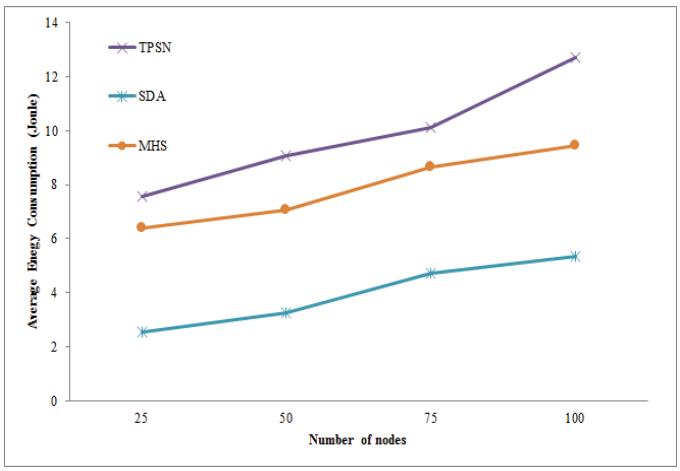

Figure 4. Comparison of Energy Consumption

Also, the distribution of global time scale across the whole network require a larger amount of energy and will be utilized from the share of nodes. Uneven time stampings of TPSN leads to increase in synchronization errors and also require more energy to keep it. At another side, SDA and MHS mechanism apply global time scale level-by-level, which gives less overhead and leads to reduced energy consumption. The energy consumption of MHS is more than SDA, due to increased overheads in finding the paths with the random mobility of nodes and updating the clock of the neighbour node used for synchronization.

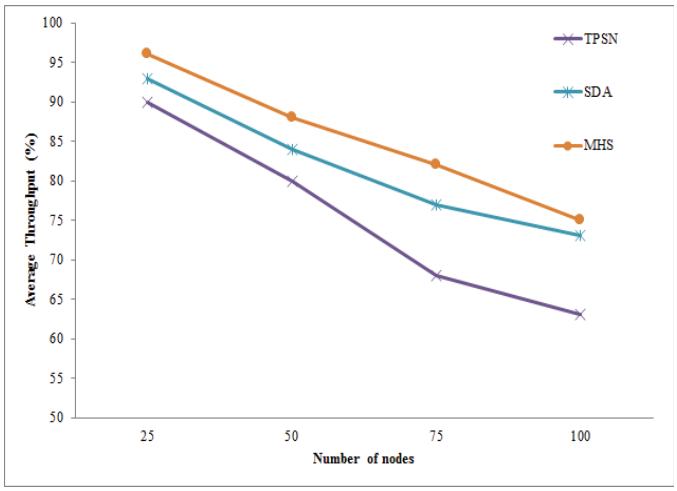

Figure 5. Comparison of Throughput

Figure. 5 shows the average throughput of the hybrid mechanism (synchronization and scheduling) applied on the three synchronization algorithms TPSN, SDA and MHS with spanning tree synchronization techniques. With an increase in the number of nodes, throughput increases by 11.73% and

4.10% in case of MHS as compared to TPSN and SDA. This improvement in the result is due allocation of collision-free scheduling slots and synchronizing clocks of parent and child node level by level. Also, data gathering time reduces due to level by level synchronization since clock drifts are minimum. However, in TPSN, it will change every time the nodes go under random mobility and need to update the global state in the whole network, hence reduced throughput.

Figure 6 shows the average delay of the hybrid mechanism. With the introduction of controlled random mobility to nodes, an avg delay in matching the local and global clock is reduced by 24.26% and 9.07% with SPT as compared to TPSN and SDA. The larger time drifts introduced in TPSN takes a large time to make a decision on schedule as compared to MHS. Also, retransmission delay is caused due to the improper balancing of slot allocation during scheduling and difference in the local clock of the node and global clock of the network. The process of exchanging a global state of information increases the overhead in the network, which leads to increased delay and reduced throughput in case of TPSN.

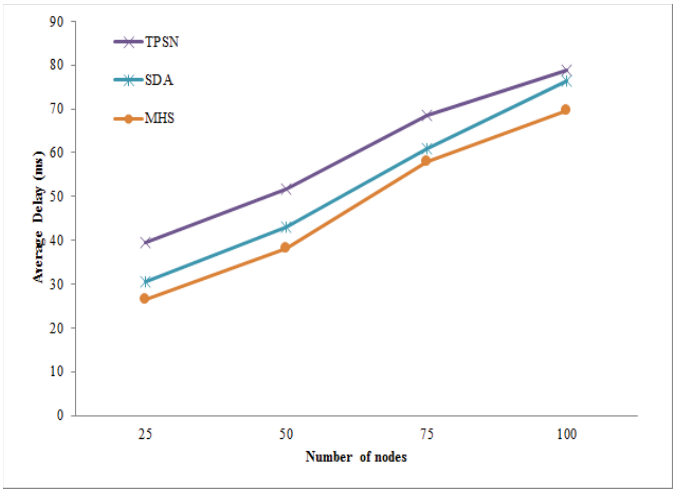

Figure 6. Comparison of Average Delay

VI. Conclusions and Future Work

The proposed mobility-aware hybrid synchronization algorithm with spanning tree mechanism shows improvement in throughput, delay, and has reduced energy consumption as compared with TPSN. The addition of heterogeneous nodes in the network along with the synchronization of local and global clock helps to increases the lifetime of the network. The clock synchronization reduces the clock drifts and hence errors which result in an increase of the throughput, and reduces the delay. It also reduces the energy consumption by 29.32%. With the introduction of random node mobility and heterogeneity, the performance of the synchronized algorithm is improved by 4%. The work can be extended by considering sink mobility in the network.

***Abstract*—RFID is a wireless technology that uses radio frequency to transfer data. It is mostly used in tracking and identifying objects. Recently its applications are rapidly growing in health-care industry to store data related to patient's medication. Transfer of data between server and RFID tag is controlled by some protocols. If these protocols are insecure, then it is possible for an attacker to gain access and fake the report which can be harmful to patient's health. In this paper, RFID Authentication Protocol has been modified to provide enhanced security in transmission of data between server and RFID tag.**

Keywords: Radio frequency identification tag, Elliptic curve cryptography, Authentication protocol.

I. Introduction

The medical data stored in a patients tag attract increasing security and privacy concerns since its modification or damage will influence patients health. The RFID-based patient's medication system consists of tags, readers and the back-end sever [1]–[5]. The hospitals are open environments and radio waves are used for mutual communication. The adversary may read or clone the data stored in patient's tag.

Radio Frequency Identification technology is an automatic tracking mechanism that uses radio signals to detect and identify people, and other things like goods, vehicles etc., without using any physical contact. Radio Frequency Identification technology can track the objects by using radio signal over a distance of few meters to several meters.

Elliptic Curve Cryptography was proposed by **Neal Koblitz** and **Victor Miller**. It is a public-key cryptography technique which is based on the elliptic curves over finite fields of prime numbers [6]. Terms that are used in Elliptic Curve Cryptography are discuss below.

- **Prime fields**
  Let q be a prime number. The modulo q, containing a set of the integers from 0 to q - 1 with addition and multiplication modulo q, is a finite field of order of prime number q. This field is usually denoted by Z_q.

$$Z_q = \{0, 1, 2, ..., q-1\} \quad (1)$$

  eg. : Z_8 = {0 , 1 , 2 , ... , 7}

- **Additive group**
  Let q be a prime number, and let Z_q = {0, 1, 2,..., q - 1} denote the set of integers modulo q. Then (Z_q, +), where the operation + is defined to be addition of integers modulo q, is a finite additive group of prime number q with identity element 0 for addition.

- **Generator**
  The positive elements of a finite field Z_q, denoted as Z_q^* form a cyclic group including multiplication. Therefore there exist element b $\in$ Z_q^* called generator as shown below.

$$Z_q^* = \{b^i : 0 \leq i \leq q-2\} \quad (2)$$

An authentication protocol is a kind of cryptographic protocol with the aim of authenticating entities which want to communicate securely to each other. It is a main characteristic of system security in medication [7], [8]. It verifies the identity of each and every user which are trying to access network resources.

Since authentication play an important role in system security. Therefore, we need such type of authentication protocol which provide security against various security attacks as well as reduce the communication between server and tag.

This paper is organised as follows. Section I is an introduction part. Section II discuss about existing protocol i.e., Zhang and Qi RFID authentication protocol. Proposed RFID authentication protocol is discribe in section III. Then correctness of proposed protocol is included into section IV. Security analysis is presented in section V whereas section VI and section VII represent advantage of proposed protocol and conclusion part respectively.

II. Review Of Zhang and Qi RFID Authentication Protocol

An efficient RFID authentication protocol was developed by **Zhang** and **Qi** [9] to provide security in patient's online medication system. This protocol consists of two phases, i.e., setup phase and authentication phase. They have incorporated

some notations which are used in this protocols are discussed below.

q	A large prime number.
G	Additive group with order *q* consisting of points on an elliptic curve.
P	A generator of *G*.
X_i	The identifier of the i^{th} tag which is a random point in *G*.
y	The private key of the server.
Y	The public key of the server where *Y = yP*.
r,k	Two random numbers.
h( )	A secure hash function.

A. Setup phase

In setup phase, the server generates a random number as its private key and use this to computes the public key. It also selects a identifier of each tag randomly from G.

B. Authentication phase

In authentication phase, the server starts the communication with the tag. Steps of authentication phase are as follows:

1) In this step a random number r $\in Z_q$ is generated by server and assigned to C_0, i.e., C_0 = r. The value $\{C_0\}$ is sent to the i^{th} tag.

2) The i^{th} tag generates a random number k $\in Z_q$, after receiving $\{C_0\}$. Then the parameters K = kY, C_1 = kP, $C_2 = X_i$ + K and C_3 = h(X_i,K,C_0,C_1,C_2) are computed. Then this computed $\{C_1,C_2,C_3\}$ are send to server.

3) The values of $\{C_1,C_2,C_3\}$ are used by server to compute K = yC_1 and $X_i = C_2$ - K. Then the server matches the value of C_3 = h(X_i,K,C_0,C_1,C_2). If these values matches then the tag is declared as legal tag otherwise the system is rejected by the server. After that database is explored for X_i value which is then used for C_4 = h(X_i,K,C_0,C_1,C_2,C_3) and transmits $\{C_4\}$ to i^{th} tag.

4) After receiving {C4} the i^{th} tag finds whether C_4 and h(X_i,K,C_0,C_1,C_2,C_3) are equal. If they are equal then the tag confirms the server is legal otherwise rejects the session.

Server[y,Y,X_i]	Tag[P, Y, X_i,]
Generate r $\in Z_q$	
C_0 = r	
	$\{C_0\}$ $\longrightarrow$
	Generate k $\in Z_q$
	K = kY
	C_1 = kP
	$C_2 = X_i$ + K
	C_3 = h(X_i,K,C_0,C_1,C_2)
	$\{C_1,C_2,C_3\}$ $\longleftarrow$
K = yC_1	
$X_i = C_2$ - K	
Verification :	
C_3 = h(X_i,K,C_0,C_1,C_2)	
If yes, then search X_i in database	
C_4 = h(X_i,K,C_0,C_1,C_2,C_3)	
	$\{C_4\}$ $\longrightarrow$
	Verification :
	C_4 = h(X_i,K,C_0,C_1,C_2,C_3)

Zhang and Qi RFID Authentication Protocol

In this protocol, the tag, after receiving request, first sends data then verifies the user. So anyone (authorized or unauthorized user) can send the request. Therefore a lot of requests may arrive at the tag. So it increases the traffic between server and the tag. Hence, the protocol needs to be modified to reduce the communication between server and tag.

III. Proposed Modified RFID Authentication Protocol

In this section, we propose a modified RFID protocol that also has two phases, namely setup phase and authentication phase

A. Setup phase

In setup phase, the server generate a random number as it's private key and compute its public key and also selects a random point in G as identifier of each tag.

B. Authentication Phase

When interrogating a tag, the server starts the phase to authenticate each other. The details of the phase are presented as follows.

1) The server generates a random number r $\in Z_q$ and computes :
   - C_0 = rP [10]
   - C_1 = h(P, C_0)

   And send the message $\{C_0,C_1\}$ to the i^{th} tag.

2) On receiving $\{C_0,C_1\}$, the i^{th} tag check whether C_1 and h$\{P,C_0\}$ are equal or not. If they are not equal, the i^{th}

tag rejects the session, otherwise, the i^{th} tag confirms that the server is a legal one and generates a random number k $\in Z_q$ and computes :

- $K = kY$
- C_2 = kP
- C_3 = X_i + K
- C_4 = h(X_i,K,C_0,C_1,C_2,C_3)

Then the *i*th tag send the message $\{C_2,C_3,C_4\}$ to the server.

3) Upon receiving $\{C_2,C_3,C_4\}$, the server computes:
   - K = yC_2
   - X_i = C_3 - K

   Then the server checks whether C_4 and h(X_i,K,C_0,C_1,C_2,C_3) are equal or not. If they are not equal, the server rejects the session, otherwise, the server searches its database for X_i. If succeeds, the server confirms that the tag is a legal one.

Server[y,Y,X_i]	Tag[P, Y,X_i]
Generate r $\in Z_q$	
C_0 = rP	
C_1 = h(P,C_0)	
	$\{C_0,C_1\}$ $\longrightarrow$
	Verification:
	C_1 = h(P,C_0)
	Generate k $\in Z_q$ and
	Computes :
	K = kY
	C_2 = kP
	C_3 = X_i + K
	C_4 = h(X_i,K,C_0,C_1,C_2,C_3)
	$\{C_2,C_3,C_4\}$ $\longleftarrow$
K = yC_2	
X_i = C_3 - K	
Verification :	
C_4 = h(X_i,K,C_0,C_1,C_2,C_3)	
If yes then search X_i in its database.	

Proposed RFID Authentication Protocol

IV. Correctness Proof of the Proposed Authentication Protocol

Let :
q = 53
P = 1331 (let b = 11 and i = 3 in eq. 2)
X_i = 29
y = 41
Y = $y \times P$
= 41×1331
= 54571

Now,

Server[y,Y,X_i]	Tag[P, Y,X_i]
Generate r $\in Z_q$ = 31	
C_0 = rP	
= 31×1331	
= 41261	
C_1 = h(P,C_0)	
	$\{C_0,C_1\}$ $\longrightarrow$
	Verification:
	C_1 = h(P,C_0)
	Generate k $\in Z_q$ = 37 and
	Computes :
	K = kY
	= 37×54571
	= 2019127
	C_2 = kP
	= 37×1331
	= 49247
	C_3 = X_i + K
	= 29 + 2019127
	= 2019156
	C_4 = h(X_i,K,C_0,C_1,C_2,C_3)
	$\{C_2,C_3,C_4\}$ $\longleftarrow$
K = yC_2	
= 41×49247	
= 2019127	
X_i = C_3 - K	
= 2019156 - 2019127	
= 29	
Verification :	
C_4 = h(X_i,K,C_0,C_1,C_2,C_3)	

Hence we get the value of i^{th} tag i.e., 29 which we assume in the starting of this section.

V. Security Analysis

The main purpose of modified protocol is to reduce communication between server and tag as well as make the protocol secure against various security attacks. This protocol uses the generator in the start up (step 1) of the communication so that it remove the chances of any unauthorized person to take part in communication. Suppose if an attacker generate a random number and send the value without using generator value to tag, then the tag simply reject the session (step 2) on the basis of verification (verification is based on the value of

generator). This protocol is also secure against various attacks as described below.

1) **Privacy** : This protocol provide privacy, since to get the ID of each tag, Private key is required which is kept secure by server.

2) **Replay Attack** : For our protocol, the tag is identified by the tag personal ID, and the personal ID is changed after every session as the tags information is accessed by a reader.

3) **Eavesdropping** : For the proposed protocol, when the tag is actually communicating its on chip information to a reader, the information sent through a message encrypted by a session key. This ensures that an eavesdropper cannot easily obtain the information in plain text.

4) **Impersonation** : Impersonation is not possible as long as the personal ID is changed every time and the key between the server and tag is secure, since the cloned tag with the obsolete personal ID cannot be recognized by the server in the next session.

5) **De-Synchronization** : The back-end server stores both the current and previous pairs of personal IDs so that the protocol can still work even when the tag fails to update its personal ID by a de-synchronization attack between the tag and the reader.

6) **Cloning** : An adversary cannot clone the tag since the key and other secret information are used with the random number when it is transmitted in the insecure channel.

VI. Advantage of The Proposed Protocol

1) There are only 3 steps in the proposed protocol against 4 steps in the existing protocol.

2) Proposed protocol verifies server without sending any data whereas the existing protocol first sends data then verify server.

VII. Conclusion

An efficient RFID authentication protocol of Zhang and Qi provide maintain system security but it doesn't reduce the communication steps between server and tag. Therefore we need a modified RFID protocol which is more efficient than the existing protocol The modified proposed protocol is more efficient because it consists only three steps in comparison to existing protocol and it can be applied to any random tag. In this protocol the tag ID of any random tag can be easily calculated and on the basis of this ID the details of that tag can be searched in the server database. This protocol uses the benefits of both Chous protocol and Zhangs Protocol in making the RFID protocol more secure and applicable to a wide range of tags.

***Abstract*— Gesture recognition as a topic in computer science and language technology has the goal of interpreting human gestures via mathematical algorithms. Gestures can originate from any bodily motion or state but commonly originate from the face or hand. Current research focus includes on the emotion recognition from the face and hand gesture recognition. Gesture recognition enables humans to communicate with the machine and interact naturally without any mechanical devices. This paper investigates the possibility to use non-audio/video sensors in order to design a low-cost gesture recognition device that can be connected to any computer on the market. The paper proposes an equation that relates the distance and voltage for a Sharp GP2Y0A21 and GP2D120 sensors in the situation that a hand is used as the reflective object. In the end, the presented system is compared with other audio/video system that exist on the market.**

Keywords*— gesture recognition, infrared detectors, hand gesture detection, hand gesture recognition, motion presence;

I. INTRODUCTION

This paper presents a simple implementation of a gesture control interface that can ease the human – computer interaction. It allows the user to control various computer applications with simple hand gestures. The system we implemented uses only infrared sensors for gestures detection and an Arduino Leonardo to process them. We used a method based on the hand position detection to recognize the gestures. Different gestures can be detected based on the position and the moving direction of the hand.

The research in the field of gesture recognition is in full progress and many authors have different methods of implementation. In [1] the authors present a method of gesture recognition based on multiple sensors fusion technique: three kinds of sensors, namely surface Electromyography (sEMG) sensor, 3-axis accelerometer (ACC) and camera are used together to capture the dynamic hand gesture. In [2] and [3] the camera from the Kinect sensor is used. In [4] a hand gesture detection and classification system using two differential Pyro-electric Infrared (PIR) sensors for motion detection and a camera is introduced.

This paper proposes a non-audio/video sensor-based system comprising hardware and software components. The sensors used in the system (e.g. the sharp sensors) were properly calibrated in order to have a reliable system. The paper demonstrates that, with a good calibration of the sensors and a good software components, a low cost non-audio/video system can recognize a hand gesture in at least 95% of the cases with a low CPU usage of the microcontroller and a time of execution (from the gesture is made to the time the PC executes the command) of minimum 60 ms per gesture. Moreover the paper derives equation that shapes the interaction between the hand skin and the Sharp sensors.

This paper is organized as follows. Section II presents the hardware used for the implemented gesture control interface and the structure of the interface. Section III proposes the algorithm used for the gesture recognition, Section IV gives the conclusions regarding the implemented system.

II. THE HARDWARE

This section presents the hardware we used to implement the gesture control interface, the calibration of the sensors (where it was necessary) and the subsystems that compose the interface.

A. Arduino Leonardo Development Board

Arduino is an open source development board based on the Atmega32u4 microprocessor. The Leonardo model [5] differs from all previous Arduino boards in that the Atmega32u4 supports direct USB communication, eliminating the need for a secondary dedicated processor. This way the board can emulate different peripheral devices (mouse, keyboard) while connected to a computer.

One of the major advantages of using a single chip for code processing and USB communication is the increased flexibility in the communication with the computer. While the development board is recognized by computer's operating system as a virtual serial port, it can emulate a peripheral device. Also, using a USB communication makes the final device available for any person that has a PC with USB ports. Thus, the final system will have a worldwide audience.

B. Ultrasonic sensors - PING)))™

The ultrasonic sensors are active sensors that emits an ultrasonic wave (frequency greater than 20 kHz) and receives the signal reflected on the target object. The distance to the target object is directly proportional to the time the ultrasonic wave needs to get to the object and then back to the sensor.

The ultrasonic Parallax PING))) sensor [6] provides an accurate method for measuring distances between 2cm and 3m. The sensor emits a 40 kHz burst under the control of a microcontroller. It will generate as output signal a pulse whose width is proportional to the distance to the target. In the system, described in this paper, the PING))) sensor is part of the motion

detection subsystem. It will detect the movement inside a specified perimeter and activates/deactivates the other subsystems. Hence, we when the user is in the device area, at less than 50 cm of the device, the gesture recognition will begin. As the PING))) sensor output is influenced by the environmental temperature, the sensor output was calibrated for a temperature between 20°C -30°C.

C. *Passive infrared sensors - SE-10 PIR*

A motion detector is a device that can detect moving objects around it. In this category of sensors are included the passive infrared sensors (PIR). A PIR sensor measures infrared (IR) light radiating from objects. It can work in far infrared (FIR) and intermediate infrared (IIR) light for wavelengths between 4 and 20 µm.

The SE-10 sensor [7] can detect moving light sources whose wavelength is in the domain 7…14 µm. The human body emits infrared radiation in the wavelength interval of 8 to 14 µm. This means that the SE-10 sensor is an excellent detector for moving people. The sensor will 1-2 seconds after it is power on in order to calibrate itself to the background infrared radiation and detect motion.

In this project the SE-10 PIR sensor is used in the motion detection subsystem along with the PING))) ultrasonic sensor. If it detects a person close to the system then it will trigger the PING))) sensor.

D. *IR sensors for distance measurement - Sharp*

The IR sensors use the infrared light to detect and measure the distance to the target object. The main limitation of these sensors is the maximum distance that they can measure.

Typically, they are used to measure distances between 4-150 cm. In this project two models of IR sensors are used (both produced by Sharp company):

- Sharp IR GP2D120 [8] – can measure distance in the interval [4, 30] cm;
- Sharp IR GP2Y0A21 [9] – can measure distance in the interval [10, 80] cm.

The output voltage of these sensors is non-linear and the producer provides in the datasheets the graphics needed to convert the output voltage to the corresponding distance.

During the tests we noticed that the distance obtained using the data provided by the datasheet did not match the real one. This is because the datasheet calibration is done using a white or gray paper as the reflective object. Our system uses the hand as the reflective object (the hand skin).

TABLE I. THE EXPERIMENTAL OUTPUT VOLTAGE FOR SHARP IR GP2Y0A21

Distance[cm]	Voltage [V]	Distance [cm]	Voltage[V]
6	3.278667	45	0.700667
8	2.752000	55	0.641333
10	2.536667	60	0.622000
15	1.816667	70	0.632667
25	1.176667	75	0.627333
30	1.011333	80	0.631333

TABLE II. THE EXPERIMENTAL OUTPUT VOLTAGE FOR SHARP IR GP2D120

Distance [cm]	Voltage[V]	Distance[cm]	Voltage[V]
2	2.970	16	0.866
4	2.757	18	0.766
6	1.969	20	0.695
8	1.589	22	0.630
10	1.367	24	0.551
12	1.085	26	0.513

Thus, in order to fix this issue the sensors had to be calibrated. The calibration method was done experimentally. For different predefined distances the output voltage was measured. Based on the results, the distance-voltage variation law was determined for each sensor model.

In Fig. 1 and Fig. 2 the inverse of the measured distance, 1/L, is represented with a blue line. In this case, we observed that the inverse distance parameter could be approximated by a linear function for both sensors. Based on the red curves (Fig.1 and Fig. 2) the relations between the measured distance and the output voltage for the two sensors are given by (1) for Sharp GP2Y0A21 and (2) for Sharp GP2D120:

$$L = 6787/(V-3) - 4 \quad (1)$$

$$L = 2914/(V+5) - 1 \quad (2)$$

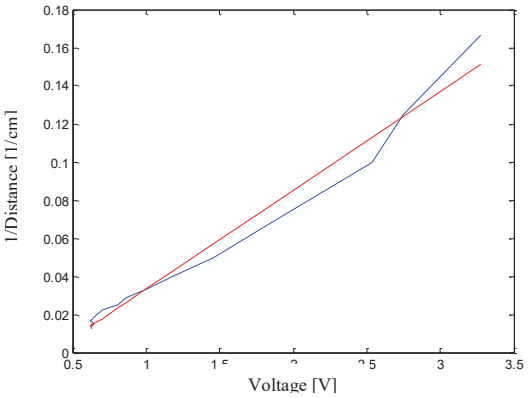

Fig.1: Linearized characteristic for Sharp IR GP2Y0A21

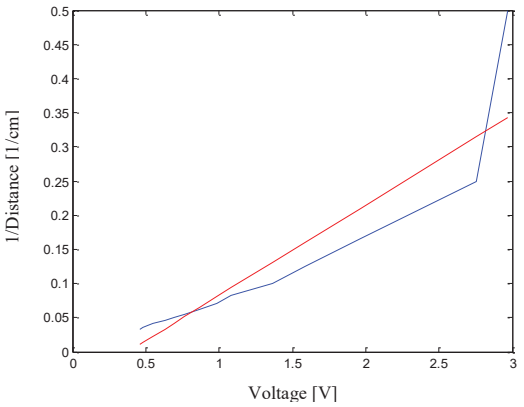

Fig.2: Linearized characteristic for Sharp IR GP2D120

Another issue that we observed at the Sharp sensors is that the output signal of the sensors is affected by noise from the power supply or from the other electronic components of the

circuit. The noise impacts the quality of the measurements as it can determine fast variations of the output voltage. To remove the effect of the noise on the output signal two capacitors, a 100nF and a 10 µF were connected between the Vcc (power supply) and GND (ground) pins of the sensor. The connection mode can be seen in Fig.3 and Fig.4.

This optimization of the Sharp sensor resulted in an increase from 80 to 95% of the gestures sensed by this sensors.

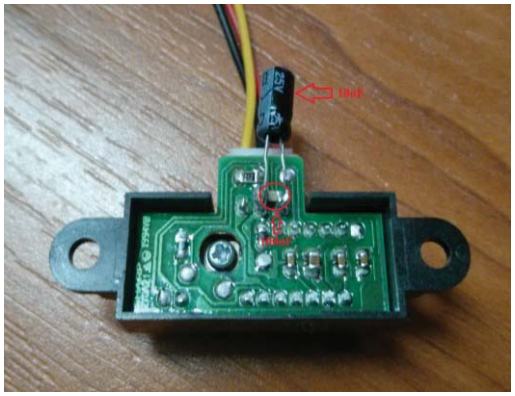

Fig. 3 Connection of the capacitors to eliminate noise in the output signal (Sharp sensor)

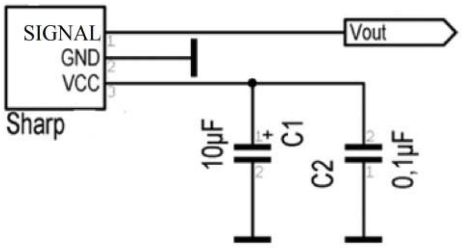

Fig. 4 Electric scheme for connection of the two capacitors

E. TFT Arduino display

The system has also a display that shows different information to the user (e.g. it can display the gesture made by the user, the state of the system).

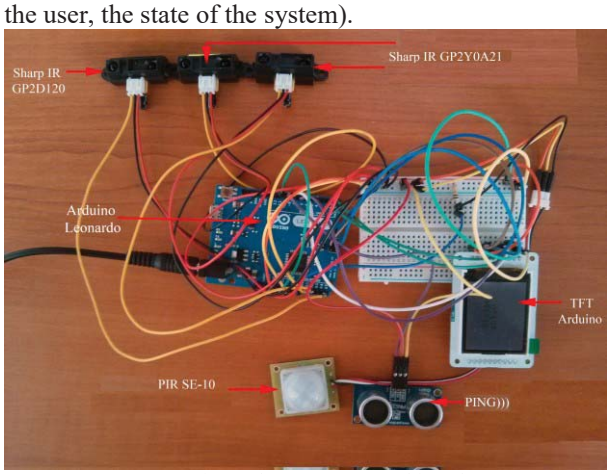

Fig. 5 The gesture control interface

We used the Arduino TFT LCD Screen [10] with a 1.77" diagonal, and 160 x 128 pixel resolution.

In Fig. 5 is the physical implementation of the gesture control interface (the first prototype). The prototype was made more user friendly (i.e. developing a PCB to integrate the Arduino board and the sensors and designing a case), as one can see in Fig. 6. The design of the final product is still under research as we want to make it smaller so that the system can be view as a small accessory.

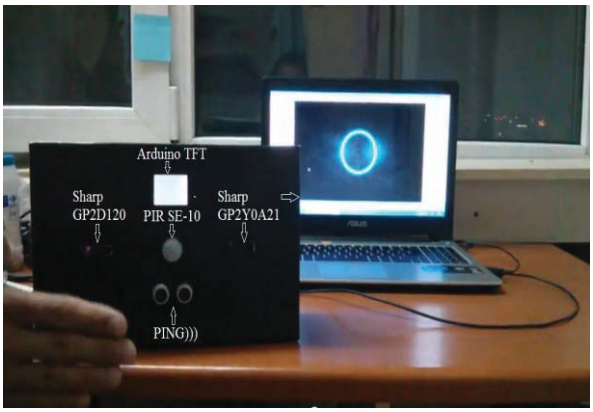

Fig. 6 The gesture control interface

III. THE LOGIC BLOCKS OF THE SYSTEM

Fig. 7 shows the diagram of the modules that we used to implement the gesture control system. All the modules are explained in the next paragraphs.

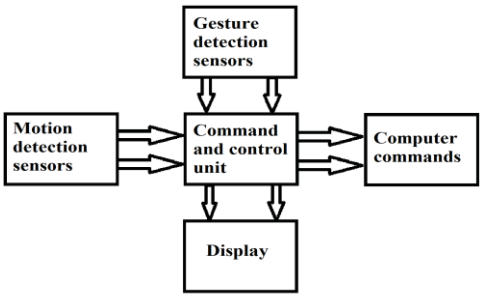

Fig. 7 The modular diagram of the gesture recognition system

A. The modules description

1) Motion detection module

It contains two sensors: the SE-10 PIR and the ultrasonic PING))).

First the PIR sensor will detect the motion of a person. Based on our work with the PIR sensor in the eWALL EU-project but also some internal projects [11][12] and the experiments with the gesture recognition system we can conclude that the SE-10 PIR sensor can sense the presence of a person from a maximum distance of 140cm.

After the PIR sensor detects that a person is in the proximity of the device the PING))) sensor will measure the distance to the person. If this distance is lower the 50 cm the gesture recognition system will start interpret the person gestures. The threshold of 50 cm distance was chosen experimental based on how far a person is sitting from the PC.

2) Gesture detection module

Three Sharp IR sensors are used to detect gestures: two GP2Y0A21 sensors and one GP2D120. If one sensor detects a gesture the others are not sensing for that period.

The GP2D120 sensor is used to detect if the hand, positioned at a maximum distance of 15 cm from the device, is not moving for a period between 300ms and 2s. If this is the case and the user is watching a movie the movie is paused or resumed (an explanatory video can be seen here: https://goo.gl/OoTSZl).

In order to determine the time from the moment the sensor sensed the hand and the moment the video is paused/resumed a time stamp, with the moment the sensor is sensed by the microcontroller, is sent alongside the command that the PC should interpret. This timestamp is compared with the timestamp from the moment the command sent is executed. The difference was of 20ms. Thus, the time from the sensing moment to the execution of the command by the PC is 60ms, regarding the fact that the typical response time of the GP2D120 sensor is 40ms. We choose a range between 300ms and 2s so that we avoid any errors caused by an accidental hand gesture. The gesture is recognized in 95% of the cases. Moreover a period of 2s, we found that is a good period for a user to feel like the action is caused by his actions.

The two GP2Y0A21 sensors are used for: one of them for detecting the right->left or left->right movement of the hand; the other one for detecting how far/close is the hand from the device. The distance rage that the hand has to be from the sensors is 4-40cm. For lower or higher distances than this one the gesture recognition decreases with 35-45%. Each sensor is used for sending a different command to the computer (e.g. scrolling, moving left/right a slideshow) an explanatory videos can be seen here: https://goo.gl/gZT9QQ ; https://goo.gl/ajwTZw). As explained, in the case of the GP2D120, a timestamp was used in order to see the reaction of the system. The time between the sensing and the PC execution of the command is 60ms.

3) Command and control subsystem

It represents the ‚brain' of the entire system. It is based on the Arduino Leonardo development board. It collects the data from all the sensors and processes it. Depending on the results Arduino can transmit to computer specific commands for controlling different applications (PowerPoint, internet browser, image viewer). In order to transmit the commands Arduino Leonardo emulates a peripheral device (either a mouse or a keyboard). The use of the Arduino Leonardo board makes the system easy to use and no additional software has to be installed. As the user receives the system and plugs it into the computer the system will interpret the predefined gestures accordingly.

4) Display subsystem

It contains the Arduino TFT LCD screen and it is used to inform the user about the state of the system or the gesture he made.

B. Comparison with other systems existed on the market

In order to evaluate the performances of our system we compared it with other gesture recognition system: the Microsoft Kinect and the Video Camera from a SonyVaio laptop with the SonyVaio gesture recognition built in software.

First of our system is a non-audio vide system. That means that the system is free from any image processing or skeleton processing algorithms, thus, making it computational light. This is shown by the fact that the process is running on a 16MHz processor with a CPU usage of 20%. The Kinect for Windows has recommended requirements of 3.1GHz [13] and the SonyVaio built in camera uses 5% CPU from a computer with a processor of 2GHz. Hence, the system that we built can be used for any computer regardless of the type or specifications. Also, our system is a plug and play one without the need of installing additional software on the user PC.

In terms of gesture recognition, the system that we described in this paper has a gesture recognition of 95% with a very fast learning curve of how to use the device. The SonyVaio built in gesture recognition is around 90% with a lot of faults especially because the system doesn't always sense the position of the hand. The KINECT has a gesture recognition percentage of 95-97% but it requires additional software to be installed. In terms of costs the Kinect is around 200 EUR and the device that we presented is less than half that amount.

IV. SOFTWARE

The software application that runs on the Arduino board is realized according to the diagram shown in Fig. 8. The code for reading the sensors and for sending commands to computer is placed inside a loop. At every iteration of the loop Arduino will read the output data from the SE-10 PIR sensor to check if a person presence is detected. If true, then the ultrasonic PING))) sensor is read to determine the distance to the person. If the person is close enough to the system then a reading cycle is started (the outputs of the Sharp IR are read in order to detect any possible gesture made by the user).

If it is possible to detect a gesture based on the output of one sensor then this sensor is kept active and the other ones are disabled. The output of the active sensor is read and interpreted (translated into a command that is sent to computer). Once there is no more gesture detected the other sensors are enabled and the reading cycle restarts. Arduino emulates the mouse and keyboard to send commands to computer. For example, if the user moves his hand from left to right/from right to left then the command sent is "press right arrow key"/ "press left arrow key". In order to do this Arduino has to emulate the keyboard. If the user moves his hand forward/backward then Arduino has to emulate the mouse and sends the command for scroll wheel movement.

The gestures that can be detected by the system are: left/right/forward/backward/motionless hand movement. With these basic commands the user can change the pictures in a slideshow, change the sides in a PowerPoint presentation, seek forward/backward in a movie, zoom in/out a picture, increase/ decrease the volume of a movie or song.

In the last part of the code is checked if the time from activation is higher than a preset value. If the measured time

interval is greater than the preset one, then the presence of the user is checked again. If the result of this checking is negative, then the system becomes inactive; otherwise, the system remains active and continues interpreting gestures made by the user.

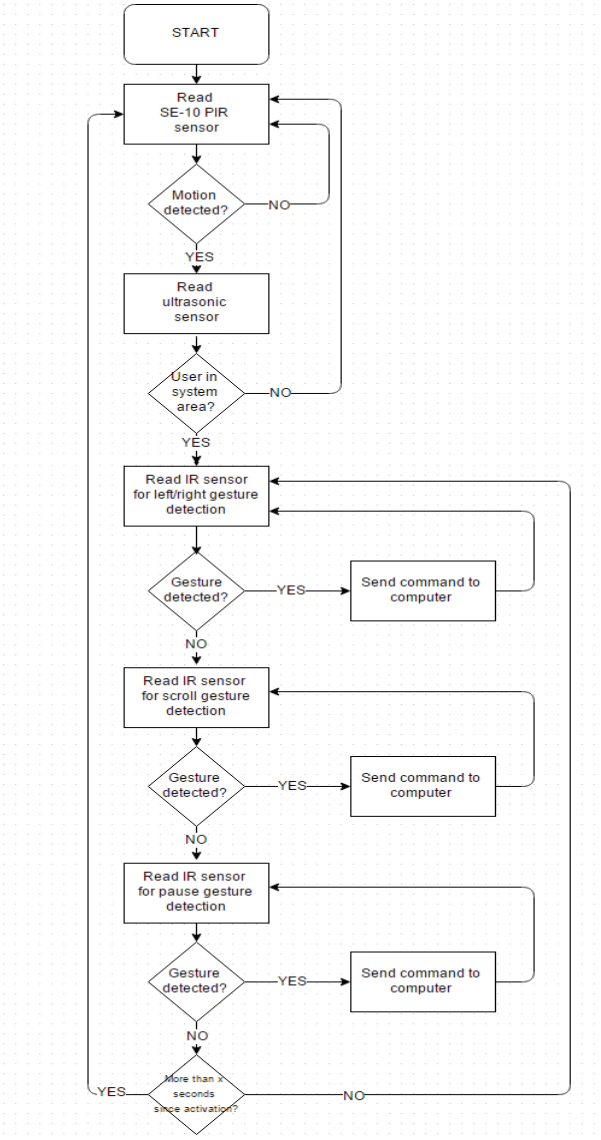

Fig. 8 Diagram of the algorithm used to detect gestures

V. Conclusions

The system presented in this paper proves the fact that a one can implement a simple gesture control interface by using only an Arduino Leonardo development board, motion detection PIR sensor and distance measurement sensors (infrared and ultrasonic sensors). The system can recognize a limited number of gestures but it can prove very useful for PowerPoint presentations, browsing photos, watching a movie etc. The cost of this system is relatively low compared to the solutions that are based on image processing to detect gestures. Also, this is a low power consumption system.

Another advantage of this gesture control interface is the fast response time. Since the amount of information processed by Arduino is small, the main cause of delays is the frequency of Sharp sensors reading.

This system is independent from the computer to which it connects. It can be connected to any computer, regardless of its operating system or specifications.

The functionality and the performance of this system can be improved by adding new sensors (for example, accelerometers) or by replacing the existing ones with more efficient ones. Using a network of IR sensors can allow the detection of more complex gestures (3D gestures).

***Abstract*—Delay tomography means to estimate link delays in a network by measuring end-to-end path delays. In order to perform delay tomography accurately, strict clock synchronization is required between a transmitter node and a receiver node, but it is difficult in reality. As a delay tomography method without clock synchronization between them, a differential delay tomography using compressed sensing has been proposed and its performance has been theoretically analyzed. In the differential delay tomography, path delays are first measured between a transmitter node and a receiver node in the same way as a conventional method, and then a selected path delay is subtracted as the reference from all other path delays to eliminate the clock synchronization error between them. In this paper, taking into consideration the effects of the random delays in normal links and the clock skew between a transmitter node and a receiver node in a network, we propose a path ordering and reference selection method to reduce the effects and evaluate the performance by computer simulations.**

I. Introduction

Network tomography means to estimate internal link states by end-to-end path measurements in a network. In particular, when end-to-end path delays are measured to estimate link delays, it is called delay tomography [1], [2]. Any path delay between a transmitter node and a receiver node is the sum of the delays in all links over the path, so the delay tomography is formulated as an inverse problem to estimate unknown link delays from measured path delays. Furthermore, when we are interested in only identification of a limited number of abnormal links giving much longer delays, thanks to the sparsity of the abnormal links, compressed sensing can be efficiently applied to the identification problem [3]. Here, compressed sensing is a theory in signal/image processing for reconstructing a sparse vector based on its linear measurements of dimension smaller than the size of the unknown vector [4].

In delay tomography, when a transmitter node sends a probing packet to a receiver node though a path, the transmitter node writes the transmission time in the packet. This is because the transmitter node needs to notify the packet transmission time of the receiver node to calculate the difference between the transmission time and reception time as the transmission delay for the packet. Therefore, to perform the delay tomography accurately, strict clock synchronization is required between the transmitter node and receiver node, but it is difficult in reality. To identify abnormal links without clock synchronization in a network, a differential delay tomography with compressed sensing has been proposed [5]. In the differential delay tomography, after measuring all path delays between a transmitter node and a receiver node, the delay in a path is first selected as a reference and then the reference delay is subtracted from all the other delays to eliminate the clock offset between them.

In [5], for the differential delay tomography, the performance degradation due to differentiation has been theoretically analyzed. The performance is affected by the random delays in normal links and the clock skew between a transmitter node and a receiver node, however, their effects have not been well investigated. Therefore, in this paper, taking into consideration of the two effects, we re-formulate the problem of the differential delay tomography in detail, propose a path ordering and reference selection method for reducing the effects, and evaluate its performance by computer simulations.

II. Preliminary of Compressed Sensing

First, we define the ℓ_p norm ($p \geq 1$) of a vector $\mathbf{x} = [x_1\ x_2\ \cdots\ x_N]^\top \in \mathbb{R}^N$ as

$$\|\mathbf{x}\|_p = \left(\sum_{i=1}^{N} |x_i|^p \right), \tag{1}$$

where $[\cdot]^\top$ denotes the transpose operator.

Next, we define the mutual coherence $\mu(\mathbf{A})$ of a matrix $\mathbf{A}$, which is defined as the largest absolute inner product between any two columns $\mathbf{a}_i$, $\mathbf{a}_j$ of $\mathbf{A} \in \mathbb{R}^{M \times N}$:

$$\mu(\mathbf{A}) = \max_{1 \leq i,j \leq N, i \neq j} \frac{|\mathbf{a}_i^\top \mathbf{a}_j|}{\|\mathbf{a}_i\|_2 \|\mathbf{a}_j\|_2}. \tag{2}$$

If

$$k < \frac{1}{2} \left(1 + \frac{1}{\mu(\mathbf{A})} \right), \tag{3}$$

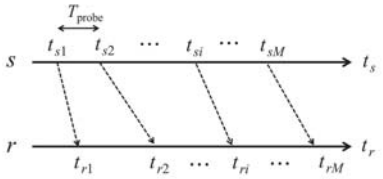

Fig. 1: Delay tomography session time chart.

then there exists at most one sparse vector $\mathbf{x}$ with k nonzero components that $\mathbf{y} = \mathbf{A}\mathbf{x}$, where a vector $\mathbf{y} = [y_1\ y_2\ \cdots\ y_M]^\top \in \mathbb{R}^M$ is a linear measurement vector.

Given a measurement vector $\mathbf{y}$ and a measurement matrix $\mathbf{A}$, compressed sensing estimates a sparse vector $\mathbf{x}$ by means of ℓ_1 optimization of the form:

$$\hat{\mathbf{x}} = \arg\min_{\mathbf{x}} \|\mathbf{x}\|_1 \quad \text{subject to } \mathbf{y} = \mathbf{A}\mathbf{x}. \tag{4}$$

ℓ_1 optimization is feasible when $\mathbf{x}$ is a completely sparse vector. However, if $\mathbf{x}$ is an approximately sparse vector, compressed sensing should estimate $\mathbf{x}$ by means of ℓ_1-ℓ_2 optimization of the form:

$$\hat{\mathbf{x}} = \arg\min_{\mathbf{x}} \left(\frac{1}{2}\|\mathbf{y} - \mathbf{A}\mathbf{x}\|_2^2 + \lambda \|\mathbf{x}\|_1 \right), \tag{5}$$

where $\lambda (> 0)$ is a constant [6].

III. System Models and Assumptions

A. System Model

Let $\mathcal{G} = (\mathcal{V}, \mathcal{E})$ denote an undirected network, where $\mathcal{V}$ and $\mathcal{E}$ denote sets of nodes and links, respectively. In the network, we select a transmitter node $s \in \mathcal{V}$ and a receiver node $r \in \mathcal{V}$ to measure the end-to-end paths delays between them. We formulate $\mathcal{E}$ as $\mathcal{E} = \{e_1, e_2, \ldots, e_N\}$, and define $\mathcal{Q} = \{q_1, q_2, \ldots, q_M\}$ as a subset of all paths from s to r, where $q_i = \{(s, v^{(i,1)}), (v^{(i,1)}, v^{(i,2)}), \ldots, (v^{(i,|q_i|-1)}, r)\} \subset \mathcal{E}$ represents the i-th path in $\mathcal{Q}$ and $v^{(i,m)} \in \mathcal{V} \setminus \{s, r\}$ are intermediate nodes in the path. We assume that link delay d_{e_j} arises independently in each link $e_j \in \mathcal{E}$ $(j = 1, 2, \ldots, N)$, and that path delay D_{q_i} is the sum of the delays in all links included the i-th path q_i.

Fig. 1 shows an overview of one delay tomography session. In the delay tomography session, the transmitter node s sends probing packets to the receiver node r to make r measure the end-to-end path delays on the pre-defined paths between them. The i-th probing packet is transmitted from s at time of t_{si} in terms of clock of s through measurement path q_i, and is received at r at time of t_{ri} in terms of clock of r $(i = 1, 2, \ldots, M)$. The i-th probing packet experiences a delay D_{q_i}, and D_{q_i} is actually calculated from t_{si} and t_{ri} as

$$D_{q_i} = t_{ri} - t_{si}. \tag{6}$$

The probing packets are transmitted with packet transmission interval of T_{probe}, and the delay tomography session repeats until all pre-defined end-to-end path delays are measured. From all the end-to-end path delays, the abnormal links in the network are finally identified based on compressed sensing.

B. Links Delay Model

We consider two kinds of links: abnormal link and normal link. The abnormal link is a link giving a constant longer delay x_A, whereas the normal link is a link giving a random shorter delay x_N which is independent and identically Gaussian distributed (i.i.d.) with average α_N and standard deviation σ_N [7]. We define a set of abnormal links as $\mathcal{E}_A \subset \mathcal{E}$.

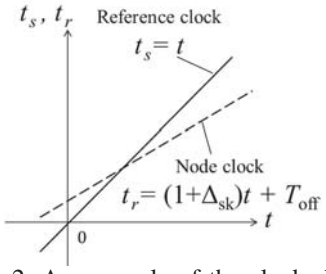

Fig. 2: An example of the clock skew.

C. Clock Error Model

Crystal oscillator (XO) is widely used as a clock generator in wireless or wired nodes. Since the oscillating frequency of XO is instable in its temperature characteristic, there is always an inevitable deviation in the oscillation frequency. Therefore, even if clock synchronizes between s and r is established at a time, the error between the clocks of s and r arises in time, which is called "clock skew."

Fig. 2 shows an example of the clock skew. On the basis of the clock of s, the clocks of s and r are respectively written as

$$t_s = t, \tag{7}$$

$$t_r = t + T_{\text{off}} + \Delta_{\text{sk}} t, \tag{8}$$

where T_{off} denotes the time offset between the clocks s and r at $t = 0$, and Δ_{sk} denotes the clock skew parameter. Assuming that the clock frequency uniformly deviates in $[-\Delta, +\Delta]$, Δ_{sk} follows the triangular distribution $[-2\Delta, 0, +2\Delta]$, so the average and variance of Δ_{sk} are respectively written as

$$E(\Delta_{\text{sk}}) = 0, \tag{9}$$

$$E(\Delta_{\text{sk}}^2) = \frac{2}{3}\Delta^2, \tag{10}$$

where $E[(\cdot)]$ denotes the ensemble average of $(\cdot)$.

IV. Conventional Delay Tomography

A. Formulation of Delay Tomography

The measured path delay over q_i is written as $(i = 1, 2, \cdots, M)$

$$y_i = t_{ri} - t_{si}, \tag{11}$$

$$= z_i + T_{\text{off}} + \Delta_{\text{sk}}(t_{si} + z_i), \tag{12}$$

$$z_i = \sum_{e_j \in q_i} d_{e_j}, \tag{13}$$

where d_{e_j} is the link delay in e_j. Defining a measured path delay vector $\mathbf{y} \in \mathbb{R}^M$, a link delay vector $\mathbf{x} \in \mathbb{R}^N$, a clock offset vector $\mathbf{x} \in \mathbb{R}^M$, and a clock skew vector $\mathbf{x} \in \mathbb{R}^M$ respectively as

$$\mathbf{y} = [y_1\ y_2\ \cdots\ y_M]^\top, \tag{14}$$

$$\mathbf{x} = [x_1\ x_2\ \cdots\ x_N]^\top, \tag{15}$$

$$\mathbf{v} = [v_i\ v_2\ \cdots\ v_M]^\top, \tag{16}$$

$$\mathbf{w} = [w_1\ w_2\ \cdots\ w_M]^\top, \tag{17}$$

where

$$x_j = d_{e_j}, \tag{18}$$

the delay tomography is formulated as

$$\mathbf{y} = \mathbf{A}\mathbf{x} + (\mathbf{v} + \mathbf{w}). \quad (19)$$

In (19), $\mathbf{A} \in (0,1)^{M\times N}$ is the binary routing matrix of $\mathcal{Q}$, whose components $a_{i,j}$ $(i = 1, 2, \ldots, M, j = 1, 2, \ldots, N)$ are 1 if $e_j \in q_i$, and 0 otherwise, and the i-th elements of $\mathbf{v}$ and $\mathbf{w}$ are written respectively as

$$v_i = T_{\text{off}}, \quad (20)$$

$$w_i = (t_{si} + z_i)\Delta_{\text{sk}}. \quad (21)$$

When we are interested in identification of a limited number of abnormal links, even for $N > M$, due to the sparsity of the abnormal links, we can solve (19) by means of the ℓ_1-ℓ_2 optimization given by (5).

B. Effect of Random Delay

Let us set $\mathbf{v} + \mathbf{w} = \mathbf{0}$ in (19) for a whole. In this case, the link delay vector $\mathbf{x}$ can be furthermore decomposed as

$$\mathbf{x} = \mathbf{x}_N + \mathbf{x}_A, \quad (22)$$

$$\mathbf{x}_A = \begin{cases} x_j - x_G & (\text{if} \quad e_j \in \mathcal{E}_A) \\ 0 & (\text{otherwise}) \end{cases}, \quad (23)$$

where $\mathbf{x}_N$ and $\mathbf{x}_A$ are the normal link delay vector and abnormal link delay vector, respectively. Thus we can rewrite (19) as

$$\mathbf{y} = \mathbf{A}\mathbf{x}_A + \mathbf{u}, \quad (24)$$

$$\mathbf{u} = \mathbf{A}\mathbf{x}_N, \quad (25)$$

where $\mathbf{u}$ is the error vector contributed from normal link delays. The average power of the normal link delays, namely, the average of the squared norm of $\mathbf{u}$ limits the performance of the delay tomography, so it can be calculated as

$$\begin{aligned} \varepsilon_{\text{delay}} &= E[\mathbf{u}^\top \mathbf{u}] \\ &= \sum_{i=1}^{M} E[u_i^2] \\ &= \sum_{i=1}^{M} (\rho_i^2 \alpha_N^2 + \rho_i \sigma_N^2). \end{aligned} \quad (26)$$

where ρ_i is the number of links through the i-th path q_i. Eq. (26) shows that the conventional delay tomography has no parameters to reduce the effect of random delays in normal links.

C. Effect of Clock Error

Now, let us set $\mathbf{u} = \mathbf{0}$ in (19) for a whole. In this case, the average of the squared norm of $\mathbf{v}$ also limits the performance of the delay tomography, so it can be calculated as

$$\begin{aligned} \varepsilon_{\text{offset}} &= E[\mathbf{v}^\top \mathbf{v}] \\ &= \sum_{i=1}^{M} E[v_i^2] \\ &= \sum_{i=1}^{M} T_{\text{off}}^2. \end{aligned} \quad (27)$$

Furthermore, the average of the squared norm of $\mathbf{w}$ limits the performance of the delay tomography, so it can be calculated as

$$\begin{aligned} \varepsilon_{\text{skew}} &= E[\mathbf{w}^\top \mathbf{w}] \\ &= \sum_{i=1}^{M} E[w_i^2]. \end{aligned} \quad (28)$$

The i-th path delay z_i is bounded by T_{probe}, so we assume that z_i is uniformly distributed in $[0, T_{\text{probe}}]$ for the sake of simplicity. In this case, Eq. (28) is calculated as

$$\varepsilon_{\text{skew}} = \frac{2\Delta^2}{3} \sum_{i=1}^{M} \left(t_{si}^2 + t_{si} T_{\text{probe}} + \frac{T_{\text{probe}}^2}{3} \right). \quad (29)$$

Eqs. (27) and (29) show that the conventional delay tomography has also no parameters to reduce the effects of the clock error, namely, there is no way except for estimating T_{off} accurately to compensate for T_{off} by $T_{\text{off}} - \hat{T}_{\text{off}}$ and employing an XO with high frequency stability for each node.

V. Reference Path Selection

A. Formulation of Delay Difference Tomography

In order to get rid of the effect of T_{off}, defining the m-th component y_m and the m-th row vector $\mathbf{a}_m \in \mathbb{R}^{M-1}$ of a reference component and a reference vector, respectively, we subtract the reference component and the reference vector from all the other components and all the other vectors. That is, defining a new measurement vector $\mathbf{y}^{(m)}$ and a new routing matrix $\mathbf{A}^{(m)} \in \{-1, 0, 1\}^{(M-1)\times N}$ as

$$\mathbf{y}^{(m)} = [y_1 - y_m \; y_2 - y_m \; \cdots \; y_M - y_m]^\top, \quad (30)$$

$$\mathbf{A}^{(m)} = \quad (31)$$

$$\begin{bmatrix} a_{1,1} - a_{m,1} & a_{1,2} - a_{m,2} & \cdots & a_{1,N} - a_{m,N} \\ a_{2,1} - a_{m,1} & a_{2,2} - a_{m,2} & \cdots & a_{2,N} - a_{m,N} \\ \vdots & \vdots & \ddots & \vdots \\ a_{i,1} - a_{m,1} & a_{i,2} - a_{m,2} & \cdots & a_{i,N} - a_{m,N} \\ \vdots & \vdots & \ddots & \vdots \\ a_{M,1} - a_{m,1} & a_{M,2} - a_{m,2} & \cdots & a_{M,N} - a_{m,N} \end{bmatrix}.$$

we have the following equation:

$$\mathbf{y}^{(m)} = \mathbf{A}^{(m)}\mathbf{x} + \mathbf{w}^{(m)}, \quad (32)$$

where the link delay vector $\mathbf{x}$ does not change by the subtraction, the time offset vector $\mathbf{v}$ disappears completely, and $\mathbf{w}$ is also changed to

$$\mathbf{w}^{(m)} = [w_1 - w_m \; w_2 - w_m \; \cdots \; w_M - w_m]^\top. \quad (33)$$

By the subtraction, although the clock skew still affects the accuracy of identifying abnormal links, it is possible to accomplish the delay tomography without the clock synchronization between the transmitter node and receiver node. The trade-off for getting rid of the clock offset is reducing the number of expressions, however, compressed sensing can estimate a unique solution from an underdetermined linear system, so it is still simply applicable in the proposed method.

Using (22), we can rewrite (32) as

$$\mathbf{y}^{(m)} = \mathbf{A}^{(m)}\mathbf{x}_A + \mathbf{u}^{(m)} + \mathbf{w}^{(m)}, \quad (34)$$

$$\mathbf{u}^{(m)} = \mathbf{A}^{(m)}\mathbf{x}_N. \quad (35)$$

Eq. (34) shows that selecting a path as a reference, $\mathbf{A}$, $\mathbf{u}$ and $\mathbf{w}$ change $\mathbf{A}^{(m)}$, $\mathbf{u}^{(m)}$ and $\mathbf{w}^{(m)}$, respectively. It is proven in [5] that, if $\mathbf{A}$ is 1-identifiable, then $\mathbf{A}^{(m)}$ is also still 1-identifiable, in other words, as long as the number of abnormal links is guaranteed to be one, we can select any path as the reference to identify the abnormal link. In the following two subsections, we discuss a path ordering and reference selection method for reducing the effects of the normal link delays $\mathbf{u}^{(m)}$ and the clock skew $\mathbf{w}^{(m)}$.

B. Reference Path Selection for Reducing the Effect of the Normal Link Delays

The average of the squared norm of $\mathbf{u}^{(m)}$ is calculated as

$$\begin{aligned}\varepsilon_{\text{delay}}^{(m)} &= \sum_{i=1,i\neq m}^{M} E\left[(u_i-u_m)^2\right] \\ &= \sum_{i=1,i\neq m}^{M} \left\{(\rho_i-\rho_m)^2\alpha_N^2+(\rho_i-\rho_m)\sigma_N^2\right\} \\ &= \sum_{i=1,i\neq m}^{M} \alpha_N^2\left\{\rho_m-\left(\rho_i-\frac{\sigma_N^2}{2\alpha_N^2}\right)\right\}^2 \\ &+ \sum_{i=1,i\neq m}^{M}\left(2\rho_i\sigma_N^2-\frac{\sigma_N^4}{4\alpha_N^2}\right). \end{aligned} \quad (36)$$

Applying the Cauchy-Schwarz inequality to the first term of (36) results in

$$\begin{aligned}\varepsilon_{\text{delay}}^{(m)} &\geq \frac{\alpha^2}{M-1}\left[\sum_{i=1,i\neq m}^{M}\left\{\rho_m-\left(\rho_i-\frac{\sigma_N^2}{2\alpha_N^2}\right)\right\}\right]^2 \\ &+ \sum_{i=1,i\neq m}^{M}\left(2\rho_i\sigma_N^2-\frac{\sigma_N^4}{4\alpha_N^2}\right). \end{aligned} \quad (37)$$

To minimize $\varepsilon_{\text{delay}}^{(m)}$, ρ_m needs to satisfy the following expression on (37):

$$\rho_m = \frac{\sigma_N^2}{2\alpha_N^2}+\frac{1}{M-1}\sum_{i=1,i\neq m}^{M}\rho_i \approx \frac{1}{M-1}\sum_{i=1,i\neq m}^{M}\rho_i. \quad (38)$$

This implies that it is better to select the path as a reference, whose number of links is closer to the number of links averaged over all the paths.

C. Reference Path Ordering for Reducing the Effect of the Clock Skew

The average of the squared norm of $\mathbf{w}^{(m)}$ is calculated as

$$\begin{aligned}\varepsilon_{\text{skew}}^{(m)} &= \sum_{i=1,i\neq m}^{M} E\left[(w_i-w_m)^2\right] \\ &= \frac{2\Delta^2}{3}\sum_{i=1,i\neq m}^{M} E\left[\left\{(t_{si}-t_{sm})+(z_i-z_m)\right\}^2\right] \\ &= \frac{2\Delta^2}{3}\sum_{i=1,i\neq m}^{M}\left\{(t_{si}-t_{sm})^2+\frac{T_{\text{probe}}^2}{6}\right\}. \end{aligned} \quad (39)$$

Applying the Cauchy-Schwarz inequality to (39) also results in

$$\varepsilon_{\text{skew}}^{(m)} \geq \frac{2\Delta^2}{3(M-1)}\left\{\sum_{i=1,i\neq m}^{M}(t_{si}-t_{sm})\right\}^2+\frac{\sigma^2(M-1)T_{\text{probe}}^2}{9}. \quad (40)$$

To minimize $\varepsilon_{\text{skew}}^{(m)}$, t_{sm} needs to satisfy the following expression on (40).

$$t_{sm} = \frac{1}{M-1}\sum_{i=1,i\neq m}^{M} t_{si}. \quad (41)$$

This implies that it is better to select the path as a reference, whose probing packet is transmitted around at the middle of the delay tomography session.

Fig. 3: Network topology.

D. Proposed Path Ordering and Reference Selection Method for Reducing the Effect of the Normal Link Delays and the Clock Skew

From the results in the above two subsections, we can conclude that, in order to jointly reduce the effect of the normal link delays and the clock skew, one method is to order the measured paths with the numbers of links in an ascending order, transmit probing packets in the order, and finally select the path as a reference whose probing packet is transmitted around at the middle order. This is because the selected path automatically has the number of links close to the one averaged over all the measured paths.

VI. Performance Evaluation

A. Computer Simulation Environment

Fig. 3 shows the network topology with 14 nodes and 29 links for the performance evaluation, where the clock of s is not synchronized to the clock of r. We constructed the routing matrix for the network topology according to the method in [8], and we obtained the 15×29 matrix (15 path measurements for 29 links). In the computer simulation, applying the delay tomography method for a wireless network, we assumed that the delay of normal link is Gaussian-distributed with $\alpha_N = 15$ msec and $\sigma_N = 3$ msec [10], whereas that of abnormal link is $x_A = 500$ msec. In addition, we assumed the clock frequency deviation of each node is $\Delta = 40$ ppm [11]. Furthermore, we set the probing packet transmission interval $T_{\text{probe}} = 1$ sec. Finally, as the algorithm of solving (5), we employed the fast iterative shrinkage-thresholding algorithm (FISTA) [9] with optimized values of λ.

The procedure of the performance evaluation is as follows: we randomly select a link as an abnormal link and identify it using the proposed delay tomography method. We define the abnormal link identification ratio R as the number of correctly identified abnormal links divided by the total number of simulation runs.

B. Effect of the Normal Link Delays

For the constructed routing matrix, the maximum and minimum numbers of links are 10 and 3, respectively, and the average of the number of links over all the paths is around 6. Fig. 4 shows the abnormal link identification ratio versus the index of the path selected as a reference, where the number of links is shown for each path index. Here, we are interested in the effect only from the normal link delays, so we set $\Delta = 0$. We can see from this figure that we should select the path with index of 9 as the reference, whose number of links is 6, that is, is close to the average number of links over all the paths, since it can give the highest abnormal link identification ratio.

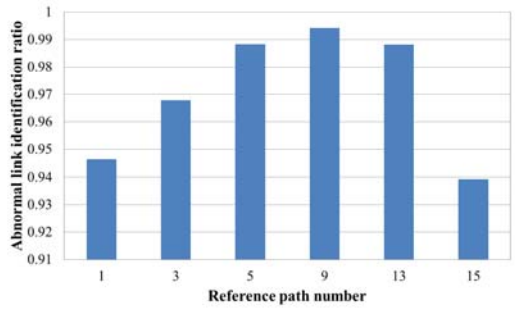

Fig. 4: abnormal link identification ratio vs. reference path number.

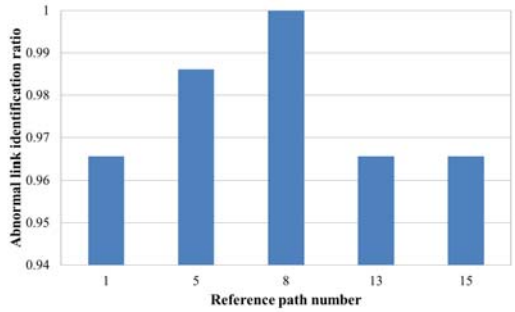

Fig. 5: abnormal link identification ratio vs. reference path number.

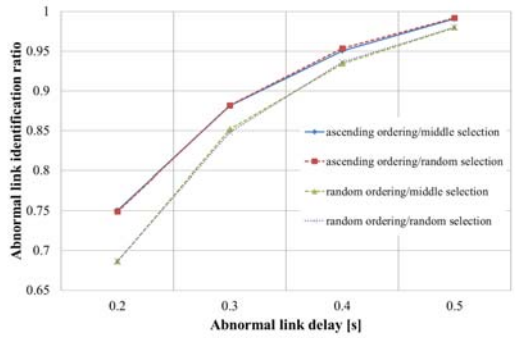

Fig. 6: abnormal link identification ratio vs. abnormal link delay.

C. Effect of the Clock Skew

For the constructed routing matrix, the number of paths is $M = 15$, so probing packets are transmitted fifteen times in a delay tomography session, so the middle order of probing packet transmission is around the 8th $(M/2) \approx 8$. Fig. 5 shows the abnormal link identification ratio versus the order of the referenced probing packet. We can see from this figure that we should select the path with order of 8 as the reference, whose probing packet is transmitted around at the middle of delay tomography session, since it can give the highest abnormal link identification ratio.

D. Performance of the Proposed Path Ordering and Reference Selectioning Method

Finally, Fig. 6 shows the performance of the proposed ascending ordering/middle selection method, which orders the paths with the numbers of links in an ascending order and selects a path with the middle order as the reference. For comparison purpose, this figure includes the performances of a random ordering/middle selection method, a ascending ordering/random selection method and a random ordering/random selection method. From the figure, we can see that the proposed ascending ordering/middle selection method performs best among the four methods. We can also see that, in the system setting, the random normal link delay is the dominant factor for determining the performance.

VII. Conclusion

In this paper, for the differential delay tomography, we analyzed the effects of the normal link delays and the clock skew on the abnormal link identification ratio, and proposed the path ordering and reference selection method for the reducing the effects. By computer simulations, we showed that the proposed ascending path ordering/middle reference selection method performs best, achieving the highest abnormal link identification ratio for smaller value of abnormal link delay.

***Abstract*—In this paper, a new prediction based dynamic scheduling mechanism is proposed to ensure quality of service (QoS) especially in Internet of Things (IoT) by dynamically allocating bandwidth. The scheduling scheme is analyzed for two different applications: i) to accommodate various streaming data of IoT applications or for medical applications. Traffic is segregated based on different traffic characteristics such as bit rate, packet loss rate and tolerable delay into different classes and they are prioritized based on these characteristics; and ii) a scenario when continuous data for a long time is generated such as, from many lightweight devices like sensors. The algorithm allocates bandwidth such that its utilization can be optimized for different applications. The scheduler decision is divided into two steps: (i) calculating average increase in queue length of high priority and medium priority services at current time slot from the previous time slot and, (ii) adding these values to previous weight values for corresponding services and multiplying with a coefficient. The performance is carried out under different system loading and scenarios. The results show the improvement of the proposed scheduler with respect to end to end delay distributions, packet drop and end to end jitter values.**

Keywords— Packet Scheduler, Service Differentiation; Internet of Things; Quality of service; Queue Management.

I. INTRODUCTION

From the day of emergence, the Internet of Things (IoT) has got wide identification for its prospective applications. For the IoT applications, such as video surveillance, smart metering [1], smart homes and malls equipped with certain security devices [2], medical application (fall detection) [3] etc, devices need to report various events and streaming data to a central server over a long period of time in an efficient way. In the network of smart devices, ensuring QoS to certain delay sensitive applications is of prime importance. IoT technology also provides added value to emergency response operations in terms of obtaining efficient cooperation. The response time for such applications and QoS requirements need to be guaranteed. Kleoec and Kos [4] proposed a priority model with two queues and presented packet transit time behaviour for a delay sensitive application with minimum bandwidth constraint. The model is simple; the utilization of higher priority was shown at the cost of high data loss for low priority data. Furthermore, various approaches have been developed in order to analyze and monitor energy efficiency [1], network topologies, performance related issues [2-3] and the availability of bandwidth [5]. The solution to delay sensitive applications is not efficient as discussed in the above studies. To ensure instant communication without packet loss and queuing delay especially for the delay critical applications, an efficient packet scheduling scheme becomes necessary.

This paper proposes a round robin based packet scheduling scheme to provide QoS by dynamically allocating bandwidth. Two main important features which make this scheduler different are: (i) most of the recent round robin or rate adaptive round robin policies do not consider previous slot allocation data for allocation of current slot; and (ii) most schedulers which consider service differentiation are designed to provide precedence only to high priority packets at the cost of poor performance of medium and low priority packets. This scheduler is designed to determine the weighing coefficient of high priority queue based on the number of packets arrived in the queue in the previous cycle and allocates required bandwidth to satisfy QoS. It then determines weighing coefficient of the medium priority queue based on number of packets arrived in this queue and the weights allocated to high priority queue. Finally, weights are calculated for low priority queue and packets are accordingly scheduled.

We analyzed this scheduler for two different applications: (i) lightweight sensors which are continuously transmitting data of few kbps to few hundreds of kbps; and (ii) on biomedical data such as fall detection application which detects patient falls, for which many different services may be required with different QoS constraints. For example, one service may rely on a network of video cameras in the ceiling, while other service may use an accelerometer on the patient and yet another may use pressure sensors in the floor [3]. Different input data files are created for these applications and tested using proposed scheduling scheme to provide QoS to different services in terms of end to end delay, packet loss ratio, etc. In various applications, traffic is prioritized based on different traffic characteristics like traffic bit rate, packet loss rate and tolerable delay into different high priority, medium priority and low priority classes, stored in different buffers and scheduled to provide better QoS.

The rest of the paper is organized as follows. Section II presents a system architecture and related work. In section III, the proposed scheduling scheme for dynamic bandwidth allocation is discussed. Simulation results and performance

parameters are discussed in section IV while section V concludes the paper.

II. System Architecture and Related Work

Selection of proper architecture is very important before designing any algorithm to be implemented for the same. QoS architectures in traditional networks like DiffServ, IntServ do not satisfy the requirement of IoT which involves large number of heterogeneous devices and tasks like collection, transmission, storage and processing of complex data. QoS architectures in IoT must consider the dynamic nature of IoT otherwise it may lead to service failures. Authors in [6] presented a service modeling approach for different components in IoT framework. There are many models based on Markov chain concept to provide QoS. Markovian QoS models in traditional networks like DiffServ [7-8] do not satisfy the requirement of IoT. In [2], Markov Chain based cost-effective analytical model is proposed to ensure QoS for transmission of delay sensitive information.

Also, several devices and heterogeneous networks integrated in IoT make it complex to satisfy different QoS requirements [9]. Packet scheduling is one of the QoS mechanisms used to select the packets which should be serviced or dropped. Packet scheduling can provide service provisioning and help in differentiating emergency messages from non-critical messages. So, QoS awareness can be established in IoT by allocating traffic priorities and scheduling them with appropriate algorithm [10]. In [10] a QoS aware massage scheduling algorithm is proposed in IoT environment. The authors classified messages into two classes, high priority (emergency messages) and best effort (non critical messages) and proposed QoS scheduling algorithm. The algorithm proposed is efficient in terms of energy and waiting time however the loss and other performance parameters are not considered. In [11] a Multi-Dimensional QoS decision is proposed based on IoT estimate approach, in which each stakeholder is mapped into a single value to establish best configuration of interactions. Authors in [12] discussed a modeling approach on IoT based solutions using Human centric wireless sensor networks (WSNs). This approach supports emergency response activities which is one of the biggest challenges. We propose a QoS model at network layer to ensure QoS for emergency traffic.

III. The Proposed Scheduling Scheme and Analysis

In this section, we present dynamic bandwidth allocation prediction based scheduling scheme to optimize its utilization for different kinds of applications. The scheme includes following important features:

1.) Traffic from different applications segregated based on different traffic characteristics like traffic bit rate, packet loss rate and tolerable delay into different classes and prioritized them into high priority data, medium priority data and low priority data based on these characteristics.

2.) We assume three different queues: high priority queue, medium priority queue, and low priority queue to store packets of respective type defined above and scheduled in a round robin manner.

3.) Buffer space used for high priority queue is kept small because these services are sensitive to delay and jitter and cannot tolerate more queuing delay. But buffer space for medium and high priority queue is considered large to reduce the packet loss.

4.) Exponential Weighted Moving Average (EWMA) is used to calculate average queue size of high priority service [13]. Average queue size of medium priority queue is calculated using simple average formula.

5.) Algorithm predicts average increase or decrease in average queue length of high priority and medium priority services, and in case of high priority service, add these values to previous weight values of high priority services and then multiply with a coefficient (explained later). This helps in optimizing weights for current time slot based on this increase or decrease to allocate bandwidth required for high priority and medium priority services.

6.) For keeping delay jitter in tolerable limits for high priority traffic (<10ms), minimum and maximum thresholds are assigned which will be the indicator to assign the appropriate weights.

A. *Dynamic Weight Standardization*

To reduce the fluctuations in instantaneous queue size, we calculated the average queue size of high and medium priority services by using a low pass filter with exponential weighted moving average. Average queue length of high and medium priority queue is predicted as [13]:

$$l_avg = (1 - 0.01) * l_avg + 0.01 * l_inst \qquad (1)$$

where, l_avg is average queue size, l_inst is instantaneous queue size and 0.01 is scaling factor to reduce fluctuations in instantaneous queue size.

Threshold levels are introduced for buffer management. If average queue size is below minimum threshold, high priority weight taken is 0.3, which will provide low queuing delay, if average queue size is between minimum and maximum threshold, weights are proportionally varied with increase or decrease in the average queue length at consecutive time slots.

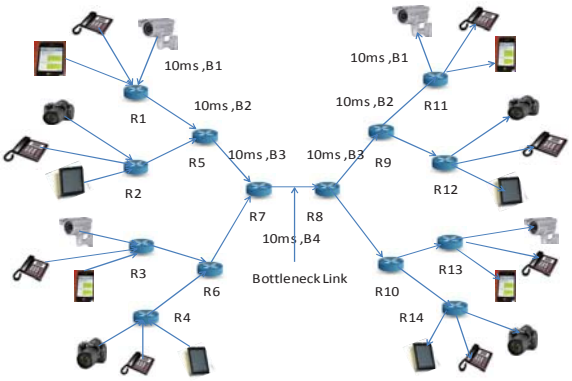

Fig 1: Network Topology used to analyze the performance of scheduling scheme

If it increases beyond maximum threshold, more but bounded to upper limit bandwidth is allocated. In this scheme, the weights are calculated in a circular fashion, starting from high, medium and then low priority queue.

Weight of high priority queue is calculated as:

$$high_{pri_{wt}} = \begin{cases} high_{wt_{init}} & l_avg \epsilon \{0,0.833\} \\ \left(C1 * high_{diff_{avg_{queue_{len}}}}\right) + high_{prev_{avg_{wt}}} & l_avg \epsilon \{0.833,3.667\} \\ high_{Upper_{bounded_{value}}} & l_avg \epsilon \{3.667,10\} \end{cases} \quad (2)$$

where, $high_{pri_{wt}}$ is $high_wt_{init}$=0.3 if average queue size is between 0 and minimum threshold, if average queue size is between maximum threshold and 10, $high_{pri_{wt}}$ is $high_Upper_{bounded_{value}}$= 0.7, i.e. a maximum of 70% bandwidth can be allocated to high priority service , C1 is a constant = $\frac{0.3}{(high_th_{Max} - high_th_{min})}$ where $high_th_{Max}$ is 3.667 and $high_th_{min}$is 0.833 which are nothing but the maximum and minimum threshold of the high priority buffer considered. Minimum threshold defines desired delay and maximum threshold covers tolerable delay. $high_diff_{avg_{queue_{len}}}$ is the difference (increase or decrease) in average queue length of high priority service queue length at current time cycle from previous cycle. The weight of medium priority queue can be calculated by:

$$med_{pri_{wt}} = \begin{cases} med_{wt_{init}} & l_avg \epsilon \{0,60\} \\ \left(1 - high_{pri_{wt}}\right) & l_avg \epsilon \{61,100\} \end{cases} \quad (3)$$

med_wt_{init} is assigned to 0.3 when the average queue size of medium priority queue is between 1 and 60, if it exceeds 60, then $med_{pri_{wt}}$is assigned as difference of total bandwidth and the bandwidth allocated to high priority service. Finally, if the bandwidth is unutilized from high and medium priority it is allocated to low priority traffic. The weight of low priority queue can be obtained as:

$$low_{pri_{wt}} = 1 - (high_{pri_{wt}} + med_{pri_{wt}}) \quad (4)$$

IV. Performance Evaluation and Simulation Results

A. Network Topology

A typical internetwork as shown in Fig.1 consists of multiple nodes. These nodes may act as sensor devices, generate data of CCTV camera or it may act as intermediate routers. We have investigated many performance measures of the proposed algorithm for different applications using different system loads. The various performance measures considered to evaluate the performance of proposed packet scheduling scheme are average end to end delay, the average delay jitter, and the average packet loss ratio for different service classes. The traffic characteristics chosen for different applications are summarized in a Table 1.

In different experiments, we analyzed average one way end to end queuing delay, average delay jitter and average packet loss ratio for high, medium and low priority service. If P is the total number of packets transmitted from *nth* source to *nth* destination, $T_n(i)$ is the time at which *ith* packet was sent by the source n, $R_n(i)$ is the time at which *ith* packet was received by the destination n, then one way end to end delay $eed_{n(i)}$is calculated as:

$$eed_{n(i)} = Rn(i) - Tn(i) \quad (5)$$

Average end to end delay Avg_{eed} for high, medium and low priority traffic is calculated as (6) where n is the source generating different traffic.

$$Avg_{eed} = (\sum_{n=1}^{S}(\sum_{i=1}^{P} eed_{n(i)})/P)/S \quad (6)$$

where, S is the maximum number of sources for each service and P is the number of packets which has been sent so for by each source.

Delay jitter is defined as the absolute difference between end to end delays of two consecutive packets. If one way end to end delay of *ith* packet from *nth* source is given by (5) then end to end Delay Jitter for packets from source n to destination n is calculated from (7):

$$Jitter = abs(eed_{n(i+1)} - eed_{n(i)}) \quad (7)$$

Also, if P_n is the total number of packets transmitted by *nth* source, R_n is the total number of packets received by corresponding *nth* receiver, then Packets lost ratio is given as::

$$Packet\ Loss\ Ratio = \frac{(P_n - R_n)}{P_n} \quad (8)$$

The simulated results obtained in different experiments are presented next. The simulation results are plotted using MatLab R2013b. Proposed scheduler is tested for two main applications under a complex topology shown in Fig.1. Traffic is prioritized based on different traffic characteristics like traffic bit rate, packet loss rate and tolerable delay into high, medium and low priority services.

TABLE I: Traffic Characteristics in Different Scenarios

Parameters	Scenario 1 with Bottleneck Bandwidth of 1.2Mbps			Scenario 2 with Bottleneck Bandwidth of 112Mbps		
Service Type (Priority)	High	Medium	Low	High	Medium	Low
Traffic Type	Poisson	Poisson	Poisson	MPEG-4	Poisson	Poisson
Packet size in bytes	100 Bytes	20 to 571 bytes	100 bytes	136 to 348250 bytes	20 to 571	100 to 500 bytes
Number of flows	12 flows at same time			12 flows at same time		
Node Topology	Random			Random		
Data rate	2Mbps			2.1Mbps to 114Mbps		
No. of Nodes	38			38		
Traffic direction	Left to right			Left to right		
No. of Packets sent	17828	499996	499996	10084	420104	420464
Link Delay	10ms			10ms		

Fig.2, 3, and 4 describe the average packet loss, average end to end delay, and the average jitter from all twelve sources which are sending a constant data of three different types as discussed in Scenario1 (Details given in Table 1). In Scenario 1, we consider sensors emergency data as high priority data. Poisson arrival process can be assumed for traffic model to each individual sensor node. So, for high, medium and low priority, Poisson traffic with variable size packets is considered. In Exp2, high priority service class in which packets are expected to be delivered in time are taken as MPEG traces. MPEG file format is considered because CCTV captured video images are normally converted into MPEG file format and is commonly used. Medium and low priority service class includes all non detrimental applications such as peer to peer applications. Query initiation model is one of the examples of peer to peer application and can be modeled as Poisson traffic. Packets are classified as high priority, medium priority and low priority packets, and are stored in different buffers of sizes 10,100,100 respectively for high, medium and low priority and finally they are scheduled using proposed packet scheduling. The results show that the average end to end delay for high and medium packets is approximately 62ms (this is the delay due to addition of all link delays in the path travelled by packets). It is increased for low priority packets by small amount but these packets are insensitive to delay. Average delay jitter for high priority packets is very less and within tolerable limits (<10ms). Delay jitter has increased for medium and low priority packets due to more bandwidth get allocated to high priority packets to guarantee its QoS performance. The no. of packets sent for high priority service is 17828 and received packets are 17500. Data rate at which high priority packets are sent from all four sources is 64000bits/sec. For a data rate less than 64000bits/sec, there is no loss for high priority packets using the scheduling scheme. For medium priority, out of 499996 packets sent 485162 packets are received successfully but for low priority out of 499996 packets, received packets are 372910. Data rate from medium priority is 0.7Mbits/s at which loss is 3% packets but for a data rate less than 0.7Mbits/sec there is no packet loss for medium priority.

Data rate for the low priority is 1.2Mbits/s at which loss is approximately 24% packets and for an overall data rate less than 1.2Mbits/sec there is no loss of any packet from any service class. All the QoS performance parameters are satisfied for all three services under the conditions mentioned in Table 1. Similarly, results for the average packet loss, the average end to end delay and the average jitter for Scenario 2 (Table 1) are described in Fig.5, 6 and 7. The results show that average end to end delay for high and medium packets is approximately 62ms for high priority and 62.12 ms for medium priority. It is increased for low priority packets by small amount but these packets are insensitive to delay.

Average delay jitter is better for all three services in Scenario 1. The no. of packets sent for high priority service is 10084 and received packets are 10020. Data rate at which high priority packets are sent from all four sources varies between 171520bits/s to 110Mbits/s.

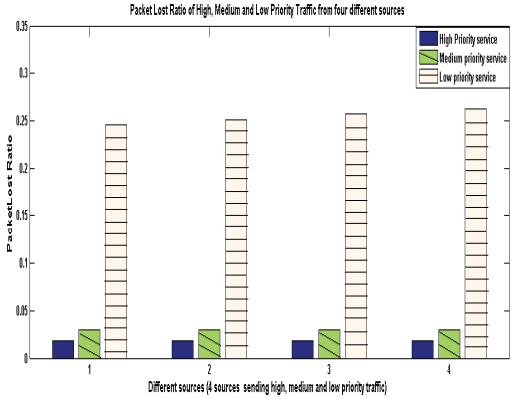

Fig. 2. Average packet lost ratio for high, medium and low priority traffic with bottleneck link bandwidth of 1.2Mbps

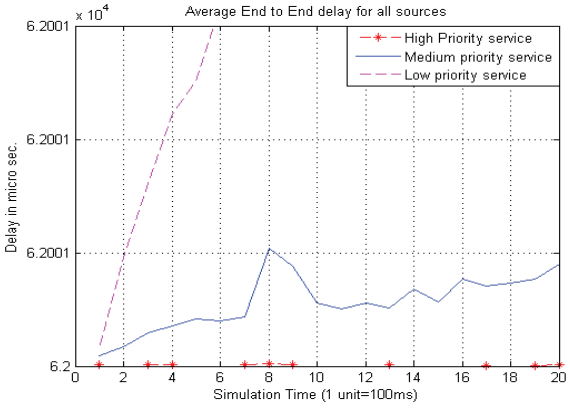

Fig. 3.Average end to end delay for high, medium and low priority traffic with bottleneck link bandwidth of 1.2Mbps

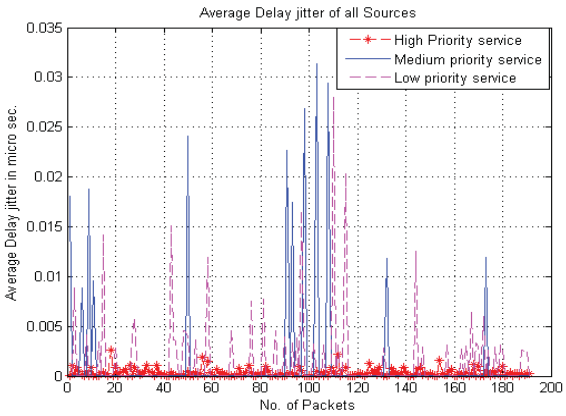

Fig. 4.Average jitter for high, medium and low priority traffic with bottleneck link bandwidth of 1.2Mbps

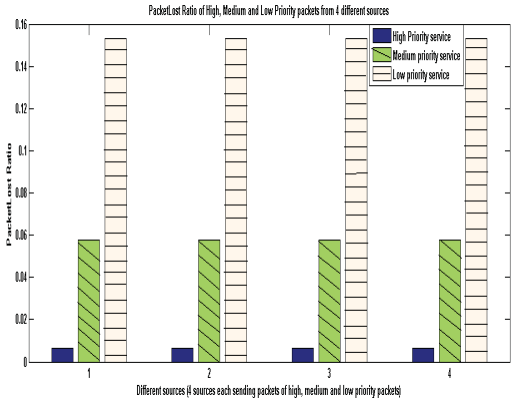

Fig. 5. Average packet lost ratio for high, medium and low priority traffic with bottleneck link bandwidth of 112Mbps

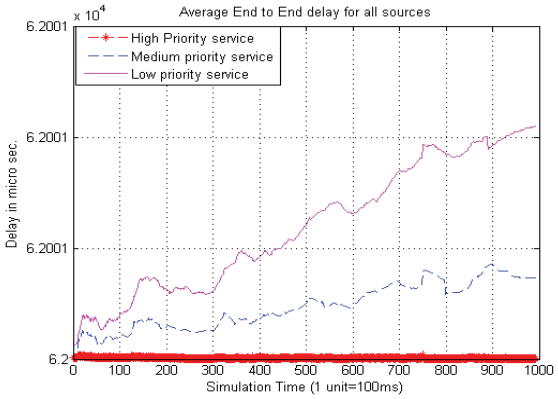

Fig. 6.Average end to end delay for high, medium and low priority traffic with bottleneck link bandwidth of 112Mbps

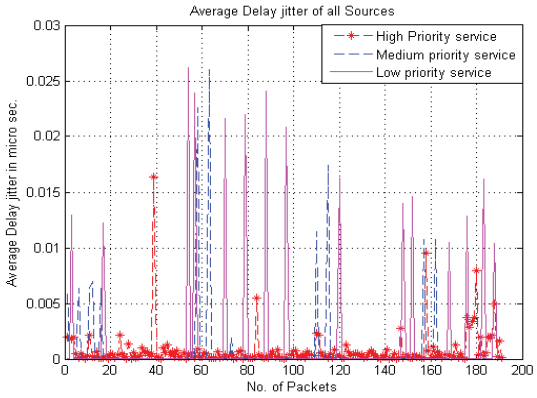

Fig. 7.Average jitter for high, medium and low priority traffic with bottleneck link bandwidth of 112Mbps

With the same data rate if simulation time is less, there is no loss for high priority packets using proposed packet scheduling scheme. The packet size varies from 136 bytes to 348250 bytes. We also observe that the high priority loss is zero if the maximum packet size is reduced to 9999 bytes and simulation time can be extended for a longer time. For medium priority out of 420104 packets sent 395904 packets are received successfully but for low priority out of 420104, received packets are 356148.

Data rate for medium priority is 0.7Mbits/s at which loss is 5.76% packets but for a data rate less than 0.7Mbits/sec there is no packet loss for medium priority provided packet size of video packets (high priority) is taken less than equal to 9999bytes. Data rate for low priority is 1.2Mbits/s at which loss is 15.0% packets and for a data rate less than 112Mbits/sec there is no loss from any service class. Even if data rate is more than 112bits/sec, packet size of video packets is <=9999bytes, simulation time is long, there is no loss for high priority, medium priority and less than 10% losses for low priority. This satisfies all the QoS requirements in IoT. Therefore, the proposed scheduler is expected to efficiently perform under many conditions.

The average delay jitter is better for all three services and is within tolerable limits. We have observed that if the number of video packets keeps on increasing as high priority packets, the lost packets will increase for low priority only if the packet size of video is more than 9999bytes but performance will be as expected for high and the medium priority in terms of all QoS parameters.

The average computation time required using this packet scheduling scheme which is calculated using profiler report generated by Matlab2013b is reported to be 2.87ms.

V. Conclusion

The proposed joint packet scheduling and dynamic bandwidth allocation scheme designed with an aim for IoT applications have been discussed. The performance results are encouraging especially guaranteeing QoS parameters. It works efficiently for continuously generated small size packets, continuously generated large packets up to 9999 bytes packet size and for 7000 packets of size 96456 bytes. Loss for BE packets is approximately up to 8% for small packet size while increases up to 12% if high priority packet length keeps on increasing. All the conditions of no loss from any differentiated service class are clearly mentioned and discussed in the results. The proposed scheme performs well in terms of all QoS parameters and is within tolerable limits.

***Abstract*—Opinion-unaware (OU) General purpose blind image quality assessment (BIQA) is an important yet difficult task in computer vision and machine learning. In this paper, we present a sparse representation based quality-unaware BIQA approach which utilizes NSS features from three different domains. At the training stage, we extract quality scores of training image blocks by full-reference image quality assessment method and NSS features of image blocks. The score-feature pairs are learned by the dictionary for sparse representation. At the testing stage, the NSS feature vector of a test image is represented via sparse coding and the final predictive quality score is obtained through weighting quality scores by the sparse coding coefficients. Experiments on the LIVE database show that the proposed algorithm has better performance than the state-of-the-art opinion-unaware method NIQE. And it also has excellent database independence.**

***Index terms*— no-reference image quality assessment (NR IQA), sparse representation, phase congruency**

I. Introduction

Thanks to the easier availability of digital images from the internet and the popularization of wireless digital imaging devices, digital images have been becoming one of the most important way of representing and transmitting information in our everyday life. However, the perceptual quality of digital images may be declined by the process of acquisition, transmission, compression, restoration, etc. For example, images could be distorted by packet loss when transmitted through a congested wireless network. Moreover, in most real life cases the undistorted version of the observed image is not available, thus assessing image quality blindly and automatically is becoming increasingly important [1].

In terms of whether specifying the distortion types of test images, the current blind image quality assessment (BIQA) methods can be classified as distortion specific methods [2], [3], [4] or general purpose methods [5], [6], [7], [8], [9]. The application of distortion specific BIQA methods is therefore limited to test images with known distortion types. Thus the general purpose BIQA methods which do not require prior knowledge of distortion types of test images are more practical in real-world applications. General purpose BIQA methods can be further classified into two categories: opinion-aware (OA) methods [6], [7], [5], [8] and opinion-unaware (OU) methods [10], [9], [11]. OA methods need subjective scores for training while OU methods can build prediction models without human opinions which is obviously a much more challenging task than OA approaches. In this paper we focus on the OU-BIQA methods.

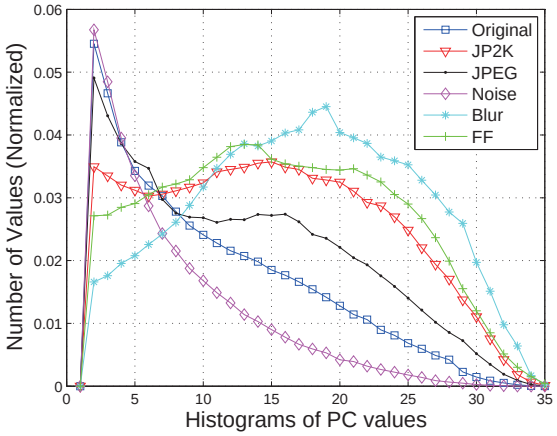
We propose a general-purpose opinion-unaware BIQA approach based on sparse representation (SP). At the training stage of the proposed method, natural scene statistics (NSS) features of the training image blocks and their corresponding quality scores obtained by gradient magnitude similarity deviation (GMSD) [12] which is a state-of-the-art full-reference image quality assessment (FR-IQA) method are computed for dictionary learning. At the testing stage, the NSS feature vector of a test image is represented via sparse coding and the final predictive quality score is computed through weighting GMSD scores by the sparse coding coefficients. Our sparse representation based OU-BIQA approach offers the following advantages. 1) We extract NSS features from three different domains, i.e., phase congruency domain, DCT domain and spacial domain in order to fully employ the quality information of images. 2) The dictionary for sparse representation can be trained completely without human subjective scores since training quality scores are obtained from top performing FR-IQA method. 3) The quality relevant NSS features and the quality scores for constructing the dictionary are extracted from both the whole images and image blocks to make a denser dictionary. 4) By using sparse representation to constuct the dictionary, we do not have to retrain the model when samples of new distortion types are available, we just need to add new samples into the dictionary. 5) At the testing stage, NSS features of the entire image rather than image blocks are used for sparse representation which is highly efficient.

The performance of the proposed opinion-unaware BIQA metric is thoroughly validated on the LIVE IQA database [13]. The experimental results demonstrate that the proposed opinion-unaware BIQA metric is highly consistent with human opinions. It has performance which is very comparable to state-of-the-art OU-BIQA NIQE [9]. It outperforms OU-BIQA QAC [10] and FR-IQA PSNR [14] and its performance is nearly comparable to state-of-the-art OA-BIQA BRISQUE [6]. It also has good extensibility through databases.

The remainder of this paper describes SROUB (Sparse Representation based Opinion-Unaware Blind image quality assessment) in detail and is organized as follows. The details of

This work is supported by the National Science Foundation of China (61271190).

Fig. 2. Histograms of PC for different distortion types. The 6 curves correspond to the reference image "sailing1.bmp" and its distorted counterparts. "Origianl" (DMOS = 0), "JP2K" (DMOS = 67.6968), "JPEG" (DMOS = 70.5024), "Noise" (DMOS = 55.0675), "Blur" (DMOS = 68.0166), "FF" (DMOS = 64.7162).



the proposed framework are described in Section 2. In Section 3, experimental results and a thorough analysis of our results are presented. Finally, Section 4 concludes our work.

II. Sparse Representation Based Opinion-Unaware BIQA

Fig. 1 is the framework of SROUB, which includes five key modules, i.e., features and GMSD scores extraction for dictionary, dictionary learning, feature extraction for quality computation, sparse representation and quality computation.

A. Features and GMSD scores extraction for dictionary

In order to get a dense overcomplete dictionary, we extract image features and image GMSD [12] scores not only from each whole image but also from image blocks in order to build a dense dictionary.

We extract image NSS features from three different domains, i.e., phase congruency [15], [16] domain, DCT domain, and spatial domain. The GMSD [12] score of each image block is also computed as the training quality labels of each image block . GMSD is one of state-of-the-art FR-IQA methods whose predictive scores correlate well with human opinions. The Spearman rank order correlation coefficient (SROCC) between GMSD scores and subjective scores on LIVE IQA database [13] is 0.960.

1) PC domain NSS features: Phase congruency (PC) [17], [16] measures the degree of congruency of image local Fourier waves frequencies. The physiological and psychophysical evidences had corroborated that visually cognizable features coincide with points of high PC values [17], [16].

Kovesi [16] proposed an efficient approach of computing PC which is widely used in literature. A 2-D extended logarithmic Gabor filters [18] is adopted for wavelet transform:

$$G_2(\omega,\theta_{\mathrm{k}}) = \exp\left(-\frac{\left(\log(\frac{\omega}{\omega_0})\right)^2}{2\sigma_l^2}\right)\cdot\exp\left(-\frac{(\theta-\theta_{\mathrm{k}})^2}{2\sigma_\theta^2}\right) \tag{1}$$

where $\theta_k = k\pi/K$, $k = \{0,1,...,K-1\}$ is the filter's orientation angle, K is the number of orientations, ω_0 is the center frequency of the filters, σ_l controls the filter's bandwidth and σ_θ determines the filter's angular bandwidth.

By convolving G_2 with an image and modulating ω_0 and θ_k, we get a set of responses at each point i as $\lfloor e_{n,\theta_k}(i), o_{n,\theta_k}(i)\rfloor$, where $e_{n,\theta_k}(i)$ and $o_{n,\theta_k}(i)$ are the real and imaginary parts of a log-Gabor filter respectively on scale n and orientation θ_k at location i. The local amplitude on scale n and orientation θ_k is $A_{n,\theta_k}(i) = \sqrt{e_{n,\theta_k}(i)^2 + o_{n,\theta_k}(i)^2}$, and the local energy along orientation θ_k is $E_{\theta_k}(i) = \sqrt{L_{\theta_k}(i)^2 + T_{\theta_k}(i)^2}$, where $L_{\theta_k}(i) = \sum_n e_{n,\theta_k}(i)$ and $T_{\theta_k}(i) = \sum_n o_{n,\theta_k}(i)$. The 2-D PC at i is as follows:

$$PC(i) = \frac{\sum_k E_{\theta_k}(i)}{\gamma + \sum_n \sum_k A_{n,\theta_k}(i)} \tag{2}$$

where γ is a small positive constant to keep the fraction stable when all the Fourier amplitudes are very small. $PC(i)$ is a real number within $[0,1]$.

We found that the histogram of PC values of one image would change with different distortion types and extents. Fig. 2 shows the histograms of PC values of the image "sailing1.bmp" of the LIVE database [13] and its 5 distortion versions, number of zeros of PC are excluded. We can see that the mean and skew values of PC histograms change with distortion types and extents.

For NSS features from PC domain, the first step is computing pixel based PC values of image blocks. Then by sorting PC values in ascending order, the ordered set $P = (p_1, p_2, ..., p_m)$ is yielded. The percentile pooling is implemented to P based on the assumption that distortions only occur in a subset of pixels. Extracting the central 60% elements from P yields $P_p = (p_{\lfloor 0.2n\rfloor}, p_{\lfloor 0.2n\rfloor+1}, ..., p_{\lfloor 0.8n\rfloor})$. Where n is the number of pixels of the relevant image scale. The mean value of P_p and the skew value of P are the NSS features of PC domain on one scale in our approach.

$$f_{PC} = (mean(P_p), skew(P)) \tag{3}$$

2) DCT domain NSS features: DCT coefficients based on 8×8 nonoverlapping patches is computed first. Then the spectral entropy F is computed based on the DCT coefficients.

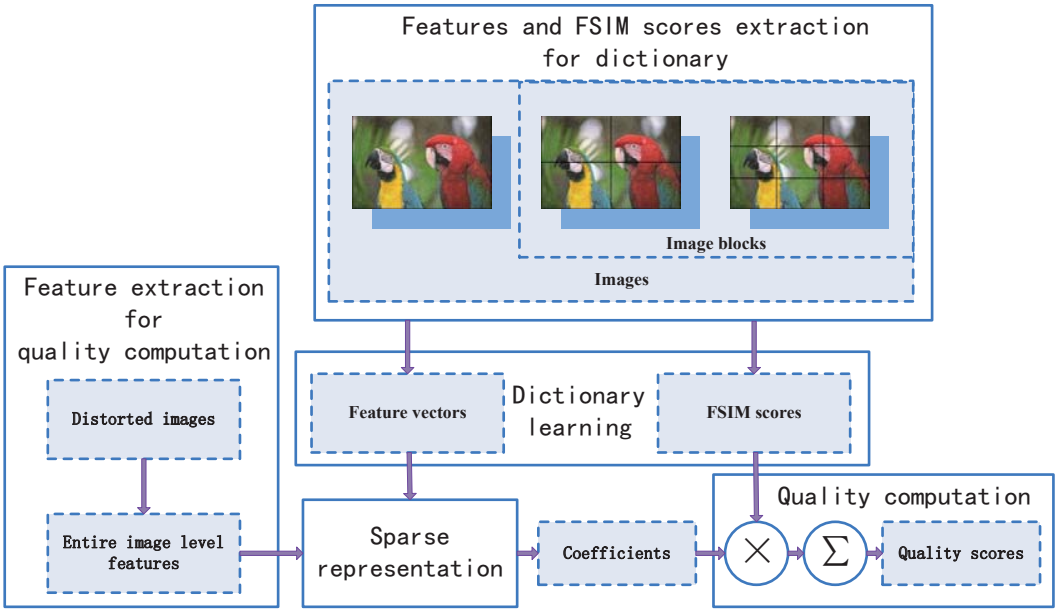
The spectral entropy is

$$F = -\sum_x \sum_y P(x,y)\log_2 P(x,y) \tag{4}$$

where

$$P(x,y) = \frac{C(x,y)^2}{\sum_x \sum_y C(x,y)^2} \tag{5}$$

Fig. 1. Framework of sparse representation based opinion unaware blind image quality assessment.



where $P(x,y)$ is the spectral probability of normalized DCT coefficients $C(x,y)^2$, $1<i\leq 8, 1<j\leq 8$ (DC is excluded).

The same percentile pooling strategy used for PC NSS features is also implemented to the ascending ordered F resulting $Fp=(f_{\lfloor 0.2m\rfloor}, f_{\lfloor 0.2m\rfloor+1}, ..., f_{\lfloor 0.8m\rfloor})$. Where m is the number of blocks within each scale. The mean values of F_p and the skew values of F are used as NSS features of DCT domain in our approach.

$$f_{DCT}=(mean(F_p), skew(F)) \tag{6}$$

3) Spatial domain NSS features: For NSS features from spatial domain, we adopt the same features used in BRISQUE [6] since they require very low time complexity and have strong representing power for image quality. 18 $(2+4\times 4)$ spatial feature vector elements in total are extrated for each scale including parameters of generalized Gaussian distribution (GGD) with zero mean of local mean subtract contrast normalization (MSCN) coefficients and parameters of a zero mode asymmetric generalized Gaussian distribution (AGGD) of products pairs of adjacent coefficients .

B. Dictionary learning

In SROUB, the dictionary learning is extremely simple by directly combining feature vectors and GMSD scores of the training blocks.

$$\begin{bmatrix} D \\ scores \end{bmatrix} \doteq \begin{bmatrix} f_1 & f_2 & ... & f_n \\ score_1 & score_2 & & score_n \end{bmatrix} \tag{7}$$

where the dictionary D is a $k\times l$ matrix ($k=44$ and l is the number of image blocks for training). Vector $scores$ is the corresponding GMSD scores of the training blocks. f_i is the NSS feature vector of the ith training image block and $score_i$ is its GMSD score.

C. Sparse representation

Sparse representation with an overcomplete basis in human perception has been strongly corroborated by studies of the human visual system (HVS) [19]. And the sparsity characteristic is one of the most important features of HVS.

The following optimizing problem can yield the sparsest and the most precise representation of the feature vector of a test image by the atoms in the dictionary $D=[f_1, f_2, ..., f_n]$.

$$\rho^*=\arg\min_{\rho\in R^N} \|\rho\|_0 \quad s.t. \quad f=D\rho \tag{8}$$

where N is the number of atoms in D, ρ^* is the sparse representation coefficients for f over the dictionary D.

The approximate solution of the above optimize problem via l_1-minimization [20] is usually used because the l_0-minimization of equation (8) is an NP hard problem. Then we have

$$\rho^*=\arg\min_{\rho\in R^N} \|\rho\|_1 \quad s.t. \quad f=D\rho \tag{9}$$

This l_1-minimization problem can be transformed into an unconstrained problem

$$\rho^*=\arg\min_{\rho\in R^N} \gamma\|\rho\|_1+\|f-D\rho\|_2 \tag{10}$$

where γ is the regularization parameter. A specialized interior-point method for solving large-scale l_1-regularized least-squares programs is used to solve the above problem [20].

D. Quality computation

Based on the assumption that image blocks with identical quality scores have similar feature distributions, the quality of a test image can be quantified by

$$Q = \frac{\sum_{i=1}^{M} \rho_i^* score_i}{\sum_{i=1}^{M} \rho_i^*} \quad (11)$$

where $score_i$ is the GMSD score of the i-th image block in the dictionary. The estimation Q is the final predictive quality score of the test image.

III. Experiments and results

In the training stage, each image is uniformly partitioned into 4 and 9 neighboring nonoverlapping blocks as shown in Fig. 1. Feature-score pairs are extracted from those blocks which means that each image for building the dictionary would contribute 15 $(1 + 4 + 9)$ feature-score pairs in total. We extract all NSS features at 2 scales to capture multi-scale characteristics via downsampling by a factor of 2 after low pass filtering. For efficiency, only the entire image NSS features are used for sparse representation in the testing stage.

A. Correlation with human opinions

We tested SROUB on LIVE IQA database [13] which consists of 29 reference images and their distorted versions with five different types of distortion, i.e., JPEG2k (JP2K), JPEG, white noise (WN), Gaussian blur (BLUR) and fast fading (FF). DMOS values of those images are offered by the database. We compared performance of SROUB with other IQA approaches. PSNR [14] and SSIM [21] are two classic FR-IQA algorithms. BRISQUE [6] is one of state-of-the-art OA-BIQA methods. QAC [10] and NIQE [9] are state-of-the-art OU-BIQA methods.

Two performance indices were used in our experiments. The Spearman rank order correlation coefficient (SROCC) between DMOS and objective scores is a measure of the prediction monotonicity. The Pearson linear correlation coefficient (LCC) is an evaluation of the prediction accuracy. LCC were calculated after a logistic non-linearity mapping [22].

Since SROUB and BRISQUE require training. We randomly chose 80% of reference images and their corresponding distorted versions in the LIVE database for training and the rest images in the database for testing. This train-test pair is performed 1000 times and the median of the results are reported. For a fair comparison, PSNR, SSIM, QAC and NIQE which do not require training are tested on 20% of randomly chosen reference images and their corresponding distorted versions of the LIVE database for 1000 iterations and the median of the results are reported.

The results are listed in Tab. I. The overall performance across 5 distortion types are shown in the columns labeled by "ALL". We can see that SROUB has higher SROCC and LCC in "ALL" than the FR-IQA PSNR and the two OU-BIQA algorithms QAC and NIQE, its overall performance is slightly inferior to FR-IQA SSIM and OA-BIQA BRISQUE.

B. Variation with dictionary size

In order to investigate the influence of dictionary size to the overall performance of the proposed algorithm, we conduct the $80\%/20\%$ train-test trails for 100 times for different dictionary sizes, the median values of SROCC on the LIVE database are reported. The median values of SROCC are shown in Tab. II, in Tab. II the subscript of a particular dictionary "D" means the number of blocks used for feature extraction, subscript of "1" corresponds to the entire image, subscript of "4" or "9" corresponds to number of adjacent uniformly partitioned blocks of an image used for dictionary construction. From Tab. II, we can conclude that a denser dictionary of the proposed approach results in better correlation with human opinions.

TABLE II
Median SROCC across 100 train-test trials with dictionaries of different sizes on the LIVE IQA database.

	D_1	D_4	D_{1+4}	D_9	D_{1+4+9}
SROCC	0.8361	0.8805	0.8863	0.9058	0.9084

TABLE III
SROCC yielded by models using different features for sparse representation on the LIVE database.

	JP2K	JPEG	Noise	Blur	FF	ALL
Curvelet features	0.7336	0.8891	0.8354	0.8554	0.6792	0.8154
Spatial features	0.4955	0.8681	0.9604	0.8590	0.8100	0.8198
Curvelet & Spatial features	0.7714	0.8683	0.9315	0.8670	0.7553	0.8495

C. Representing powers of features

We also conducted experiments with features from different domains to determine representing powers of features. Here we refer to DCT domain features together with PC domain features as curvelet features. Image blocks in D_1 were used for building dictionaries. We randomly chose 6 reference images (sailing3.bmp, caps.bmp, parrots.bmp, sailing1.bmp, statue.bmp) and their distorted versions from the LIVE database as test images, the rest images in the database are used as training images. The performance of models utilizing only curvelet features or only spatial domain features or both curvelet features and spatial domain features are reported in Tab. III.

The model utilizing both curvelet features and spatial domain features yields relatively high SROCC values on each distortion type and across five distortion types which means that our combination of NSS features from different domains has better representation power for image distortion.

D. Database independence

In order to determine the database independence degree of SROUB, we also test SROUB and the compared algorithms on the TID2008 [23] database. The SROCC values of four distortion types (JPEG2000, JPEG, WN and BLUR) and across four distortion types are listed in Tab. IV. Compared with other approaches, the correlation with subjective perception of SROUB remained consistently competitive.

SROUB	0.9221	0.9191	0.8212	0.8987	0.8892

IV. CONCLUSION

We presented an opinion-unaware general purpose BIQA based on sparse representation which utilizes NSS features from three different domains. The quality of a test image is expressed as a simple linear combination of training blocks' GMSD scores with sparse representation coefficients. Via comprehensive experimental validations, we could have the following conclusions. First, SROUB can be trained completely without human subjective scores. Second, SROUB can assess image quality consistently with the subjective scores across various types of distortions. Third, on the LIVE database, SROUB has superior performance to that of the state-of-the-art OU-BIQA method NIQE. Finally, SROUB also has excellent database independence.

***Abstract*—Transceiver designs for multiple-input multiple-output (MIMO) two-way relaying are being actively explored. Most of the state-of-the-art studies optimize a system-wide objective function subject to the transmit power constraints of the two source nodes and the relay. Transceiver designs with quality-of-service (QoS) constraints have lacked attention in two way relaying literature. In this work, we study a MIMO transceiver design, based on the generalized singular value decomposition, that incorporates per-stream QoS constraints specified as the rate required by the individual transmit streams of two source nodes. With these QoS constraints, we use geometric programming to jointly allocate power at the source and relay nodes to optimize the sum-rate. Through extensive numerical evaluations, we show that the proposed design outperforms the existing solutions not only with the QoS constraints but also without them.**

***Index Terms*—Geometric program (GP), generalized singular value decomposition (GSVD), quality-of-service (QoS).**

I. Introduction

Relaying is a well known cooperative communication technique that is used to enhance the throughput and coverage of wireless systems [1]–[3]. Two relaying protocols are widely studied in the literature – one-way [1] and two-way [2], [3]. A relay is usually assumed to be half-duplex as it is easy to implement; a half-duplex relay, however cannot simultaneously transmit and receive on the same spectral resource. This reduces the spectral efficiency of one-way relaying, as two spectral resources are now required to transmit a single data unit. This is twice the number of channel uses when two nodes communicate directly without a relay. Two-way relaying (TWR) requires two spectral resources to transmit two data units and recovers the loss in spectral efficiency.

The relay in TWR protocol is designed commonly using two different technologies – regenerative decode-and-forward [2] and non-regenerative amplify-and-forward [3]–[5]. A non-regenerative two-way relay is of special interest as it is easy to implement and has lower delay, when compared with a regenerative two-way relay. To further enhance the spectral-efficiency of non-regenerative TWR, multiple antennas are also employed in all the nodes. Many studies have investigated transceiver designs for non-regenerative TWR to explore the potential of multiple antennas [3]–[13].

The authors in [3], [4] investigated space-time coding designs for multiple-input multiple-output (MIMO) TWR. Lee *et al.* in [5] designed source and relay precoders to maximize sum-rate. In [6], the source and relay precoders are jointly constructed to minimize sum-MSE. Reference [7] developed a unified framework to optimize a broad class of Schur-convex and Schur-concave functions for MIMO TWR. Transceiver designs to minimize the MSE and maximize the sum-rate using MSE duality are recently investigated in [8] and [9], respectively. Park *et al.* in [10] proposed a transceiver based on the principles of signal alignment and uses generalized singular value decomposition (GSVD). The channel orthogonalization involves zero-forcing operation at the relay, which degrades the sum-rate for ill-conditioned channels due to noise enhancement. The design in [11] avoids zero-forcing operation at the relay but only semi-orthogonalizes the end-to-end MIMO channels for small number of antennas. This design is shown to have better sum-rate than the [10], if the residual inter-stream interference due to semi-orthogonalization of MIMO channels is ignored.

All the aforementioned references optimize a given objective function e.g., sum-rate or MSE, subject to the constraints on the transmit power of two source nodes and the relay. They, however, ignore quality-of-service (QoS) constraints which affect the user experience and are therefore crucial in practical systems. A few recent efforts have considered QoS-constrained transceiver designs for TWR [12], [13]. Leow *et al.* in [12] designed source and relay precoders to minimize the total network transmit power subject to per-stream QoS constraints expressed as the transmit rate required by the individual streams of the two source nodes. Reference [13] also jointly optimized source and relay precoders to minimize total network transmit power subject to the QoS constraints which are expressed as upper-bounds on the mean-squared error (MSE) of the signal waveform estimated at the destination nodes.

In the present work, motivated by [10], [11], we first construct a MIMO transceiver using GSVD for TWR. We then maximize sum-rate subject to the per-stream QoS constraints that similar to [12], are expressed as the transmit rates required by the individual streams of two source nodes. Optimization of these objectives, for the GSVD-based transceiver design considered herein, reduces to joint power allocation at the source and relay nodes.

We next list the **main contributions** of this paper when compared with [10]–[13].

1) We propose a novel modification to the existing GSVD-based transceiver designs in [10], [11] that overcomes two limitations: i) noise enhancement in ill-conditioned channels in [10]; and ii) residual inter-stream interference for small number of antennas in [11]. Though in this work we concentrate on

optimizing objectives with per-stream rate constraints, we also show that the proposed design yields better sum-rate than the designs in [10], [11] without the per-stream rate constraints.

2) We maximize the sum-rate, via joint power allocation at the source and relay nodes, subject to the per-stream transmit rate required by both source nodes and individual transmit power. We will show that this problem can be cast as a convex geometric program (GP). We note that both [12], [13] do not investigate this problem; it is important to analyze the effect of the per-stream transmit rate demanded by each source node on the overall sum-rate. Further, we consider more granular per-stream rate constraints unlike [13] that expresses QoS constraints in terms of upper-bounded MSE for each link (not transmit stream). *To the best of our knowledge, sum-rate maximization with per-stream rate constraints for TWR has not been considered earlier in the literature.* We show through extensive simulations that the proposed design yields significantly better performance than the state-of-the-art transceiver designs.

Notation: The symbols $\mathbf{A}$ and $\mathbf{a}$ denote a matrix and a column vector, respectively. $\mathrm{Tr}(\mathbf{A})$, $\mathbf{A}^T$, $\mathbf{A}^H$, $\mathbf{A}^\dagger$, $[\mathbf{A}]_{i,j}$ and $\mathbf{A}^*$ are the trace, transpose, Hermitian, pseudoinverse, (i,j)th element and complex-conjugate of the elements of $\mathbf{A}$, respectively. We denote the Hadamard product of two matrices $\mathbf{A}$ and $\mathbf{B}$ as $\mathbf{A} \odot \mathbf{B}$ and an $N \times N$ identity matrix as $\mathbf{I}_N$. The notation $\mathrm{diag}(x_1, \cdots, x_n)$ represents a diagonal matrix with x_1 to x_n as its diagonal elements. The notation $\boldsymbol{x} \succeq 0$ implies that all the elements of vector $\mathbf{x}$ are ≥ 0. The symbol $\mathbb{E}(\cdot)$ is the expectation operator.

II. System model

We consider MIMO TWR where two multi-antenna source nodes S_1 and S_2, as shown in Fig. 1, exchange data via a half-duplex non-regenerative multi-antenna relay. We assume that both source nodes have N_s antennas each, while the relay has N_r antennas. We also assume, as conventionally assumed in TWR literature [5], [6], that the direct links between two source nodes are absent due to high path loss and fading.

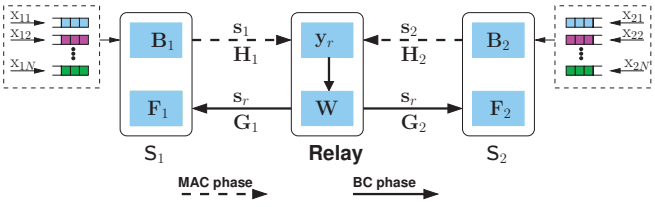

Fig. 1: QoS-constrained two-way relaying: Both source nodes have N streams to transmit, and each stream requires a particular rate.

In the first phase of TWR, commonly known as multiple access (MAC) phase, both source nodes simultaneously transmit their respective signals to the relay; the relay receives an $N_r \times 1$ signal given as

$$\mathbf{y}_r = \mathbf{H}_1\mathbf{s}_1 + \mathbf{H}_2\mathbf{s}_2 + \mathbf{n}_r. \tag{1}$$

Here the matrix $\mathbf{H}_i \in \mathbb{C}^{N_r \times N_s}$ is the MIMO channel for the $\mathsf{S}_i \rightarrow$Relay links for $i = 1, 2$,[1] and the vector $\mathbf{n}_r \in \mathbb{C}^{N_r \times 1}$ is the circularly-symmetric complex additive white Gaussian noise at the relay with $\mathbb{E}(\mathbf{n}_r\mathbf{n}_r^H) = \sigma_r^2\mathbf{I}_{N_r}$. The vector $\mathbf{s}_i \in \mathbb{C}^{N_s \times 1}$, transmit signal of the node S_i, is obtained by linearly precoding the normalized complex information data vector $\mathbf{x}_i \in \mathbb{C}^{N \times 1}$ using a precoder matrix $\mathbf{B}_i \in \mathbb{C}^{N_s \times N}$ such that $\mathbf{s}_i = \mathbf{B}_i\mathbf{x}_i$. We assume that with N_s antennas, both source nodes transmit $N = \min(N_s, N_r)$ independent source streams; therefore $\mathbb{E}(\mathbf{x}_i\mathbf{x}_i^H) = \mathbf{I}_N$. The precoded data vector $\mathbf{s}_i$ satisfies the transmit power constraint:

$$\mathrm{Tr}(\mathbb{E}(\mathbf{s}_i\mathbf{s}_i^H)) = \mathrm{Tr}(\mathbf{B}_i\mathbf{B}_i^H) = \mathrm{Tr}(\mathbf{\Xi}_i) \leq P_i, \tag{2}$$

where P_i is the maximum transmit power of the node S_i.

In the second phase of TWR, commonly known as broadcast (BC) phase, the relay multiplies its received signal with a precoder matrix $\mathbf{W} \in \mathbb{C}^{N_r \times N_r}$. The $N_r \times 1$ signal vector transmitted by the relay is $\mathbf{s}_r = \mathbf{W}\mathbf{y}_r$. The maximum transmit power of the relay is P_r, which results in the following constraint on its transmit signal

$$\begin{aligned} P_r &\geq \mathrm{Tr}\left(\mathbb{E}(\mathbf{s}_r\mathbf{s}_r^H)\right) \\ &= \mathrm{Tr}\left(\mathbf{W}(\mathbf{H}_1\mathbf{\Xi}_1\mathbf{H}_1^H + \mathbf{H}_2\mathbf{\Xi}_2\mathbf{H}_2^H + \sigma_r^2\mathbf{I}_N)\mathbf{W}^H\right). \end{aligned} \tag{3}$$

The signal received by the node S_i in the BC phase is

$$\mathbf{y}_i = \mathbf{G}_i\mathbf{s}_r + \mathbf{n}_i = \underbrace{\mathbf{G}_i\mathbf{W}\mathbf{H}_i\mathbf{s}_i}_{\text{BI}} + \mathbf{G}_i\mathbf{W}\mathbf{H}_{\bar{i}}\mathbf{s}_{\bar{i}} + \mathbf{G}_i\mathbf{W}\mathbf{n}_r + \mathbf{n}_i.$$

The term labelled BI is the back-propagating interference. The matrix $\mathbf{G}_i \in \mathbb{C}^{N_s \times N}$ is the MIMO channel for the Relay$\rightarrow\mathsf{S}_i$ link, and the vector $\mathbf{n}_i$ is the circularly-symmetric complex additive noise at the node S_i with $\mathbb{E}(\mathbf{n}_i\mathbf{n}_i^H) = \sigma_i^2\mathbf{I}_{N_s}$. We assume that all the channel matrices are frequency-flat and constant over one cycle of MAC and BC phases, but vary independently across multiple cycles as in [5]–[7]. Since S_i knows $\mathbf{s}_i$, it can cancel the back-propagating interference from its received signal with the knowledge of necessary channel state information (CSI) as in [5]–[7]. The equivalent receive signal at S_i after cancelling the back-propagating interference from $\mathbf{y}_i$ is $\widehat{\mathbf{y}}_i = \mathbf{G}_i\mathbf{W}\mathbf{H}_{\bar{i}}\mathbf{B}_{\bar{i}}\mathbf{x}_{\bar{i}} + \mathbf{G}_i\mathbf{W}\mathbf{n}_r + \mathbf{n}_i$. The node S_i recovers its desired data by processing its received signal using a decoder matrix $\mathbf{F}_i \in \mathbb{C}^{N \times N_s}$:

$$\widetilde{\mathbf{y}}_i = \mathbf{F}_i\widehat{\mathbf{y}}_i = \mathbf{F}_i\mathbf{G}_i\mathbf{W}\mathbf{H}_{\bar{i}}\mathbf{B}_{\bar{i}}\mathbf{x}_{\bar{i}} + \mathbf{F}_i\mathbf{G}_i\mathbf{W}\mathbf{n}_r + \mathbf{F}_i\mathbf{n}_i. \tag{4}$$

III. Transceiver design

We begin this section by outlining the principles of GSVD-based transceiver design. We then briefly describe two existing GSVD TWR designs in [10], [11]. We conclude this section by proposing a novel modification that will significantly improve the sum-rate of the GSVD designs in [10], [11]. For the proposed design, we assume that the relay perfectly knows $\mathbf{H}_i$ and $\mathbf{G}_i$ and that it designs the precoders/decoders and distributes them to other nodes. The perfect channel knowledge at the relay and design/distribution of precoders/decoders by it is commonly assumed in the literature on joint design [6], [7].

[1]To avoid repetition, we assume that $i = 1, 2$ throughput this paper. Further, $\bar{i} = 2$ for $i = 1$ and $\bar{i} = 1$ for $i = 2$.

A. Principles of GSVD-based transceiver design

To design a transceiver based on the GSVD, the MAC-phase MIMO channels $\mathbf{H}_1$ and $\mathbf{H}_2$ are jointly decomposed using GSVD [14]:

$$\mathbf{H}_1 = \mathbf{T}_h^H \mathbf{\Sigma}_{h_1} \mathbf{U}_{h_1} \text{ and } \mathbf{H}_2 = \mathbf{T}_h^H \mathbf{\Sigma}_{h_2} \mathbf{U}_{h_2}. \quad (5)$$

Here $\mathbf{U}_{h_1} \in \mathbb{C}^{N \times N_s}$ and $\mathbf{U}_{h_2} \in \mathbb{C}^{N \times N_s}$ are matrices with N orthonormal rows, $\mathbf{\Sigma}_{h_1} \in \mathbb{R}^{P \times N} = [\mathbf{0}_{h_1}^T \ \bar{\mathbf{\Sigma}}_{h_1}^T]^T$ and $\mathbf{\Sigma}_{h_2} \in \mathbb{R}^{P \times N} = [\bar{\mathbf{\Sigma}}_{h_2}^T \ \mathbf{0}_{h_2}^T]^T$. The matrix $\bar{\mathbf{\Sigma}}_{h_i} \in \mathbb{R}_+^{N \times N} = \text{diag}(\sigma_{h_i,1}, \cdots, \sigma_{h_i,N})$, $\mathbf{0}_{h_i} = \mathbf{0}_{N \times (P-N)}$, and $\mathbf{T}_h \in \mathbb{C}^{P \times N_r}$ is a full-rank matrix, where $P = \text{rank}([\mathbf{H}_1 \ \mathbf{H}_2]) = \min(N_r, 2N_s)$. Next, the BC-phase MIMO channels $\mathbf{G}_1$ and $\mathbf{G}_2$ are jointly decomposed using GSVD [14]

$$\mathbf{G}_1 = \mathbf{U}_{g_1} \mathbf{\Sigma}_{g_1} \mathbf{T}_g^H \text{ and } \mathbf{G}_2 = \mathbf{U}_{g_2} \mathbf{\Sigma}_{g_2} \mathbf{T}_g^H. \quad (6)$$

Here $\mathbf{U}_{g_1} \in \mathbb{C}^{N_s \times N}$ and $\mathbf{U}_{g_2} \in \mathbb{C}^{N_s \times N}$ are matrices with N orthonormal rows, $\mathbf{\Sigma}_{g_1} \in \mathbb{R}^{N \times P} = [\mathbf{0}_{g_1} \ \bar{\mathbf{\Sigma}}_{g_1}]$ and $\mathbf{\Sigma}_{g_2} \in \mathbb{R}^{N \times P} = [\bar{\mathbf{\Sigma}}_{g_2} \ \mathbf{0}_{g_2}]$. The matrix $\bar{\mathbf{\Sigma}}_{g_i} \in \mathbb{R}_+^{N \times N}$ =diag$(\sigma_{g_i,N}, \cdots, \sigma_{g_i,1})$, $\mathbf{0}_{g_i} = \mathbf{0}_{N \times (P-N)}$ and $\mathbf{T}_g \in \mathbb{C}^{N_r \times P}$ is a full-rank matrix, where $P = \text{rank}([\mathbf{G}_1^T \ \mathbf{G}_2^T]^T) = \min(N_r, 2N_s)$.

Following the decomposition, the MAC-phase transmit precoder of the node S_i is chosen as [10]

$$\mathbf{B}_i = \mathbf{U}_{h_i}^H \mathbf{\Lambda}_i. \quad (7)$$

Here $\mathbf{\Lambda}_i \in \mathbb{R}_+^{N \times N}$ is a diagonal power allocation matrix at S_i such that $\mathbf{\Lambda}_i \mathbf{\Lambda}_i^H = \text{diag}(\lambda_{i,1}, \cdots \lambda_{i,N})$. Similarly, the BC-phase decoder matrix for the node S_i is chosen as [10]:

$$\mathbf{F}_i = \mathbf{U}_{g_i}^H. \quad (8)$$

With the precoder/decoder in (7) and (8), the received signals at S_1 and S_2 in (4) can be expressed as

$$\begin{aligned} \widetilde{\mathbf{y}}_1 &= \mathbf{\Sigma}_{g_1} \mathbf{T}_g^H \mathbf{W} \mathbf{T}_h^H \mathbf{\Sigma}_{h_2} \mathbf{\Lambda}_2 \mathbf{x}_2 + \mathbf{\Sigma}_{g_1} \mathbf{T}_g^H \mathbf{W} \mathbf{n}_r + \mathbf{U}_{g_1}^H \mathbf{n}_1, \\ \widetilde{\mathbf{y}}_2 &= \mathbf{\Sigma}_{g_2} \mathbf{T}_g^H \mathbf{W} \mathbf{T}_h^H \mathbf{\Sigma}_{h_1} \mathbf{\Lambda}_1 \mathbf{x}_1 + \mathbf{\Sigma}_{g_2} \mathbf{T}_g^H \mathbf{W} \mathbf{n}_r + \mathbf{U}_{g_2}^H \mathbf{n}_2. \end{aligned} \quad (9)$$

To design the relay precoder $\mathbf{W}$, the earlier work in [10], [11] have considered two different approaches. In [10], the relay precoder orthogonalizes the end-to-end MIMO channels. To this end, the relay precoder is decomposed into a MAC precoder $\mathbf{W}_c \in \mathbb{C}^{P \times N}$, BC precoder $\mathbf{W}_b \in \mathbb{C}^{N \times P}$ and a power-allocation and permutation matrix $\mathbf{\Delta} \in \mathbb{R}_+^{P \times P}$ such that $\mathbf{W} = \mathbf{W}_b \mathbf{\Delta} \mathbf{W}_c$, where $\mathbf{\Delta}$ is an anti-diagonal matrix such that $\mathbf{\Delta} \mathbf{\Delta}^H = \text{diag}(\delta_1, \cdots, \delta_P)$. To orthogonalize the MIMO channels, precoders $\mathbf{W}_b$ and $\mathbf{W}_b$ are chosen as $(\mathbf{T}_g^H)^\dagger$ and $(\mathbf{T}_h^H)^\dagger$, respectively. The channel inversion, however, severely degrades the performance by enhancing the noise when the channels are ill-conditioned.

The design in [11] avoids channel-inversion by constructing $\mathbf{W}_b$ and $\mathbf{W}_c$ such that they have orthonormal columns and rows, respectively. This design, however, does not orthogonalizes the MIMO channels for *small* number of antennas, which leads to residual inter-stream interference between multiple transmit streams. This design ignores the residual inter-stream interference, and is shown to have better sum-rate than [10]. We will show later in Section V that the residual inter-stream interference, *if not ignored*, can significantly degrade the performance.

The objective of the relay precoder design herein, as discussed earlier, is to maximize sum-rate with per-stream transmit rate constraints. To achieve this, we do not diagonalize the end-to-end MIMO channels; we instead design the relay precoder to triangularize the MIMO channels. *This novel modification, as shown later in Section IV, is crucial in casting the optimization as a convex GP.*

The inter-stream interference due to triangular MIMO channels can be easily cancelled at the destination nodes by employing successive interference cancellation and need not be ignored as in [11]. Further, the MIMO channel triangularization is achieved by designing $\mathbf{W}_b$ and $\mathbf{W}_c$ with orthonormal columns and rows respectively. The proposed precoder, consequently, does not enhance the noise unlike [10]. Due to these two reasons, the proposed approach leads to better performance than in [10], [11]. We next discuss the proposed relay precoder design.

B. Proposed channel triangularization relay precoder

We first design the MAC-phase relay precoder $\mathbf{W}_c$ by factorizing the full-rank matrix $\mathbf{T}_h^H$ into a unitary matrix $\mathbf{Q} \in \mathbb{C}^{N_r \times N_r}$ and an upper-triangular matrix $\mathbf{R} \in \mathbb{C}^{N_r \times P}$ using QR factorization [14]

$$\mathbf{T}_h^H = \mathbf{Q}\mathbf{R} = \begin{bmatrix} \mathbf{Q}_h & \mathbf{Q}_0 \end{bmatrix} \begin{bmatrix} \mathbf{R}_h \\ \mathbf{0} \end{bmatrix}. \quad (10)$$

The bottom $(N_r - P)$ rows of matrix $\mathbf{R}$ are zeros. The matrix $\mathbf{Q}$ is therefore partitioned into $\mathbf{Q}_h \in \mathbb{C}^{N_r \times P}$ and $\mathbf{Q}_0 \in \mathbb{C}^{N_r \times (N_r - P)}$. Also, $\mathbf{R}_h \in \mathbb{C}^{P \times P}$ is an upper-triangular matrix. To reduce $\mathbf{T}_h^H$ to an upper-triangular matrix, we choose $\mathbf{W}_c = \mathbf{Q}_h^H$. Note that $\mathbf{W}_c$ is not unitary; only its rows are orthonormal. We now design the BC-phase relay precoder $\mathbf{W}_b$ by factorizing the full-rank matrix $\mathbf{T}_g^H$ into a lower-triangular matrix $\mathbf{L} \in \mathbb{C}^{P \times N_r}$ and a unitary matrix $\mathbf{V} \in \mathbb{C}^{N_r \times N_r}$ using LQ factorization [14]

$$\mathbf{T}_g^H = \mathbf{L}\mathbf{V} = \begin{bmatrix} \mathbf{L}_g & \mathbf{0} \end{bmatrix} \begin{bmatrix} \mathbf{V}_g \\ \mathbf{V}_0 \end{bmatrix}. \quad (11)$$

The last $(N_r - P)$ columns of matrix $\mathbf{L}$ are zeros. The matrix $\mathbf{V}$ is therefore partitioned into $\mathbf{V}_g \in \mathbb{C}^{P \times N_r}$ and $\mathbf{V}_0 \in \mathbb{C}^{(N_r - P) \times N_r}$. The matrix $\mathbf{L}_g \in \mathbb{C}^{P \times P}$ is a lower-triangular matrix. To reduce $\mathbf{T}_g$ to a lower-triangular matrix, we choose $\mathbf{W}_b = \mathbf{V}_g^H$. Note that $\mathbf{W}_b$ is not a unitary matrix; it only has orthonormal columns. The precoder $\mathbf{W}$ is given as

$$\mathbf{W} = \mathbf{V}_g^H \mathbf{\Delta} \mathbf{Q}_h^H. \quad (12)$$

With the above relay precoder, the received signal at S_1 and S_2 in (9) can be expressed as

$$\begin{aligned} \widetilde{\mathbf{y}}_1 &= \mathbf{\Sigma}_{g_1} \mathbf{L}_g \mathbf{\Delta} \mathbf{R}_h \mathbf{\Sigma}_{h_2} \mathbf{\Lambda}_2 \mathbf{x}_2 + \underbrace{\mathbf{\Sigma}_{g_1} \mathbf{L}_g \mathbf{\Delta} \mathbf{Q}_h^H \mathbf{n}_r + \mathbf{U}_{g_1}^H \mathbf{n}_1}_{\widetilde{\mathbf{n}}_1}, \\ \widetilde{\mathbf{y}}_2 &= \mathbf{\Sigma}_{g_2} \mathbf{L}_g \mathbf{\Delta} \mathbf{R}_h \mathbf{\Sigma}_{h_1} \mathbf{\Lambda}_1 \mathbf{x}_1 + \underbrace{\mathbf{\Sigma}_{g_2} \mathbf{L}_g \mathbf{\Delta} \mathbf{Q}_h^H \mathbf{n}_r + \mathbf{U}_{g_2}^H \mathbf{n}_2}_{\widetilde{\mathbf{n}}_2}. \end{aligned} \quad (13)$$

The lower-triangular $\mathbf{L}_g$, anti-diagonal $\mathbf{\Delta}$ and upper-triangular $\mathbf{R}_h$ result in the reflected lower-triangular structure of the end-to-end channel between $\widetilde{\mathbf{y}}_i$ and $\widetilde{\mathbf{x}}_{\bar{i}}$ as

$$\begin{bmatrix} \widetilde{y}_{i,1} \\ \widetilde{y}_{i,2} \\ \vdots \\ \widetilde{y}_{i,N-1} \\ \widetilde{y}_{i,N} \end{bmatrix} = \begin{bmatrix} 0 & 0 & \cdots & 0 & \times \\ 0 & & & \times & \times \\ \vdots & & \iddots & \vdots & \vdots \\ 0 & \times & \cdots & \times & \times \\ \times & \times & \cdots & \times & \times \end{bmatrix} \begin{bmatrix} x_{\bar{i},1} \\ x_{\bar{i},2} \\ \vdots \\ x_{\bar{i},N-1} \\ x_{\bar{i},N} \end{bmatrix} + \widetilde{\mathbf{n}}_i. \tag{14}$$

With this channel structure, the Nth transmit stream ($x_{\bar{i},N}$) does not experience inter-stream interference and is detected first. The $(N-n)$th transmit stream is then detected by successively subtracting the interference from *already-detected* streams numbered from $(N-n+1)$ to N, $n=1$ to $N-1$. After detection, the signal-to-noise ratio (SNR) of the nth receive stream of the source nodes S_1 and S_2 respectively are

$$\begin{aligned} \text{SNR}_{1,n}(\boldsymbol{\delta},\boldsymbol{\lambda}_2) &= \frac{\delta_{\widetilde{n}}\lambda_{2,\widetilde{j}}(\sigma^2_{g_1,n}\sigma^2_{h_2,\widetilde{j}}|[\mathbf{L}_g]_{\widetilde{n},\widetilde{n}}[\mathbf{R}_h]_{\widetilde{j},\widetilde{j}}|^2)}{\sigma_r^2\sum_{l=1}^{P}\delta_l[\mathbf{L}_{g_1}\odot\mathbf{L}^*_{g_1}]_{n,l}+\sigma_1^2}, \\ \text{SNR}_{2,n}(\boldsymbol{\delta},\boldsymbol{\lambda}_1) &= \frac{\delta_{n}\lambda_{1,\widetilde{j}}(\sigma^2_{g_2,n}\sigma^2_{h_1,\widetilde{j}}|[\mathbf{L}_g]_{n,n}[\mathbf{R}_h]_{j,j}|^2)}{\sigma_r^2\sum_{l=1}^{P}\delta_l[\mathbf{L}_{g_2}\odot\mathbf{L}^*_{g_2}]_{n,l}+\sigma_2^2}. \end{aligned} \tag{15}$$

Here $n=1$ to N, $\widetilde{n}=P-N+n$, $j=P-n+1$ and $\widetilde{j}=N-n+1$. Further $\boldsymbol{\delta}=[\delta_1,\cdots,\delta_P]$ and $\boldsymbol{\lambda}_i=[\lambda_{i,1},\cdots,\lambda_{i,N}]$. In the denominator of the above SNR expressions, we denote $\mathbf{L}_{g_i}=\mathbf{\Sigma}_{g_i}\mathbf{L}_g$. The above SNR expressions can be derived from (13) after simple algebraic manipulations and by noting that $\mathbf{Q}_h^H\mathbf{n}_r$, $\mathbf{U}_{g_1}^H\mathbf{n}_1$ and $\mathbf{U}_{g_2}^H\mathbf{n}_2$ have the same statistical properties as $\mathbf{n}_r$, $\mathbf{n}_1$ and $\mathbf{n}_2$, respectively. *Note that the coefficients of the power-distribution variables, δ_l for $l=1$ to P, λ_{1n} and λ_{2n} for $n=1$ to N, are non-negative. We will use this fact to prove the convexity of the optimization problems*. The complete procedure for the proposed GSVD triangularization (GSVD-TRI) design is summarized in Algorithm 1.

Algorithm 1 GSVD-TRI design.

1: *GSVD design*: Design source precoders $\mathbf{B}_i$ and decoders $\mathbf{F}_i$, as in (7) and (8), to partially diagonalize $\mathsf{S}_i\rightarrow$relay$\rightarrow\mathsf{S}_{\bar{i}}$ MIMO channels.
2: *Channel triangularization*: Design relay precoder $\mathbf{W}$, as in (12), to triangularize the end-to-end MIMO channels using LQ and QR decompositions.
3: *Power allocation*: Jointly allocate power at the source nodes and relay to maximize sum-rate (see next section).

IV. Joint power allocation

We now jointly allocate power to optimize the sum-rate subject to the per-stream transmit rate required by both source node. We next prove two lemmas that will be useful in showing that the optimization is a GP; a GP has a posynomial objective and upper-bounded posynomial constraints [15, pg. 160].

Lemma 4.1: The transmit power of the node S_i, defined in (2), is a posynomial in optimization variable $\boldsymbol{\lambda}_i$, where $\boldsymbol{\lambda}_i=[\lambda_{i,1},\cdots,\lambda_{i,N}]$.

Proof: With the transmit precoder $\mathbf{B}_i$ designed in (7), we rewrite the transmit power of S_i as $\text{Tr}(\mathbf{B}_i\mathbf{B}_i^H) = \text{Tr}(\mathbf{U}_{h_i}^H\mathbf{\Lambda}_i\mathbf{\Lambda}_i^H\mathbf{U}_{h_i}) \overset{(a)}{=} \text{Tr}(\mathbf{U}_{h_i}\mathbf{U}_{h_i}^H\mathbf{\Lambda}_i\mathbf{\Lambda}_i^H) = \sum_{j=1}^{N}\lambda_{i,j}$. In (a), we have used Tr($\mathbf{AB}$)=Tr($\mathbf{BA}$). Wee see that the constraint is a posynomial in $\boldsymbol{\lambda}_i$, as the coefficients of optimization variable $\lambda_{i,j},\forall j$ are positive [15, pg. 160]. ■

For notational convenience, the transmit power of the node S_i is henceforth denoted as $p_i(\boldsymbol{\lambda}_i)$.

Lemma 4.2: The transmit power of the relay, defined in (3), is a posynomial in $\boldsymbol{\lambda}_1$, $\boldsymbol{\lambda}_2$ and $\boldsymbol{\delta}$, where $\boldsymbol{\delta}=[\delta_1,\cdots,\delta_P]$.

Proof: This can also be proved on lines similar to Lemma 4.1. Please see [16] for details. The transmit power of the relay is now denoted as $p_r(\boldsymbol{\delta},\boldsymbol{\lambda}_1,\boldsymbol{\lambda}_2)$. ■

We next define the sum-rate as

$$R(\boldsymbol{\delta},\boldsymbol{\lambda}_1,\boldsymbol{\lambda}_2) = \frac{1}{2}\sum_{i=1}^{2}\sum_{n=1}^{N}\log_2(1+\text{SNR}_{i,n}(\boldsymbol{\delta},\boldsymbol{\lambda}_{\bar{i}})) \tag{16}$$

$$\overset{(a)}{\approx} \frac{1}{2}\sum_{i=1}^{2}\sum_{n=1}^{N}\log_2(\text{SNR}_{i,n}(\boldsymbol{\delta},\boldsymbol{\lambda}_{\bar{i}}) \tag{17}$$

$$= -\frac{1}{2}\log_2\prod_{n=1}^{N}\prod_{i=1}^{2}\text{ISNR}_{i,n}(\boldsymbol{\delta},\boldsymbol{\lambda}_{\bar{i}}) \tag{18}$$

The factor of half is due to the half-duplex constraint. The term $\text{ISNR}_{i,n}$ denotes the inverse of $\text{SNR}_{i,n}$, that is $\text{ISNR}_{i,n}=1/\text{SNR}_{i,n}$. Each $\text{ISNR}_{i,n}$ term, due to positive coefficients of power distribution variables in $\text{SNR}_{i,n}$ terms in (15), is a posynomial. The sum-rate in (16) can easily be shown as a ratio of two posynomials. As posynomials are not closed under division [15, pg. 161], the sum-rate is not a posynomial and its optimization therefore cannot be cast as a GP. We approximate the sum-rate as in (a) to cast the problem as a GP; the loss in the sum-rate due to this approximation is minor and becomes negligible in the high-SNR regime [17].

The QoS-constrained sum-rate optimization is now cast as

$$\begin{aligned} \underset{\{\boldsymbol{\lambda}_1,\boldsymbol{\lambda}_2,\boldsymbol{\delta}\}\succeq 0}{\text{Minimize}} \quad & \prod_{n=1}^{N}\prod_{i=1}^{2}\text{ISNR}_{i,n}(\boldsymbol{\delta},\boldsymbol{\lambda}_{\bar{i}}) \\ \text{subject to} \quad & \text{ISNR}_{1,n}(\boldsymbol{\delta},\boldsymbol{\lambda}_2)\le 1/(2^{r_{1n}}-1) \\ & \text{ISNR}_{2,n}(\boldsymbol{\delta},\boldsymbol{\lambda}_1)\le 1/(2^{r_{2n}}-1) \\ & p_1(\boldsymbol{\lambda}_1)\le P_1, p_2(\boldsymbol{\lambda}_2)\le P_2 \\ & p_r(\boldsymbol{\delta},\boldsymbol{\lambda}_1,\boldsymbol{\lambda}_2)\le P_r \end{aligned} \tag{19}$$

Here first two constraints, which can be equivalently expressed as $\log_2(1+\text{SNR}_{i,n}(\boldsymbol{\delta},\boldsymbol{\lambda}_{\bar{i}}))\ge r_{in}$, are on the per-stream transmit rate; here r_{in} is desired rate of nth stream of node i. The last three are transmit power constraints of different nodes. We have dropped $\frac{1}{2}\log_2$ factor from the objective as $\log(\cdot)$ is a monotonically increasing function. We see that the objective is a product of posynomials and is therefore a posynomial [15, pg. 161]. The problem is a GP as it has a posynomial objective and upper-bounded posynomial constraints.

V. Numerical results

We now investigate the effect of the per-stream QoS constraints on the sum-rate of the proposed GSVD-TRI transceiver

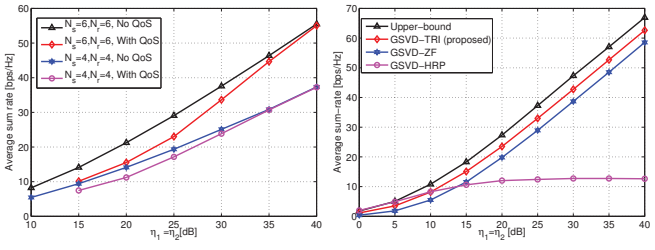
using Monte Carlo simulations. We assume Rayleigh flat-fading channels where the elements of $\mathbf{H}_i$ and $\mathbf{G}_i$ are independent and identically distributed complex Gaussian random variables with zero mean and variance h_i^2 and g_i^2 respectively. We fix the maximum transmit power and noise variance at all the nodes to unity and define the average SNR of the $\mathsf{S}_i \rightarrow$Relay and Relay$\rightarrow \mathsf{S}_i$ links as $\eta_i = h_i^2 = g_i^2$. We assume that both source nodes employ Gaussian signalling. The simulation results are averaged over 5000 statistically independent channel realizations.

In Fig. 2a, we plot the sum-rate of the proposed GSVD-TRI transceiver, with and without the per-stream QoS constraints for two different antenna configurations. We first focus on the scenario when each node has $N_s = N_r = 6$ antennas. The per-stream rate required by each source nodes is assumed to be 0.75 bps/Hz that is, $r_{1n} = r_{2n} = 0.75$ bps/Hz, $\forall n$. We make two key observations: 1) the per-stream rate requirement cannot be met below $\eta_1 = \eta_2 = 15$ dB; the per-stream rate requirement for $\eta_1 = \eta_2 \leq 15$ dB should therefore be reduced from the current one; and 2) the per-stream rate requirement leads to degradation in the sum-rate performance when compared with the scenario when there is no such rate requirement. This is because the system now sacrifices the overall sum-rate to satisfy the per-stream transmit rate of the individual streams. Moreover the degradation reduces at high SNR values where the probability of automatically meeting the per-stream rate requirement while maximizing the sum-rate is higher than at low SNR. For $N_s = N_r = 4$ antennas, where again $r_{1n} = r_{2n} = 0.75$ bps/Hz, $\forall n$, we see that the per-stream rate-requirement cannot be met below $\eta_1 = \eta_2 = 15$ dB. Further, similar to $N_s = N_r = 6$ antennas, the degradation due to the rate constraints reduces at high SNR values.

We now demonstrate the improved sum-rate of the proposed design over the other two GSVD-based designs: i) GSVD-ZF [Eq. (12), Eq. (13)] [10]; and ii) GSVD-HRP [Eq. (13), Eq. (15)] [11]. The improved sum-rate is because, as discussed earlier, the current transceiver overcomes the limitations of these two designs. Since both GSVD-ZF and GSVD-HRP designs do not incorporate QoS constraints, for the sake of fairness, we also maximize the sum-rate of the proposed design after dropping the QoS constraints. We also do not ignore the residual inter-stream interference of GSVD-HRP design. We see that the proposed GSVD-TRI design comprehensively outperforms both other designs.

VI. Conclusion

We investigated a GSVD-based joint transceiver design for MIMO TWR that triangularizes the end-to-end MIMO channels of the two source nodes. With MIMO channel triangularization, optimization of per-stream rate-constrained sum-rate reduce to joint optimal power allocation at the source and relay nodes, which is then cast as a convex geometric program. We analysed the impact of the per-stream rate constraints on the overall sum-rate. We also showed that the proposed design outperforms other state-of-the-art designs without rate constraints also.



(a) (b)

Fig. 2: a) Average sum-rate of the proposed GSVD-TRI transceiver design for two different antenna configurations; and b) Average sum-rate comparison of the GSVD-TRI design with the existing GSVD-ZF and GSVD-HRP designs; here $N_s = 6$ and $N_r = 10$.

Abstract— **The Mobile ad-hoc Network (MANET) is a communication network of a mobile node without any prior infrastructure of communication. The network does not have any static support; it dynamically creates the network as per requirement by using available mobile nodes. This network has a challenging security problem. The security issue mainly contains a denial of service attacks like packet drop attack, black hole attack, gray hole attack, etc. The mobile ad-hoc network is open environment so; working is based on mutual trust between mobile nodes. The MANETs is vulnerable to packet drop attack in which, packets are travelers through the different node. The network while communicating, the node drops the packet, but it is not attracting to the neighboring nodes to drop the packets.**

This proposed algorithm works with existing routing protocol. The concept of trusted list is used for secure communication path. The trusted list along with trust values show how many times node was participated in the communication. It differentiates between altruism and selfishness in MANET with the help of energy level of mobile components. The trust and energy models are used for security and differentiation between altruism and selfishness respectively.

Keywords— Altruism, Blackhole attack, Denial of Service, Gray hole attack, Mobile ad-hoc networks, Packet Drop Attack, Selfishness, Trust.

I. INTRODUCTION

The MANET is an own manageable network in which, any node can participate in the communication. The network is working with limited resources like the strength of signal, power, etc. The nodes are communicating each other by using routing protocols operating at different levels of the MANET. For communication between nodes, it uses insecure media channels; they fall into malicious activity. In the MANET devices are acts as an autonomous system, so the malicious device can join the network at any time without any notification. Once a malicious node enters in the network much valuable information passed to the malicious node. A malicious node may misuse that useful information.

The MANET has different denial of service attack like gray hole attack, black hole attack, and packet drop attack, etc. In the packet drop attack, The attacker node drops all the packets passing through it similar to black hole node, but it does not attract the neighboring nodes to drop the packet.

This paper is organized as follows: Section II discusses the related work. Section III gives detailed description about proposed work. Section IV provides simulation work. Section V provides a comparision with existing work and proposed work. Section VI gives the conclusion.

II. RELATED WORK

Neelavathy et. al. [1] introduced a Novel Reputation Based Algorithm to Detect the Misbehaving nodes (NRMDM) [1]. NRMDM uses local reputation value. Each node maintains the reputation value of its k-hop neighbourhood. The maintaining reputation values of all neighbouring nodes, if neighbouring nodes are more it need more overhead. This method is excellent for small network.

S. Buchegger et. al. [2] proposes performance analysis of the CONFIDANT reactive protocol. The protocol works as an extension to a reactive protocol. Given an algorithm mainly focuses on trust relationship based on experience, observation and forwarding behavior of intermediate nodes. Given an algorithm works with dynamic source routing (DSR) protocol. This protocol has primary four pillars the monitor, the reputation, the path manager and trust manager.

A. M. Kanthe et al. [3] proposed the impact of packet drop attack and solution for the overall performance of AODV in mobile ad-hoc networks. In this paper, the reputation and trust-based mechanism is used against packet drop attack and improves the network performance in terms of throughput, packet drop rate, packet delivery ratio, normalized routing overhead and end-to-end delay.

Ing-Ray Chen et al. [4] proposed trust management in mobile ad-hoc network for bias minimization and application performance maximization. It states the trust management mechanism in the MANET and its implementation to increase the performance. This approach is an integrated social and quality-of-service trust to improve the bias and performance.

Jin-Hee Cho et al. [5] proposed on the tradeoff between altruism and selfishness in MANET trust management. In which considered the tradeoff between a node's individual welfare vs. global well-being and identify the best design condition of this behavior model to balance to selfish vs. altruism behaviors.

III. PROPOSED WORK

The MANET is a large open environment network. The mobile node can participate in the communication. The existing algorithms are available for mobile ad-hoc network security. Due to the open environment of MANET there is chance of malicious activity like purposefully dropping packets, traffic observation, etc. The existing algorithms for packet drop attack are based on local reputation of the node. The different reasons behind the packet drop like power of node, network congestion, purposefully drops the packets, and queue length etc. The hard task is to differentiate the reason for dropping of packets. If the node is purposefully dropping packets, then the node is malicious node. When node is dropping packets due other reason; the node is not malicious. The node purposefully drops the packet is known as selfish node.

The proposed works have considered two concepts, namely Trust and Energy. The mobile ad-hoc network works on mutual trust between neighboring nodes. The communication is done in the mobile ad-hoc network with help of intermediate nodes. The intermediate nodes may be unknown, they can be malicious nodes. The trust is major notion for the communication. Trust is mutual understanding between different nodes present in the MANET. Trust is used to identify the node is malicious or not. The trust management in the MANET is usually Route Request (RREQ) and Route Reply (RREP) message passing between nodes. The nodes are dropping packets because of insufficient energy or purposefully. The energy is used to distinguish between altruism and selfish node.

A. Trust

The concept of trust is as subjective degree of belief. The trust management is important to avoid the malicious activity and increase the throughput. The trust can be generated with exchanging RREQ and RREP. This proposed work deals with trust values assigned to each node. When RREP got back to source, then source node increase the trust value by 0.1. The trust value is assigned 0.5 as a trust value of a particular node, when they are communicating first time. It is threshold values [6]. The trust value varies from 0 to 1. Every RREP has made strong relationship between a source node and neighboring node. The source node creates a list of all nodes having a trust value greater than 0.5. It is known as Trusted List. The nodes in the trusted list have stronger relation as compare to other nodes. When source wants to communicate with any of the destination node, then source node can pickup intermediate nodes from the trusted list to establish a path. The selected path will be most secure path for the communication. The construction of trusted list is based on RREQ and RREP. Trust list along with trust value is also calculated, it shows that how many times that a node was participated in the communication. The trust value defines the strength of the relationship between the two neighboring nodes. The Trusted list decreases the overhead of detecting malicious node. Once all nodes can start communication by picking nodes form trusted list as intermediate node, the network communication will be free from malicious nodes.

B. Energy

The concept of trusted list is purely depends upon RREQ and RREP. The network has many problems due to which nodes unable to send RREP. The problems may be congestion in the network, inefficient energy, etc. When source node does not have RREP from neighboring node, the source node does not add into trusted list. There is no concept to know the reason for failure of the RREP. To differentiate between altruism and selfish node, proposed algorithm uses energy model. While generating trust in which node is not replied due to inefficient energy, that node is not entered into trusted list even though it is not a malicious node. The selfish node does not participate in the communication process; it decreases the performance of the network. Distinguish between altruism and the selfish node is done with the help of energy model. This model calculates the energy level of each node; it classifies lower energy node and higher energy node. If any node is not replying on RREQ, then it checks energy level. If energy level is lower then it not considered as malicious node and if it has higher energy level then it considered as a selfish or malicious node.

C. Proposed Algorithm for Trust based solution to Packet Drop Attack

Basically, this algorithm works on the trusted list along with trust value and energy of the mobile node. Initially all nodes trust value and energy level will be zero. All neighboring node details are stored in local storage. When any source wants to communicate with destination, it will start sending RREQ to all neighboring nodes. When requesting node get RREP then it will add that node to the routing table and check for the trust value. Initially trust value is zero. In beginning of communication, the trust value 0.5 is assigned when first RREP received by the source node. Otherwise add 0.1 to pervious trust value and it increments up to 1 as RREP received by the node. While creating a trusted list it will check for both trust as well as energy level. Trust value must be greater than 0.5 and energy levels must be above 20 % of total energy of a node, it will add to trust list. If trust condition is true and energy level condition is false, then it will not directly declare as malicious node. Here the algorithm creates the difference between altruism and selfishness node.

The reliable flags are used while creating a trusted list. The flags are helping while selecting a communication path between the source node and the destination node. While selecting node from the trusted list as intermediate node, it checks to reliable flag if it is 1 then select otherwise not.

The trusted list along with trust values and energy level is used to select a secure communication path between the source and the destination. This will helps in creating a difference between altruism and selfishness nodes.

This algorithm creates the trusted list. The generated trusted list contains only trusted and working energy level.

[Initialization E (Energy Level) and T (Trust Level) to 0]
Step 1 Start (send RREQ to each neighboring node)
Step 2 Check if reply from node
If yes goto step 3
If no goto step 9
Step 3: Add details of replying node into routing table
If rt=rtable.rt_lookup(rp->rp_dst)
If yes T=T + 0.1 and E=received E
If T > 1 then T=1
If no T=0.5 and E=received E
Step 4 Check if replying node is in the trust list
If yes check E < 20 then remove from trust list
If no goto step 5
Step 5 Check replying node T and E values
If T > 0.5 && E > 20 Add to trust List and
reliable = 1
If no goto step 6
Step 6: Reset the reliable flag
reliable = 0
Step 7: Check if replying node is final destination node
If yes do not add node to trust list
If no goto step 8
Step 8: Execute rests part of receivreply function
Step 9: Stop

IV. Simulation Work and Result Analysis

The proposed algorithm is simulated in Network Simulator (NS-2) [9]. NS-2 is open source network simulation tool. The 802.11 MAC layer implemented in NS-2 is used for simulation. The protocol used is AODV. The various parameters are considered to compare the results. The wireless channel type with Omni-directional antenna type is used for link. This simulation uses 802.11 MAC type. The 300 × 300 m^2 simulation area is used.

A. Effect of Speed of node on Throughput

Figure 1 shows the graphs generated between the throughput and the pause time. Figure 1 shows that when the network is under attack, the average of the packet delivery ratio is 42 % and when it's under attack with the the solution it improved up to 80 %. When we applied solution on the packet drop attack the throughput is increased because packet dropping rate is decreased. The packet dropping rate is inversely proportional to throughput. The malicious node is included in the establishment of a path. This gives a secure path for the communication.

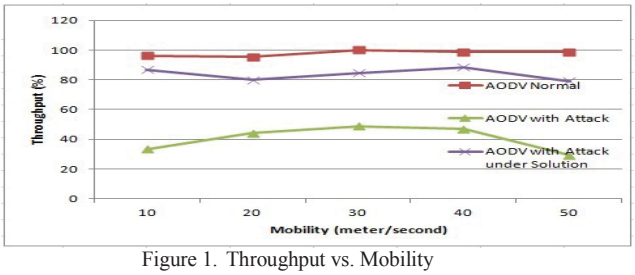

Figure 1. Throughput vs. Mobility

The throughput with an attack degrades the performance of the network. The packet dropper is dropping the packets if the packets are coming in route. The packet dropper node is not attracting the neighboring nodes. Throughput with an attack and solution improves the performance. If the packet dropper node is the busiest node in the simulation then, the performance of the network is less affected due to not attract the neighboring packets.

B. Effect of Number of node on Throughput Delay:

Figure 2 shows throughput Vs. number of nodes. Figure 2 shows, when the network is under attack, the average of the packet delivery ratio is 40% and when it under the solution it improved up to 83%. The proposed work differentiates between altruism and selfishness nodes. When any node wants to communicate with other node. There will a maximum number of secure next hops for the communication.

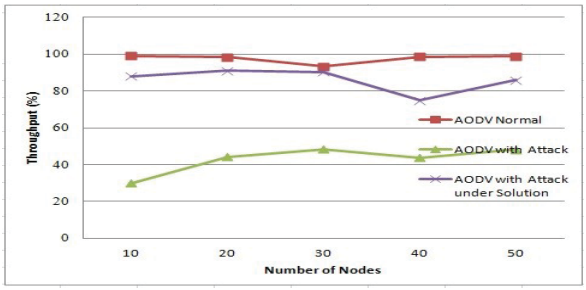

Figure 2. Throughput vs. Number of Nodes

V. Comparision of Proposed Algorithm Against Existing Work

Neelavathy [1] introduced a Novel Reputation Based Algorithm to Detect the Misbehaving nodes (NRMDM). NRMDM uses Local values are assigned for k-hop neighbouring nodes. Each node maintains all local values about its k-hop neighbourhood. NRMDM solution has large overhead when large numbers of nodes are present in the network. It is suitable for small network. Buchegger [2] proposed new protocol namely the CONFIDENT protocol, which is a solution to identify the misbehaving nodes in the MANET. The overhead of computation is more because of increase in the message exchange like ALARM messages. The effect of speed of nodes on CONFIDENT protocol is affected. Each node maintains a large table for reputation. The throughput at a law pause time is less. A. M. Kanthe [3] introduces new trust based reputation algorithm against packet drop attack is to detect a packet drop attack and improve the performance of the network. The concepts used in this dissertation are trust list and direct reputation. The node who not replied to source node it does not add into a Trust List. The node may be not replied because of energy, network issues. These existing algorithms not works with differentiated between altruism and selfishness node. Trust based detection and elimination packet drop attack in MANET, detect the packet drop attack. This proposed algorithm works on detecting and eliminating packet drop attacks with very low overhead and end-to-end delay. This

algorithm also works on the energy model to differentiate between altruism and selfishness node.

The comparative study of proposed work and existing system includes throughput, delay, overhead, technique, and packet delivery ratio and packet dropping rate [9]. The comparison of the proposed work against attack with the existing work is shown in Table I.

TABLE I. COMPARISON OF THE ALGORITHM AGAINST A PACKET DROP ATTACK WITH THE EXISTING WORK

Sr. No.	Algorithm/ Solution	Protocol	Enhancement
1.	Local values assigned based on reputation [1]	DSR	In case of a large network, numbers of possible path are available. The maintenance of all path increments overhead, it's decrement overall throughput of the network. Local value assignment increases overhead for every node, so decreases throughput. Unnecessarily paths are cached and their computation of local reputation values, it increment end-to-end delay.
2.	Trust based detection of packet drop attack [2]	DSR	DSR algorithm basically works on cache memory, maintaining local reputation, it decreases overall throughput of the networks. It uses ALARM packet with every RREQ and RREP messages. It consumes extra energy. Due which many nodes are unable to participate in the communication. So the less number of next hops available for the communication. It decreases throughput of the network.
3.	Trust List [3]	AODV	Trust based creation of trust list with the help of RREQ and RREP, gives less overhead of ALARM packet. The trust list gives the more secure node for nodes for establishing the path. Throughput will be more because malicious node cannot participate in the communication. The creation of trust list does not consider low energy node which is unable to send RREP to the source node. Many nodes from the network declared as malicious node due to inefficient energy.
4	Proposed Work	AODV	The proposed work is also depends upon the trusted list. The concept of creation of trusted list is based upon both trusts with trust values as well as the energy of the node. The trusted list includes only secure node. This will helps to increment in throughput of the network. This work considers energy to differentiate between altruism and selfishness node. So the maximum number of nodes can participate in the communication. It increases approximately 30-35 % throughput of the network.

VI. CONCLUSION

Trust based detection and elimination of the packet drop attack in MANET. This proposed work helps to detect the malicious node from the network. The trust based idea is better rather than cryptography, the cryptography increases overhead of computation. The proposed work does a considerable improvement in throughput and performance of the network. The mobile ad-hoc network with open nature of communication, security can be improved with a trust based idea.

The trust list helps to detect the malicious activity on the network and also differentiate between an altruism and selfishness nodes that avoid getting blacklisted because of the energy level of nodes. Each node maintains a list, in the local buffer that contains the list of trusted and un-trusted nodes. This helps to detect malicious node and also differentiate between altruism and selfishness node.

***Abstract*— The mobile Ad-hoc network does not have the fixed topology. The nodes are in moving state and participate in the communication. Due to open network it is more prone to the attack. The various attacks can be possible as any malicious node can enter into the communication. The gray hole attack is DoS kind of attack which drops the partial packets passing through them. Due changing behavior of the node from black to honest, it is difficult to detect the malicious node in the network.**

The Proposed work implements the TrueLink concept to check the link between the two intermediate nodes is valid or not. The data routing information (DRI) is used to check the behavior of the nodes which do not have a valid link between them. The primary detection is done with the help of DRI table and confirmation is done with the sequence number of the packets. The confirmation of the node being malicious or not is done using the number of packets that are forwarded by the node in particular time frame or not. The performance of the network can be improved with this proposed concept.

Keywords— gray hole attack, mobile devices, malicious, dynamic nature, security, self-configuring, Mobile Ad-hoc Network.

I. INTRODUCTION

A mobile Ad-hoc network is a collection of autonomous systems. The network is independent of infrastructure and hence it reduces the cost and deployment time [1, 2]. The MANET is highly susceptible to various routing attacks. In gray hole attack, the node drops some amount of packets and hence ultimately affects the performance of the network. The node can act in two states as an honest node and as a black hole where all the incoming packets are dropped. The node changes its state from honest to black and vice versa.

The gray hole attack is difficult to detect because some amount of packets may get dropped by the network congestion and some other issues in the network. The partial dropping of packets affects the efficiency of the network hence it's important to detect and remove the gray hole in the established network. The gray hole attack is difficult to detect because some amount of packets may get dropped by the network congestion and some other issues in the network. The partial dropping of packets affects the efficiency of the network hence it is important to detect and remove the gray hole in the established network.

This paper proposes an algorithm based on the TrueLink concept. The TrueLink is used to verify the valid link between the two nodes. Depending on the link between the two nodes, the node can be detected as a malicious node.

This paper is organized like section II discusses about related work, section III discusses about MANET and gray hole attack, section IV discusses about TrueLink, Section V discusses about the Gray hole attack detection and removal using TrueLink, Section VI discusses about simulation result and analysis and Section VII describes the conclusion.

II. RELATED WORK

This section gives the information about the previous research work done related to gray hole attack.

A. Kanthe et al. [3] have proposed a gray hole detection mechanism based on the false replies getting from the node. The counter is used to maintain the count of false replies. The proposed algorithm totally depends on the count of false replies. When the node switches from honest to black and vice versa the node produces the false replies. This information is stored in the local buffer and depending on that the malicious nodes are detected and removed from the network.

G. Wahane et al. [4] have proposed the detection of cooperative black hole and crosschecking it with TrueLink. The TrueLink is used cross check the detection of cooperative black hole attack. The DRI table entries are used to detect the black hole attack.

Payal N. Raj et al. [5] have proposed the black hole attack detection mechanism based on detection, prevention and reactive AODV (DPRAODV). The DPRAODV solution checks the Route Reply (RREP) packet sequence number which is higher than the threshold value. The threshold value is dynamically updated through simulation using the dynamic learning method. The alarm packet is sent to all the neighboring nodes to inform about the malicious nodes.

J. Eriksson et al. [6] have proposed a True-link concept for detecting the gray hole attack. Using True-link, a node can verify the existence of a direct link to an apparent neighbor. Verification of a link operates in two phases. In the rendezvous phase, the nodes exchange nonce. The TrueLink concept is totally based on the timing constraint so that the node does not enter into the network.

III. Approch for Detection of Gray Hole Attack

A. TrueLink [6]

The TrueLink is used to check the adjacency of apparent neighbor. It uses combination of timing and authentication. Truelink helps to check the authentication of the nodes participating in the communication. The reliability of the intermediate nodes is checked with the help of TrueLink. Authentication is important for communication. TrueLink performs link verification between two nodes i and j in two phases: the rendezvous phase, and the authentication phase. In the rendezvous phase, i and j exchange nonce _j and _i, where the subscript indicates the node that generated the nonce. The time constraint is an important factor to check the adjacency of the neighboring node; only a direct neighbor can respond in time. In the authentication phase, i and j each sign and transmit the message (_j, _i), mutually authenticating themselves as the originator of their respective nonce. The timing constraints of the rendezvous phase makes TrueLink immune to limits the range of attacks based on bit-by-bit or "cut-through" forwarding. TrueLink is used as an extension to the IEEE 802.11 MAC layer. TrueLink verification between two nodes i and j operates in two phases. In the rendezvous phase, i and j exchange nonces randomly generated numbers. This phase is completed as a single RTS-CTS-DATA-ACK exchange. The features of TrueLink are as follows:

Deploy ability with minimal requirements:

TrueLink does not rely on precise clock synchronization, GPS coordinates, overhearing, or geometric or statistical methods.

Backwards compatibility with IEEE 802.11:

TrueLink can be implemented using standard IEEE 802.11 hardware with a minor, backwards compatible, firmware update. TrueLink enabled terminals continued to interoperate with non-enhanced 802.11 hardware, albeit without TrueLink protection.

Compatible with most authentication methods:

TrueLink can be used equally well with asymmetric, symmetric, hash based or other authentication mechanisms.

Widely applicable:

TrueLink is independent of the routing protocol used and improves the security of both proactive and reactive routing protocols. TrueLink effectively protects the network against such attacks and the cost of protection with TrueLink is small.

B. Proposed Algorithm

The proposed work is used to detect the malicious nodes from the network. The TrueLink is used to detect whether the nodes have the valid link between the neighbors or not. When the link between the two neighbors is not valid then the confirmation is done with the help of the amount of packets forwarded by the node in particular time frame or not. The invalid link may occur between the two nodes because of the network issues so it is important to cross check the behavior of that particular node. The node forwards each and every packet coming to it. When the link between the particular node may be invalid because of the node's behavior. The behavior of the node can be checked with the help of number of packets that are forwarded by the particular node in the fixed time frame. The forwarding node forwards the packet in the form of RTS-CTS-DATA-ACK exchange. This exchange is done in single phase. The TrueLink is implemented in two phases rendezvous and authentication phase. In rendezvous phase the data is exchanged between the neighboring nodes. The authentication phase is validation of the node i.e. the node authenticates itself as an originator of the message. Depending on this the link between the two nodes is verified. When the link between the nodes is valid then the node will not drop the packet. When the link is not TrueLink, the node can drop the packet. To detect the gray hole attack the link is checked multiple times when the link is not TrueLink in multiple check at such times the node can be detected as a malicious node.

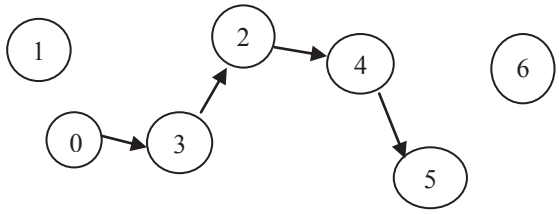

Figure 1: Scenario for Gray Hole Attack

Figure 1 shows the scenario for detection of gray hole attack. Here node "0" is Source and node "5" is destination. The path established between node "0" and "5" is 0-3-2-4-5. Here node 2 and 4 are acting as a gray hole nodes.

The TrueLink is implemented as follows:

The rendezvous phase is implemented as a single RTS-CTS-DATA-ACK exchange. We describe the operation of the protocol for each of these frames. The rendezvous operation includes following steps:

Request to Send (RTS): Node i called initiator, calls init ( ). Node i send an RTS to node j.

Clear to Send (CTS (α_j)): After receiving the RTS, node j calls HandleRTS ( ). A locally generated value α_j is included in the CTS, which is sent after a delay of one Short Interframe Space (*SIFS*), is the small time interval between the data frame and its acknowledgment.

DATA (βi): Having received the CTS, i generate value β_i. After a SIFS delay, the nonce is sent as the packet payload, together with a header, identifying the packet as a rendezvous packet.

ACK: When node j receives the payload packet containing values β_i, the HandleRTS () function sends the ACK frame, after a SIFS delay. The received packet and the locally generated values α_j are handed to the upper layer for processing. When node i receives the ACK, the init () function at i returns the pair (α_j, β_i) to its caller.

When the link is invalid between the two nodes, the nodes are checked for the malicious nature. The SEQUENCE_NUMBER is used to check the behavior.

MAX_SEQ_TH is maximum number of packets that can be used as threshold value to decide the nature of the particular

node. MAX_VALUE is used to check the threshold value for the particular node.

Comparing the MAX_SEQ_TH with SEQUENCE_NUMBER, the behavior of the suspect node can be examined. When the SEQUENCE_NUMBER is greater than the threshold the node is forwarding the packets more than that it can forward in normal scenario. The node is not malicious node.

When the SEQUENCE_NUMBER is less than MAX_SEQ_TH, the node is not forwarding the packets that it can forward in normal state. The node is detected as a malicious node and the route is dropped and new route can be selected.

Before implementing the solution to the gray hole attack, the node is created as a black hole and the results are observed. In gray hole attack the node changes its state so it is important to observe the behavior of the node when it is acting as black hole node. The black hole node is then converted into the gray hole node and the results are observed.

When the node is acting as a black hole, the node drops all the incoming packets through it. In ideal case the node forwards all the incoming packets towards destination. Hence a threshold value is considered to detect the gray hole attack.

Algorithm to detect a gray hole node from the network:

SN: Source node DN: Destination node IN: Intermediate node
α,β: nonce key DRI: Data Routing Information
Step 1: SN broadcasts the RREQ packet
Step 2: SN receives RREP
Step 3: if RREP is from any IN then
Step 4: SN verify the RREP of the node which sends RREP
Step 5: SN verify updates entry of DRI value of the intermediate node that initialized RREP
Step 6.then sendRTS();
Step 7.# recvCTS() times out after $t_{timeout}$ = SIFS
Step 8.α=recvCTS();
Step 9.if α != nil then
Step 10.β->nonce();
Step 11: # success = true if ACK received
Do reactive Link verification and routing method
Step 12 success=sendPacket([VerifyLink,β]);
Step 13.if success == true then
Step 14: Consider the route to be safe and start routing the data packets
Step 15: else Add node as suspect list
Step 16: check again for number of packets transmitted
Step 17: if SEQUENCE_NUMBERS > max_val and
max_val > MAX_SEQ_TH then
Node is not malicious node
Else
The node is malicious.

IV. Simulation Result and Analysis

The proposed algorithm is simulated in Network Simulator (NS-2) [8]. NS-2 is open source network simulation tool. The 802.11 MAC layer implemented in ns-2 is used for simulation. The protocol used is AODV. The various parameters are considered to compare the results.

The parameters used during simulation helps to analyse the network. The channel type used during simulation is wireless channel. Omnidirectional antenna is used for the communication. The Two-ray Ground propagation model is selected for simulation. The link layer type used during simulation is LL. The simulation is done on AODV protocol. The attack and solution is implemented on AODV protocol. Initially 30 nodes are created for the simulation and results are observed by varying the number of nodes. The pause time during simulation was 0.1 milliseconds and the scenario is simulated for 100 milliseconds.

The performance of the network is studied with the help of the graphs plotted by varying the number of nodes and the speed of the nodes i.e. mobility of nodes. The performance of the network is observed in terms of packet delivery ratio. Packet delivery ratio is the amount of the packets that reach to the destination.

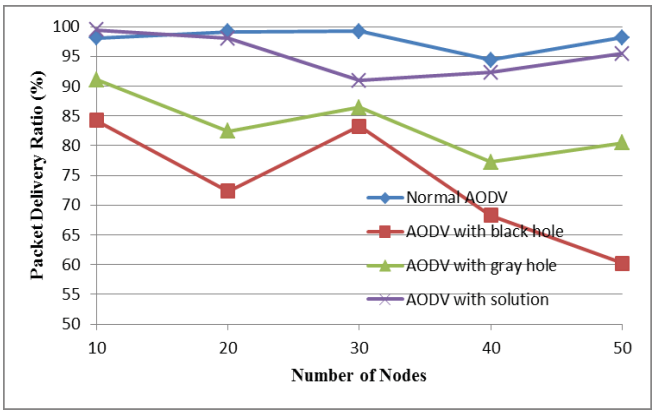

Figure 2: Packet Delivery Ratio Vs. Number of Nodes

Figure 2 shows the variation in packet delivery ratio Vs. number of nodes. When the node is acting as a black hole node, the node drops all the incoming packets to it. The packet delivery ratio is the amount of packets that reach to the destination out of the total packet sent from the source. When a black hole node is present it drops all the incoming packets through it so the packet delivery ratio will be less. When the node is acting as a gray hole, the nodes drops only few amount of packets passing through it. The packet delivery ratio will be more. When the malicious node is removed from the network the packet delivery ratio is improved approximately equal to that in normal scenario. As the malicious nodes are removed from the network, the path is established with the help of honest node only.

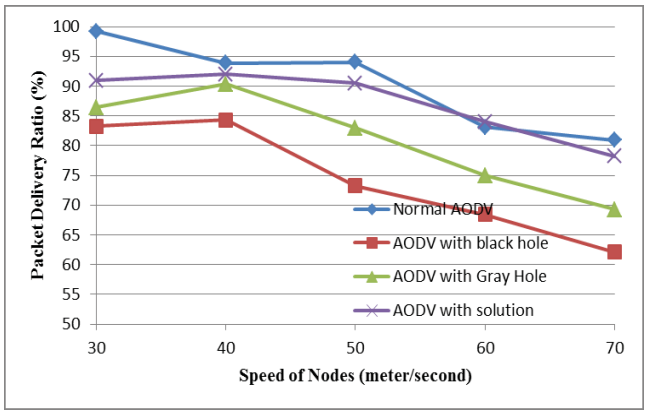

Figure 3: Packet delivery ratio Vs. speed of nodes

Figure 3 shows the variation in packet delivery ratio with respect to the speed of the nodes. The nodes in the MANET are always in moving state. The packet delivery ratio is plotted by varying the speed of nodes from 30 to 80 meter/second. It is observed from figure 3 that when the node is acting as a black hole node the packet delivery ratio decreases as the speed of the nodes increases. When the node is acting as gray hole node the packet delivery ratio is slightly greater than when the node is black hole node. When the solution is implemented the packet delivery ratio is improved.

V. Comparision of Proposed Algorithm with Existing Algorithms

The results of the proposed algorithm are compared with the existing algorithms and it is seen that the overhead is decreased as compared to the existing algorithm.

The existing algorithm proposed by A. M. Kanthe et al. [3] has used the false reply count from the particular node. The false reply count is checked for the each node so the routing overhead increases. The algorithm proposed in this paper checks the nodes for gray hole attack only if getting the invalid link from the nodes. Only suspect nodes are checked for the malicious node hence the overhead decreases.

The existing algorithm DPRAODV [5] used to detect the black hole attack from the network. Once the malicious node is detected from the network an alarm packet is sent to all the neighboring nodes. Due to alarm packets the routing overhead increases as each node checks the neighboring node is in the list of malicious nodes or not. The algorithm proposed in this paper does not send any alarm packet so the routing overhead will be less.

The proposed work is compared with existing work in terms of packet delivery ratio. Table 1 shows the comparison of existing algorithms with the proposed algorithm.

Table I Comparison with existing algorithms

Technique	Performance matric	Analysis
False reply based [3]	Overhead	False replies are calculated at each node. The counter is maintained to store the number of false replies.
DPRAODV [5]	Overhead	After detection of black hole, an alarm packet is broadcasted.
Proposed Algorithm	Overhead	The nodes which do not have valid link with neighbors are only checked for gray hole.

VI. Conclusion

The performance of the network is totally dependent on the behavior of the nodes in the network. For securing the network it is important that each node in the network must be honest node i.e. it must forward all the incoming packets to next node in the path. When a malicious node is present in the path the proper transmission of data is not possible. When a node drops some packets the data which is to be transmitted does not reach to the destination correctly. Detection of gray hole attack is important to ensure proper transmission of data. Because of partial dropping of packets, it is difficult to detect the gray hole in the network.

TrueLink is helpful for verification of the valid link between the neighboring nodes. Depending on how much packets are forwarded by the particular node the node can be detected as the malicious node. The proposed solution reduces the routing overhead by reducing the calculations at each node. Due to continuous changing state of the nodes from honest to black and vice versa the gray hole detection is difficult. So the proposed work will be helpful to keep the nodes with valid link in the network and establish the path through those nodes.

The results obtained with the proposed algorithm are compared with the results of existing algorithms. It is observed that the performance matrices are improved as compared to the previous algorithms.

***Abstract*— When a disaster happens in an urban area, it is essential to localize survivors and rescue workers in burning and collapsing buildings, however, conventional localization methods do not work well for such indoor localization. One promising method is a two-layered localization using unmanned aerial vehicles (UAVs) where UAV flying outdoors, which are localized by the global positioning system (GPS), act as anchor nodes for localizing target nodes located indoors. When localizing a target node in a building by measuring the received signal strength (RSS), in order to achieve accurate indoor localization, UAVs need to know the internal architectural structure of the building, since the walls, windows and doors of the building give different attenuations for the wireless signal used for localization. However, it is impossible to know them in advance.**

In this paper, we call the distribution of the attenuation for the wireless signal ``the attenuation map,'' and propose to estimate it by wireless tomography based on compressed sensing. To explore the possibility of wireless tomography, we conducted an experiment in an anechoic chamber to estimate the three-dimensional attenuation map.

Keywords—wireless tomography; attenuation map; compressed sensing; styling; three-dimensional space

I. INTRODUCTION (*HEADING 1*)

When a disaster happens in an urban area, to search for survivors and prevent the secondary disaster, it is essential to localize survivors and rescue workers in burning and collapsing buildings. However, conventional localization methods do not work well indoors; the wireless signal from the global positioning system (GPS) cannot reach indoors, and wireless local area network (WLAN) access points and wireless sensor network (WSN) nodes with known locations are not pre-installed in buildings.

One promising method is to use unmanned aerial vehicles (UAVs) flying outdoors for indoor localization of target nodes, where the UAVs are localized by the GPS and then they act as anchor nodes for target nodes with unknown indoor locations. In this case, there are mainly two considerable techniques for the part of the indoor localization, such as time of arrival (TOA) and received signal strength (RSS). The TOA technique achieves higher localization accuracy but its realization is not easier. Therefore in this paper, we focus on the RSS technique, since almost all transceivers have a function of measuring the RSS.

When UAVs flying outdoors localize a target node in a building, the wireless signal from/to the target node experiences much attenuation when penetrating the wall and doors. The attenuation changes according to the internal architectural structure of the building, so in order to localize the target node accurately by the RSS method, the UAVs need to know it to compensate for the RSS, namely, to distinguish the attenuation by the distance for the target node from by the architectural structure. However, it is almost impossible to know the architectural structure in advance, and even when we can know it, the attenuation changes according to the carrier frequency of the wireless signal and the material of the building, so it is difficult to estimate the distribution of the attenuation for the wireless signal used for localization. One possible approach is the use of wireless tomography.

Tomography is a technique for identifying the internal structure of a monitored region by analyzing wireless waves traversed across the region or reflected in the region. The tomography using the same wireless signal as for communication thus localization is called ``wireless tomography [1],'' and the wireless tomography can be represented as a system of linear equation by using the propagation property of wireless signal [2]. Furthermore, the space of building is constructed suitably for human lives, so the

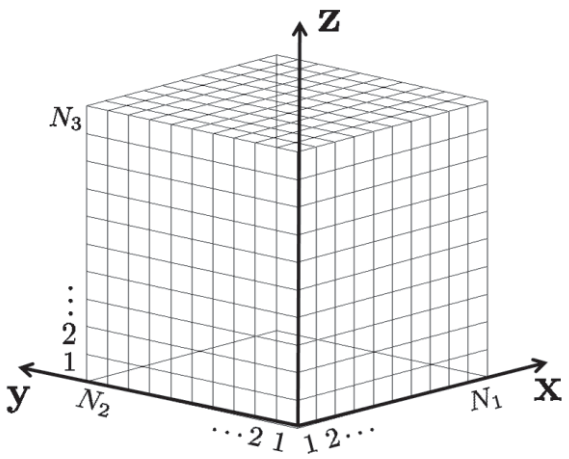

Fig. 1: Three-dimensional monitored region.

walls, windows and doors are not randomly laid out, namely, they are structured. This means that, when giving 1's to the parts with higher attenuations (such as walls and doors) and giving 0's to those with lower attenuations (such as human living spaces), the ground plan of building can be represented by a sparse matrix with the smaller number of 1's, since the human living spaces are dominant. Therefore, taking into consideration that compressed sensing [3] is a technique for solving underdetermined linear inverse problems when the solution has the sparsity, it can be successfully introduced into the wireless tomography encountered in the attenuation map estimation for the indoor localization using UAVs.

In this paper, we call the distribution of the attenuation for the wireless signal used for localization ``the attenuation map'' and in order to explore the possibility of the wireless tomography for estimating the three-dimensional attenuation map, we evaluate the performance by experiment. Three-dimensional space is represented with a tensor, so a tensor-based compressed sensing [2] can be directly applied to estimate the attenuation map, but in the paper, for the sake of simplicity, we slice a three-dimensional space into multiple two-dimensional horizontal planes and apply a matrix-based compressed sensing to estimate them.

This paper is organized as follows. Section II presents the problem formulation in the three-dimension space. Section III shows the principle of the wireless tomography based on compressed sensing. Section IV explains the confirmation experiment of the wireless tomography method and shows the results. Finally, Section V concludes the paper.

II. Principle of Three-Dimensional Wireless Tomography

As shown in Fig. 1, the attenuation map for a three-dimensional monitored region is written with a tensor as

$$\mathbf{G} = \{G_{n_1 n_2 n_3} \mid n_1 = 1,2,\ldots,N_1, \\ n_2 = 1,2,\ldots,N_2, n_3 = 1,2,\ldots,N_3\} \tag{1}$$

where N_1, N_2 and N_3 denote the numbers of grids dividing the monitored region in the x-axis, y-axis and z-axis directions, respectively, and each element of the attenuation map is defined as the amount of attenuation per unit volume of the corresponding grid. Furthermore, we define the (n_1,n_2,n_3)-th grid as $\gamma_{(n_1,n_2,n_3)}$.

Let I denote the number of combinations of wireless nodes which are deployed on the border of the monitored region, and also let us assume that a wireless signal is transmitted from a transmitter $\mathbf{T}_i = [T_{xi},T_{yi},T_{zi}]^T$ to a receiver $\mathbf{R}_i = [R_{xi},R_{yi},R_{zi}]^T$ (i = 1,2,..., I). In this case, defining P_i, d_i and L_i as the received signal power at R_i in dBm, the length of the i-th path, and the loss over the i-th path in dB, respectively, we can model the shadowing loss due to obstructions $S_i[dB]$ between $\mathbf{T}_i$ and $\mathbf{R}_i$ as

$$\begin{aligned} S_i &= L_i - P_i \\ L_i &= \alpha d_i^{-\beta} \\ d_i &= \|\mathbf{T}_i - \mathbf{R}_i\| \end{aligned} \tag{2}$$

where α and β are the propagation constants when there are no obstructions between $\boldsymbol{T}_i$ and $\boldsymbol{R}_i$. In this paper, α and β are assumed to be known in advance.

On the other hand, let us define a set of indexes of the grids which the i-th path penetrates as

$$\Gamma^i = \{(n_1^i,n_2^i,n_3^i) : \textit{the } i\textit{-th path penetrates } \gamma_{(n_1^i,n_2^i,n_3^i)}\}. \tag{3}$$

In this case, defining the length of the partial path in $\gamma_{(n_1^i,n_2^i,n_3^i)}$ as $\delta_{n_1^i,n_2^i,n_3^i}$, S_i is given by (i = 1,2,..., I)

$$\mathrm{S_i} = \sum_{(n_1^i,n_2^i,n_3^i)\in\Gamma^i} \delta_{n_1^i,n_2^i,n_3^i} G_{n_1^i,n_2^i,n_3^i}. \tag{4}$$

Therefore, defining the attenuation vector as $\mathbf{S} = [S_1,S_2,\ldots,S_I]^T$, it is written as

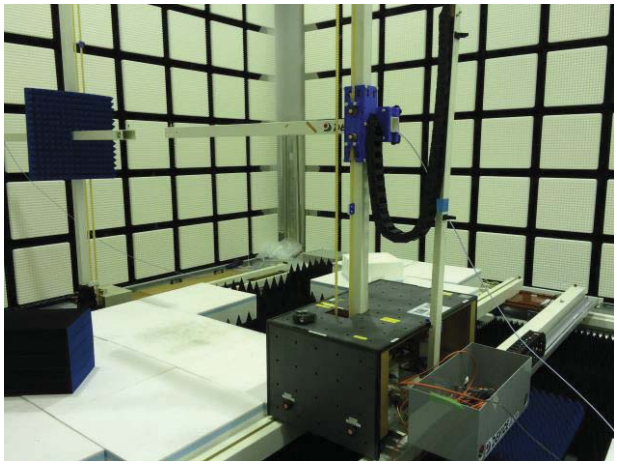
$$\mathbf{S} = A(\mathbf{G}) \tag{5}$$

where $A(\cdot)$ denotes a linear map $A : \mathbb{R}^{N_1N_2N_3} \rightarrow \mathbb{R}^I$. Wireless tomography means a linear inverse problem to estimate $\mathbf{G}$ from measured $\mathbf{S}$ and a given linear map A.

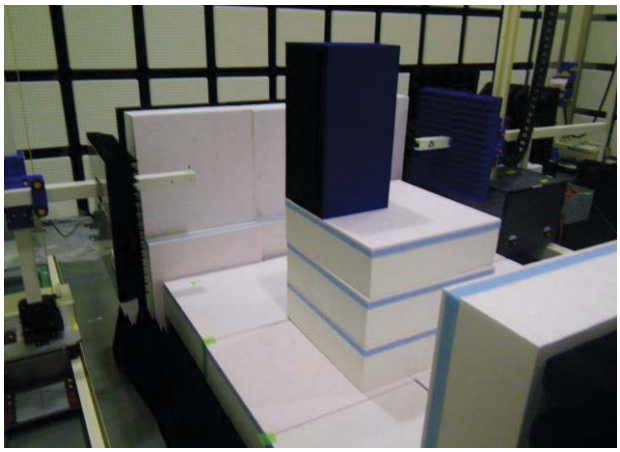
III. Wireless Tomography With Compressed Sensing

Buildings are generally designed suitably for human lives, so there are more empty spaces than obstructions such as walls, doors and windows. This implies that we can assume that the number of elements with exactly or approximately zero values is much larger than the number of elements with larger values in the attenuation map. Therefore, even if the number of measurements, namely, the dimension of the measurement vector I is much smaller than that of total grids $Q = N_1 \times N_2 \times N_3$ ($I << Q$), $\mathbf{G}$ can estimated from $\mathbf{S}$ using the compressed sensing theory. Measurement is always noisy, so we cannot have exactly zero values for empty spaces. In this case, we can estimate $\mathbf{G}$ using the following l_1/l_2 optimization [4]:

$$\hat{\mathbf{G}} = \arg\min_{\mathbf{G}} \left(\frac{\mu}{2}\|\mathbf{S} - A(\mathbf{G})\|_2^2 + \sum_{l=1}^{3} \|\mathbf{G}_{(l)}\|_* \right) \tag{6}$$



(a) A transmitter and a receiver.



(b) An obstruction.

Fig. 2: Experimental setup.

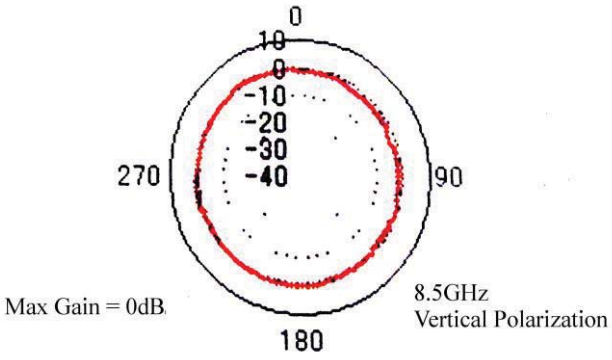


Fig. 3: Antenna radiation pattern.

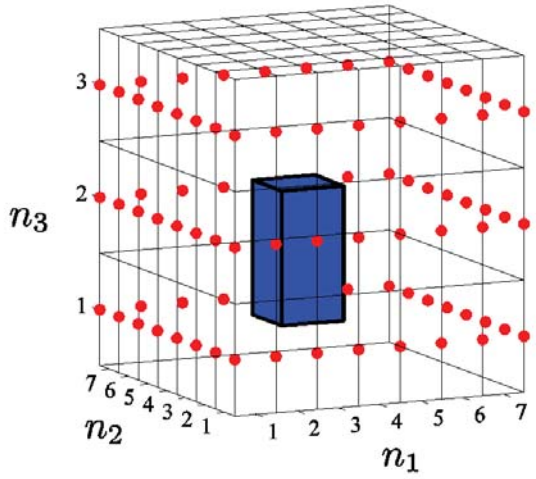
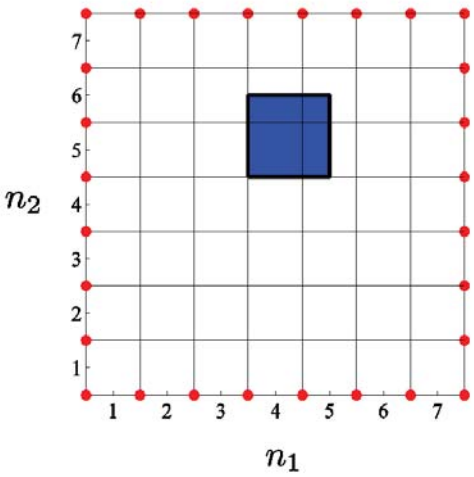
where $\mathbf{G}_{(l)}$ denotes the mode-l of $\mathbf{G}$, and $\|\mathbf{G}(l)\|_*$ denotes the nuclear norm of $\mathbf{G}$, and μ ($\mu > 0$) is a regularization parameter.



(a) Three-dimensional.



(b) x-y plane.

Fig. 4: Monitored region and placement points of wireless nodes.

In this paper, instead of directly solving the tensor-based l_1/l_2 optimization given by (6), we slice the tensor $\mathbf{G}$ into multiple matrices $\mathbf{g}_{n_3}$ on different horizontal planes under the constraint that T_{zi} and R_{zi} are located on the same plane:

$$\mathbf{G} = \{\mathbf{g}_{n_3} \mid n_3 = 1,2,\ldots,N_3\} \quad (7)$$

$$\mathbf{g}_{n_3} = \{g_{n_3} \mid n_1 = 1,2,\ldots,N_1, n_2 = 1,2,\ldots,N_2\}. \quad (8)$$

IV. Experiment on the Possibility of Wireless Tomography

A. Experimental environment

As a preliminary study to explore the possibility of the proposed wireless tomography method, we conducted an experiment in an anechoic chamber of National Institute of Information and Communications Technology (NICT)

TABLE I: Specifications of the experiment.

Location	NICT Headquarter
Anechoic chamber	840cm×720cm×660cm
Monitored region	140cm×140cm×100cm
Obstruction(Wave Absorber)	30cm×30cm×60cm
Signal emission	8GHz(CW)
RSS	-60dBm～-30dBm
Antenna	UWB antenna(Omni)
Placement points of wireless nodes	28(each plane)×3=84
Number of measurement paths	270(each plane)×3=810
Horizontal resolution	20cm
Vertical resolution	50cm

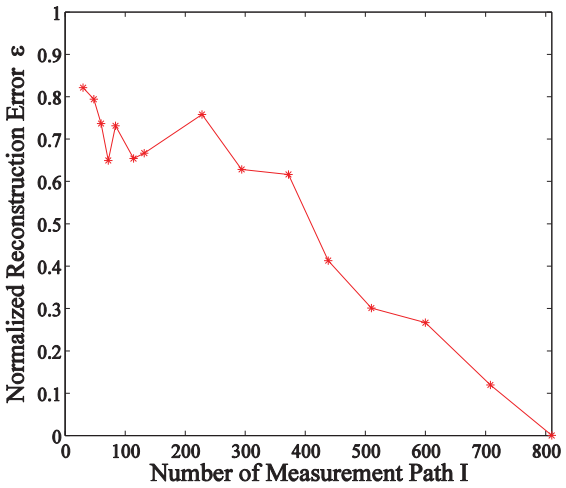


Fig. 5: Number of measurements vs the estimation error characteristics.

Headquarter. Fig. 2 shows the experimental setup with a transmitter, a receiver and an obstruction.

The wireless signal transmitted from a transmitter was a continuous wave in the 8GHz band, and its power was adjusted to be received at a receiver in -60dBm ~ -30dBm. The transmitter and receiver had the same type of antenna with almost omni-directional antenna radiation pattern as shown in Fig. 3. In addition, we used a radio wave absorber as an obstruction in the monitored region.

As shown in Fig. 4, we divided the three-dimensional monitored region to 3 slices with 50cm interval in the height direction along the *z*-axis, and in each horizontal plane, we divided the monitored space by 20cm internal along the *x*-axis and *y*-axis. Therefore, we had $N_1 = 7$, $N_2 = 7$ and $N_3 = 3$, and the number of placeable points for the transmitter or receiver was 28. As a result, the number of measurable paths was 270 on each planes, so the total number of measurable paths was $270 \times 3 = 810$.

Finally, Table I summarizes the specifications of the experiment.

B. *Experimental result*

We evaluate the estimation accuracy of the attenuation map in terms of the error using I measurements normalized by the one using the maximal number of measurements I_{max} = 810, which is defined as

$$\varepsilon(I) = \frac{1}{3}\sum_{n_3=1}^{3} \frac{\left\| \mathbf{g}_{n_3}^{I} - \mathbf{g}_{n_3}^{\max} \right\|_F}{\left\| \mathbf{g}_{n_3}^{,\max} \right\|_F} \qquad (9)$$

where $\mathbf{g}_{n_3}^{I}$ is the attenuation map matrix estimated using I, $\mathbf{g}_{n_3}^{\max}$ is the one estimated using I_{max}, and $||(\cdot)||F$ denotes the Frobenius norm of $(\cdot)$.

Fig. 5 shows the normalized estimation error versus the number of measurements (I). From Fig. 5, we can see that the normalized estimation error almost linearly decreases as the number of measurements increases. That is, if we need to achieve the 50% estimation accuracy, we can reduce the number of measurements by around 50%.

Finally, Figs. 6 and 7 compare the attenuation maps estimated using I = 114 (= 38×3) paths and I_{max} = 810 (= 270 ×3) paths, respectively. Note that the transmitter and receiver were located on the same plane, so from Fig. 4, no obstruction should appear in the attenuation map at n_3 = 3. As expected, there are no obstructions estimated in both Figs. 6 (c) and 7 (c) at n_3 = 3.

For the case of I = 114, which corresponds to around 85% reduction of the number of paths, from Fig. 5, we can see that the normalized estimation error is relatively large, but there is no large difference in these illustrative comparisons. That is, in Figs. 6 (a) and 7 (a) at n_3 = 1 and Figs. 6 (b) and 7 (b) at n_3 = 2, the obstruction is clearly estimated by the proposed wireless tomography method based on compressed sensing.

V. CONCLUSION

In this paper, we proposed the wireless tomography based on compressed sensing to estimate the attenuation map, and demonstrated the preliminary results obtained from the experiment in an anechoic chamber. Instead of estimating the three dimensional attenuation map directly by means of the tensor-based compressed sensing, after slicing the three-dimensional region into three two-dimensional regions, we estimated the three two-dimensional attenuation maps by applying the matrix-based compressed sensing to each sliced regions. In the experiment, a higher sparsity was guaranteed for the three dimensional region. Therefore, when reducing the number of measured paths by around 85%, a large estimation error was observed in the quantitative evaluation, on the other hand, no large estimation error was confirmed in the illustrative evaluation.

***Abstract*—In this paper, we propose a new pricing model for Dynamic dual-operator spectrum sharing in GSM. Existing GSM pricing models will not work in case of dynamic spectrum sharing (DSS) as there is a possibility of users belonging to one operator getting served by another operator. To solve this problem, we introduce spectrum sharing co-ordinator (SSC); with database attached to it, for storing such type of entries and executing proposed pricing scheme. As GSM is expected to sustain for 15-20 years in India and other developing countries, it is important to consider spectrum sharing for GSM to improve spectrum utilization. Different DSS schemes are discussed for maximizing revenue generation, from the point of view of network operators.**

***Index Terms*—Dynamic spectrum sharing, pricing, GSM.**

I. Introduction

Measurement studies done in several parts of India [1], [2], showed in-efficient utilization of spectrum. This problem of in-efficiency in spectrum utilization can be solved by introducing dynamic spectrum sharing between mobile network operators (MNOs). We have proposed different DSS schemes between two GSM operators to improve spectrum utilization. Now, there is a need for new pricing models which suit these schemes.

Hierarchical bandwidth sharing in dynamic spectrum access networks presented in [3] gives iterative algorithms for price adaptation. The problem of profit maximization for spectrum utilization in presence of both primary and secondary users is illustrated in [4] by using stochastic dynamic programming and in this case an optimal pricing policy. Realistic pricing model for dynamic spectrum access network is given in [5] by considering factors such as reputation of sellers, incentive mechanism to attract buyers and timing requirements. Competitive pricing schemes for spectrum sharing in cognitive radion networks with the help of game theory is presented in [6]–[8].

There are many pricing models for dynamic spectrum sharing [9]–[13], but they deal in selling of spectrum licenses for short duration to secondary services which is done generally by primary service or spectrum broker/ server. Spectrum broker pools unused spectrum from MNOs and sells this spectrum on demand basis. Our proposed scheme does not deal with selling of spectrum licenses, but uses other operator's free resources based on own users requirement.

In proposed system model, spectrum sharing coordinator (SSC) is just a piece of code and not an independent entity which is responsible for carrying out spectrum sharing activities between two GSM operators. While designing pricing model for such case, we need to keep track of one operator's resources which are getting utilized by other operator users. This task is also done by SSC with the use of database where it stores all such entries.

In this paper, we propose new pricing model by considering factors such as call blocking probability, average call holding time and utilization of one operator's spectrum by other. With the focus on the maximization of spectrum utilization, the economical benefit is also equally important from proposed spectrum sharing scheme. From this point of view, we will discuss several DSS schemes.

The rest of the paper is organized as follows. The new system architecture is proposed in Section II. Section III analyses different DSS schemes between two GSM operators and gives their comparison. Section IV explains existing GSM pricing functional model. The new pricing model for DSS between two GSM operators is proposed in Section V. Conclusions and future work is given in Section VI.

II. System Architecture

The system architecture consisting of two GSM operators (OP1 and OP2) with spectrum sharing co-ordinator (SSC) is shown in Fig. 1. We can observe that both the GSM base stations are connected

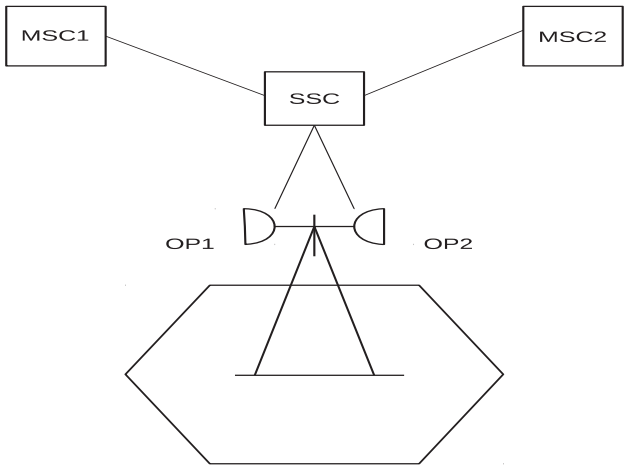

Fig. 1. Two GSM operators with spectrum sharing co-ordinator.

to their corresponding mobile switching centers (MSCs) through common SSC. BS is a combination of base transceiver station (BTS) at tower site and base station controller (BSC) which is remote radio resource management device. The SSC performs all the spectrum sharing activities such as user migration between two GSM networks and carrier allocation.

Assumption of considering both the BS to be co-located is valid, because, in many cases, we observe that location of BSs belonging to different GSM operators are on same tower or building. These BSs will be active on different absolute radio frequency channel numbers (ARFCNs) but with same coverage area. If BSs are not located at same place, then their coverage areas will be different. So, we need to consider this issue in DSS schemes. It will add complexity as well as call setup delay; and will be considered in a future study. The poisson process is used to model call arrival process and exponential distribution for call duration parameter [14].

There are many spectrum sharing approaches are discussed in [15], [16]. However, for dual-operator sharing case considered in this paper, there are mainly two approaches i.e. centralized [17], [18] and distributed [19], [20]. The centralized approach controls spectrum allocation among the operators with help of spectrum server/ broker. But, the transmitter chooses channel from available channels with the transmission power in distributed sharing approach. This paper concentrates on centralized way of sharing between two GSM operators by introducing the logical entity SSC. Many times, it can be observed that the different operators may have coinciding peak hour periods, but different peak loads. So, we can take advantage of instantaneous spectrum opportunities even during coinciding peak hour due to different call arrival rates.

III. Dynamic Spectrum Sharing between two GSM Operators

There are many different ways in which we can do dynamic spectrum sharing between two GSM operators. These ways are mainly classified based on the outcome we are expecting from sharing. Most of the papers consider two parameters such as spectrum utilization and call blocking probability or Quality of Service (QoS).

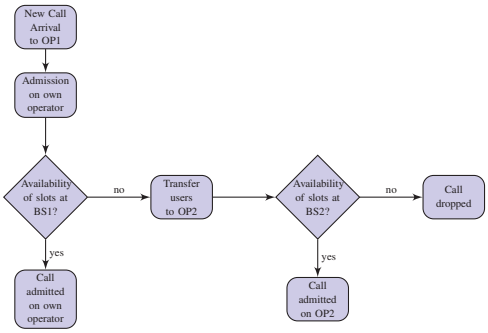

Fig. 2. DSS Scheme I flowchart

We also considered same two parameters while designing the sharing algorithm and describe it in context of DSS scheme I as shown in Fig. 2. But, when it comes to the practical deployment, the operators will be mainly focusing on the economical benefits from this type sharing. So, while designing DSS algorithm, we should consider this parameter. From an economical point of view, we can think of several different spectrum sharing techniques based on the charging schemes. The charging scheme is a vital parameter which affects the spectrum sharing algorithm. We further identify two cases i.e. DSS scheme II and DSS scheme III which are discussed in subsection III-B and subsection III-C respectively.

In these schemes, an operator is allowed to use only the free resources of another operator. An operator using other operator‘s free resources will pay less charges compared to normal call rate. To gain more economical benefit, operator will target to serve own customers preferentially as compared to other operators users. Keeping this in mind, there are two ways of spectrum sharing by considering two new parameters; call handover and QoS.

Each BS is allotted with four ARFCNs and used to transmit GSM frames. Each GSM frame of duration 4.615ms is divided into eight slots. So, each ARFCN can support seven to eight users/calls by allotting traffic channel (TCH) slots. So, each BS at any time can allow thirty one active calls.

A. DSS Scheme I

The flowchart in Fig. 2 explains DSS Scheme I between two GSM operators. This is the simplest scheme with least complexity without forced handover and call drop. For convenience, new call arrival is considered to OP1 with BS1 in all schemes.

The steps involved in DSS Scheme I are as follows:

Step 1. A new call arrives at one of the two base stations i.e. BS1 which belongs to OP1.

Step 2. OP1 tries to accommodate call by allotting free time slot.

Step 3. If call is admitted on own network, then the procedure stops as shown in flowchart in Fig. 2.

Step 4. Otherwise, user is transferred to OP2 through SSC. The call will be permitted based on the availability of free resources with OP2 at that particular time.

Step 5. If call is not admitted on OP2 also, then the call will be dropped.

B. DSS Scheme II

In this scheme, first, a new call will try to occupy TCH at its own operator. If it fails in doing that, it will check for the availability of free resources at other operator. If other operator is also not having any free TCH, then rather than dropping the call like in DSS Scheme I, it will come back to own operator. Now, it will check occupancy details of own operator. If it is serving other operator users, then one of other operator users will be forced to drop the call. Then, new call will be accommodated on own operator. But, in case, all users with active call are his own, then new call will be dropped.

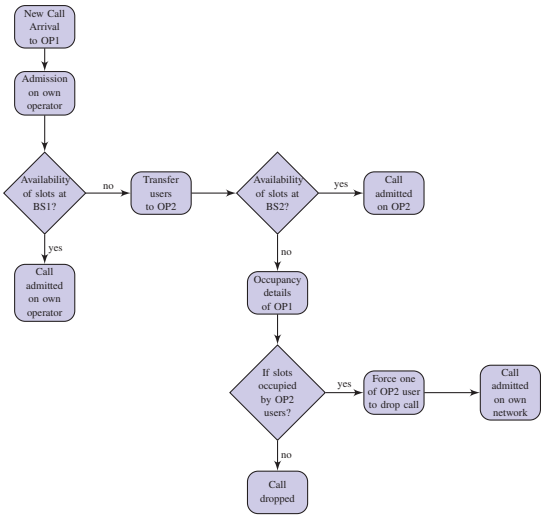

Fig. 3. DSS Scheme II flowchart

The steps involved in DSS Scheme II are as follows:

Step 1. A new call arrives at one of the two base stations i.e. BS1 which belongs to OP1.

Step 2. OP1 check for free slots and try to accommodate the call.

Step 3. If call is successfully admitted on own network/ OP1, then procedure stops as shown in flowchart in Fig. 3.

Step 4. Otherwise, user is transferred to OP2 through SSC. The call will be allowed based on slot availability with OP2 at that time.

Step 5. If OP2 also fails in serving call, then user occupancy details of BS1 (of OP1) will be checked.

Step 6. If some of BS1 resources are used by OP2 users, then one of OP2 users will be forced to drop the call and new call of OP1 user will be admitted on own network/ OP1.

Step 7. If only OP1 users are using resources of BS1, then the new call arrived will be dropped.

C. DSS Scheme III

The flowchart for DSS Scheme III is shown in Fig. 4. Similar to DSS Scheme I and II, new call will be tried to be accommodated on own operator first. If it is unsuccessful in that, then occupancy details of own operator will be checked rather than going to other operator as in previous cases. If other operator's users are not using any of resources, then new call will be transferred to other operator and based on availability of free resources, it will be served or dropped.

If operator of arrived new call is serving other operator users, then instead of simply dropping one of operator users call, handover attempt will be done. One of other operator's user will be forced to handover the ongoing call to his own operator. If handover fails due to un-availability of resources, then the call will be dropped and finally, new call will be admitted.

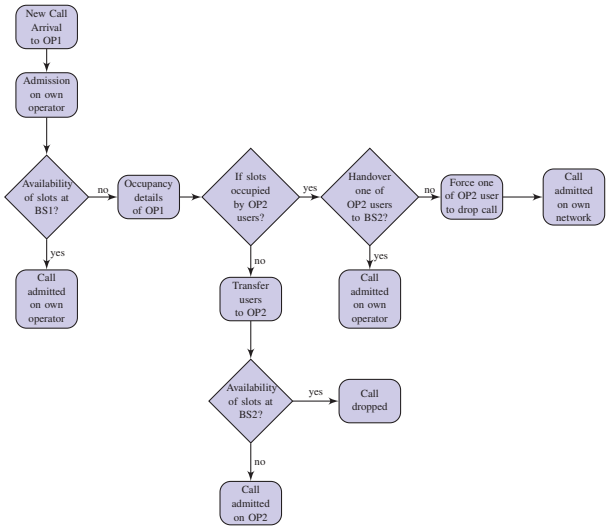

Fig. 4. DSS Scheme III flowchart

The steps involved in DSS Scheme III are as follows:

Step 1. A new call arrives at one of the two base stations i.e. BS1 which belongs to OP1.

Step 2. OP1 tries to serve his own user.

Step 3. If call is admitted on OP1, then the procedure stops as shown in flowchart in Fig. 4.

Step 4. Otherwise, user occupancy details of BS1 will be checked. If OP2 users occupied some resources of BS1, then the following subroutine will be executed.

a. One of OP2 users will opt for handover of call to BS2.

b. If handover is successful, then OP1 user will be admitted on freed resources.

c. In case of failed handover, the ongoing OP2 user call will be dropped and then OP1 user call will be admitted.

Step 5. If only OP1 users are using resources of BS1, then following subroutine is followed.

a. New call arrived at BS1 will be transferred to BS2.

b. If there are free resources with BS2 at that particular time, then call will be admitted on BS2.

c. Otherwise, the call will be dropped.

D. Comparison of the Three DSS Schemes

DSS Scheme I is the simplest sharing technique which involves lower complexity compared to DSS Schemes II and III. Even Scheme I gives exactly same spectrum efficiency gain as other two schemes and call blocking probability is less in this scheme. This is because operator is not giving preference to own customer and not forces other operator user to drop the call. But by doing this, operator looses the economical benefits; in Scheme I. That's why, even if with higher complexity, we consider other two schemes.

DSS Scheme II gives more economical benefit compared to Scheme I but less compared to Scheme III. Because, in Scheme III, new call will not go to other operator even if own operator is busy. Before going to other operator, the occupancy details of own operator will be verified. In terms of QoS, Scheme II outperforms Scheme III, because it does not involve any additional delays due to handovers. The handover considered is not normal handover but it is a forced handover as demonstrated in [21].

IV. Existing GSM Pricing

The existing GSM pricing schemes have been discussed in [22]–[24]. The functional model for GSM pricing can be divided into (mainly) three parts as shown in Fig. 5.

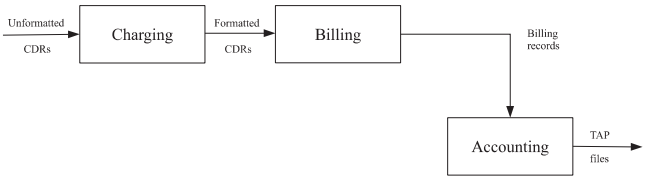

Fig. 5. GSM Pricing Model.

I. Charging

It collects information related to chargeable events which is generally structured into the form of a charging data record (CDR) from several network nodes. CDRs corresponding to all calls made are generated by the MSC's. The GGSN and SGSN produces CDRs based on Internet traffic usage done in GPRS sessions. CDR contains different fields which mainly categorized as mandatory (M) and conditional (C). Mandatory fields should be included always in the CDRs and conditional fields shall be present based on certain conditions. Some fields are operator-specific and again sub-categorized into mandatory, O_M, and conditional, O_C. The information contained in the fields categorized above as follows.

1. Mandatory (M): calling party, called party, call duration, location area code, call reference, radio channel type (full or half rate).

2. Conditional (C) : IMEI of called and calling party, Transparency indicator, Supplementary services, Event time stamps, partial record sequence number, etc.

3. Operator mandatory (O_M) : Speech version, Radio traffic channel requested by mobile, reason for connection release.

4. Operator conditional (O_C) : Roaming number, Change of service, change of radio channel, etc.

The charging functionality is carried out by a mediation system. Mediation systems collect CDRs in different formats from network elements and convert them into a format compatible for billing system. Finally, formatted CDRs will be transferred to billing system using File Transfer Protocol (FTP).

II. Billing

This function processes the CDRs arriving from mediation system based on the tariffs stored in Home Location Register (HLR) which

stores the information related to every customer. A customer can be charged based on the parameters such as local call, international call, night time calls, call per second or minute and many more.

III. Accounting

It is responsible for dividing the charges between home and serving network. The records corresponding to roaming users will be forwarded to its home network operator using transferred account procedure (TAP) in a specific format.

V. New Pricing Model

In this section, we propose a new pricing model which is combination of existing GSM pricing and an additional support for DSS scheme between two GSM operators. The proposed model is only for voice calls not for data. In existing GSM pricing, CDRs generated by MSCs will be collected by a mediation system and then forwarded to corresponding operator's billing system. Similarly, we can observe that three MSCs (MSC1, MSC2 and MSC X) have separate branch containing mediation and billing system as shown in Fig. 6. For the settlement between two GSM operators, a new branch containing series of red blocks is added.

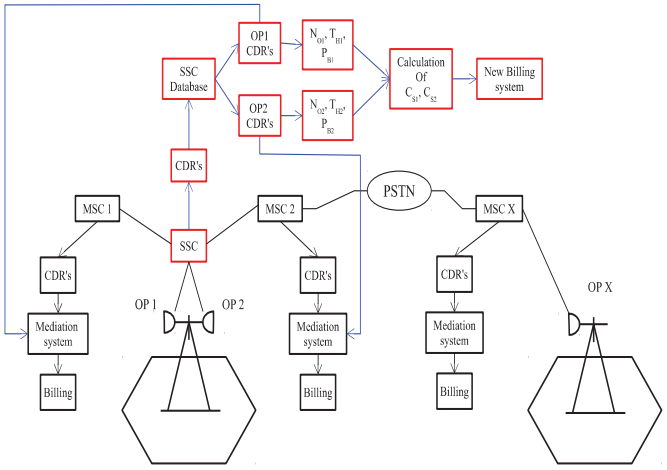

Fig. 6. New GSM Pricing Model.

As calls are getting served randomly by either OP1 or OP2 based on available free resources, we have to charge calls with variable call rates every time. This adds more complexity to pricing model. So, in our proposed model, we considered same call rates will be applied to all calls (from user's point of view) as in existing GSM pricing by operator's billing system. The CDRs for calls using other operator's resources is generated by SSC and will be stored at SSC Database. Periodically, this database separate out CDRs corresponding to different operator and send one copy to respective mediation system. Later, such CDRs will be processed by billing system to charge users accordingly.

The important point to note is that new billing system is used for the settlement between two GSM operators rather than charging users. The proposed billing system will be invisible from normal users and only operators involved in co-ordination will be aware of that. New billing system generates invoices for both GSM operators monthly or at a time interval decided by operators. This invoices shows usage of one operator's resources by another operator's users and how it is charged with variable call rates. The need of variable call rates in the proposed billing system is explained below.

Dynamic nature of DSS Schemes: There may be chances of reduction in QoS in one of the operators even if there is overall increase in spectrum utilization. By considering such a dynamic nature, variable charging scheme with time period T is adopted. The database entries at SSC will be processed with charging scheme. Now, we will define some terms which plays an important role in charging scheme and evaluated every T time period are as follows.

P_{B1}, P_{B2} : The call blocking probabilities for two GSM operators; observed during time period T.

C_{S1}, C_{S2} : The call rates to be applicable to the call entries at the database at SSC during time period T.

T_{H1}, T_{H2} : The average call holding times for each GSM operator during time period T.

N_{O1}, N_{O2} : The number of users corresponding to one operator served by another operator during time period T.

The GSM operator that observes less call blocking probability and uses more resources of other operator has to be charged more compared to other operator. This leads to following relationships.

$$C_{S1} \propto \frac{1}{P_{B1}} \propto T_{H1} \propto N_{O1} \quad (1)$$

$$C_{S1} \propto P_{B2} \propto \frac{1}{T_{H2}} \propto \frac{1}{N_{O2}} \quad (2)$$

Similar relations can be written for the C_{S2}.

Now, we will discuss how CDRs will be generated for different type of calls and how these calls will be charged in perspective of user and operator in detail below.

CASE I : Normal Call

In this case, calls will be getting served by its own operator and there is no need of routing the calls through SSC. The calls belonging to this category will be charged according to existing GSM pricing. That means, CDRs will be generated by corresponding MSCs and then collected by mediation system. After formatting CDRs, mediation system will forward them to billing system of operator. For example, suppose OP2 user initiates the call and called subscriber belongs to OP X and lies under the coverage of MSC X as shown in Fig. 6. The call will be established by finding route through PSTN. In this case, MSC2 will produce CDR which will be collected by the mediation system and finally processed by OP2's billing system. If the called party is in roaming, then it should be charged. This type of CDR will be generated by MSC X and finally will reach to OP X's billing system.

CASE II : Calls through SSC

This is an important case for dynamic spectrum sharing between two GSM operators. The calls falling in this category will be getting served by other operator not his own. The calls from one operator will be using other operator's resources and routed through SSC and then serving operator's MSC to targeted destination. This case arises only when own operator has no free resources to serve own user. In this case, MSC through which call is getting routed cannot generate CDR as it is not authorized to do that. As call is routed through SSC, we propose a new way of generating CDR by SSC, which is different from standard GSM case and is given as follows.

1. The calls which are utilizing the radio resources of other GSM operator will be routed through SSC.

2. The CDRs for such type of calls will be generated by SSC.

3. These CDRs will be stored at SSC database which will be cleared after every time period T.

4. Now, separation of these CDRs will be done based on the operator to which it belongs.

5. The separated CDRs will be sent to corresponding mediation system which further forwards it to operator's billing system. So, users will be charged accordingly.

6. Now, for settlement between GSM operators, parameters such as average call holding time, number of users served and call blocking probability will be obtained from separated CDRs as shown in Fig.6.

7. Based on these parameters and relations defined in (1), (2), calculation of call rates i.e. C_{S1} and C_{S2}, will be done.

8. The call rates decided in step 7 will be applied to corresponding operator's CDRs by new billing system to generate amount that one GSM operator should pay to another.

For example, OP1 user initiates the call to OP X subscriber under the coverage of MSC X. But, OP1 is lacking of resources and OP2 is having free resources. So, the call will be admitted on OP2 resources by routing through SSC. The call connection will be established through SSC-MSC2-PSTN-MSC X path. The CDR for this call will be generated by SSC and processed according to the procedure mentioned above.

CASE III : Calls handover to own operator

In this case, initially users will be using the radio resources of other operator. But as discussed in DSS Scheme III, some times, these progressing calls will be 'handovered' to its own operator. So, call is served partially by other operator and remaining by its own operator. In such situation, two CDRs will be generated. First CDR by SSC for the part of call served by other operator and second by own MSC for remaining part of call served by own operator.

First CDR will go to SSC database and from there, it will be forwarded to new billing system and mediation system of operator. Second CDR will directly go to mediation system and will be combined with first CDR to get complete call entry. Now, operator's billing system can charge that call entry based on total call duration.

For example, OP1 user initiates the call to OP X user. Intially, call gets accommodated on OP2 resources through SSC. After some time, OP2 user request channel to start new call. But, it comes to notice that OP2 is not having any free resources and at this time, OP1 is having free resources. So, as discussed in DSS scheme III, ongoing OP1 user call on OP2 resources will be 'handovered' to OP1 and OP2 user will allowed on its own operator. For the 'handovered' call, one CDR will be generated by SSC and other by MSC1. The user will be charged by combining these two CDRs at mediation system. But, one copy of SSC generated CDR will go to the new billing system.

VI. Conclusions and Future Work

This paper has presented new pricing model for dynamic spectrum sharing between two GSM operators. The proposed pricing model is discussed in detail for three types of calls from a user as well as an operator perspective. The three DSS Schemes between two GSM operators is presented to provide more economical benefit to operators. Future work will try to obtain generalized pricing model for dynamic spectrum sharing between any number of GSM operators.

***Abstract*—With the increase in mobile traffic and the bandwidth demand, Device-to-Device (D2D) communication underlaying Long Term Evolution (LTE) networks has gained tremendous interest by the researchers, cellular operators and equipment manufacturers. However, the application of D2D communication has been limited to emergency services and it needs to be explored in commercial applications. In this paper, we have introduced a novel commercial D2D offloading scheme for users who may be at cell edges, inside isolated environments like basement or large buildings, etc. Our proposed scheme discovers the available idle D2D neighbors for such poor channel users and offloads its data to the D2D neighbor, which then relays the data to the eNB. We have developed a D2D offloading simulation model in MATLAB, have conducted extensive simulations and have observed that the proposed scheme can provide better efficiency to the network as well as satisfy the poor channel users significantly.**

I. Introduction

There is a huge demand for high data rate services like video sharing, online gaming, proximity-aware-social-networking, etc., in today's cellular network (2G/3G/4G). However, the vulnerability of the cellular networks significantly affects the performance of these services; not only hampers the data communication, but also adds unfairness to network usage of the users. Because of the vulnerability, cell edge users, users inside a lift or basement, etc., do not get a fair Quality of Services (QoS) experience as compared to other users in the network. Studies have been conducted by various researchers in this direction so as to ensure high data rates to poor channel users and to maximally utilize the wireless resources.

Today, Device-to-Device (D2D) communication [1], [2], in which close proximity User Equipments (UEs) can directly communicate among themselves using the cellular resources and bypassing the Evolved NodeB (eNB) is getting focus under Long Term Evolution (LTE) networks. In D2D communication, UEs directly can communicate under the control and assistance of the eNB. This helps in direct transfer of data between two close-by UEs at a higher rate with lower transmission power and delay. D2D can also be applied for many other applications; one such use-case is using D2D communications for opportunistic offload of poor channel users' data. Under opportunistic offload, whenever a poor channel user gets an idle close-proximity neighbor UE with a good channel profile to the eNB, it can offload its data to the neighbor UE using D2D communication and then the neighbor UE can relay the data to the eNB using regular cellular communication. Though this is a two hop communication, it provides higher level of assurance on the data delivery and is spectrally efficient. This kind of offloading can also be used for multi-hop relays in cellular networks, multi-casting [3], peer-to-peer communication, video dissemination, Machine-to-Machine (M2M) communication, and so on. We believe that cellular operators and the mobile users will be greatly benefited by D2D offloading and will show interest to incorporate the changes related to it.

D2D offloading requires network assistance. Therefore, appropriate modifications are required in terms of signaling, scheduling, and synchronization by the eNB. This also requires the knowledge of the location information of the UEs and channel conditions between UE-UE and UE-eNB transmissions. The location information of the UEs can be availed using the control messages and by the possible use of Global Positioning System (GPS) or any other efficient localization techniques. The eNB needs to identify if any neighbor of the poor channel UE is eligible and willing to be the D2D offloader. Once the eNB identifies the D2D offloader, it allocates resources for D2D offloading (UE-UE) and for the cellular relay (UE-eNB) serially so that UE-eNB relaying happens only after the UE-UE offloading.

In this paper, we have introduced a novel D2D offloading scheme and have extended the 3rd Generation Partnership Project (3GPP) proposed method for discovery in Proximity Services (ProSe) [4], [5] using an optimization framework. We have also proposed a 2-phase scheduling scheme to schedule D2D as well as cellular communication. The rest of this paper is organized as follows. In Section II, we provide a brief literature survey on D2D offloading. Section III describes the system model and formulation of the problem. In Section IV, we describe the offloading process, in Section V, we evaluate the performance of our scheme and conclude in Section VI.

II. Related Works

The use of cellular spectrum resources in uplink/downlink for the D2D communication is mentioned in [1], [2]. It is also proposed as a form of relaying [6]. Radio aspects of D2D discovery and communication was submitted by Qualcomm to 3GPP in 2011 [4]. The main focus of 3GPP is to design a LTE-enabled proximity service for the emergency conditions wherein two devices can communicate directly to each other without the intervention of the operator when

the network is non-functioning. Offering D2D services as a commercial service has not gained much attention due to the standardization, billing, regulatory and security related issues. In commercial case, the D2D users have to be guaranteed with better QoS than the traditional technologies such as Bluetooth, Infrared, etc., which are being offered at no cost but with lower speed and compromised security. Data offloading has been considered as one of the key solutions to handle the traffic on the networks by 3GPP.

In [7], the basic concepts of offloading methods in Internet Protocol (IP) networks are discussed. Offloading the cellular traffic to the WiFi networks are studied in [8], [9]. In a similar way, studies have also been carried out in offloading the traffic to small cells or femto cells [10]. The authors in [11] have explored offloading the cellular traffic onto the WiFi Direct links and have analyzed their performance with respect to the LTE networks. Assisted offloading has been presented in [12] where the authors have modeled the dynamic network and demonstrated the offloading process by assuming cellular users in licensed spectrum and the D2D users in the unlicensed spectrum. However, these data offloading schemes are different from D2D offloading as they follow a different network architecture; availability and reliability can not be guaranteed.

In this paper, we have proposed a novel optimal D2D offloading scheduling scheme for users with unfavorable channel conditions to eNB in LTE-based cellular networks.

III. System Model and Problem Formulation

We consider a single cell with one eNB and multiple UEs as shown in Fig. 1. The UEs are assumed to be static (full-fledged mobility of the UEs is out of scope of this paper) so that there will be minimum fluctuations in the channel conditions. The network is assumed to have technologies in place to accommodate the D2D communication with all the necessary synchronization and control mechanisms. We further assume that the following two types of communications are possible: (i) Cellular communication where the UE directly transmits to the eNB and (ii) D2D offloading where UE relays data to the eNB via another close-by UE. Based on the wireless channel condition between the UEs and the eNB, we divide the UEs into two sets: $Type-1$ users - who have a good channel to the eNB and $Type-2$ users - who have a poor channel to the eNB. Note that, while the $Type-1$ users communicate using cellular mode, $Type-2$ users use D2D offloading communication. In a typical scenario as shown in Fig. 1, UE_3 has a poor channel to the eNB, can offload its data to the close-by user UE_4 to be ultimately relayed to the eNB. Once eNB receives the request of the data offload for UE_3, it initiates the D2D offload process along with necessary scheduling and controlling methods. We further assume that the users transmit at fixed rates between the UE to eNB and UE to UE using fixed modulation scheme. However, the same model can be extended to the case of variable data rate and modulation schemes. The transmission power of the UEs can be controlled by the eNB, such that the received Signal to Noise Ratio (SNR) is above a specified threshold (SNR_{th}).

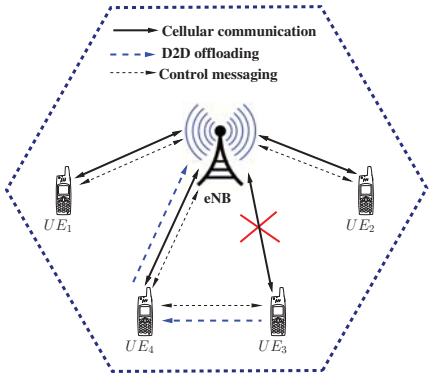

Fig. 1. Single Cell D2D Offloading

A. Frame Structure

We consider standard LTE Time Division Duplex (TDD) frame structure - periodicity: 5 ms, frame length: 10 ms and each frame consists of 10 sub-frames (1 ms each). The sub-frames can either be uplink (U), downlink (D) or special (S). As shown in the Fig. 2, six sub-frames are used for uplink scheduling. We assume that the system bandwidth is 1.4 MHz and consists of six Resource Blocks (RBs); bandwidth of each RB is 180 kHz. Each RB consists of 12 sub carriers. For D2D communications uplink frames are only preferred.

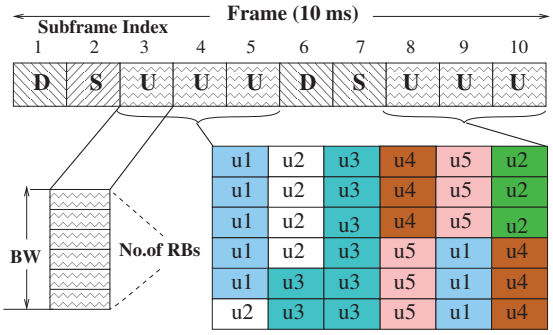

Fig. 2. LTE Uplink TDD Frame Structure

We also assume that the UEs have different amount of uplink data to transmit to the eNB. With fixed modulation scheme and fixed data rate in place, the eNB can compute the number of RBs required by each UE before hand and can schedule the number of RBs in a frame by frame basis. Note that, the performance of the network depends upon the selection of the mode of communication, i.e., using direct cellular or D2D offloading and the selection of the offloader in the possible case when multiple neighbors can act as an offloader for a particular UE. With multiple D2D offloaders available, the eNB has to choose the offloader which ensures optimal throughput as discussed below.

B. Optimal Mode and Offloader Selection

Let m be the number of D2D offloaders available for UE_i. This can be feasible in a real scenario by scanning for D2D

offloaders within a small D2D radius of r_d. Now, UE_i has one direct (cellular) and m offloading paths to choose from. Let $x_{ij}, \forall j \in (1, ..., m, e)$ be a Boolean variable which indicates whether the communication between node i and j is active or not (symbol e indicates eNB). For example, $x_{ie} = 0$ indicates that there is no direct path from node i to eNB and $x_{ij} = 0$ indicates that node j can not be an offloader for UE_i because of unavailability, mobility, etc., of the offloader. Let p_{ij} be the probability of an unsuccessful transmission of an RB between node i and j. Expected number of Hybrid Automatic Repeat reQuest (HARQ) retransmissions required per RB between node i and j can be given as $r_{ij} = \frac{1}{p_{ij}}$. Let k_{ij} be the number of RBs required to transmit the desired data from node i to j (computed by eNB as assumed earlier) and c_{ij} is the cost associated for each RB transmission. Then, the total cost associated with the transmission between node i and j is:

$$C_{ij} = \ k_{ij} \times \ r_{ij} \times \ c_{ij}. \tag{1}$$

In addition to the above, UE_j also needs to relay the data received from UE_i to eNB. The cost associated with this relay can also be calculated as in Eqn. (1). Let the cost associated with this relay be C_{je} and C_{ie} be the cost associated with the direct transmission between UE_i and eNB. Using the above costs for transmission, eNB solves the following optimization problem such that the communication mode (direct or via offloader) and the optimal D2D offloader can be selected.

$$\begin{aligned}
&\min\ (C_{ie} \times x_{ie} + \sum_{j=1}^{m} (C_{ij} + C_{je}) \times x_{ij}), \qquad \text{s.t.} \\
&(i)\ SNR_{ij} \geq SNR_{th} :\ \ \forall j \in (1, .., m), \\
&(ii)\ SNR_{ie}, SNR_{je} \geq SNR_{th} :\ \ \forall j \in (1, .., m), \\
&(iii)\ x_{ie}, x_{ij} = 0/1 :\ \ \forall j, \\
&(iv)\ x_{ie} + \sum_{j=1}^{m} x_{ij} \leq 1 :\ \ \forall j.
\end{aligned} \tag{2}$$

Constraints (i), (ii) of Eqn. (2) ensure the SNR profiles for communications. Constraint (iii) defines the Boolean variables for the possibility of a path, and constraint (iv) ensures that out of $(m+1)$ available paths, eNB selects only one. We now discuss the D2D offloading process as a solution to the above mathematical formulation.

IV. Offloading Process and Channel Model

We now explain the five-phase offloading process and power control mechanism that needs to be used for the successful data transmission.

A. Offloading Phases

1) Offloading Initiation Phase: Offloading initiation can either be made by the eNB or by the UE. In the eNB initiated type, eNB offers D2D offloading option depending on the UE's location and availability of D2D offloader. In UE initiated type, if the UE with a poor channel can send the control messages (usually transmitted at a higher power) to the eNB, then the eNB can make the necessary arrangements for D2D offloading. In case the UE is in a completely isolated environment, it can relay the offloading initiation request through a known close-by UE who has a good channel to the eNB.

2) Offloader Discovery Phase: In this phase, optimal offloader is discovered as a solution to Eqn. (2) which can be either network assisted or ad-hoc type. In network assisted type, the channel condition between the UE (UE_3 in Fig. 1) and the eNB is such that only offloading request can be communicated through control channels. The eNB which is capable of extracting information of the UE, its neighbors' locations (UE_3 and its neighbors in example), their load and channel conditions, etc., can select a suitable offloader (UE_4 for UE_3). In the ad-hoc discovery type, the $Type-2$ UE itself finds a suitable offloader among its nearest neighbors with a request/reply method and then conveys this to the eNB. In this case, the part of the optimization problem Eqn. (2) is solved by the UE itself. Although, network assisted discovery is more power consuming, it is reliable and backward compatible.

3) Handshaking Phase: In this phase, control messages are exchanged between the $Type - 2$ UE and eNB and between eNB and D2D offloader. After the finalization of the D2D offloader, eNB collects the required information like availability, channel condition, etc., and exchanges the synchronization information with the offloader UE. The handshaking mechanism is diagrammatically shown in Fig. 3.

4) Scheduling Phase: For data transmission, UE sends Scheduling Request (SR) signaling in the Physical Uplink Control Channel (PUCCH) to the eNB. The eNB then assigns RBs to the requester and the offloader. We propose a two-phase scheduling scheme; in the first phase, D2D transmission is scheduled and in the second phase the transmission of D2D offloader to the eNB is scheduled. These two phases can take place in same or in different LTE time frames without any time overlapping of a Phase-1 RB with any Phase-2 RB. The scheduling can be overlapping or non-overlapping type [2]; we have assumed non-overlapping type of scheduling in this paper, i.e., both cellular and D2D communication will use non-overlapped RBs for their communication.

5) Communication Phase: This is the actual data communication phase between D2D transmitter and offloader followed by between offloader and eNB. The control flow diagram is illustrated in Fig. 3 and the corresponding algorithm for offloading process is described in Algorithm 1. Note that, it is not necessary for all five phases to be executed serially.

B. Channel Model

The channels between the UE-eNB and UE-UE are assumed to be remain constant for at least one LTE frame duration. We assume that the channel variations follow a combination of log-normal shadowing and multi-path Rayleigh fading in addition to the variations due to distance and other factors. Let Pt_{max} be the maximum transmit power in dBm, d_{ij} be the distance between the UE_i and node j (j: eNB/UE). Received power Pr_{ij} can be expressed in logarithmic form as:

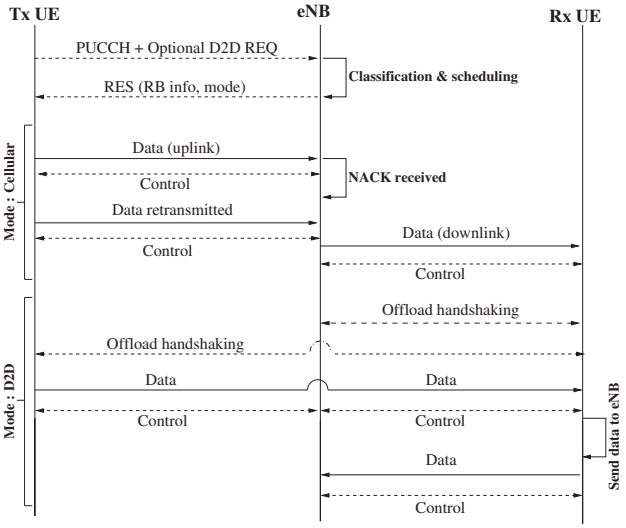

Fig. 3. Control Flow Diagram

Algorithm 1 : D2D Offloading Algorithm

1: eNB receives SR signal from UEs: {location, No. of RBs required, channel condition}
{Offloading Initiation Phase}
2: eNB computes SNR_{ie}
{Offloader Discovery Phase}
3: **if** $SNR_{ie} > SNR_{th}$ **then**
4: UE_i is a $Type-1$ user; Go to Line 8
5: **else**
6: Find the D2D offloader as a solution to Eqn. (2).
7: **end if**
{Handshaking and Scheduling phase}
8: Phase-I: Schedule the $Type-1$ cellular and D2D offload (UE-UE) transmissions
9: Indicate the RBs, transmission power and modulation scheme to be used by the UE
10: Phase-II: Schedule the D2D relay (UE-eNB) transmissions
11: Indicate the RBs, transmission power and modulation scheme to be used by the UE
{Communication Phase}
12: Starting of actual communication

$$\begin{aligned} Pr_{ij} &= Pt_{max} - P_{ij}^{loss}, \\ P_{ij}^{loss} &= \gamma log_{10}(d_{ij} + f) + L_{sh} + L_{rl} + L_a, \end{aligned} \tag{3}$$

where, f is the frequency of operation, and γ is the path loss exponent, L_{sh} and L_{rl} be the losses due to the Log normal shadowing and Rayleigh fading respectively and L_a is the location specific loss where the user is placed. Location specific loss should be factored in the path loss computation as the $Type-2$ user can be placed inside a lift or in the basement or some other place similar to this. We assume that the eNB can compute the path loss parameters and the total loss value P_{ij}^{loss}. If N_o is the Additive White Gaussian Noise power, then instantaneous $SNR_{ij} = \frac{Pr_{ij}}{N_o}$. For successful data transmission, $SNR_{ij} \geq SNR_{th}$.

1) Power Control for D2D Communication: Optimal transmission power required for D2D communication should be computed by the eNB as follows and should be informed to the UE in the handshaking phase. Since, it is difficult to have continuous values for $Pt_{c_{ij}}$, we have defined discrete levels for $Pt_{c_{ij}}$: [-5, 5, 15] mw and select the appropriate level based on the distance and SNR_{th} condition.

$$Pt_{c_{ij}} \geq \quad SNR_{th} \times N_o + P_{ij}^{loss}. \tag{4}$$

V. Experimental Evaluation

We have considered a single eNB with 100 UEs placed at random positions within a radius of 150 m. On an average maximum 50 users are assumed to be ready for transmission and termed as active transmitter UEs. The remaining users are considered to be idle and can be used as potential D2D offloaders. In order to realize a practical scenario, we have assumed on an average 40% of the active transmitter UEs as $Type-2$ users. The received power of each UE is calculated using Eqn. (3). We have considered two different scenarios: (a) cellular only communication and (b) cellular with D2D offloading. We have also implemented a simple Round Robin uplink scheduling scheme. The offloaders are assumed to have sufficient battery power. The other simulation parameters used are mentioned in Table I.

TABLE I
Simulation Parameters

Parameter	Values
Tx Power and Range	23 dBm, 150 m
Path loss component (γ)	3
Shadowing standard deviation(σ)	6 dB
Frequency of operation (f)	2300 MHz
Modulation	16 QAM
Maximum D2D distance	20 m
SNR threshold (SNR_{th})	10 dB

A. Simulation Results

Sufficient simulation runs with different UE populations have been conducted with 100 different seed values to have results with a confidence interval of $\pm 2\%$ of the mean value with a confidence level of 95%. Fig. 4 explains the average RBs utilization with varying number of active transmitters. From this figure, we observe that the average number of RBs consumed in case of D2D mode are much lower as compared to the conventional cellular mode; 40% of RBs can be saved on an average results in significant improvement in spectral efficiency. This is due to the fact that multiple retransmissions have occurred in regular cellular communications as the channel between the UE and the eNB is bad. For the very same reason the average per user delay is also less for the D2D offload case (c.f. Fig.5); improves QoS of the users.

From Fig. 6, we observe that the total energy consumption is higher in case of regular cellular mode as compared to the D2D mode. This is due to the lower transmit power usage of the UEs and higher success rate of the D2D offloading as compared to the regular ones. Energy consumption is computed by considering the maximum transmission power of UE and the transmission time interval (TTI) of an RB. Energy performance also includes the overhead energy consumption in

the D2D offloader discovery, handshaking, and control signal transmissions. System performance shown here in terms of RB utilization, delay and energy consumption only considers the Medium Access Control (MAC) level performance; further improvement is possible when higher layer parameters are taken into consideration.

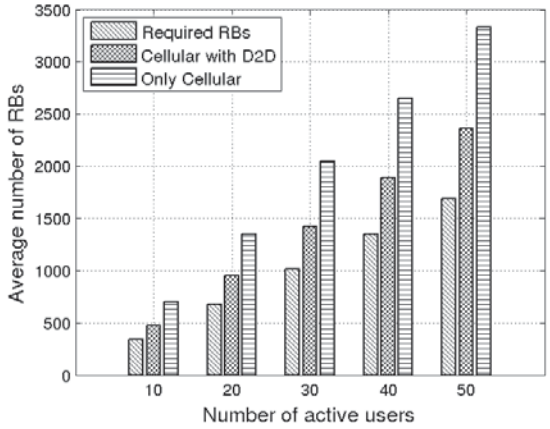

Fig. 4. Average RB utilization vs. Number of active users

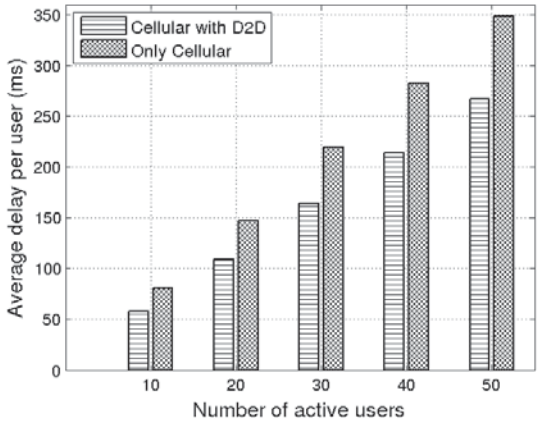

Fig. 5. Average delay per user vs. Number of active users

VI. Conclusion

In this paper, we have proposed a D2D offloading mechanism to benefit the users who are experiencing a poor channel to the eNB. We have discussed an optimization framework which selects an appropriate communication mode for uplink and also the optimal offloader in case of D2D offloading. We have also proposed a 2-phase scheduling algorithm for D2D offloading. The proposed scheme is evaluated through extensive Matlab simulations. Our simulation results exhibit that with D2D offloading technique embedded in cellular network, network performance can be improved significantly.

Implementing D2D offloading in LTE cellular networks requires appropriate signaling techniques. Moreover, the eNB should be able to compute the expected received signal strength at any UE location. Even at device level the UEs should be capable of changing their transmission powers as well as collecting their location informations. These modifications should be incorporated in the future LTE releases and should be standardized under 3GPP such that D2D offloading can be made possible seamlessly. The standardization effort should also encourage operators and vendors to adopt D2D implementation in future.

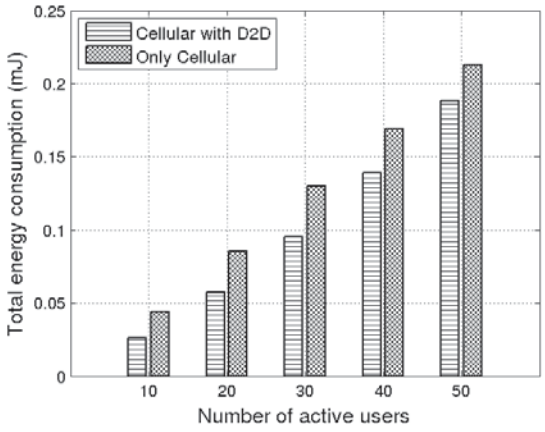

Fig. 6. Total energy consumption vs. Number of active users

***Abstract*—Human detection is one of the important and fundamental steps in advanced applications like human activity analysis, gait recognition, human centric surveillance, intelligent video surveillance system, etc. Inaccurate detection of human in all these application leads to false alarms. The proposed method consists of four steps namely; moving object detection, blob detection, feature extraction and classification. Moving object detection is done by performing background subtraction technique which uses fuzzy logic approach. After performing background subtraction blobs are identified. Then blob feature extraction is done by using simple and efficient features like height, width, number of black and white pixels. These features are trained using Support Vector Machine (SVM). The Support Vector Machine is capable to learn all features of blob, and it is used for human or non-human classification. The system is tested on INRIA and PETS 2000 standard data-set.**

Index Terms*—Object Detection; Blob Detection; Feature Extraction; SVM classification

I. Introduction

Over the recent years, detecting human beings accurately from video scene of a surveillance system is attracting field due to its wide range of applications in event detection, human gait characterization, person identification, gender classification, etc. Video surveillance system having two sub-problems, one is moving objects detection and another one is determining whether moving object is human or not.

For moving object detection there are three basic approaches used: Background subtraction, Temporal differencing, and Optical flow. Background subtraction is one of the most popular approach for moving object detection. This method consists in finding the difference of current frames with respect to a background frame in order to detect pixels whose difference is greater than threshold value [1]. A popular mixture of gaussian technique for background subtraction approach consists in modeling each pixel with a Gaussian distribution [2]. The adaptive version of this algorithm works well when the background is dynamic. Temporal differencing approach for moving object detection simply takes difference between previous and next frame, if this difference is greater than threshold value, then moving object is detected [3]. Optical flow is another approach for moving object detection. This approach calculate motion of field, and flow distribution characteristics of image using different methods to estimate optical flow. Optical flow approach is sensitive against noise, and it is highly complex [4]. Lijun, Xiao proposed an approach for moving object segmentation using fuzzy logic algorithm [5]. Basically the fuzzy logic algorithm used for thresholding as well as background updation part. Object segmentation is done using background subtraction which uses fuzzy approach, that is responsible for improving segmentation accuracy and reducing under-segmentation problem. In [6] Gambhir, D and Manchando presented an algorithm that automatically segment moving object in video by creating multiplicative mask, and it contains less number of noisy, false pixels. The segmented object tracked via color features, and then position of moving object predicted using kalman filter. In [7] Kalyan Kumar, and Pankaj Kumar has presented an approach for moving object detection using simple thresholding technique for background subtraction. This scheme depends on two basic algorithms; the first algorithm models background depends on first few frames, and second algorithm extract moving object based on simple thresholding. The strength of this simple thresholding technique is lies in its simplicity, and intensity range for each pixel location define in background.

There are different methods to detect human beings from video. Template based human detection method is based on predefined template dataset defined by users. In [8] Zhujie and Yu has presented face recognition method based on eigen face technique. This face recognition method works in two part. The first part is responsible for constructing eigen faces of training images, and second part include test images that is recognized by computing the euclidean distance. In [9] Ali, Syed Sohaib and Zafar has presented method for human detection and recognition. This approach uses very effective features such as area, perimeter, centroid, principal axis of inertia for classification part. In [10] Osuna, Edgar, and Federico Girosi has presented an application for face detection using support vector machine, that is responsible for determining appropriate class, either human or non-human. Kong, Yinghui, and Lei wang [11] proposed a method for moving object classification based on feature combination and Support Vector Machine. The method for moving object classification includes various steps such as object detection, post processing, feature extraction and SVM classification. Mahapatra, Tusar Kanti Mishra [12] proposed scale and view invariant approach for human detection based on template dataset. Scale and view invariant contour features like distance, angle, and cord to arc ratio are effective for template based human detection from video. The proposed human detection approach is simple and very efficient one, because we directly worked on color video, so there will be less chances of data loss. The fuzzy algorithm for background subtraction proves it's importance compare to simple background subtraction technique, and accurately detect moving object. At last SVM classifier is classifying object class, thus the combination of fuzzy approach for background subtraction and Support Vector Machine for classification proves the effectiveness of proposed method. The human detection method requires following four steps; (a) Moving Object Detection, (b) Blob Detection, (c) Feature Extraction, (d) SVM Classification. Rest of the paper is presented as follows. Section II is the discussion about system architecture and its implementation details. Section III introduces comparative analysis and discussion. Section IV is all about

experimental evaluation part. Section V is all about conclusion and future scope of the work. Fig. 1 shows flow for proposed human detection system.

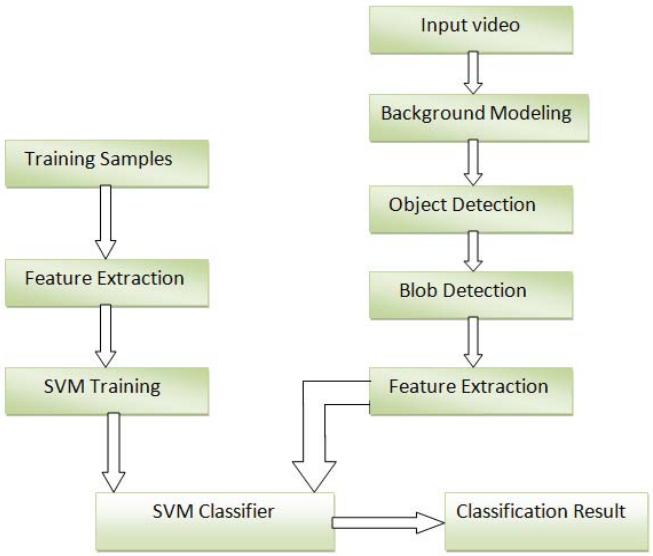

Fig. 1. Human Detection System

II. System Architecture

For human detection, the first essential step is to detect moving object from video, and then classifies it to human or non human.

A. Frame Extraction

The frame extraction module takes video as input and produces number of frames based on time delay between frames. The number of maximum frames depends on length of video and time delay between frames. Mathematically, this is shown in eq (1).

$$X_n: n>1 \ \& \ n = \text{Video length} / T_d, \ \& \ T_d > 1 \qquad (1)$$

Where,

- X_n is the n^{th} frame.
- n is the number of frames required.
- T_d represents time delay between frames.

TABLE I
Frame Extraction

Video Set	Size(MB)	Length (sec)	fps	Time delay(msec)	Number of frames
1	6.23	58	19.40	50	1161
2	6.23	58	25.0344	40	1452
3	6.23	58	33.3793	30	1936
4	6.23	58	1	1000	58
5	6.23	58	2	500	116

Table I shows number of extracted frames that mainly depends on video length and delay factor (T_d).

B. Background subtraction

Background subtraction is the process of separating out foreground objects from maintained background model. The proposed background subtraction method uses fuzzy logic approach for calculating background frames. A foreground object is an entity that is separated based on minimum and maximum frame, these two frames are calculated using fuzzy approach. For background model creation, consider first N numbers of frames are background frames, where all these background frames doesn't contain foreground objects. Apply fuzzy logic on these background frames. Let $\{F_1, F_2, ..., F_N\}$ be the fuzzified background frames, which are used for background modeling part. After getting fuzzified background frames, calculate minimum and maximum background modeling frames. When new frame comes with foreground object each pixel of frame is applied to fuzzy inference system, if pixel value is in between minimum and maximum then consider background pixel, otherwise foreground pixel. Mathematically foreground or background separation is shown below in eq (2).

$$a(i, j) - \alpha < i < b(i, j) + \alpha \qquad (2)$$

where, α is very useful parameter in variety of illumination conditions, and it's value is constant, a (i, j) is the minimum frame, while b (i, j) is maximum frame, and i is the fuzzified pixel value of current frame. The value of minimum frame a (i, j) and maximum frame b (i, j) is calculated from first N fuzzified background frames. The proposed fuzzy background subtraction approach directly works on color video, so that is the main reason, this background subtraction approach is efficient one. Using this proposed background subtraction method, there is no need for post processing of frames. Each pixel having three different values (i.e. for red, green, and blue) are given to fuzzy inference system for calculating fuzzified pixel value as shown in Fig. 2. A fuzzy inference system consists of four main parts: fuzzification, rule base, inference engine, and defuzzification.

C. Fuzzy Algorithm for Background subtraction

The basic steps required for fuzzy logic algorithm are shown in below:

1) Define the linguistic terms and variable, that comes under initialization part.
2) Then construct the membership functions, that comes under initialization part.
3) Then construct the fuzzy rules, that comes under initialization part.
4) First step is convert the crisp input data to fuzzy values using defined membership functions, that is the part of fuzzification.
5) Second step is to evaluate the rules in the rule base.
6) Third step is to combine the results of each rule, that is the part of inference engine.
7) Last step is convert the output data to non-fuzzy values, that is the part of defuzzification.

Fig. 3 shows fuzzy rules, and the abbreviation for these rules are L-Low, M-Medium, H-High, VL-Very Low, VH-Very High. There are various types of membership function such as Triangular, Trapezoidal, S, Gaussian etc. [13]. Fig. 4 shows Triangular membership function for red color. This membership function having three linguistic term Low, Medium, and High. After fuzzifying inputs, fuzzy rules in the form of (if.... then) are applied for calculating final crisp value. The proposed fuzzy background subtraction method is compared with simple thresholding technique [7]. Fig. 5 shows the result of simple background subtraction technique using thresholding method, this approach

does not give proper output as shown in Fig. 5, while Fig. 6 shows proposed fuzzy logic based background subtraction approach.

D. Blob Detection

After completion of background subtraction method, object is detected. Once moving object gets detected, then capture the blob of respective moving object as shown in Fig. 7. Blob is defined as a collection of bunch of pixels within region. Whereas blob

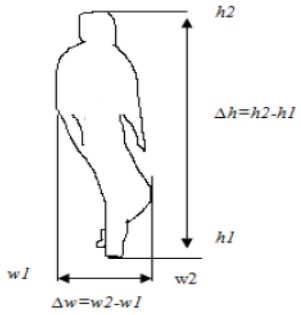

Fig. 7. Identified Blob

is analysed based on the identification of connected pixel regions from the image. The blob detection algorithm distinguishes pixels by their value and mark them in two categories: white blob (foreground) or black blob (background).

E. Feature Extraction

Feature extraction holds an important stepping stone to pattern recognition and machine learning problems. To recognize and classify an object in an image, first extract useful features out of the image. Feature extraction is necessary step for extracting image attribute, to identify or interpret meaningful object from image. Four important features like height, width, number of black and white pixels are extracted from blobs of human and car. These four features are converted into two features i.e. aspect ratio of height to width, and aspect ratio of number of black to number of white pixels.

1) Width: This feature is calculated having difference of Leftmost pixel and Rightmost pixel. Mathematically, this is shown in eq (3).

$$\Delta w = w2 - w1 \quad (3)$$

2) Height: This feature is calculated having difference of Topmost pixel and Bottommost pixel. Mathematically, this is shown in eq (4).

$$\Delta h = h2 - h1 \quad (4)$$

3) Aspect Ratio (W/H): It is the ratio of width to height. Mathematically, this is shown in eq (5).

$$\Delta w/\Delta h \quad (5)$$

4) Aspect Ratio (B/W): It is the ratio of number of black pixel to number of white pixel.

F. SVM Classification

In recent years, SVM classifier is very effective for solving classification and regression problems [14]. The features of human and non-human blobs are given to support vector machine training part. Support vector machine is capable to learn all those features. In training part these features are divided into two classes using SVM linear kernel function i.e positive and negative class.

In proposed method of human detection, SVM is based on a linear classifier in a high dimensional feature space, which has allowed the development of somewhat fast training techniques, even with a large number of input variables and training datasets. In proposed method support vector machine classifies the objects either as a human or non-human.

III. Comparative Study and Discussion

In the recent, there were several systems have been developed for human detection from videos. That are almost similar approaches, the proposed algorithm performed better in terms of detection accuracy rate. Lipton et.al. [14] used a simple multi-feature classification approach with features like dispersedness, area and detection rate of 82.8%. Kong, Lei Wang [15] had obtained 80% detection rate of human and car. Table II shows comparative analysis with existing system. See, J., Lee [16] had obtained 93.75 % detection rate of human motion. On other hand, we introduced a novel and efficient approach for moving object detection using fuzzy logic algorithm, and support vector machine classifier gives 95.29 % classification rate of human and non human.

TABLE II
Comparison of Classification Accuracy With Existing System

Sr.No	Algorithm	Detection Accuracy
1	Moving Target Classification and Tracking From Real Time Video [14]	82.80 %
2	Moving Target Classification in Video Sequences based on Feature combination and SVM [15]	80%
3	Human Motion Detection Using Fuzzy Rule base Classification of Moving Blob Regions [16]	93.75%
4	Proposed Method	95.29 %

IV. Experimental Evaluation

The proposed system uses standard dataset INRIA and PETS 2000. The dataset comprises .avi or .mp4 videos having resolution (320×240), duration 1-58 seconds, and with 2-24 frames per second. The SVM classifier was trained using 800 blobs. Among these, 500 were positive samples indicating human blobs and rest 300 were negative samples indicating car blobs for training. Table III shows classification rate of moving object. The dataset has used in this experiment is tested over 9 different videos that contain 2 objects (i.e human and car). Among these first six videos i.e (Video 1 to Video 6) contain only human and remaining three videos contain only car object class. For Video 1, first 40 frames have considered, and found total number of 48 blobs, out of that 44 blobs are correctly classified as a human. For Video 2, first 52 frames have considered, and found total number of 77 blobs, out of that 72 blobs are correctly classified as a human. For Video 3, first 42 frames have considered, and found total number of 58 blobs, out of that 55 blobs are correctly classified as a human. For Video 4, first 40 frames have considered, and found total number of 62 blobs, out of that 59 blobs are classified as a human. For Video 5, first 45 frames have considered, and found total number of 64 blobs, out of that 60 blobs are correctly classified as a human. For Video 6, first 55 frames have considered, and found total number of 80 blobs, out of that 74 blobs are correctly classified as a human. For Video 7, first 30 frames have considered, and found total number of 38 blobs, out of that all 38 blobs are correctly classified as a car. For Video 8, first 50 frames have considered, and found total number of 80 blobs, out of that 77 blobs are correctly classified as a car. For Video 9, first 40 frames have considered, and found total number of 60 blobs, out of that all 60 blobs are correctly classified as a car.

TABLE III
Classification Rate of Different Moving Objects

Sr.No	Test Video	Total number of blobs	Correctly classified blobs	Accuracy
1	Video 1	48	44	91.66 %
2	Video 2	77	72	93.50 %
3	Video 3	58	55	94.82 %
4	Video 4	62	59	95.16 %
5	Video 5	64	60	93.75 %
6	Video 6	80	74	92.50 %
7	Video 7	38	38	100 %
8	Video 8	80	77	96.25 %
9	Video 9	60	60	100 %

A. Sample output

In output part video contains human. The red line depicts detected human blob, that gives result human. Fig. 8 gives classification result of human.

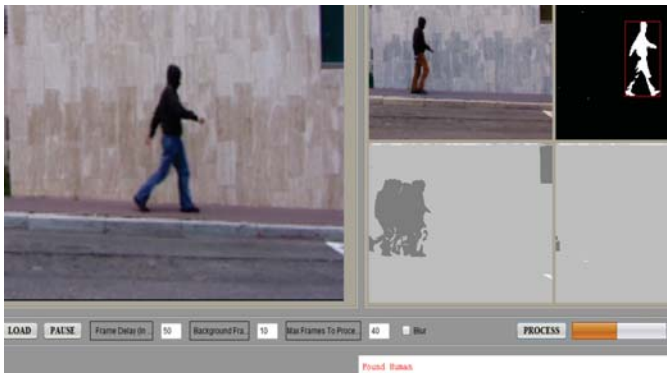

Fig. 8. Classification result of human video

Fig. 9 gives classification result of car. The red line depicts detected car blob below, that gives result car.

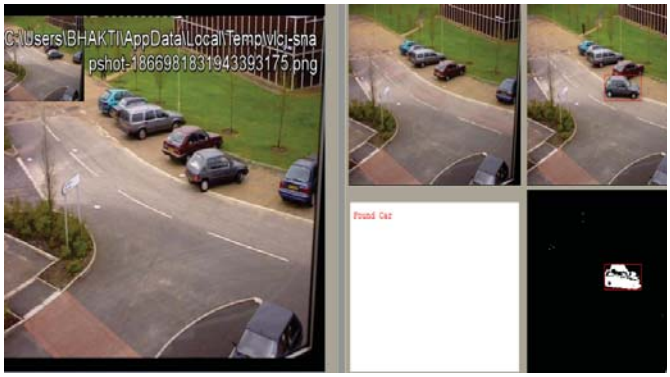

Fig. 9. Classification result of car video

V. Conclusion and Future Work

A method for human detection in video sequences is based on mainly two aspects: Fuzzy approach for moving object detection, and Support Vector Machine is used for moving object classification. In this paper, a novel and efficient approach for background subtraction using fuzzy logic has presented. Features are extracted after detecting the blobs. These features are given as input to Support Vector Machine (SVM) to classify the object, whether it is human or non-human. SVM is used as a binary classifier, means it is used for human and non-human classification. The proposed human detection method doesn't work more accurately on manual dataset (Not-Standard dataset). The proposed method will not work if there will be occlusion, and moving camera dataset i.e (works only on Non-Moving camera dataset or steady dataset). The proposed human detection system have many aspects that can be improved in future. This system will further used for object tracking and recognition purposes. The background subtraction approach for moving object detection can be extend to various image conditions (lighting or long-term scene changes), and moving camera dataset. The detected moving objects had classified for only two classes, in future this could be extended to multiple classes.

***Abstract*—This paper proposes a hierarchical mesh topology based multicast routing reducing energy consumption for transmission and reception. The protocol enables low complexity multicast route establishment and multicast routing and is aimed to be used in IEEE 802.15.4 based networks for various applications such as intelligent transportation systems, smart city or smart utility networks, etc. The proposal allows an implementer to fine tune the routing based on a link metric threshold to find the best tradeoff between robustness and the amount of traffic. Multicast routing can be achieved in non-promiscuous or promiscuous mode. The simulation results show that the proposed protocol significantly reduces the number of devices involved in the multicast routing to a multicast group, thus reducing the overall average energy consumption of the network while achieving high transmission delivery.**

I. Introduction

Recent technological trends have seen the demand for large scale networks as we seek to create a smart or intelligent version of everything. An increasing number of municipalities, companies, utilities, etc. seek to implement applications such as intelligent transportation systems (ITS), smart utility networks (SUN), smart city, factory and building automation networks, to name a few. These networks will comprise a large number of devices ranging from tens to thousands. Due to the limited coverage area of a device, data transmission may require multiple hops between a source and a destination. The devices may be subject to constraints such as limited transmission power or limited power supply. The IEEE 802.15.4 standard [5] has become the leading standard to deploy these networks. The standard provides a cluster tree topology rooted at the PAN coordinator, yielding increased coverage area of the network. Data frames can be transmitted up and down the cluster tree, however this does not always lead to optimized paths.

In applications such as ITS, smart city, SUN, an implementer may require communication with a set of nodes at once based on their location (block, street...), their function (lights, gas meter, motion sensor...), or other criteria. Since the information to be sent is the same for these devices, multicast groups are created and multicast routing in needed. The IEEE 802.15.4 standard provides specifications for the physical and MAC layer but does not address multicast group management or multicast routing. Multicast group management (join, leave...) has widely been addressed [10]-[13] and is out of the scope of this paper. Multicast groups may also be statically assigned. The multicast group assignments occur in layers above the MAC layer and therefore multicast addresses are unknown to the MAC layer of IEEE 802.15.4. Although routing has been addressed at the network layer[1][6], as far as multicast routing is concerned, multicast groups are managed but when multicast frames are sent through the IEEE 802.15.4 MAC layer, they are either unicast to each multicast group member or flooded through the network[2][6]. This leads to considerable waste of resources such as energy or bandwidth. Z-Cast is a multicast protocol built upon the IEEE 802.15.4/Zigbee stack[3]. However, Z-Cast is based on the cluster tree topology [4] which may create single point of failures (SPF), consequently causing all the descendants of a failing router not to receive a multicast frame. In [7], we proposed a routing protocol based on a hierarchical mesh focused on data collection and we demonstrate that a hierarchical mesh topology avoids these SPFs and enables robust routing. In this paper, we provide a hierarchical mesh topology based multicast routing that avoids the SPFs of a cluster tree as well as alleviates the resource waste from multiple unicast transmissions or broadcast flooding, thus yielding significant energy saving.

The rest of this paper is organized as follows: Section II describes the initialization of the hierarchical mesh topology. Section III details the upstream routing protocol while section IV describes the multicast route establishment and routing. Simulations results are presented in section V, and section VI concludes the paper.

II. Hierarchical Mesh (HM) Initialization

The network is organized into a hierarchical mesh (HM) rooted at a device called the HM root. The hierarchy is determined by the depth of a device representing the distance in hops to the HM root which has a depth 0. For a device T, the following definitions are used:

- *Neighbor*: a device within the coverage area of T.
- *Parent*: a neighbor one depth less than T.
- *Brother*: a neighbor of the same depth as T.
- *Child*: a neighbor one depth higher than T.
- *Next hop*: a neighbor to which a frame is forwarded on the way to the final destination

Each device holds a NT recording the address of its neighbors, their respective depth, and one metric used to select a next

[0]This work has been conducted as part of the development of the IEEE P802.15.10 recommended practice for routing packets in IEEE 802.15.4 dynamically changing wireless networks

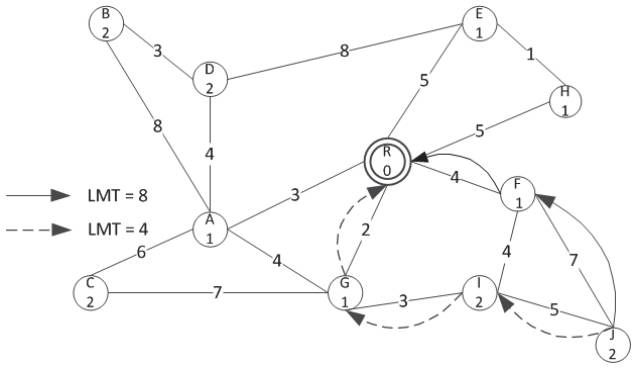

Fig. 1. Example of a HM with US routing from J to R

hop (e.g.: successful transmission ratio, error ratio, latency, etc.) The HM is constructed through the propagation of Hello frames initiated by the HM root. The HM root may fulfill different purposes such as being a center for data collection, controlling and monitoring the devices in the HM..., depending on the needs of the implementer. The Hello frame contains the address of the transmitting device and its depth. A metric field may be present if needed (some metrics such as the received power or SINR might just be measured or calculated and do not need to be exchanged[7]. The optimization of the metric selection is out of the scope of this paper. When a HM root wants to start a HM, it broadcasts a Hello frame with a depth 0. When a device receives a Hello frame for the first time, it retrieves the depth n therein and sets its depth to $n + 1$. It also records the metric information in its NT, the neighbor becomes its parent and the device starts transmitting its own Hello frame. The process continues until every device in the network has a depth. The Hello frames are transmitted after each depth update and then periodically in order to maintain the topology. A neighbor may be deleted from the NT if it has not been heard from for a prolonged period of time. Fig. 1 illustrates an example of HM where the number below each letter represents the depth of the device and the number on each link represents the metric between the devices sharing the link.

III. Upstream (US) routing

When a device wants to transmit a data frame to the HM root, it looks into its NT and finds the parent with the best metric. A link metric threshold (LMT) can be set to allow routing through the siblings while giving priority to parents to minimize the number of hops. If the LMT is set, the metric of the link shared with a parent must satisfy this threshold in order for the parent to be eligible as a next hop. If the LMT is not satisfied, a device finds the brother with the best metric. If the best brother does not satisfy the LMT, the device with the best metric between the best parent and the best brother is selected as a next hop. In order to avoid loops, a device holds a *next/previous-hop list* with the address of the devices to which it has forwarded or from which it has received or overheard a frame with a given sequence number (SN) and source address (SA). When a device forwards a data frame, it shall select a next hop that is not within the list corresponding to the (SN, SA) tuple. The *next/previous-hop list* for a given (SN, SA) tuple is deleted after a determined time. Next hop selection may be limited to parents if the LMT is not set, in this case loop avoidance is not necessary. In Fig. 1, it is assumed that a low metric value indicates a good link. The figure gives an example of US routing from device J to R. The plain arrows indicate the path when the LMT is set to 8 whereas the dashed arrows indicate the path when the LMT is set to 4. A data frame is sent along the US paths with a set of 4 addresses: the source address (SA), the destination address (DA), the transmitting address (TA) and the next hop address (NHA). In US routing, the SA is set to the address of the source of the frame and the DA, to the address of the HM root. The NHA and the TA are modified at each hop.

Transmitting address	Next hop address	Source address	Destination address	Multicast address

Fig. 2. Multicast Address Announcement frame

IV. Multicast Route Establishment and Routing

In applications such as ITS, smart city, SUN, an implementer may want to communicate with a set of nodes at once based on their location (block, street...) or their function (lights, gas meter, motion sensor...), or other criteria. Multicast groups are created and are assigned a multicast address to allow the transmission of the same information to the member devices. In the aforementioned applications, networks are relatively static and multicast group management can also be manual and fixed. Several multicast groups can be created in the same network. Multicast group management is not addressed by the IEEE 802.15.4 standard defining the MAC and physical layers, and occurs at a higher layer. As a result, the assigned multicast addresses are unknown to the MAC layer. If a device knows the MAC address of each multicast member, a multicast frame may be transmitted as a unicast frame to each member. Otherwise, the frames can be broadcast in the network and filtered by higher layers[6]. In large networks, these approaches can become very costly, especially in terms of energy consumption for transmitting and receiving. In this proposal, a set of 16-bit MAC addresses are reserved for multicast groups. The mapping between the actual multicast address, issued during the subscription procedure or manually assigned, and the 16-bit multicast MAC address is out of the scope of this paper. In the targeted applications, devices are often non mobile and 16-bit multicast addresses could be manually assigned to each members to avoid signaling for multicast group management. If a device is a member of a multicast group, it informs the HM root with a Multicast Address Announcement (MAA) frame formatted as illustrated in Fig. 2. The multicast address in the MAA frame is treated as a regular unicast 16-bit MAC address and is recorded in a route entry with the address retrieved from the *Transmitting address* field as the next hop. If another MAA frame is received announcing a multicast address that already has a route entry, the route entry is replaced only if the metric of the link shared with the transmitting device is better than that of the route entry recorded. Thus, no special multicast routing table is needed. The MAA frames are sent through the US paths according to the US routing described in section III. Multicast route establishment can be achieved in two modes: the **non-promiscuous mode** and the **promiscuous mode**.

- In **non-promiscuous mode**, only the devices receiving

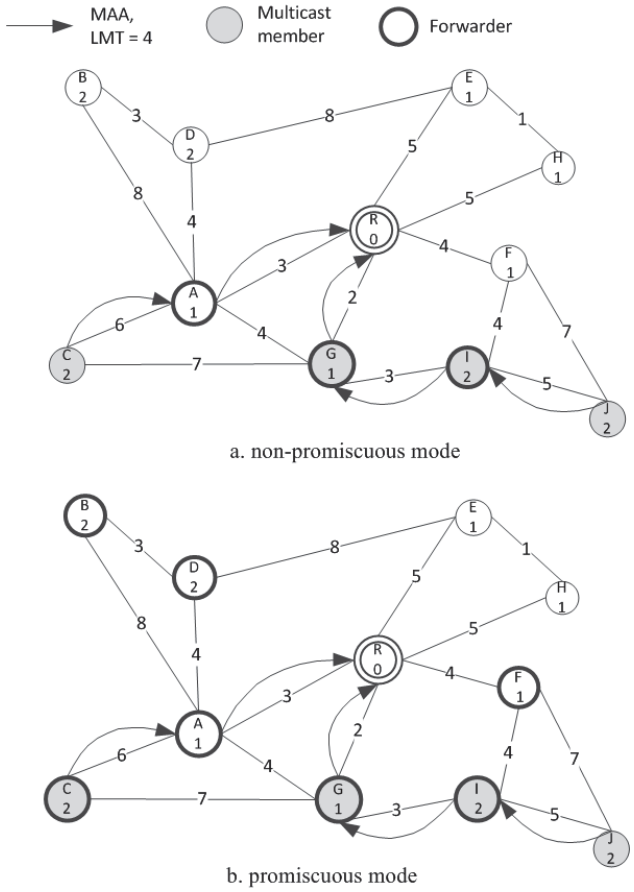

Fig. 3. Multicast route establishment in non-promiscuous and promiscuous mode

the MAA frames as next hops, i.e. with their address in the *Next hop address* field, record a route entry to the multicast address and become forwarders of any frame destined to the multicast group.

- In **promiscuous mode**, all the devices that overhear and can successfully decode the MAA frames, record a route entry to the multicast address and become forwarders, even if they are not one of the next hops on the way to the HM root.

Fig. 3 illustrates an example where the gray nodes are the members of the multicast group. The arrows represent the routes on which a MAA frame is transmitted from each member to the HM root. The nodes with bold lines represent the devices that become forwarders. In Fig. 3.a., in non-promiscuous mode, only devices A, G, I receiving the MAA frames as next hops become forwarders whereas in Fig. 3.b., in promiscuous mode, devices C, B, D and F overhearing the MAA frames also become forwarders.
When the HM root has a data frame to transmit to the multicast group, it sets the SA and the TA to its own address, the DA, to the multicast address, and the NHA, to the broadcast address so that all devices may receive the frame. When a device receives the multicast frame, the frame is forwarded only if the device has at least one route entry to the multicast address. The SA, DA and NHA are unchanged and the TA is set to the forwarder's own address. This reduces the number of transmissions needed compared to multiple unicast transmissions or flooding, especially in large scale networks based on the IEEE 802.15.4 standard, or when multiple multicast groups are present. It reduces the average energy consumption for transmitting and receiving as the number of multicast frame copies is decreased. When transmitting a multicast frame, a device records the SN and the SA of the frame. If the device receives another frame with the same SN and SA, the frame is dropped to avoid duplicate transmissions. The SN and SA records are cleared after a determined period of time.

TABLE I. SIMULATION PARAMETERS

Parameter	Value
Simulation time	24 hours
Frequency band	927MHz
Path-loss model	Two-ray
Data transmission rate	250kbps
Number of nodes	2000
Data frame size	128 bytes
Receiver sensitivity	-89 dBm
Deployment area	5000m × 5000m
Metric	SINR
LMT	5, 10
TX energy consumption (Transmission power)	16 mAh (0dBm), 15 mAh (-1dBm), 14 mAh (-3dBm)
RX energy consumption	18.83 mAh
Idle energy consumption	3.6 mAh

V. SIMULATIONS RESULTS

The proposed protocol is evaluated with extensive simulations run on version 6.1 of the Qualnet network simulator[8] with the parameters listed in Table I. The devices use the Micaz energy model provided by Qualnet. The energy consumption of a device when it is transmitting, receiving and idling is found in Table I. The devices are uniformly deployed in a 5000m×5000m square area. The HM root is placed at the center of the area and transmits a data frame to the multicast group every 5 minutes. The members of the multicast group are found in a square area in the corner of the deployment area. We compare the performance of the proposed HM based multicast routing with that of a broadcast flood, hereafter referred to as BC. The devices use CSMA/CA[9] to access the channel to transmit a frame. Four HM based multicast routing scenarios are considered:

- 5NP: LMT set to 5 in non-promiscuous mode
- 10NP: LMT set to 10 in non-promiscuous mode
- 5P: LMT set to 5 in promiscuous mode
- 10P: LMT set to 10 in promiscuous mode

The metric used for next hop selection is the SINR. The SINR measurement is provided by the Qualnet network simulator. An LMT of 5 or 10 indicates that a parent is eligible as a next hop if the SINR between the transmitting node and its parent is equal to or greater than 5dB or 10dB respectively.

In Fig. 4 and Fig. 5, the performance is evaluated when the side of the multicast group area is varied from 500m to 2500m. The transmission power of each device is set to 0dBm.

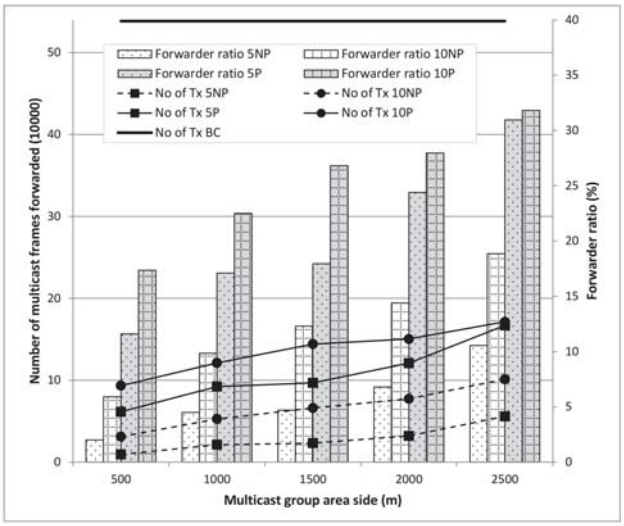

Fig. 4. Number of multicast frame forwarded and Forwarder ratio vs Multicast group area side

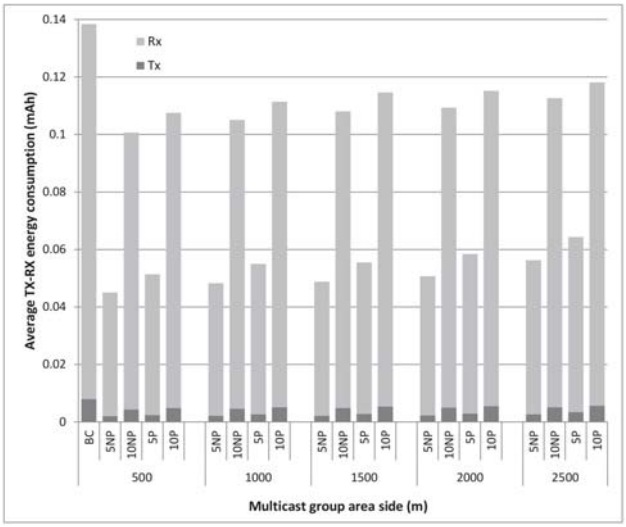

Fig. 5. TX and RX energy consumption and Forwarder ratio vs Multicast group area side

Fig. 4 depicts the number of multicast frames forwarded and the forwarder ratio. The bold line represents the number of transmissions when the multicast frames are broadcast (BC) throughout the HM, i.e. when each device forwards a multicast frame once. The dashed lines represent the number of transmissions when the HM is in non-promiscuous mode. The plain non-bold lines represent the number of transmissions when the HM is in promiscuous mode. Square markers correspond to a LMT set to 5 and circle markers correspond to a LMT set to 10. The results show that the HM based multicast routing greatly reduces the number of multicast transmissions. As the size of the area containing the multicast group widens, the number of multicast frame forwarded increases with the number of multicast members. In non-promiscuous mode, only the devices that received the MAA frame become forwarders. This explains the reduced number of multicast forwarding in non-promiscuous mode compared to that in promiscuous mode. A higher LMT results in longer paths and more devices involved in routing as seen with the plain and dashed paths in Fig. 1. Thus, the number of multicast frame forwarding is higher when the LMT is set to 10 than when the LMT is set to 5. When the side of the multicast group area is set to 2500m, this area covers a quarter of the entire deployment surface and the number of forwarders is almost the same regardless of the LMT in promiscuous mode. Consequently, the number of multicast forwarding is almost the same for both values of the LMT.

The bars represent the forwarder ratio, that is the ratio of the devices involved in the multicast routing. The dotted bars correspond to a LMT set to 5 whereas the checkered bars correspond to a LMT set to 10. The white bars represent the forwarder ratio in non-promiscuous mode, and the gray bars represent that in promiscuous mode. In all cases, less than 35% of the devices are engaged in the multicast routing. This ratio increases as the multicast group deployment area widens. At least 84% of the multicast frames are successfully delivered to the multicast members in the non-promiscuous mode of the HM based multicast routing, and 97% in promiscuous mode. This difference is due to the number of forwarders greatly reduced in non-promiscuous mode. Further, as only the devices receiving the MAA frames become forwarders, this may result in cluster-tree-like topology in some parts of the network creating single points of failures if a device only has one forwarder neighbor. The 5P scenario offers the highest frame delivery reaching more than 99%. The promiscuous mode results in a higher number of forwarders, hence a higher probability a receiving at least one copy of the multicast frame. A higher LMT in promiscuous mode further increases the number of forwarders but also increase the probability of collisions, which is why 10P does not perform better than 5P. The setting of a suitable jitter or backoff mechanism could help increase the reliability of the routing, however this is outside of the scope of this paper.

Fig. 5 represents the average energy consumption by a device for transmitting and receiving. The dark gray accounts for the average energy consumed while transmitting, the light gray accounts for the average energy consumed by a device while receiving. The graph shows that receiving consumes more energy than transmitting in average since a device forwards a multicast frame only once whereas it may receive several copies of the same frame. The first bar labeled BC represents the average energy consumption when all frames are broadcast and shows that flooding consumes more energy than any other scenario. The energy consumption in BC does not change regardless of the multicast members deployment area as all devices must forward each frame once. The energy consumption increases as the multicast members deployment area widens. This is due to more forwarders involved in the routing as seen in Fig. 4. For the same reason, the energy consumption in promiscuous mode is higher than that in non-promiscuous mode; and the increased number of forwarders when the LMT is set to 10 leads to greater energy consumption compared to when the LMT is set to 5.

Fig. 6 show the results when the devices use three different transmission power (0dBm, -1dBm and -3dBm). In all cases, at least 87% of successful frame delivery is achieved in non-

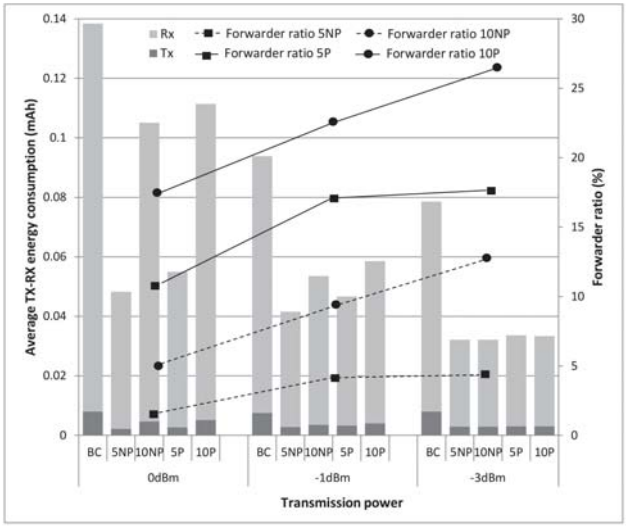

Fig. 6. TX and RX energy consumption vs Transmission power

promiscuous mode and 93% in promiscuous mode. As in Fig.4 and 5, 5P offers the highest reliability with around 99% successful frame delivery with any transmission power. A lower transmission power consumes less energy but also reduces the coverage area of a device. As a result, a MAA frame requires more hops to be transmitted to the HM root which increases the number of potential multicast forwarders as shown by the rising forwarder ratios. On the other hand, a frame is received by less devices and the energy consumption decreases with the transmission power. For the three transmission powers, the average energy consumption with BC significantly outweighs that of HM based routing especially when the transmission power is at its lowest of -3dBm. This graph demonstrates that an implementer can reduce the density of a network and save on deployment costs while maintaining a higher transmission ratio, or keep the same number of devices and reduce the transmission power to save on energy consumption.

The LMT of 5 in promiscuous mode provides the highest reliability in these simulations, however an implementer can fine tune the LMT value based on the network environment, the density or other parameters. The LMT can also be set locally on each device to allow precise MAA routing and further optimize multicast routing.

The energy consumption displayed represent that used in 24 hours. The energy saving becomes more significant as the lifetime of a network lengthens and is particularly desired in battery operated devices.

VI. Conclusion

This paper proposes a hierarchical mesh based multicast routing enabling energy saving for IEEE 802.15.4 based networks such as ITS, smart city, smart utility networks, etc. We address the need in these networks to communicate the same information to a group of devices. These devices are organised in multicast groups. The proposal enables route establishment between the HM root acting as the network controller and the members of these multicast groups. As a result, the number of copies of the same multicast frame transmitted in the network is greatly reduced compared to when the frame is flooded, yielding significant energy saving in transmission and reception. The simulation results show that the proposed protocol decreases the number of devices involved in the multicast routing, also called forwarders. This number depends on the surface of the area where the multicast members are deployed. Adequate organization of the network into several multicast groups would allow to send different information to each group while consuming less energy than when flooding is used. The proposal also maintains a high successful frame delivery percentage while reducing the transmission power to save energy. It can also reduce the number of devices deployed in the network and keeping the same transmission power to save on network deployment costs. The setting of a link metric threshold provides flexibility to an implementer to adapt to the environment globally in the entire network or locally at each device. This solution is promising to applications where a certain area of a city, a certain building of a campus, etc. needs to be controlled or reached at once.

{abhishek, hota}@hyderabad.bits-pilani.ac.in

Abstract — **Central node(s) that collect global view on delay tolerant network performance can simplify management and ensure good quality of service. Such global view can improve DTN routing without increasing the routing complexity on individual nodes. Existing research using central nodes have explored both routing control and routing relay via central node. This paper proposes central node assisted routing where message forwarding and relay continues in pure distributed manner. Global view computed by central node augments the routing decision on individual nodes.**

Additionally this paper evaluates the extra overhead and congestion effects when all application messages are relayed though central node (for policy enforcement, management etc.).

Keywords— Delay Tolerant Networks, Quality of Service, Fairness, Adaptaton, User Generated Content

I. INTRODUCTION

Delay and disruption tolerant networks (DTN) [1] come into play when end-to-end communication using mesh or ad-hoc networks are not feasible. Node mobility is the primary enabler for DTN as it emphasizes on store-carry-forward behavior for the bundles (payload or messages for DTN).

Authors in their prior work, [2], have attempted to deploy DTN based platform for rural communication with focus on applications for intra-community communications. This is a scenario where DTN based terrestrial communication service is being provided on a long term basis for the village community. In such deployments people with low mobility or nodes in the periphery of the network are treated unfairly as they have lower delivery ratios and/or significantly higher delays.

Revenue generation is essential to make DTN rural deployment sustainable. Any revenue model mandates features like - accounting, billing, security and quality of service. When offering a commercial service, it is also important to conform to local government's rules and policies, especially with respect to the ability to do security scanning, spam control etc. In this context, challenges in pure distributed DTNs are a) lack of metering and accounting of resource usage to get a consolidated view, b) tracking and enforcement of quality of service for individual nodes, c) enforcement of policies to comply with local laws, and d) ability to do security scans (like IDS/IPS in commercial TCP/IP based networks).

To mitigate the challenges of pure distributed DTN, the authors, in prior work have explored deploying a central device to simplify user management, billing, policy enforcement etc. The owner / operator of the central device can bill the end users by demonstrating the value that the system provides. Central device, referred to as CoHub (centrally optimizing hub) in this paper, creates a global view of the community DTN nodes. Such global view CoHub can drive the routing protocols on individual nodes to target specific quality of service for end nodes.

One of the applications for this rural platform is sharing highlights from farm monitoring videos. Rather than sending complete video, only masked highlights are sent (e.g. video snippet at goo.gl/hc9MuY or goo.gl/s5XA8l). Since video generates large content (megabytes) on periodic basis (30 seconds to few minutes), hence it is important to know the DTN quality of service, so that the highlight creation and compression can be adapted to the network conditions. Information shared by CoHub can drive such decisions.

This work proposes a new routing extension "Quality of Service Enforcing Centrally Optimized Routing", referred to as QoseCo in rest of the paper. In the present work, the authors use Spray-and-Wait [3] as the base protocol, on top of which QoseCo extension is demonstrated. Performance of QoseCo + Spray-and-Wait is compared with vanilla Spray-and-Wait (SNW). Message routing is done by all nodes based on information shared by the CoHub. In absence of CoHub, QoseCo will degrade to vanilla SNW. Other protocols like PRoPHET can also be adapted with QoseCo.

An extension of QoseCo is explored where all application messages are forced to be relayed via the CoHub. This is referred to as QoseCo with Central-Relay [QoseCo-CR]. Though relaying via central nodes is expected to cause congestion and make CoHub the single point of failure, it can be used for security scanning and policy enforcements. Usage of multiple CoHub (horizontal scaling) or vertical scaling are some mitigation aspects to improve QoseCo-CR, but the same is not included in the scope of this paper. This paper only attempts to measure the impact on delivery ratios for QoseCo-CR for a single deployment of CoHub.

Structure of rest of the document is as follows: Section II provides a very brief overview of related DTN routing

protocols and quality of service related work. Section III provides overview of QoseCo and QoseCo-CR along with algorithmic details. Section IV has simulation setup, results and analysis. Section V includes conclusion and a broad overview of future work targeted by the team of authors.

II. Related Work

Massri and others in [4] provide a good overview of DTN routing. They have identified three major components in DTN routing– 1) queue management, 2) forwarding decision and 3) replication. Cao and others [5] provide a more recent survey on various DTN routing approaches. In context of [5], rural deployment can be seen as suburban networks or pocket switched networks. Routing decisions in such cases can use infrastructure approach with auxiliary nodes like mule or throw box or use participant nodes for store-carry-forward. In this paper the authors use a hybrid approach wherein "infrastructure" is used to improve routing decisions, but the actual routing is done using participant nodes in a distributed manner.

Some of the newer protocols explore human / social aspects of the person carrying the device to drive the routing decisions. This increases the computation complexity on the nodes as each node needs to have visibility beyond its own contacts to calculate social characteristics like centrality and between-ness. For DTN networks with power-law, [6] explores DTN routing via hub nodes, where the (multiple) hub nodes have higher connectivity and offload computation load from other nodes. Another set of protocols use an oracle or deterministic approach to compute the future contact probabilities and drive the routing decisions accordingly. But when these protocols are applied for pocket switched networks, especially for rural people who need not keep a strict schedule, they perform poorly.

When adding an extension to an existing routing protocol, the base protocol should be as simple as possible. Naïve Spray-and-Wait [3] was the first choice as it allows for good control on overheads and is very simple in terms of computation and storage overheads on all nodes. Origin node in SNW computes the maximum number of replicas (L) that will be created. Thereafter some replicas are given to nodes on contacts. When operating in binary mode, half the replica count will be shared with other node on contact. Eventually at max L nodes will have a copy of the message. If any of these nodes come in contact of the destination, the message is delivered.

To target fairness, QoseCo allows higher L to be used for messages with poorly served nodes as origin or destination. During forwarding QoseCo allows higher share of replicas to be given to well-connected nodes. Other than SNW, PRoPHET was also considered. Tolerance limits can be relaxed for poorly served nodes if PRoPHET is used. For brevity, it is not discussed further in this paper.

A. *Quality of Service:*

Hay and Giaccone [7] have explored QoS for DTN routing when contacts between nodes is known in advance or can be predicted in advance (e.g. Bus routes etc.). Such knowledge is used to model the DTN network as time-independent graph for optimizing QoS. Sandulescu [8] uses special messages under nominal load from the source node to destination node and collects the feedback over time. Thereafter source adapts the transmission to observed network behavior. QoseCo targets to do away with such needs by periodically updating about poorly served nodes.

B. *Fairness in DTN:*

Pujol et. al. [9] attempt to measure fairness in the share of load on individual nodes. Fan [10] et. al. measure the fairness in delivery ratios for increasing number of contacts. During relay of messages their work attempts to locally compute the utility value for each message, with delivery farness of messages as a goal. Since each node tries to compute fairness without a global perspective, the impact is limited.

Similar to [10], this paper attempts fairness in delivery ratios. To the best of knowledge of the authors, control of delivery fairness w.r.t. end nodes has not been dealt with in any prior work. QoseCo uses historical contact and delivery information to adjust the priority of nodes. Since complete graph need not be built on each node, QoseCo scales quite well, though it has a time lag in sharing the global view.

III. QoseCo Routing Extensions

QoseCo: All nodes periodically share their state information with CoHub. Based on the information received, the CoHub generates a consolidated view and updates all nodes (broadcast) with control information. This is a communication overhead (below 2%), but it helps move the computation to CoHub. CoHub periodically distributes the global context to all nodes. In absence of information from CoHub, the node degrades itself to naïve routing protocol (SNW in this case).

QoseCo-CR: If complete control of the deployment (e.g. lawful interception, virus scan etc.) is required, all traffic is relayed through the CoHub.

Major decision points are captured below.

A. *New message from origin node*

Replication count (L) for the message is set by the origin node, based on the last routing control message received from the CoHub. For poorly served nodes, higher counts are allowed.

Algorithm 1: New Message on originating node (simplified)

```
function newMessage(Message M, Host origin, Host dest)
  L = Default_Max_Replica
  if (dest or origin in poorMap)
    lowQual = MIN(getQuality(dest), getQuality(origin)
    L = L * (1+AverageQuality / lowQual)
  if(routing == QoseCo-CR)
    m.setMetadata("actualDest", dest)
    m.destination = CoHub
  m.setMaxReplica(L)
  m.setDestination(destination)
end
```

For QoseCo-CR, destination is set as CoHub and actual destination is added as metadata to the message. Once CoHub gets the message, it does the required processing and relays it to the actual destination.

B. Feedback to the CoHub

All nodes periodically send status updates to CoHub (management payload). The update message includes a) information about the nodes contacts (contact count and total duration) with other nodes; b) count of messages generated and delivered from/to end applications on the node and c) list of messages received before TTL expiry.

C. Consolidation of data (Global-View) at CoHub

When a CoHub receives status update messages from the nodes, it adjusts the metrics for the nodes. Periodically the CoHub multicasts routing updates to all the nodes. This multicast status includes a) list of poorly served nodes and their priority, b) list of nodes that are good carriers with their priority, and c) list of recent messages received by destination nodes. Poorly served nodes are identified as nodes who have reported very few contacts and/or whose packets have not been delivered (either as origin or destination). Good carriers are nodes that have had large number of contacts with different nodes. Exponential weighted moving average is used to reduce impact of really old contacts.

When nodes get multicast routing updates from CoHub, they delete all messages in their local cache that are successfully delivered to the destination nodes. They cache the details of good carriers and poorly served nodes for subsequent routing decisions and new message creation.

D. Routing decesion: Message forwarding between nodes

During contacts, nodes exchange messages with each other as per following algorithm.

Algorithm 2: Forward Message Between Nodes (simplified)

```
function startTxfr(Msg[] pendingMsgs, Host[] connList)
  if (CoHub in connList &&
       CoHub in getDestinations(pendingMsgs))
    candidateMsgs = filterOnDest(pendingMsgs, CoHub)
    sortOnOriginNodeQuality(candidateMsgs)
    transferAndDelete(candidateMsgs[0])
  else
    trgtMsgs = filterOnDest(pendingMsgs, connectedList)
    if(trgtMsgs!= EMPTY)
      sortOnOriginOrDestQuality(trgtMsgs)
      transferAndDelete(trgtMsgs[0])
    else
      txrList = sort_On_EndNodes_CopyCount_Relay(
                          pendingMsgs, connList)
      relayAndAdjustL(txrList[0].msg, txrList[0].remote)
end
```

The message transfers are attempted as follows:. A) If one of the connected nodes is a CoHub, deliver messages that have CoHub as destination. B) If node has message for one of the connected forward messages for destination. C) Relay other messages and adjust copy counts.

If there is a tie w.r.t. message or connected host, the tie is broken as follows: a) messages moving towards CoHub, b) messages with nodes as source or destination of poor quality, c) current replica values of messages, and d) relay to host which are good carriers. *relayAndAdjustL* gives higher number of copies to nodes that are in "Good Carriers" list.

E. Message deletion when buffers are full

Expired messages are deleted first. If required, further messages are deleted based on priority of end nodes.

IV. Simulation and Results

A. Implementation details

QoseCo routing and forwarding, as discussed in section III above was implemented on ONE [11]. Reporting functions were added to appropriately capture the details of management packets and include measure of fairness metric. Jain's throughput fairness index [12] is used. These metrics are captured in table 1.

TABLE I. Delivery Ratio, Overhead and Fairness

Parameter	Value
T_Delivered	Total messages successfully received at destination
T_Started	Total messages sent
T_Relayed	Count of successful forwards of messages between all nodes
N_Success	Number of messages successfully delivered for a specific node (either as source or destination)
N_Attempt	Number of messages for a node (either as source or destination)
Delivery Ratio	T_Delivered / T_Started
Overhead	(T_Relayed – T_Delivered) / T_Delivered
N_Xfactor	(N_Success/N_Attempt) / DeliveryRatio
Fairness	$(\sum N_Xfactor)^2 / \sum (N_Xfactor^2)$ for nodes that participated in attempts

Two mobility models from [11] are used - (a) Working Day Movement model – WDM; and (b) Helsinki City Scenario – HCS. WDM simulates users in home, office and shopping malls etc. in a somewhat realistic scenario based on large area of Helsinki city. HCS simulates people moving randomly (walking or in car) across a smaller area within Helsinki. For each user HCS chooses the next destination randomly based on points of interests in the map. For the chosen destination, shortest path is computed based on maps; while the speed and period of stay are randomized based on configuration settings. Readers are requested to refer Keränen's work [11] for further details about these scenarios.

B. Simulation Configuration

To target rural scenarios number of nodes were significantly reduced and simulations were run for longer

intervals. Longer duration was chosen, as compared to [11] because the rural area of developing countries will not have internet connectivity at home / office. For HCS, 37 pedestrians, 3 people with cars or two wheelers and 21 static nodes were used along with three trams. For WDM, numbers from [11] were scaled down by factor of sixteen to get 64 end user nodes. For both the scenarios static CoHub node was added. CoHub location was manually chosen near road junctions to ensure good contact opportunities.

TABLE II. DEFAULT SETTINGS FOR SIMULATION RUNS

Parameter	Value	Parameter	Value
Duration	4 days	NumCopies	64
Event Gap	8 minutes (randomized)	EWMA Alpha (QoseCo)	0.002
Event Message Size	750 KB (randomized)	NumPoorService (QoseCo)	16 nodes
Message TTL	8 hours	NumGoodCarriers (QoseCo)	8 nodes

QoseCo update messages are pretty small (typically 4-16 KB for CoHub routing updates and 1-4 KB for node status updates). They have not been included in further analysis since they are smaller by order of hundred times. For a sample run, 200 megabytes of traffic relay was caused because of QoseCo management load while application payload generated 13 gigabyte of traffic.

C. Simulation Runs

From the simulation scenarios that were executed, two reports are presented here. Results for Delivery Ratio, Fairness and Overhead are presented for simulation period. For Inter-event Gap (Congestion) the results are discussed only for fairness and delivery ratio because of space limitations. All metrics are average values for eight randomized runs.

1) Simulation Duration- low load

Execution was done for simulation periods of 0.5 days, 1 day, 2 days, 4 days, 8 days, and 16 days. The results are plotted in Figure 1 for (a) Delivery ratio, (b) Fairness and (c) overheads. As simulations run for longer interval, delivery ratios improve for all scenarios. This is because higher percentages of messages are received within the simulation time. QoseCo follows similar trajectory as SNW with a slight degradation. The degradation is observed because management messages compete with application messages during contact opportunities. QoseCo-CR has lower delivery ratios. This is because the routing via CoHub requires more hops and increases congestion in the vicinity of the CoHub.

As duration increases, fairness improves since the messages are generated with random nodes as source and destination. Both QoseCo and QoseCo-CR show significant improvements till 2-4 days, with the slope tapering off for 8 days and 16 days.

For runs of less than 2 days, lots of messages are not yet delivered; hence overheads are observed to be higher. Overheads are higher for QoseCo-CR as it first sends messages to CoHub and then CoHub relays to destination. Moreover HCS has lot more contacts; hence it creates many more copies. Overhead results for QoseCo were marginally higher as it allowed larger number of replicas for poorly served nodes. All through QoseCo had fairness which was pretty close to SNW, despite the delivery ratio being poorer for QoseCo on account of added management messages.

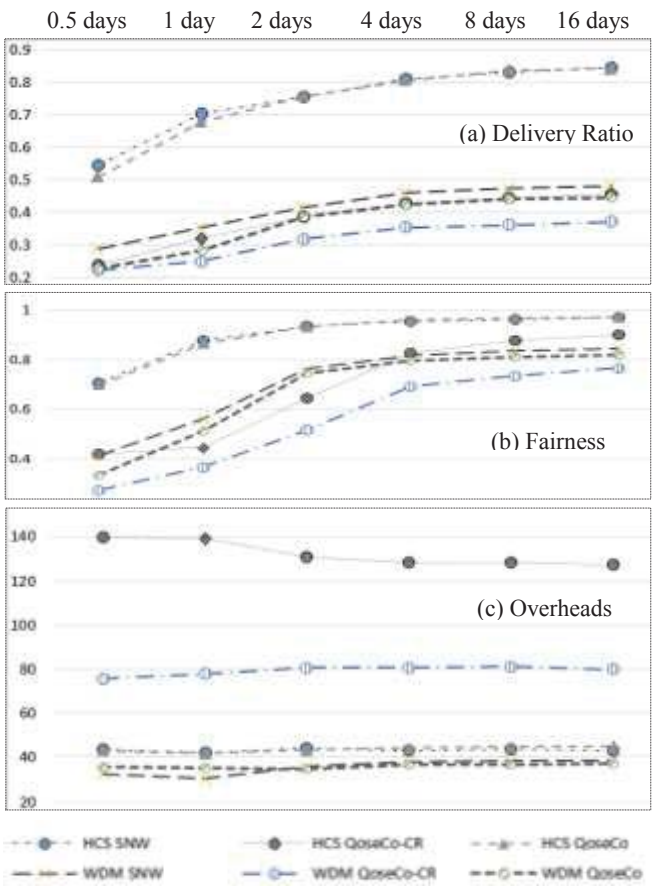

Figure 1 Simulation Duration Results

2) Inter-event Gap- Congestion

Events were randomly generated with average gap of 30 seconds, 1 minute, 2 minutes, 4 minutes, 8 minutes and 16 minutes. This scenario allows for congestion to happen in the cases where messages are generated at two minutes and below. Figure 2 plots the results for the fairness and delivery ratio for four day run.

When events are generated twice every minute, almost all nodes participate in the communication and most of them observe high losses, though the nodes on periphery will be worse off for WDM. For HCS, QoseCo does well to improve fairness in this scenario as it has values around 94% while SNW is around 90%. Similar trend is also observed for WDM (70% vs. 74% for 30 seconds). At lower frequencies since less number of nodes participate in communication, slight degradation is observed in fairness for all cases.

QoseCo-CR observes significantly higher packet loss when message frequency is high (low delivery ratio). This is because the messages get relayed via the CoHub and for all messages that get relayed, a new message is created.

D. Key Observations and Analysis

HCS scenario is completely random with respect to the mobility paths and destinations, while WDM is somewhat synchronized. With choice of 64 nodes in the simulation, and messages being randomly generated between nodes, it was observed that QoseCo improves fairness by around 4% in many scenarios.

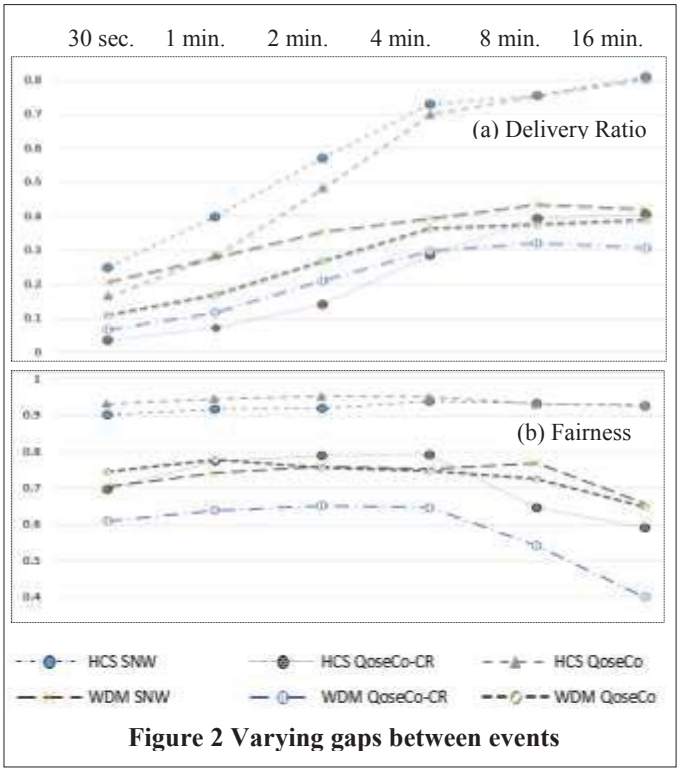

Figure 2 Varying gaps between events

Improvements for fairness in QoseCo are more pronounced when network is congested (frequently generated messages). This happens even as the overheads of QoseCo update messages are present. Poorly serviced nodes are tracked centrally. By moving this computation to central nodes, computation load for other nodes was reduced. The tradeoff was addition of QoseCo update traffic which was less than two percent for most scenarios.

QoseCo-CR is frequently worse off by a factor of about two. For 30 seconds in HCS it degraded beyond a factor of two when compared with QoseCo as severe congestion set in the vicinity of the CoHub.

V. Conclusion and Future Work

The authors proposed a new DTN routing extension and used SNW as underlying routing protocol to demonstrate centrally optimized routing. Using simulations they also showed how centralized routing extension helps improve Quality of Service under congestion. Fairness in delivery ratio was used as the quality metric to demonstrate the impact of QoseCo for real world mobility scenarios. While this work adapts SNW for centralized routing, other DTN routing protocols can also be adapted in similar manner.

This paper also studied the overheads when all messages are relayed through a central node. The cost of relaying the messages via the central nodes is found to be within 2X for most scenarios but degraded significantly as congestion sets in.

The authors are exploring the ability to include more than one location for CoHub(s) and analyze its impact. Moreover present QoseCo implementation does not explore the location and time relationships for the contact. This is another aspect that the team is exploring. Survey of real village to make the working-day-model more realistic is another area that the team is focusing on. The work is also being extended to reduce the number of copies when delivery ratio is high (e.g. above 95%).

Abstract— **Most of content in video capture from static cameras consist of fixed background. Invariably the important information in such video is associated with some motion. Background Subtraction models help extract such information. Adaptive approaches of background subtraction (like Mixture of Gaussian) do not mandate prior input for object detection. But adaptive approaches suffer from misclassification during learning phase. This work extends Mixture of Gaussian to improve upon the short comings of adaptation phase. Video chunks are processed in both forward and reverse direction. Different approaches of combining the output values in both directions are analyzed. Best results are observed when different kernel sizes are used in morphological operations for forward and reverse direction, depending on the temporal offset. Experimental results for standard video data sets and farm like scenarios demonstrate improvement in detection accuracy across numerous frames.**

Keywords- ***Multimedia, Video Processing, Motion Detection, Background Subtraction, Bidirectional Processing***

I. INTRODUCTION

This work forms a significant part of object detection, highlight generation and video compression of in farm like scenarios. Large areas are monitored using cameras mounted at strategic locations. These cameras are affordable Android devices communicating over 802.11 series of protocols. In rural scenarios, actual network connectivity should be delay and disruption tolerant [1]. Continuous video is not streamed on such networks. Video must be heavily compressed to be shared over such networks within reasonable timeframe.

For such heavy compression significant portion of the video must be discarded. The challenge is to accurately segment the regions are to be discarded, from the regions to be retained. It is obvious that for such scenarios, motion is associated with portion of video to be retained. This work improves segmentation accuracy by improving motion identification.

Typical captures, for farm monitoring, involve large open areas with trees and other vegetation. The intent is to detect human / animal or inanimate objects intruding into the farm without requiring explicit human interaction. Broader work involves highlight creation and messaging using Delay Tolerant Networks [1]. Videos are stored and processed in chunks varying from tens of seconds to a few minutes, to extract key information. It is only the key extracted information that is sent over the delay tolerant network.

Accuracy can be improved by identifying regions of significant motion while discarding small movements generated by the fixed objects. For example swaying branches, tree-tops etc. show lots of small movements and do not have significance. It is assumed that the natures of objects are not known. A priori knowledge based approach could cause unknown objects to be missed. Though the wider work involves object tracking across frames, path-identification and communication mechanisms, they are not within the scope of this work. This paper focusses only on improving segmentation accuracy.

While this paper discusses farm like scenarios as primary use case, it can be applied to any scenario where video is captured using static cameras. Such applications will have impact on information extraction from archived videos, e.g. conserving storage space for archived videos.

Layout of the document: Next section provides an overview of key object detection techniques and includes an overview of Background subtraction using Gaussian Mixture Model. Section III provides the implementation details of bi-directional video processing for object detection. Section IV covers the experiment details, and metrics. Section V presents the results and related analysis. Section VI concludes the paper including a discussion of future work.

II. BACKGROUND WORK

Multiple approaches have been developed to detect motion of objects in the video. Three of the common approaches are a) Optical Flow; b) Background subtraction; and c) Color histogram based methods [2]. For brevity of this paper only background subtraction method is discussed in details. The other two approaches need prior information (histogram based) or do not scale well for large areas (optical flow).

Motion detection using background subtraction involves segmenting each video frame into background and foreground regions. The background region stays relatively static throughout the length of the video. The foreground is the region of pixels that moves across the frames while mostly maintaining its shape and color attributes. Multiple approaches have been proposed for motion detection. This work builds

upon background subtraction based object detection [3] [4]. The background subtraction approaches performs well with modern systems that have more graphical processing cores dedicated to the algorithm [5].

A. Background subtraction - Mixture of Gaussian: A brief Overview

Background subtraction methods rely on creating a model for the background. Each frame is compared with the background model to find the difference and identify regions of motion. Background subtraction Mixture of Gaussian (referred to as BGS-MOG in subsequent parts) differs from the other background subtraction methods in the way the background model is created. The background model is continuously updated for every frame that is processed. Every pixel of the background is represented as a mixture of Gaussian distributions (mean, variance and weight) [6]. This approach allows efficient handling of gradual illumination changes (e.g. shadows, clouds etc.) as well as adapts to swaying trees and branches. BGS-MOG does not require bootstrapping (externally identifying the object) or prior learning (training). It does suffer from camouflage issues (especially for slow moving objects) and does not work if camera view is not static.

For each pixel in a new frame, the pixel value is compared to the corresponding Gaussian distributions in the background model. If a match is found then the corresponding distribution is updated for mean, variance and the weight. If no match is found a new distribution is added to the mixture (if number of distributions is exceeding the maximum allowed entries then the least probable distribution is replaced by a new distribution). This new distribution is allocated the default weights and variance. All weights are normalized following updates/additions and the mixture model is sorted on descending order for weights. A learning rate (α) drives the weights applied to updates and additions.

A Gaussian mixture model is a more accurate description of the background as compared to any single distribution. The adaptive nature of the algorithm accounts for lighting changes and works even if no pristine background model was available.

If a pixel does not match, or matches against a very low weight in the mixture, it is marked as foreground in resulting mask. The mask provided by BGS MOG for a frame is generated on individual pixels without a sense of adjacency. This results in a perforated mask with varying pixel values for a given object. Morphological operations are used to smoothen out the mask.

Morphological operations are matrix based mathematical operation on images. These operations alter a pixel's value based on the values of the pixels in its neighborhood. The area and shape of the neighborhood affects the results of the operation. The operations used in this paper are erode and dilate. The erode operation reduces the thickness (shrinks) around the edges whereas dilate increases the thickness. If random small objects are present, erode tends to remove them while dilate will end up joining them. Size and shape of kernel decides how effective the removal or joining is.

B. Shortcoming of BGS-MOG

1) Spurious motion in initial frames:

The initial frames show a lot of motion since the background model is still under construction. The learning rate (α) drives the weight for pixel value in current frame. If moving objects or swinging branches are present in the first frame, the algorithm incorrectly classifies the initial region where the moving object was present, as part of the background. In subsequent frames, a lot of incorrect motion is reported where the moving body was originally present. The inaccurate motion is removed after a few frames, as the background model adjusts to the real values for background pixels. The adjustment period depends upon the learning rate α.

2) Missed trailing edges:

Trailing edges of some objects are missed, if they are narrow along their motion path. This is because mixture model has not adapted to the object.

It's difficult to ensure that initial frame does not have any motion; hence the initial frames will have false positives. To reduce this learning period, a very high learning rate (α) can be used. However a high α causes slower moving objects to be mislabeled as background. This makes tracking slower moving objects difficult. Generally a compromise is made on the learning rate and some inaccuracy in reporting motion in the first few frames is accepted. This work targets to reduce such inaccuracy.

III. BIDIRECTIONAL PROCESSING

Bi-directional processing deals with chunks of video of 30 seconds to a few minutes. The stream is individually analysed from starting to end and from end to start. The results obtained from the two analyses are then aggregated to generate a mask that that had improvements in identifying the region of motion.

The first step in the process is to create a separate reversed video of the given video chunk (last frame to first frame).

Then BGS MOG is applied on both video chunks. The result is two separate videos of masks. One is for the first-to-last frame video (henceforth called the forward stream) and the other for the last-to-first frame. The BGS MOG stream for the reversed video frame has the masks in last to first order. The two streams need to be aligned so that for a given frame number both streams provide the mask for the same frame. This is done by reversing the mask stream for the last to first frames (subsequently referred to as the reversed stream).

The two streams can be used individually to detect motion in a given frame. However both suffer from the shortcomings mentioned in II-B.

In order to improve detection accuracy, the two streams were then aggregated. Three aggregation methods were experimented upon. In all the aggregation methods dilation and erosion have been used. Three different sized square kernels were used. SMALL(3x3), MEDIUM(5x5) and LARGE(7x7).

The initial aggregation methods used were Bitwise OR and Bitwise AND. Prior to the Bitwise operation the forward and reverse stream the frames are dilated using the MEDIUM sized kernel. After the Bitwise operation the resulting mask is eroded

using LARGE kernel. This is done to minimize the addition of noise from the individual streams. This may result in loss of information. Mathematical addition and multiplication were not used since the masks are binary in nature and bitwise operations are faster.

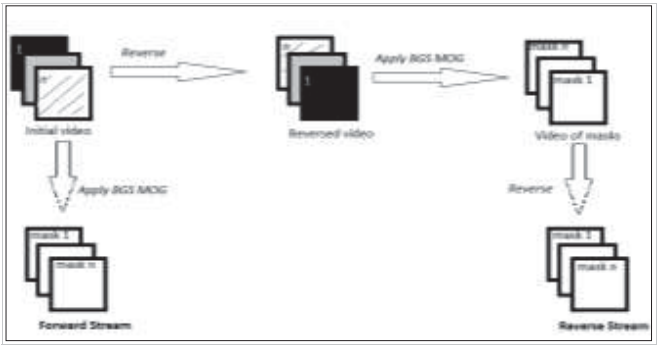

Figure 1 Creation of reverse and forward mask streams

The accuracy of the various aggregate streams was then compared to the accuracy of individual forward and reverse streams. For comparison, the individual forward and reverse streams were dilated and eroded with the same sized kernel (MEDIUM), in order to smoothen out the edges and fill in small gaps within the shapes. Figure 1 captures the processing done for individual streams (forward, reverse) and aggregated streams (AND, OR).

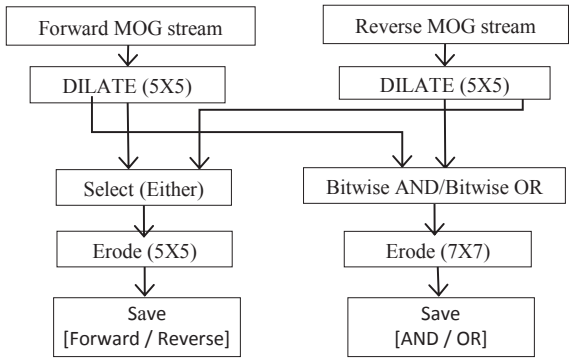

Figure 2 – Morphological operations for individual and simple aggregated streams

It was expected that the Bitwise OR aggregation method would lead to additional noise in the mask. This effect would be pronounced in the initial and terminal part of the video. Similarly it was expected that the Bitwise AND aggregation method would lead to loss of information.

To overcome these issues, a third aggregation approach based on Weighted Bitwise OR was implemented. For this method the masks from forward stream were preferred during the terminal part of the video and the masks from the reverse stream were preferred during the initial part of the video. The approach used morphological operations as weight functions for individual streams. Different sized kernels were used as function weights. The algorithm is captured below.

Algorithm 1: Weighted Bitwise OR

```
Initialization
    SMALL kernel = matrix of size (3x3) with all 1
    MEDIUM kernel = matrix of size (5x5) with all 1
    LARGE kernel = matrix of size (7x7) with all 1
    Acquire forward_MOG_stream
    Acquire reverse_MOG_stream
    Initialize output_stream
for all frames in video_stream do
    acquire forward_mask
    acquire reverse_mask
    if frame in (0 to 5% of video_stream) then
        mask1 =Dilate(forward_mask, SMALL kernel)
        mask2 =Dilate(reverse_mask, LARGE kernel)
    else if frame in (95% to 100% of video_stream) then
        mask1 =Dilate(forward_mask, LARGE kernel)
        mask2 =Dilate(reverse_mask, SMALL kernel)
    else
        mask1 =Dilate(forward_mask, MEDIUM kernel)
        mask2 =Dilate(reverse_mask, MEDIUM kernel)
    end
    combined_mask = BitwiseOr(mask1, mask2)
    final_mask = Erode(combined_mask, LARGE kernel)
    output_stream.add(final_mask)
end
```

For first 5% of the video forward stream was in learning phase. Similarly for last 5% of the video reverse stream was in learning phase. The stream that is not in learning phase was preferred in such scenarios. The preferred stream was dilated with the LARGE kernel and the other mask (corresponding less preferred) was dilated with the SMALL kernel. After the Bitwise OR operation, the resulting mask was eroded using a LAGE kernel. During the middle portion of the video (5%-95%) both the forward and the reverse stream are given equal preference and dilated by the MEDIUM kernel.

In the first 5%, since the reverse MOG stream the model is mostly accurate, hence it has better representation of actual motion. A Bitwise OR of the two dilated masks creates an aggregate that has dilated objects from both the streams, i.e. highly expanded regions from the reverse MOG and minimally expanded regions from the forward MOG stream. Subsequent erosion of the aggregate mask using the LARGE kernel diminishes the regions of motion that are only contributed by the forward MOG (as it was dilated by a smaller kernel). Most of the small random regions, contributed by forward MOG, are removed and larger regions, contributed by forward MOG, are diminished in area. For regions contributed by the reverse MOG stream, the factor of dilation is the same as the factor of erosion; hence no detail is lost for them.

Similar logic used in for frames in last 5% of the video ensures that motions identified in forward stream are prominent. For the remaining part (i.e. in the middle), both the streams are dilated by the same factor. A kernel of MEDIUM dimensions is used on both the forward and reverse MOG streams.

IV. EXPERIMENTAL SETUP

In experimental runs, Background Subtraction Model with Mixture of Gaussian is used. There were 20 mixture channels and learning rate (α) was set as 0.005. For the morphological operations square kernels were used with dimensions as 3x3, 5x5 and 7x7 for SMALL, MEDIUM and LARGE respectively.

The algorithm was implemented using OpenCV (2.4.9). "Improved adaptive Gaussian mixture model for background subtraction" implementation was used for all the experiments [7].

A. Test Videos

Two video sources were used.

- Video from within the authors' campus was chosen such that it presented challenges that were similar to the farm monitoring scenario. (From here on referred to as internal video). The video was shot in HD Ready resolution at 30 fps. Due to the large distance, the common moving objects were relatively small. The paths are such that objects are occluded by tree and shrubs. The trees and shrubs have moderate swaying motion.
- Clip from PETS 2001 video -Camera 1; from here on referred to as the PETS video [Reference: PETS2001 datasets (University of Reading, UK)]. It has motion of people and vehicles at 25 fps.

Across the video sources, series of representative frames were chosen. Each frame series consists of four individual frames (e.g. frame numbers 5, 10, 15, 20). Frame series were chosen from start, middle and end of video. The actual region of motion (Ground Truth) for the representative frames was identified manually.

For each video source, chunks of 30 seconds were used in experimental run. Sample reference frames are captured in Figure 3. The ground truth for these frames is shown in and Figure 4. Similar work was repeated for all the twenty four frames (3 series of four frames each, for both videos).

a. PETS - frame 400 b. Internal - frame 400

Figure 3 Sample Video frames

For each video the metrics were calculated for forward BGS MOG, reversed BGS MOG, Bitwise OR , Bitwise AND , and Weighted OR. The representative masks for frame 400 in PETS video is shown in each frame series are shown in Figure 5 (a. through e.).

Figure 4 Ground truth video frame 400

a. Forward MOG b. Reverse MOG c. Bitwise AND

d. Bitwise OR e.Weighted OR

Figure 5 Resulting motion masks for frame 400 zoomed 4x to bottom right

B. Metrics For evaluation

Accuracy of motion detection was measured by three metrics. These were 1) Missing Foreground, 2) Added Foreground and 3) Rate of Misclassification [8].

Missing foreground refers to the percentage of foreground pixels mislabeled as background pixel. It's calculated for each representative frame as

$$MF_{rel} = (\text{Missing foreground pixels in the mask}) / (\text{Number of foreground pixels in the Ground truth}) \quad (1)$$

Added foreground is a measure to determine the degree to which background pixels are mislabeled as foreground pixels.

$$AF_{rel} = (\text{Added foreground pixels in the mask}) / (\text{Number of Background pixels in the Ground Truth}) \quad (2)$$

MF_{rel} and AF_{rel} do not account for the degree of misclassification for a missed foreground pixel or added background pixel. A falsely detected pixel that is closer to the actual foreground is better as compared to a farther pixel. This measure is provided by the metric Rate of Misclassification. It's given as:

$$F_{SC}(n) = \frac{1}{F(n)} \sum_{j=1}^{F(n)} \left(\frac{d^j_{err}}{D} \right) \quad (3)$$

Where F(n) contains set of pixels in MF ∪ AF. d^j_{err} is the distance of the j^{th} misclassified pixel from the closest contour of the ground truth. D is the length of the frame diagonal.

V. RESULTS AND OBSERVATIONS

Table 1 captures the values for AF_{rel}, MF_{rel} and F_{SCrel}, across the three frame series for both video sets.

MF_{rel}: Bitwise AND is the worst performer as it missed the foreground objects consistently. This is visible in Figure 5 (c) where large part of the car is missed.

AF_{rel}: Bitwise AND, shows only those regions that are common to both the forward and reverse MOG streams. Since most noise generated by the two streams do not overlap therefore a very low AF_{rel} value is obtained. In the initial frame series reverse streams has the lowest AF_{rel} followed closely by Weighted Or approach. Correspondingly for the end frame series (of the PETS video) the reverse stream has the lowest values followed very closely by Weighted OR.

F_{SCrel}: It measures the distance of the misclassified pixel (missing foreground and added background) from the nearest contour. Bitwise AND has the best result in all cases followed closely by the remaining methods. The reason for high F_{SCrel} for Bitwise AND is due to the missing foreground pixels. Since the contours are small this effect is not prominent.

TABLE 1 RESULTS FOR INTERNAL VIDEO (MULTIPLIED BY 1000)

			Forward	Reverse	Bitwise OR	Bitwise AND	Weighted OR
Internal Video	Series 10	MF_{rel}	0	0	186	757	36
		AF_{rel}	17.56	0.25	0.14	0	0.07
		F_{SCrel}	298.02	1.98	11.47	1.11	1.65
	Series 400	MF_{rel}	3	15	265	480	265
		AF_{rel}	1.58	1.13	0.23	0.04	0.23
		F_{SCrel}	7.9	8.62	8.4	9.33	8.4
	Series 800	MF_{rel}	152	152	411	508	197
		AF_{rel}	1.02	3.66	0.41	0.07	0.43
		F_{SCrel}	9.63	86.66	21.75	3.02	17.42
PETS Video	Series 10	MF_{rel}	140	3	45	207	6
		AF_{rel}	1.62	1.16	2.64	0.36	1.60
		F_{SCrel}	29.77	3.25	51.60	2.81	13.52
	Series 400	MF_{rel}	36	138	36	271	36
		AF_{rel}	5.44	5.95	5.85	2.83	5.85
		F_{SCrel}	165.25	179.13	179.37	166.45	179.37
	Series 700	MF_{rel}	197	156	24	449	24
		AF_{rel}	10.78	13.08	13.76	4.48	13.76
		F_{SCrel}	269.28	289.20	294.46	260.27	294.46

We conclude from the above table that

- Forward and reverse MOG streams do not perform well in the initial and the final regions of the video respectively. Otherwise they have good performance (low AF_{rel} and F_{SCrel}) and moderate MF_{rel}.
- Combination approaches (both AND and OR) use larger dilate kernel hence they have lower MF_{rel} during the middle part of video. OR is better than AND.
- Near start / end of video chunks, either of forward or reverse are best, while Weighted-OR is close second (sometimes even tying for best performance).

When comparing the three aggregation approaches, Weighted OR algorithm effectively removed the noise while keeping good values for missed foreground across all parts of video.

VI. CONCLUSION AND FUTURE WORK

Efficient motion detection techniques enable creation of accurate tracking solutions. The proposed method provides a novel way to improve motion detection. The improvement comes at the cost of additional processing required to revere the video stream and analyzed the reversed video as well as the original video. For internal video dataset, the compressed output is shared at www.swifiic.in/sambv/index.html. Fourteen megabytes was compressed to below 600 kilobytes.

Experiments with bidirectional video processing showed excellent results for Weighted OR. It improved segmentation efficiency while keeping the false positives within the bounds. Authors' intend to extend this work to study the effects of different learning rates, kernel shapes and kernel sizes across different video datasets. Further the team intends to apply bidirectional approaches to other object detection and tracking approaches that do not expect static camera view (E.g. [9][10]).

Such advances can be put to use in the fields of surveillance, video compression, event generation etc. The method is not real time but is implemented in close to real time when using chunks of video. The authors are targeting to get the system to perform in real time when working in parallel on samples of 30 seconds to a minute.

ACKNOWLEDGEMENT

The authors would like to thank the anonymous reviewers whose feedback has helped improve the quality of this work.

QoE Based Pseudo Heartbeat Message Compression Mechanism for Wireless Networks

Zhiqun Hu, Xiangming Wen, Zhaoming Lu, Zhaoxing Li
Beijing University of Posts and Telecommunications, Beijing, China
Email: huzhiqun@bupt.edu.cn, hu208, lzy_0732, fxlizhaoxing@163.com

***Abstract*—Wireless multimedia services are increasingly becoming popular, which boosts the need for better quality-of-experience (QoE). However, there are many aspects leading to the degradation of real-time video QoE, especially, a large number of always-on-line (AOL) applications existing in future wireless networks, which require massive signaling costs and overload wireless networks. To solve this problem, we propose pseudo heartbeat message compression mechanism for future wireless networks. This mechanism reduces the number of signaling loads in the radio access network by intercepting the periodical heartbeat message at a certain frequency in the proxy client. To maintain the protocol feature of the AOL applications, the heartbeat messages are reconstructed by the proxy server installed in the air interface side and sent to the application server. The simulation results show that the proposed mechanism increases the video QoE about 1.32 times with a slight lose about 0.11 of AOL application QoE.**

I. INTRODUCTION

According to Garner's [1] market estimates, global annual shipment of smartphone handsets has increased from nearly 968 million in 2013 to 1.9 billion in 2014, resulting in the sharp increase in the use of mobile applications, such as always-on-line (AOL) applications and mobile video services. A previous study [2] reports that mobile video traffic exceeded 50 percent for the first time in 2012 and that the market share is estimated to comprise two-thirds of the world's mobile data traffic by 2017. This deluge of data has been driven chiefly by video thus far, but AOL applications can reasonably be expected to materialize in the future wireless networks. However, AOL applications require to periodically send heartbeat message to maintain the always-connected capabilities, because the macro network and mobile client actively release the connection to save wireless source and electricity consumption, respectively. This permanent features occupy considerable signaling loads and overload the air interface networks. Hence, the problem of signaling overload would significantly worsen with the continued prevalence of AOL applications in wireless networks. A great deal of signaling will utilize a considerable portion of wireless resources in the network, then the available bandwidth becomes limited for video service. Thus, the QoE of video users would be degraded as the number of AOL applications increases in the network. Therefore, how to guarantee that two kind of applications quality-of-experience (QoE) is the challenge issues that we have to face in future.

To improving the efficient of resource, the solutions to solve the signaling overload problems becomes a hot research topic and has attracted the attention of many researchers all over the world [3]- [7]. The burst traffic pattern is identified as more resource efficient with respect to signaling load than periodic traffic in [3]. Different approaches to decrease the signaling are investigated in [4]- [7]. In [4], the authors recommend to use an agent to buffer the event-triggered presence updates and reduce the network access and keep mobile devices in sleep modes as much as possible. The feasibility of decreasing signaling using timer alignment to group AOL applications has been investigated in [5]. In [6], a novel architecture is proposed to offload the particular type of applications to cloud to lessen the signaling in the networks. In [7], an keep-alive message exchange process is investigated. With the usage of push server to establish connection with several application servers, the client maintains the connectivity and an alive session with only one Internet push server.

In this paper, we present a pseudo heartbeat message compression mechanism, which solves the problem of signaling overload in mobile network by intercepting the periodical heartbeat message, to improve the video QoE. However, this mechanism inevitably impairs the AOL applications QoE. Therefore, a tradeoff between the two kind of application QoE is considered to determine the optimum intercepting frequency. We construct a network framework based on software defined network (SDN) due to it global view of the network. Based on this framework, we intercept the periodical heartbeat message in the proxy client with a certain frequency and reconstruct it in the proxy server installed in the air interface side. Thus, the proxy server pretends the mobile terminal to send the heartbeat messages to the application server at the application periodicity.

The main contribution and results of this paper are summarized as follows:

- Network framework based on OpenFlow centralized control is developed in this paper. The controller contains basic functions, including radio resource management, traffic, and QoE perception. Considering that the controller has a global view of the network, evaluation parameters of QoE can be easily and timely obtained. Moreover, network applications using the programming according to the demands of the network can be added, which can bring great flexibility for network resource management.
- A pseudo heartbeat message compression mechanism that decreases the signaling in the radio access network is designed to improve the QoE for real-time video streaming in the

network. The proposed compression mechanism is simple and easy to deploy without changing the protocol feature of AOL applications.

- We use the physical resource block to analyze the improvement of the video applications, and illustrate the packet loss model of AOL application based on the proposed mechanism.

The rest of the paper is organized as follows. Section II describes the framework of the QoE based heartbeat message compression. Section III demonstrates the influence of pseudo heartbeat message compression. Subsection A and B of Section IV introduces the QoE assessment model of video and AOL applications, respectively. Section V shows the numerical results of the proposed mechanism in detail and conclude the paper in Section VI.

II. Framework of Pseudo Heartbeat Message Compression

In this section, the framework based pseudo heartbeat message compression is proposed, which makes a clear separation between a data and control plane. The data plane consists of wireless access point performing flow-based packet forwarding and proxy server implementing heartbeat message rebuilding, and the control plane consists of one controller, whose responsibility is to allocate the radio resource and dynamically determine the corresponding parameters that guarantee the best output service quality. The southbound protocol conducts communication protocol between the two planes. This framework is depicted in Fig.1.

OpenFlow controller [8] consists of network operating system and application interfaces; hence, new functions by programming without changing the underlying networks, such as the management of QoE and pseudo heartbeat message compression (PHMC) application, can be easily realized. Considering that the controller has a global view over the radio access network, the OpenFlow controller can easily obtain the parameters of the QoE assessment algorithm. Then, the PHMC application is invoked to obtain an optimum intercept frequency if one type of service exhibits an excessively poor QoE. In this way, the optimal interception frequency can be calculated on the premise that all different QoE of services are met in the current networks environment.

Based on the framework, our proposed pseudo heartbeat message compression mechanism is achieved. When the AOL applications periodically send heartbeat message to the application services, the client proxy will intercept the heartbeat messages with a certain frequency except that the first heartbeat message. And the controller can obtain the information of the heartbeat message, such as cycle information, address information, and informs the proxy server of rebuilding a list of heartbeat messages using the proprietary protocol of each AOL application. Then, the proxy server forges the user behavior to periodically send the heartbeat messages to the AOL application server at the original frequency. Therefore, from the radio access point perspective, the cycle of heartbeat messages is extended several times, but from the application

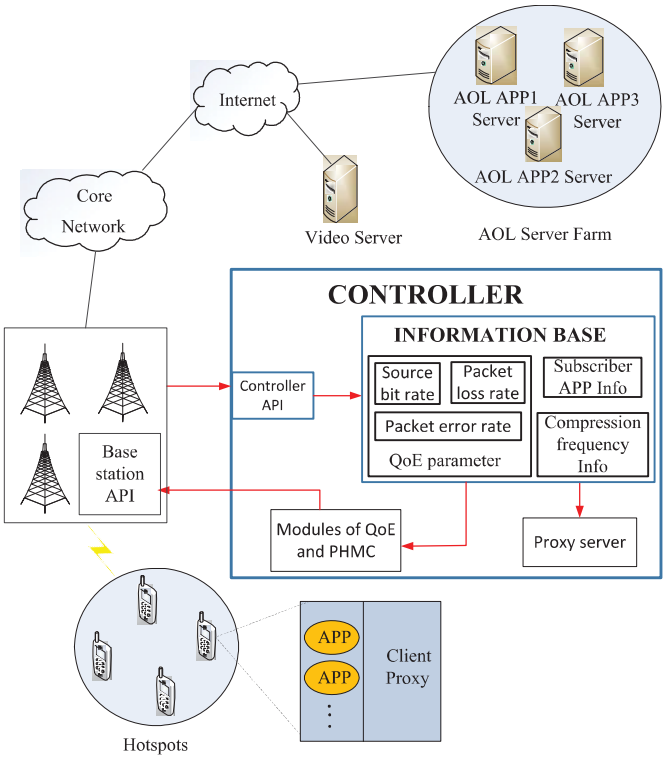

Fig. 1. Framework based pseudo heartbeat message compression.

server perspective, the periodicity of the application is not changed. This mechanism called pseudo heartbeat messages compression mechanism greatly decreases the signaling in the air interface and doesn't change the protocol feature of application. With increasing number of users with AOL applications in the networks, and enormously decreases the signaling pressure of the air interface, and more wireless resource can be saved to improve video performance.

III. Influence of Pseudo Heartbeat Message Compression

In this section, the influence of the pseudo heartbeat message compression on the video and AOL applications are presented.

A. Improvement of video application

1) Resource Saving Metric: In general, sending a heartbeat message occupies about N_b bytes of downlink (DL) resources, which consumes N_{cs} slots and every slot at least occupies N_p physical resource blocks (PRB). Therefore, the consumption of DL wireless resources for sending a heartbeat message successfully is $N_{cs} \cdot N_p$ PRBs. Supposing the compression frequency is N and the original average heartbeat message periodicity is T_h, then the average periodicity of the heartbeat message is $N \cdot T_h$ seconds according to the pesudo heartbeat message mechanism. Then, within t seconds, the number of reduced heartbeat message is equal to $\frac{t}{T_h} - \frac{t}{N \cdot T_h}$. Hence, assuming that the cell has M AOL applications running, the

number of the saved PRBs within t seconds, N_{SPRB}, can be expressed as follows:

$$N_{SPRB} = \frac{\mathrm{N}_{cs} N_p t M}{T_h}(1 - \frac{1}{N}) \quad (1)$$

2) Calculation of Transmitting Bit Rate for Real-Time Video: In this paper, the DL adapts OFDMA wherein radio resources are split into time and frequency slots, which is called resource blocks. A subframe splits into N_s slots and each slot comprises N_{OFDM} OFDM symbols. N_{CR} and N_{RS} are the number of control signal and the reference signal, respectively. N_{sc}^{RB} is the number of subcarriers in one PRB and M_{mod} is the modulation order such as QPSK, 16QAM and R_T is the coding rate. Then, the increase of the transmission bit rate ($TBR_{increase}$) within the t seconds can be written as Eq.(2) in the top of the next page.

Hence, based on the proposed pesudo heartbeat message mechanism, the TBR of video can be expressed as follows:

$$TBR_{new} = (TBR_{initial} + TBR_{increase}) * \alpha \quad (3)$$

where α denotes the factor of the current network conditions and $TBR_{initial}$ is the initial transmitted bit rate of the video.

In real-time videos, user's QoE is affected by sender bit rate (SBR), which adaptively adjusts the video coding parameters according to the available bandwidth. A high SBR in the network leads to high video quality and, ultimately, to enhance QoE of end users. Assume that the TBR is numerically equivalent to the SBR. Hence, the change of TBR can affect the video QoE.

B. Packet Loss Model of AOL application

Assume that $T = N \cdot T_h$ is the interval of the interception, which associates with the compression frequency N and the average normal frequency of heartbeat message is T_h. If the packet arrive in a Poisson manner with a mean rate u, the probability that k packets arrive in a interval T can be written as follows:

$$p(k) = \frac{(uT)^k e^{-uT}}{k!} \quad (4)$$

where uT is the average number of data arrival in a interval T.

The probability P_{loss1} is given by the probability that the packet loss occurs when the terminal drops out, i.e.,

$$P_{loss1} = P_1 \quad (5)$$

where P_1 is the probability that terminal drops out in the interval of the interception while the application server still intends to send the data to the client because the proxy server maintains the connection with the pseudo heartbeat message. Thus, the packets affirmatively loss on the fact that the terminal drops out.

Assume the observed time is $1/C$. It seems reasonable that the time of the terminal dropping should be uniformly distributed over $(0, 1/C]$. Hence, the probability that terminal drops within T can be expressed as follows:

$$P_1 = P\,(0 < x < T) = \int_0^T C dt = T \times C \qquad 0 < T < T_{\max} \quad (6)$$

Conversely, when the terminal does not drop out, the data may be lost in transmission process. Supposing that the success probability of each data packet transmission is q. The successful transmitted is defined as all packets transmit successfully. Then the average probability $Pc_{success}$ that the transmission on the channel is successful can be expressed as follows:

$$Pc(success) = \sum_{k=0}^{\infty} p(k) \cdot q^k \quad (7)$$

where $p(k)$ is the probability that k packets arrive in a time period T.

In which after rearranging yields

$$Pc(success) = e^{uT(q-1)} \quad (8)$$

Hence, let P_{loss2} be the probability that the packet loss of AOL application occurs when the terminal does not drop out, i.e.,

$$P_{loss2} = (1 - P_1)(1 - P_c(success)) \quad (9)$$

Therefore, the packet loss rate for the wireless network is approximately

$$P_{loss} = P_{loss1} + P_{loss2} \quad (10)$$

where

$$P_{loss} = N \cdot T_h \cdot C + (1 - N \cdot T_h \cdot C)(1 - e^{uNT_h(q-1)}) \quad (11)$$

IV. QoE ASSESSMENT MODEL FOR VIDEO AND AOL APPLICATION

As observed in the previous section, the framework of pseudo heartbeat message compression increases the SBR of video users as well as the packet loss rate of AOL users by intercepting the heartbeat messages. Therefore, such a situation may lead to QoE degradation for AOL users in exchange of improving the QoE of real-time video users. This section aims to introduce the assessment method of video and AOL applications.

A. Video QoE Model

In this paper, we choose a video QoE prediction model considering four most dominant factors, i.e. the video content (CT), Frame rate (FR), source bit rate (SBR), packet error rate (PER) [10]:

$$QoE = \frac{a_1 + a_2 \cdot FR + a_3 \cdot \ln(SBR)}{1 + a_4 \cdot PER + a_5 \cdot (PER)^2} \quad (12)$$

An accurate video quality assessment algorithm must consider video content because the visual quality cannot be accurately predicted by only using the bit rate and the spatial and temporal resolutions of the video streams. The video content is

$$TBR_{increase} = \frac{N_{SPRB} \cdot \left[N_{sc}^{RB} \cdot (N_s \cdot \mathrm{N}_{OFDM} - N_{CR}) - N_{RS}\right] \cdot M_{\mathrm{mod}} \cdot R_T}{t} \quad (2)$$

TABLE I
COEFFICIENTS METRIC MODELS FOR ALL CONTENT TYPES [10]

Coeff	SM	GW	RM
a_1	4.5796	3.4757	3.0946
a_2	-0.0065	0.0022	-0.0065
a_3	0.0573	0.0407	0.1464
a_4	2.2073	2.4984	10.0437
a_5	7.1773	-3.7433	0.6865

classified into three categories (Slight movement (SM), Gentle walking (GW), Rapid movement (RM)) according to video features [11]. The coefficients for all the three content types are given in Table I. Because our proposed mechanism aiming to improve the SBR of video, then we consider the source video of RM, which has great demand for wireless resource to guarantee the video quality, as our tested source, namely, the coefficients values for RM type are expressed as follow: a_1=3.0946, a_2=-0.0065, a_3=0.1464, a_4=10.0437, a_5=0.6865.

B. AOL Application QoE Model

To simplify the analysis, the QoE is assumed to be the function of a signal impairment factor. The packet loss rate is considered as the measurement of QoS. A certain amount of information is transmitted over a network simulator with variable packet loss rates.

The expression of QoE estimation model that we use in our model is the same as in [12], namely

$$QoE = 3.104 \cdot e^{(-4.472 \cdot P_{loss})} + 1.067 \quad (13)$$

where P_{loss} is the packet loss rate of AOL application.

Plugging the P_{loss}, the above Eq. (16) can be expressed as follows:

$$QoE = 3.104 \cdot e^{\left(-4.472(N \cdot T_h \cdot C + (1 - N \cdot T_h \cdot C)(1 - e^{uNT_h(q-1)}))\right)} + 1.067 \quad (14)$$

V. NUMERICAL RESULTS

In this section, pseudo heartbeat message compression among AOL applications and video applications is considered and the performance within an OFDMA communication system is tested. Assuming that M AOL applications are running in the background, and the parameters of FR and FS are 30 fps and QCIF, respectively, and the coding rate R_T is $\frac{2}{3}$. The initial TBR is set to be 100 Kbps and the average heartbeat message periodicity T_h is set to 100 seconds. The probability density function C is 1×10^{-4}. Assuming that the channel quality is stationary and the network conditions adjustment factor α is set to be 0.4. The performance analysis of the pseudo heartbeat message compression model is simulated by using matlab and the parameters are listed in table II.

TABLE II
SYSTEM PARAMETERS

System parameters	Description	Value
BW	System bandwidth	5Mhz
B_s	Bandwidth per subcarrier	15Khz
N_{sc}^{RB}	Number of subcarrier per resource block	12
N_{RS}	Number of reference signal	8
N_{CR}	Number of control signal	3
N_s	Number of slots per subframes	2
N_{OFDM}	Number of OFDM symbols per solts	7
M_{mod}	Spectral efficiency in cell	4
u	Average number of data arrival	0.006
q	The success probability of packet transmission	0.95

In Fig.2, the larger the number of AOL application users is, the higher the improvement of the QoE of video is. This result shows that the proposed scheme is quite useful to improve the QoE of video users, especially with a large number of AOL application users in the hotspot. The success of the mechanism can be attributed to the reduced number of signaling messages transmitted or received by an AOL users' device when the proposed compression scheme is used. In addition, the saved wireless resource growth for the increasing AOL users is tremendous because more signaling are intercepted, which indicates the potential of the pseudo heartbeat message compression mechanism to support large number of AOL users.

Fig.3 presents the relationship between QoE improvement of AOL application and that of video. We can obtain that the performance of real-time video users improves while the AOL user degrades as the compression frequency N increases. Fig.3 implies the evident trade-off between the QoE of AOL users and real-time video users when we choose the proper parameters of our proposed mechanism.

Fig.4 demonstrates the influence of the pseudo heartbeat message compression on the video and AOL applications. Resources saved by decreasing heartbeat messages improve the QoE of video users by 1.32 while slightly reducing the QoE of AOL users by a factor of 0.11 (from 1 to 0.89). Previous methods for solving signaling overloaded often decrease the signaling in the network by changing the network mechanism to adapt to the characteristics of the current Internet applications. However, the proposed approach, which

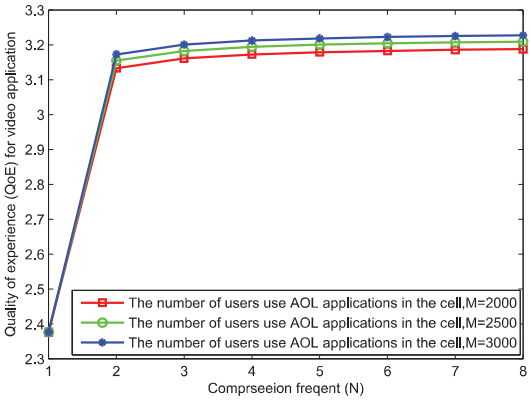

Fig. 2. Variation of QoE of video users with compression frequency N with different numbers of AOL application users in cell.

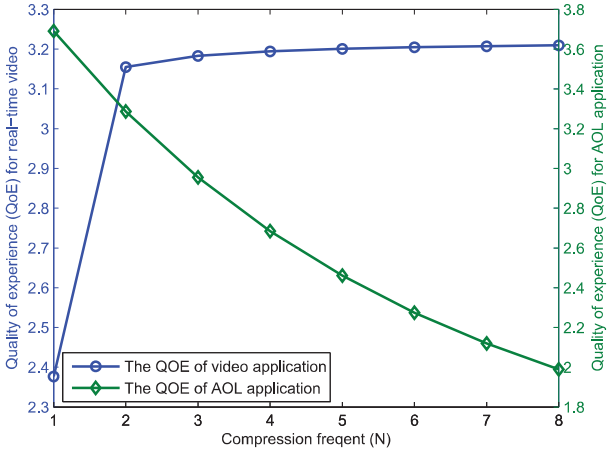

Fig. 3. Relationship between QoE improvement of AOL application and that of video.

can be considered a case of preferential treatment intercepting the heartbeat messages, is easy to deploy without changing the feature of AOL applications.

VI. CONCLUSIONS

In this paper, we proposes a pseudo heartbeat message compression mechanism to fundamentally solve the signaling overload while guarantee the QoE of services. We first construct the framework of the pseudo heartbeat message compression and then analyze the influence of the mechanism on the AOL and video services. As the prevalent of smartphone handsets and internet applications, the large number of heatbeat messages occupy the limited wireless resource, which leads to overload of network, even to paralyze the network. Simulation results show that the proposed mechanism can greatly decrease the heartbeat messages and increases the video QoE about 1.32 times with a slight lose about 0.11 of AOL application QoE. Hence, the proposed mechanism is a promising method to address the above issues. Future

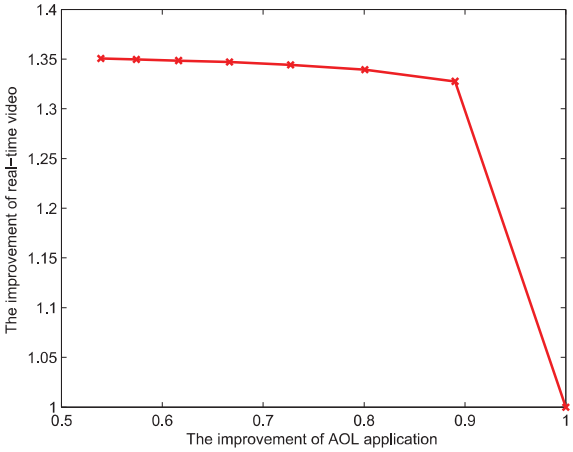

Fig. 4. Tradeoff curve between QoE improvement of AOL application and that of video.

works can involve further exploration along these dimensions by including dynamic resource allocation and considering QoE in employing offloading and load balancing techniques.

***Abstract*—Peer-to-peer or device-to-device communications is an active field of research and development. It offers the potential of great improvement in the delivery and monitoring of ever growing data services ranging from social networking, gaming, advertisement, emergency communications (especially the case when infrastructure based systems such as base stations or access points have been knocked down by natural disasters).**

The current state of the art includes device-to-device communications for proximity services currently in development by LTE. Also, Wi-Fi Direct that aims to replace Wi-Fi ad-hoc mode, and proprietary systems such as FlashLinQ by Qualcomm. However, the mentioned systems still rely on infrastructure for network synchronization and/or discovery and management.

The IEEE 802.15.8 Peer-Aware-Communications (PAC) Task Group (TG8) aims to develop ad hoc peer-to-peer communications, infrastructure-less and with fully distributed coordination. Some PAC features include discovery of peers information without association, scalable number of devices during discovery, scalable data transmission rates, simultaneous multi-group communications, among others.

***Index Terms*—Device-to-device communications; Emergency communications infrastructure-less; IEEE802.15 Standardization.**

I. Concept and architecture

A PAC system contains the following functionalities:

- For the challenging fully distributed network synchronization, TG8 introduces a modified firefly algorithm, which allows to reach network synchronization regardless of the topology.
- Once PAC devices (PDs) are synchronized, such PDs proceed to discover or being discovered during the discovery period. In this phase, discovery information are passed to/from higher layers related to PD ID, group ID, application ID, etc.
- After discovery, PDs may request a communication link. Such next phase is association; However, as this is done in a peer-to peer basis, the process is named *peering*.
- After PDs have successfully established a communication link (authentication and security included), they proceed to communicate either contention based of contention free under a TDD scheme during the communication period.
- Power control (open loop for the CFP and close loop for CAP) aims best performance by maintaining adequate SINR.
- A measurement and report unit conducts measurements for channel information, like clear channel assessment (CCA), channel scanning, channel quality indication (CQI), etc. and it reports to upper layers. An scheduling unit controls the assessment of resources for communication based on SINR and QoS for the CFP.
- The PHY consists of FEC, scrambling, interleaving, modulation, multi-carrier modulation and multiple antennas in the form of MIMO techniques or beamforming.

II. Topology

PAC network topologies support one-to-one and one-to-many (group or multicast communications), having simultaneous communication sessions for the same or different applications as illustrated in Figure **??**.

Fig. 1. *Topology.*

III. Reference model

In accordance with the IEEE 802® reference model, PAC devices are internally partitioned into a physical layer (PHY) and data link layer (medium access control (MAC) sublayer and logical link control (LLC) sublayer). Although there is a modification respect to the OSI model as higher layers can have direct access to the MAC sublayer.

IV. MAC sublayer

A. Superframe

The MAC superframe structure is defined as illustrated in Figure **??**. The superframe is divided into 5 periods in

the following order: synchronization period, discovery period, peering period, communication period containing a contention access period (CAP), and contention free period (CFP).

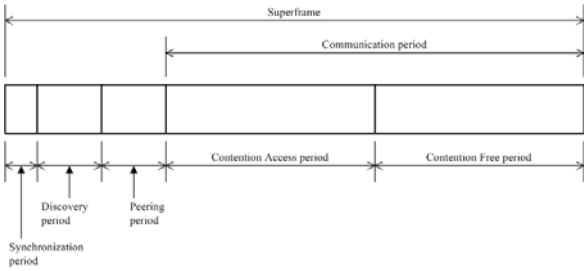

Fig. 2. *MAC superframe.*

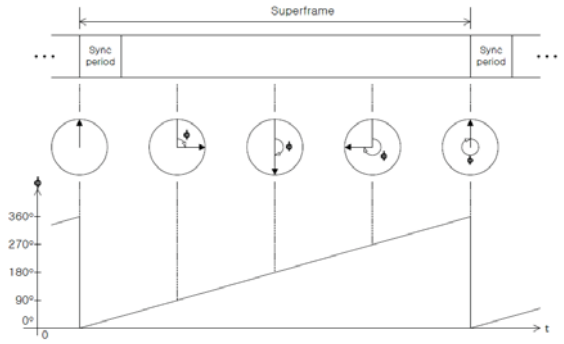

Fig. 3. *Superframe and phase of a synchronization timer.*

B. Network synchronization

The synchronization period is used to transmit a set of preambles that are used for network synchronization. In synchronized mode, PAC operates in fully distributed synchronization. Two modes of network synchronization are envisioned:

- Synchronization among PDs can be achieved by the transmission and reception of a synchronization reference signal. In case there is already synchronization among PDs, each PD may send its synchronization reference signal to maintain synchronization.
- The synchronization reference signal may be transmitted by a single PD dynamically elected from a group of PDs.

1) Transmission of synchronization signal: The synchronization signal is transmitted during the synchronization period using random access to avoid collision. The length of synchronization period is equivalent to the length of backoff slots, where one backoff slot is equivalent to the length of two OFDM symbols. The random access scheme is as follows:

a) Each PD maintains its own contention window (CW).
b) A PD selects an integer n randomly drawn from $(0, 1, 2, , CW - 1)$ and sets its backoff counter to the selected random integer n, and follows backoff procedure until its backoff counter becomes zero. Then the PD transmits a synchronization signal, and sets its backoff counter to $CW - 1 - n$, and follows backoff procedure until its backoff counter becomes zero, at which point it goes to step 3).
c) A PD updates its CW and goes to step b).

2) Adjustment of reference timing: All PDs maintain a synchronization timer whose phase ϕ varies from 0 to 360^0. Each PD does transmit a synchronization signal when its clock's phase, ϕ, reaches 360^0 and using the random access procedure described before. The relationship between the MAC superframe and synchronization timer is illustrated in Figure **??**.

When a PD receives the synchronization signal, it adjusts its reference timing by changing its phase ϕ based on the reference timing obtained from the received synchronization signal. The rule for a PD to update its phase ϕ of its synchronization timer is as follows:

1) If phase $\phi < 180^0$, then the PD does not change its reference timing.
2) If phase $\phi \geq 180^0$, then the PD adjusts such phase value to 360^0.

C. Discovery

PAC systems support the following discovery types:

- Advertisement: In this type of discovery, a PD transmits its discovery information and does not expect responses.
- Publish/Subscribe: in this type of discovery, a PD transmits its discovery information and expects responses.
- Query/Reply: in this type of discovery, a PD transmits its discovery information as response to a request to do so.

The discovery information conveys the following IDs: device ID (48 bits MAC address), peer ID (56 bits), group ID (8 bits), application ID (56 bits). The discovery procedure should support mechanisms to ensure privacy that a PD is not tracked, and protection of identity from impersonation.

D. Peering

Peering (association) is the procedure to establish a communication link among discovered PDs.

1) Random access procedure for peering for CFP: Once network synchronization and detection of discovery information are achieved, PDs may request peering to a target PD, at any time. Consequently, the random access can be requested during the peering period, in which control signals are interchanged in order to schedule the intended PDs for transmission.

E. Communication

Data packets for unicast, multicast, or broadcast are transmitted during the communication period (either CAP or CFP) as illustrated in Figure **??**. Details are still in progress in the Task Group IEEE802.15.8.

V. General PHY layer requirements

The proposed PHY layer provides a data interface to the MAC sublayer under the control of the physical layer convergence protocol (PLCP). The proposed PHYs are:

- Low mobility PHY: OFDM multi-carrier modulation with BPSK, QPSK, 16QAM and 64QAM symbols, operating in the 2.4 GHz and 5.7 GHz bands.
- High mobility PHY: OFDMA multicarrier modulation with BPSK, QPSK, 16QAM and 64QAM symbols operating in sub-GHz, 2.4 GHz and 5.7 GHz bands.
- UWB PHY: combined burts position modulation (BPM) and BPSK modulation, OOK modulation, operating in the 4.2 – 10 GHz band.

Due to the lack of space, we describe the high mobility PHY layer only.

VI. High Mobility PHY

The physical layer protocol data unit (PPDU) is formed by concatenating the synchronization preamble, the physical layer header (PHR), the discovery signal, peering signal, and the physical layer service information data unit (PSDU) signal, respectively. The PSDU is formed by N data-channels. Each data channel is sub-divided into scheduling and data frame. Each data frame consists of 10 TDD slots: two switching slots (denoted as S) and eight data slots. Each data slot consists of seven OFDM symbols with duration of 0.5 ms.

A. PSDU construction

The PSDU data is encoded by quasi-cyclic low density parity check codes (QC-LDPC), which allow performance close to turbo codes, besides that encoder/decoder enable high throughput and efficient implementation in parallel architectures. Furthermore, interleaving, scrambling, symbol modulation, MIMO layer mapping and OFDM are applied as well.

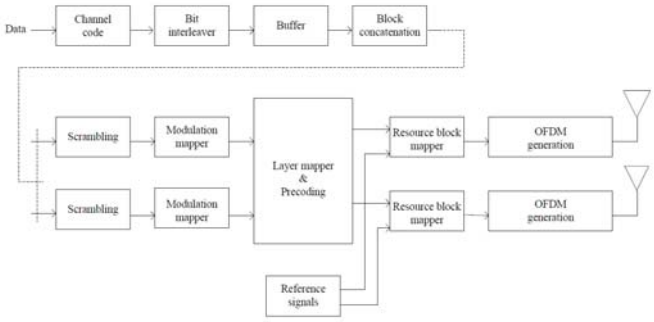

Fig. 4. *PSDU construction.*

B. QC-LDPC encoder parameters

Quasi-cyclic LDPC codes are systematic, linear codes satisfying $\boldsymbol{H}\boldsymbol{c}^T = \mathbf{0}$; where $\boldsymbol{H}_{n-k\text{x}k}$ is the parity check matrix, k is the number of information bits, n is the number of coded bits and $n-k$ is the number of parity bits.
$\boldsymbol{H}$ is constructed from a prototype matrix $\boldsymbol{H}_{p|M p\text{x}N p}$ by replacing each entry of the prototype matrix, denoted as $[H_p]_{i,j}$ with either a cyclic shift matrix, $\boldsymbol{P}_c$, or identity matrix or null matrix of size $Z\text{x}Z$. The final size of $\boldsymbol{H}$ is $MpZ\text{x}NpZ$.

$$[H_p]_{i,j} = \begin{cases} \boldsymbol{I}_{z\text{x}z} & \text{if } [H_p]_{i,j} = 0 \\ \mathbf{0}_{z\text{x}z} & \text{if } [H_p]_{i,j} = \text{"}-\text{"} \\ \boldsymbol{P}_c & \text{if } [H_p]_{i,j} = p \end{cases} \quad (1)$$

where $p > 0$ is an integer number, and "-" denotes a character. The cyclic-permutation matrix $\boldsymbol{P}_c$ is obtained by cyclically shifting the columns of $\boldsymbol{P}_0 = \boldsymbol{I}_{Z\text{x}Z}$ to the right c times. The prototype matrices are not shown for the lack of space.
The total number of coded bits in a packet is $N_{T_{cw}} = n\, N_{CW}$, where N_{CW} is the number of codewords. The coded bits are indexed as c_{nq+i} for $i = 0, 1..., n-1$ and $q = 0, 1, ..., N_{CW} - 1$.

C. Interleaver

Interleaving is based on maximum contention-free quadratic permutation interleaver. Thus, latency is minimized and the interleaver can be integrated on parallel architectures within the encoder/decoder chip implementation. A maximum contention-free quadratic permutation interleaver is defined as:

$$\Pi(i) = f_1 i + f_2 i^2 \,\text{Mod}\, N_I \quad (2)$$

where N_I is the interleaver's length. The coded bits are interleaved in blocks of N_I bits as $c_{\Pi(j \,\text{Mod} N_I)}$ for $j = 0, ..., N_{T_{cw}} - 1$.

D. Scrambler

A Gold code generator of length 63 is employed as scrambler. A scrambler is used to shape the data spectrum and randomize data across users in order to reduce interference. As the Gold code generator is formed by two PN sequences with period $L = 2^{63}$, its output remains random even for long packets. Moreover, different initialization seeds, enables a different Gold code sequence per user and consequently low correlation respect to other user using a different seed. The Gold code generator is constructed by two PN sequence generators with polynomials $x^6 + x + 1$ and $x^6 + x^5 + x^2 + x + 1$. The Gold code generator output is indicated by s_i, which is used to scramble the interleaved-coded bits as $b_i = (c_{\Pi(i \,\text{Mod}\, N_I)} + s_{i \,\text{Mod}\, L}) \,\text{Mod}\, 2$ for $i = 0, 1, ..., N_{T_{cw}} - 1$.

E. Modulation mapper

After scrambling, b_i bits are modulated with BPSK, QPSK, 16QAM or 64QAM. The modulation symbols, d_l, as function of the input bits, b_i are given in Figure **??**. The bit index $i = 0, ..., N_T - 1$ and symbol index $l = 0, ..., N_{sym} - 1$, where $N_{sym} = N_T \text{Log}_2(M)$, and N_T is the total number of bits on the air per packet. The mapping onto complex symbols $I + jQ$ for the different modulation schemes can be found in the literature.

Modulation	Complex symbol	$\text{Log}_2(M)$
BPSK	$d_l(b_l)=I+jQ$	1
QPSK	$d_l(b_i, b_{i+1})=I+jQ$	2
16QAM	$d_l(b_i, b_{i+1}, b_{i+2}, b_{i+3})=I+jQ$	4
64QAM	$d_l(b_i, b_{i+1}, b_{i+2}, b_{i+3}, b_{i+4}, b_{i+5})=I+jQ$	6

Fig. 5. *Symbol modulations.*

F. Layer mapping

Two MIMO technologies are supported: open loop spatial multiplexing and transmit diversity in the form of space-frequency block codes, for 2 and 4 antennas. The transmission in MIMO mode depends on the number of antennas that can be implemented. The complex modulation symbols for the qth codeword, for $l = 0, 1, ..., N^q_{sym} - 1$ are mapped into several layers as

$$[d^q_0, ..., d^q_{N^q_{sym}-1}] \rightarrow [x_0(i), ..., x_{\nu-1}(i)] \tag{3}$$

for $i = 0, ..., N^L_{sym} - 1$, where ν is the number of layers and N^L_{sym} is the number of symbols per layer. A layer is an independent stream of symbols in a MIMO configuration. The MIMO channel's rank is the number of layers enable.

1) Open loop spatial multiplexing: Spatial multiplexing represents the transmission of multiple parallel streams of symbols. The mapping of modulation symbols to layers is shown in Figure **??**. The number of layers is less or equal to the number of antennas, $\nu \leq P$.

No of layers	No of codewords	Mapping	Parameter
1	1	$x_0(i) = d^0_i$	$N^L_{sym} = N^0_{sym}$
2	1	$x_0(i) = d^0_{2i}$ $x_1(i) = d^0_{2i+1}$	$N^L_{sym} = N^0_{sym}/2$
2	2	$x_0(i) = d^0_i$ $x_1(i) = d^1_i$	$N^L_{sym} = N^0_{sym} = N^1_{sym}$
4	1	$x_0(i) = d^0_{4i}$ $x_1(i) = d^0_{4i+1}$ $x_2(i) = d^0_{4i+2}$ $x_3(i) = d^0_{4i+3}$	$N^L_{sym} = N^0_{sym}/4$
4	2	$x_0(i) = d^0_{2i}$ $x_1(i) = d^1_{2i+1}$ $x_2(i) = d^0_{2i}$ $x_3(i) = d^1_{2i+1}$	$N^L_{sym} = N^0_{sym}/2 = N^1_{sym}/2$

Fig. 6. *Mapping for spatial multiplexing.*

2) Transmit diversity: Transmit diversity is created by transmitting the same information from multiple antennas. The mapping of modulation symbols to layers is shown in Figure **??** (If $N^q_{sym} \,\text{Mod}\, 4 \neq 0$ add m null symbols at the end such that $N^q_{sym} + m \,\text{Mod}\, 4 = 0$).

G. Precoding

The block of symbols obtained from the layer mapping, $\boldsymbol{x}_p$, are mapped onto the block of symbols $\boldsymbol{y}_p$, to be transmitted by P antennas as illustrated in Figure **??**.

No of layers	No of codewords	Mapping	Parameter
2	1	$x_0(i) = d^0_{2i}$ $x_1(i) = d^1_{2i+1}$	$N^L_{sym} = N^0_{sym}/2$
4	1	$x_0(i) = d^0_{4i}$ $x_1(i) = d^0_{4i+1}$ $x_2(i) = d^0_{4i+2}$ $x_0(i) = d^0_{4i+3}$	$N^L_{sym} = \begin{cases} N^0_{sym}/4 & \text{If } N_{sym}\text{Mod}4 = 0 \\ \dfrac{N^0_{sym}+m}{4} & \text{If } N_{sym}\text{Mod}4 \neq 0 \end{cases}$

Fig. 7. *Mapping for transmit diversity.*

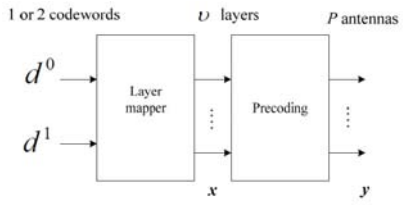

Fig. 8. *Precoding mapping.*

1) Open loop spatial multiplexing: Precoding for open loop spatial multiplexing delivers performance robustness by feeding back the channels rank. Such channels rank is indicated by 2 bits in the control channel of the TDD frame. Consequently, the transmitter can choose a pre-fixed codeword according to the channels rank.

2) Transmit diversity: Transmit diversity is aimed to increase robustness in scenarios with low SNR, low delay tolerance or no feedback to the transmitter is available or reliable. In case of 2 antennas, the space-frequency block codes (SFBC) are defined by

$$\begin{bmatrix} y_0(2i) & y_0(2i+1) \\ y_1(2i) & y_1(2i+1) \end{bmatrix} = \frac{1}{\sqrt{2}} \begin{bmatrix} x_0(i) & x_1(i) \\ -x^*_1(i) & x^*_0(i) \end{bmatrix} \tag{4}$$

where $i = 0, ..., N^L_{sym} - 1$ and $N^P_{sym} = 2N^L_{sym}$. In case of 4 antennas a combination of SFBC for 2 antennas with frequency switch transmission diversity is employed.

H. Multicarrier modulation

The multicarrier modulation parameters for OFDM are given in Figure **??**. The subcarrier spacing of 15 KHz ensures a good compromise for handling delay spread in radio channels and digital radio implementations availability.

Description	Notation
Total No of subcarriers	MFFT=1024
Subcarrier spacing	Δf=15 KHz
Sampling time	T_s=1/(Δf MFFT)=65.1 nsec
Clock rate	R_c=1/T_s=15.36 MHz

Fig. 9. *Multicarrier parameters.*

The cyclic prefix length covers 73 sampling points with duration $73Ts = 4.75$ μsec.

1) Resource block : A resource block (RB) is a set of time-frequency slots for data communication and enabling multiple access. A RB is formed by a slot time of 0.5 msec ($N_{symb} = 7$ OFDM symbols) and $N_{sc}^{RB} = 6$ subcarriers or 90 KHz spectrum. The total number of RBs is $N_{RB} = 170$ (the 2 upper and lower subcarriers are empty). Different transmission bandwidths are obtained by concatenating RBs as $BW = nN_{sc}^{RB}\Delta f$, where $12 \leq n \leq 111$.

I. Carrier aggregation

In order to have coexistence with Wi-Fi, carrier aggregation with one more channel of 10 MHz can be added to increase the transmission bandwidth to 20 MHz. Such carrier aggregation is granted by the MAC and signaled to the PHY by one bit in the control channel of the TDD frame. The aggregated channel can be considered as a single enlarged channel of 20 MHz from the RF viewpoint. Hence, the same RF front end can be used without modifications.

VII. Simulations

A. Receivers

The optimum detection of coded MIMO systems is performed in terms of joint detection and decoding. However, such optimum implementation complexity is prohibited high in practical applications. On the other hand, there are plenty of proposed suboptimum techniques that try to balance implementation complexity and performance. One popular approach is MMSE-SIC (minimum mean square error-successive interference cancelation) detection. However, the most promising sub-optimum approach with close optimum performance and [relative] low complexity implementation is iterative MIMO decoding, as illustrated in Figure **??**. The core idea is independent MIMO detection and iterative channel decoding.

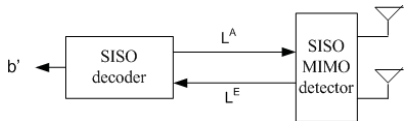

Fig. 10. *Iterative MIMO decoding.*

B. Channel models

The small scale channel models are based on the ITU and ETSI-BRAN channel models. Such models were extended to the popular correlated MIMO fading channel model as well. Details, including MatLab® scripts, can be found in [**?**].

C. Results

Figure **??** shows the PER performance with 1/2 rate CC, OFDM with 16QAM symbols and spatial multiplexing MIMO configuration for 4x4 antennas (ITU MIMO channel for low correlation and pedestrian).
Additionally, We present the PER performance for QC-LDPC(324,648), rate 1/2, OFDM with BPSK symbols for 1x1 antennas configuration and decoding with SPA=sum-product algorithm, MPA=message passing algorithm and OMS=offset min-sum algorithm, (ITU channel model for pedestrian), as it is shown in Figure **??**.

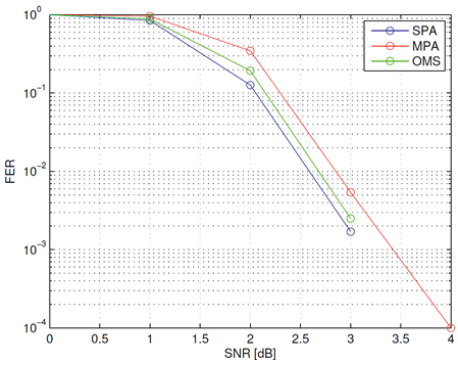

Fig. 12. *Performance of QC-LDPC with one antenna.*

VIII. Conclusions

A survey of IEEE 802.15.8 Peer-Aware-Communications (PAC) Task Group (TG8) activities towards the standardization of technologies to develop peer-to-peer or device-to-device (D2D) communications, infrastructure-less and with fully distributed coordination. Peer-to-peer communications is an active field of research and development, in particular for gaming, advertisement and emergency communications. Some performance results are presented for the high mobility PHY.

***Abstract*—A cooperative spectrum sensing (CSS) scheme for cognitive radio network (CRN) is proposed in this paper. The energy values from different cognitive radios (CRs) are used to perform the soft combining operation. More precisely, we analyze the performance of CSS with several soft data fusion schemes: square law selection (SLS), maximal ratio combining (MRC), square law combining (SLC), and selection combining (SC) in Nakagami-n (Rician) fading environment. Towards that, an expression of detection probability in closed-form for each soft data fusion scheme in Rician fading channel is derived. A comparative performance of soft data fusion schemes has been illustrated for different network and channel parameters. Further, the performance comparison between soft data and hard decision combining schemes (such as majority-rule, AND-rule, and OR-rule) is also investigated.**

***Index Terms*—Cooperative spectrum sensing, soft data fusion, fading channel, detection probability.**

I. Introduction

The spectrum of primary users (PUs) can be opportunistically accessed and shared by secondary users (SUs) provided it does not cause detrimental interference to the PUs [1]. Therefore, sensing the spectrum of a PU is important, since it is essential to detect the presence of PUs reliably. The operation is quite challenging when the PU signal format is unknown. In such scenarios, utilization of an energy detector (ED) is the suitable choice to detect the status of a PU [2], [3]. When compared to a single CR sensing, cooperative spectrum sensing (CSS) helps increasing the reliability of detection in the presence of uncertainties in sensing (S) channel. More precisely, in CSS, it is possible to improve the detection performance where all CRs sense the PU individually and report their sensing information to a fusion center (FC) via reporting (R) channels. Next, the FC fuses the received local sensing information to decide about the presence or the absence of the PU and reports back to the CRs. There are several soft and hard decision combining fusion schemes which can be implemented at FC to perform the fusing operation [4]. In the case of soft data fusion, CRs forward the entire sensing data (i.e., received energies at each CR) to the FC without performing any local binary decision at each CR (where '1' or '0' is forwarded to the FC in the case of hard decision fusion).

The existing literature on ED based CSS [5], assumes several fading models in S-channels such as Rayleigh, Nakagami-m, Rician, Hoyt, Weibull, and Log-normal shadowing for sensing. In these cases, the performance of CSS is evaluated only under several hard decision fusions such as majority-rule, AND-rule, and OR-rule. In contrast to hard decision fusion, it is possible to implement soft data fusion schemes (SLS, MRC, SLC, and SC) at FC to improve the performance of CSS further [6]. However, in [6], the results on the basis of simulation framework is only presented. This has motivated us to develop analytical framework and to evaluate the performance of CSS with soft data fusion schemes in fading channel. For analytical tractability, we assume that the R-channels are considered as ideal [7] where as S-channels are assumed to be noisy and Nakagami-n (Rician) fading. Rayleigh fading channels in which the reflected and scattered waves are dominated by one strong component are modeled by Nakagami-n distribution, known as the Rician distribution [8]. In this paper, we investigate the performance analysis of CSS with different soft data fusions: SLC, MRC, SLS, and SC, through complementary receiver operating characteristics (CROC) in Rician fading channel. Appropriate analytical formulations and a simulation test bed has been proposed using which our formulations have been validated. Specifically, in this paper, our contributions are as follows:

- The expressions of overall probability of detection ($\bar{Q}_d$) for different soft data fusion schemes such as SLS, MRC, SLC, and SC in Rician channel are derived analytically. To the best of our knowledge the derivation of $\bar{Q}_d$ for Rician case is not available in the literature.
- The variable substitution method (or theta approach) is proposed in this paper to solve the unsolvable expression of $\bar{Q}_d$ for SC fusion scheme in Rician channel.
- Impacts of channel and network parameters: fading parameter (K); time-bandwidth product (u); average S-channel SNR; and the number of CRs (N) on overall sensing performance is investigated.
- Qualitative performance comparison of soft data fusion schemes (SLC, MRC, SLS, and SC) with the hard decision fusion schemes has been studied.

The work is partitioned in to next three sections. The system model related to several soft schemes for CSS has been discussed in Section II. Further, the probability of detection expressions for various fusion schemes in Rician fading are derived. In Section III, simulation and analytical results are discussed. In Section IV, conclusions are presented.

II. System Model

Fig. 1 shows a proposed CSS system with N CRs, a fusion center (FC), and a primary user (PU). Each CR senses the PU individually using energy detector (ED) which is shown in Fig. 2 and send its sensing data in the form of energy values to the FC through R-channels. Next, the FC gathers these sensing data (energy values) which are coming from individual CRs. Then, FC employs any one of the soft data combining techniques such as square law selection (SLS), square-law combining (SLC), selection combining (SC), and maximal ratio combining (MRC) to make the decision of PU (presence or absence) globally. Signals from multiple CRs are combined to achieve an improved average SNR. In this paper, we assume that Nakagami-n (Rician) fading and noise affecting the S-channels while the R-channels are considered as ideal (noiseless) channels.

The received signal at k-th CR, $x_k(t)$ can be written as:

$$x_k(t) = \begin{cases} n_k(t) & : H_0 \\ h_k(t)s(t) + n_k(t) & : H_1 \end{cases} \quad (1)$$

where $s(t)$ is the PU signal with energy E_s and $n_k(t)$ is the additive white Gaussian noise (AWGN) at k-th CR. The S-channel fading coefficient for the k-th CR is denoted as h_k. Two hypotheses, denoted as H_0 and H_1 which indicates PU's absence and presence, respectively. When the PU is absent i.e. under hypothesis H_0, CR receives only the noise signal at the input of the energy detector and the noise energy at k-th CR can be approximated over the time interval $(0, T)$, following [2], [3] as:

$$\int_0^T n_k^2(t)dt = \frac{1}{2W}\sum_{i=1}^{2u} n_{k_i}^2 \quad (2)$$

where $n_{k_i} = n(i/(2W))$, $u = TW$ indicates time-bandwidth product, T indicates observation time, and W indicates PU signal's bandwidth. It can check easily that n_{k_i} is Gaussian with mean zero and variance $N_{01}W$ ($n_{k_i} \sim \mathcal{N}(0, N_{01}W); \forall i$ where $N_{01}W$ is spectral density of one-sided noise power). If we define $n'_{k_i} = n_{k_i}/\sqrt{N_{01}W}$, the received signal energy under H_0 at k-th CR, denoted as E_k, can be written as:

$$E_k = \sum_{i=1}^{2u} n'^2_{k_i} \quad (3)$$

The same approach is followed to evaluate the received signal energy under hypothesis H_1 at the k-th CR when the primary signal is present with the replacement of each n_{k_i} terms with $n_{k_i} + s_i$, where $s_i = s(i/(2W))$.

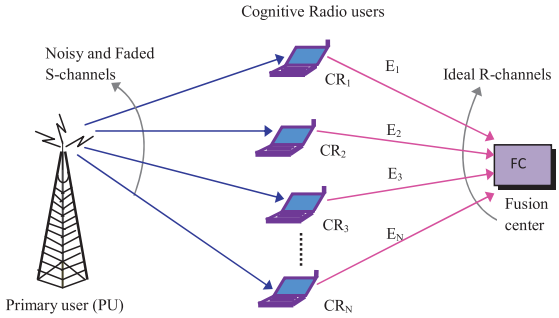

Fig. 1. Cooperative spectrum sensing scenario.

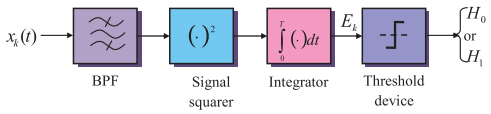

Fig. 2. Energy detector with local decision.

A. Soft Data Fusion Schemes Over Non-fading Channel

In the case of CSS with MRC fusion scheme, all CRs send their respective energy values with appropriate weighting to the FC. Then FC gathers all the data (energy values with appropriate weighting) from all CRs, and combines. The combined energy value is passed through an ED and makes a global decision about the PU. It may be noted that as we assume R-channels to be ideal (noiseless), the MRC rule at FC becomes simple summation of the received signals from all the CRs [9]. The SC scheme which selects the signal from the branch with the largest instantaneous S-channel SNR, and performs energy detection based on the signal from the selected path. The less complexities and less power consumption are offered by SC scheme as compared to MRC fusion scheme. In low SNR, a significant improvement in SNR with a limited number of branches is not guaranteed by the MRC and SC schemes. It is also noted that, MRC (a coherent combining technique) needs information on each channel status in the case of non-coherent detection, which results in high design complexity. SLC and SLS (energy-law combining techniques) are more attractive diversity techniques for energy detection [10] to overcome the drawbacks of MRC. The final test statistic can be obtained by the energy-law combining techniques which fuse the energy of each branch. Under the SLC fusion scheme, the squared and integrated energy vectors $E^1, E^2, \cdots, E^N$, from N distributed CRs are gathered at a FC, where the test statistic, $E_{lc} = \sum_{k=1}^{N} E^k$ is formed at FC. Under the SLS fusion scheme, the FC only selects the branch with the largest energy i.e. $E_{ls} = max(E_1, E_2, \cdots, E_N)$. This largest energy is compared with the threshold and final decision is taken place at FC.

Table I shows the expressions for overall detection and false alarm probabilities at FC under the SLS fusion, MRC

TABLE I
Q_d AND Q_f EXPRESSIONS FOR DIFFERENT SOFT DATA SCHEMES FOR AWGN ENVIRONMENT.

Combining Schemes	Q_d	Q_f
SLS	$1-\prod_{k=1}^{N}[1-Q_u(\sqrt{2\gamma_k},\sqrt{\lambda})]$	$1-[1-\Gamma(u,\lambda/2)/\Gamma(u)]^N$
MRC	$Q_u(\sqrt{2\gamma_{rc}},\sqrt{\lambda})$	$\Gamma(u,\lambda/2)\Gamma(u)$
SLC	$Q_{Nu}(\sqrt{2\gamma_{lc}},\sqrt{\lambda})$	$\Gamma(Nu,\lambda/2)/\Gamma(Nu)$
SC	$Q_u(\sqrt{2\gamma_{sc}},\sqrt{\lambda})$	$\Gamma(u,\lambda/2)/\Gamma(u)$

fusion, SLC fusion, and SC fusion schemes following [9], [11] under non-faded (AWGN) environment. The symbols $\gamma_{rc}=\sum_{i=1}^{N}\gamma_i$ denotes the instantaneous SNR at the output of the MRC combiner; $\gamma_{lc}=\sum_{k=1}^{N}\gamma^k$, where γ^k denotes the instantaneous S-channel SNR at k-th CR; and γ_{sc} = $\max(\gamma^1,\gamma^2,...,\gamma^N)$ denotes the instantaneous SNR at the output of the SC combiner [12]. Also one can easily observe that the expressions for Q_d and Q_f for SLC scheme can be obtained from the expressions of MRC scheme by substituting simply u with Nu as we know that $\gamma_{rc}=\gamma_{lc}$.

B. Soft Data Fusion Schemes Over Rician Fading Channel

It is seen from Table I that the expression for Q_d of any soft data fusion scheme gives as a function of the S-channel SNR (γ). Under fading scenario, by averaging Q_d of any fusion scheme, the average overall detection probability ($\bar{Q}_d$) may be derived i.e.,

$$\bar{Q}_d=\int_0^\infty Q_d f_\gamma(\gamma)d\gamma \tag{4}$$

where $f_\gamma(\gamma)$ indicates the PDF of γ under fading and it depends on type of fusion scheme. From [9] and [11], it is observed that the PDF of SLS combining scheme for Rician fading channel is same as its basic PDF of SNR under that fading and the PDF of SLC scheme for Rician channel is same as PDF of MRC of that faded channel, only is replaced γ_{rc} with γ_{lc}. The average overall false alarm probability ($\bar{Q}_f$), is same as the expressions for Q_f for all soft data fusion schemes, as given in Table I, when the S-channel is corrupted by fading due to independence of Q_f from SNR.

Assuming independent and identically distributed (i.i.d) N number of Rician faded S-channels, the average Q_d in Rician fading under SLS scheme, $\bar{Q}_{d,ls,Ric}$, can be obtained by substituting PDF of the SNR of SLS and Marcum-Q function of Q_d in the form of infinite series [5, (21)] given in Table I in (4) as:

$$\begin{aligned}\bar{Q}_{d,ls,Ric}=1-\prod_{k=1}^{N}\Bigg(1-\frac{1+K}{\bar{\gamma}_k}\exp(-K)\\ \times\sum_{n=0}^{\infty}\frac{\Gamma(u+n,\lambda/2)}{\Gamma(u+n)}\left(\frac{\bar{\gamma}_k}{1+K+\bar{\gamma}_k}\right)^{n+1}\\ \times{}_1F_1\left[n+1;1;\frac{K(1+K)}{1+K+\bar{\gamma}_k}\right]\Bigg).\end{aligned} \tag{5}$$

An alternative expression of $\bar{Q}_{d,ls,Ray}$ can be achieved by putting $K=0$. The above result is an entirely new result and is not available in the literature.

Under MRC fusion scheme, the average Q_d in Rician fading, $\bar{Q}_{d,rc,Ric}$, can be evaluated by substituting PDF of the SNR at the output of MRC combiner [6] and Q_d given in Table I in (4) i.e.,

$$\begin{aligned}\bar{Q}_{d,rc,Ric}=\exp(-NK)\left(\frac{1+K}{\bar{\gamma}}\right)\left(\frac{1+K}{NK\bar{\gamma}}\right)^{\frac{N-1}{2}}\\ \times\int_0^\infty Q_u\left(\sqrt{2\gamma_{rc}},\sqrt{\lambda}\right)\exp\left(-\frac{(1+K)\gamma_{rc}}{\bar{\gamma}}\right)\\ \times\gamma_{rc}^{(N-1)/2}I_{N-1}\left(2\sqrt{\frac{NK(1+K)\gamma_{rc}}{\bar{\gamma}}}\right)\end{aligned} \tag{6}$$

By expressing Marcum-Q function in the form of infinite series as below, the integral in (6) can be evaluated as

$$\begin{aligned}\bar{Q}_{d,rc,Ric}=NK\exp(-NK)\left(\frac{1+K}{NK\bar{\gamma}}\right)^{\frac{N+1}{2}}\\ \times\sum_{n=0}^{\infty}\frac{\Gamma(u+n,\lambda/2)}{\Gamma(u+n)n!}\int_0^\infty\exp\left[-\gamma_{rc}\left(\frac{1+K+\bar{\gamma}}{\bar{\gamma}}\right)\right]\\ \times\gamma_{rc}^{n+\frac{N-1}{2}}I_{N-1}\left(2\sqrt{\frac{NK(1+K)\gamma_{rc}}{\bar{\gamma}}}\right)d\gamma_{rc}\end{aligned} \tag{7}$$

and with the help of result given [8, (B.16)], the above integral can be solved as to obtain

$$\begin{aligned}\bar{Q}_{d,rc,Ric}=\left(\frac{1+K}{1+K+\bar{\gamma}}\right)^N\exp(-NK)\\ \times\sum_{n=0}^{\infty}\frac{\Gamma(u+n,\lambda/2)}{\Gamma(u+n)n!}\frac{\Gamma(n+N)}{\Gamma(N)}\left(\frac{\bar{\gamma}}{1+K+\bar{\gamma}}\right)^n\\ \times{}_1F_1\left[n+N;N;\frac{NK(1+K)}{1+K+\bar{\gamma}}\right].\end{aligned} \tag{8}$$

An alternative expression of $\bar{Q}_{d,rc,Ray}$ can be achieved by putting $K=0$ in (8). This is also a new result and is not available in the literature.

Under SLC scheme, the average Q_d in Rician fading, $\bar{Q}_{d,lc,Ric}$, can be evaluated by substituting Nu in place of each u in (8). Using [13], we have verified that $\bar{Q}_{d,lc,Ric}$ reduces to $\bar{Q}_{d,lc,Ray}$ for $K=0$. The expression for SLC fusion in case of Rician fading channel is also a new result. In a communication whose faded channel is diversity assisted, considering N-order SC for receivers, the CDF of N-order SC combiner output SNR is

$$F_{\gamma_{sc}}(\gamma)=[F_\gamma(\gamma)]^N. \tag{9}$$

By differentiating the CDF, it's PDF can be obtained as

$$f(\gamma_{sc})=\frac{\partial F_{\gamma_{sc}}(\gamma)}{\partial\gamma}=N\left[F_\gamma(\gamma)\right]^{N-1}f_\gamma(\gamma). \tag{10}$$

where $f_\gamma(\gamma)$ and $F_\gamma(\gamma)$ are the PDF and CDF for single fading channel, respectively [8]. For SC fusion scheme, the expression for the PDF of SNR at the SC combiner output is

obtained by substituting the basic PDF and CDF of SNR under Rician faded channel in (10). However, it becomes difficult to evaluate (4) after making substitutions of Q_d given in Table I and (10). There is an another alternative approach that states: An alternative expression for $\bar{Q}_{d,sc}$ obtained from (4) can be expressed by substituting γ_{sc} with $\tan\theta$ and $d\gamma_{sc}$ with $\sec^2\theta d\theta$ following the variable substitution approach studied by [8], [14]

$$\bar{Q}_{d,sc} = \int_0^{\pi/2} Q_{d,sc}(\tan\theta) f(\tan\theta) \sec^2\theta d\theta. \tag{11}$$

The average detection probability, under SC scheme, in case of Rician channel, $\bar{Q}_{d,sc,Ric}$ is evaluated as

$$\bar{Q}_{d,sc,Ric} = C \int_0^{\pi/2} Q_u\left(\sqrt{2\tan\theta}, \sqrt{\lambda}\right) \times \exp\left[-\frac{(1+K)\tan\theta}{\bar{\gamma}}\right] I_0\left(2\sqrt{\frac{K(1+K)\tan\theta}{\bar{\gamma}}}\right) \times \left[1 - Q_1\left(\sqrt{2K}, \sqrt{\frac{2(1+K)\tan\theta}{\bar{\gamma}}}\right)\right]^{N-1} \sec^2\theta d\theta. \tag{12}$$

where $C = N(1+K)\exp(-K)/\bar{\gamma}$. The above result is a new result.

III. Results and Discussions

In the current section, numerical results are presented and discussed for relevant values of the network parameters such as average S-channel SNR ($\bar{\gamma}$), Rician parameter (K), number of CRs (N), and time-bandwidth product (u) as well as for different soft data fusion schemes (SLS, MRC, SLC, and SC) .

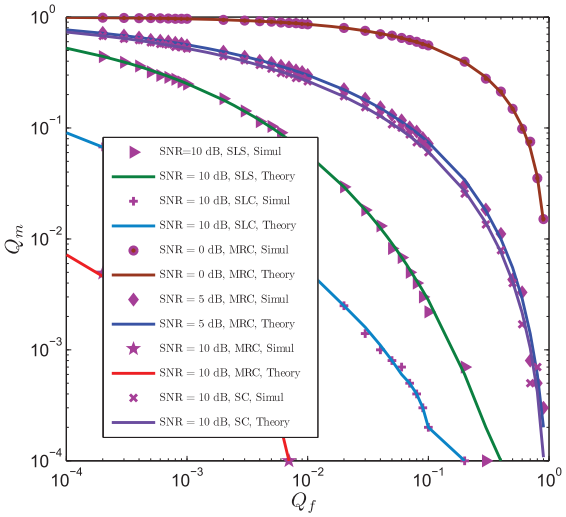

Fig. 3. Performance of soft data fusions (SLS, MRC, SLC, and SC) for various values of $\bar{\gamma}$ in AWGN channel (u=5, N=3, both simulation and analytical results are shown).

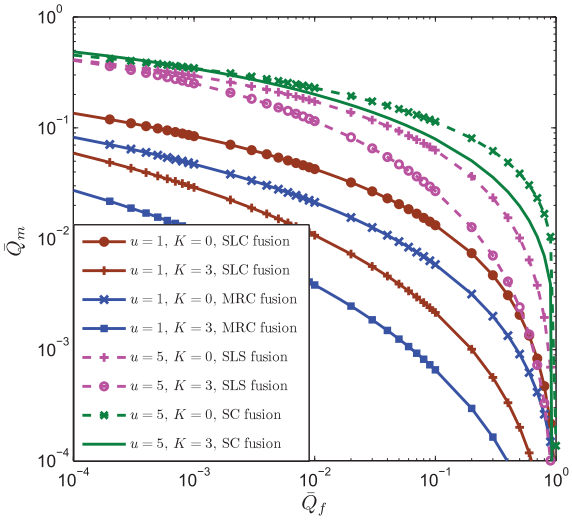

Fig. 4. Impact of Rician parameter (K) and u on performance of soft data fusions ($N=3$ and $\bar{\gamma}=10$ dB).

In Figure 3, CROC ($\bar{Q}_m$ versus $\bar{Q}_f$) in AWGN environment is shown for various soft data fusion schemes such as SLS, MRC, SLC, and SC. The impact of $\bar{\gamma}$ on performance of CSS with MRC fusion case is also shown. It is observed that $\bar{Q}_m$ reduces when any one of $\bar{\gamma}$ and $\bar{Q}_f$ increases. Higher $\bar{\gamma}$ (noise power is low) improves $\bar{P}_d$ of individual CR which further improves $\bar{Q}_d$ after cooperation i.e. overall $\bar{Q}_m$ (=1-$\bar{Q}_d$) reduces. Results based on derived expressions match with the results based on simulation testbed) under the same SNR conditions, which shows our simulation test bed and analytical approach are validated with each other. We also observe that MRC fusion based CSS performance is better as compared to the other schemes such as SLS, SLC, and SC but MRC scheme requires channel state information. The SLC fusion does not require any information about channel status and still present better performance than SLS, and SC. Thus when no channel information is available, the best scheme is SLC.

In Figure 4, the impacts of two different Rician fading parameters such as $K=0$ and $K=3$ on the CSS performance are shown. Different fusion cases such as SLS, MRC, SLC, and SC are performed at FC. For $K=0$, characteristics of Rayleigh faded channel would be obtained. Decrease in fading severity (characterized by a higher value of K) decreases the overall missed detection probability at FC. We also observe from this figure that a smaller u results in a smaller $\bar{Q}_m$ for a fixed value of $\bar{Q}_f$, K, N, and $\bar{\gamma}$ for all fusion schemes. Again MRC guarantees best performance among all fusion schemes under same network and channel parameters.

Figure 5 depicts the performance comparison between hard decision (majority-rule, AND-rule, and OR-rule) and soft data (SLS, MRC, SLC, and SC) combining fusion rules based on $\bar{Q}_d$ vs $\bar{Q}_f$ plots (ROC). In this case, the same detection threshold (λ) is assumed at each CR. The CSS performance

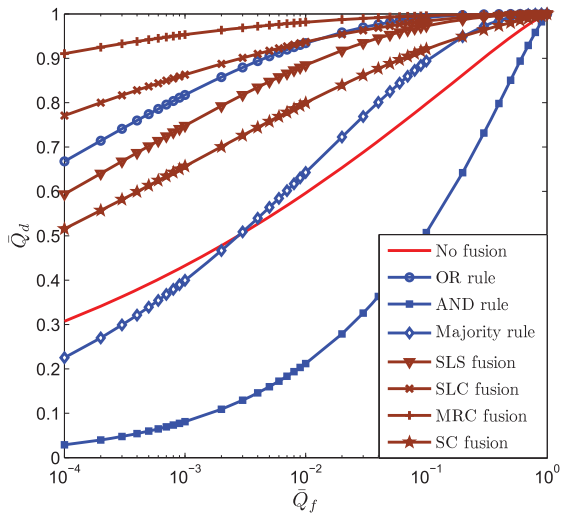

Fig. 5. Performance comparison between hard decision [5] and soft data fusions under Rician fading ($K = 3$, $\bar{\gamma} = 10$ dB, $u = 5$, and $N = 3$).

with no-fusion ($N = 1$) case is also shown for the comparison purpose. As the figure indicates, all fusion schemes outperform the single CR ($N = 1$) based sensing except AND rule. From the figure, we observe that the OR-rule performs better than the other hard decision fusion rule majority-rule or AND-rule and . The MRC soft data fusion outperforms all other soft data fusion schemes (SLS SLC, and SC) as well as all hard decision fusion rules (majority-rule, AND-rule, and OR-rule). More precisely, it is shown that all soft data fusion schemes outperform hard decision fusion rules (AND-rule and majority-rule) except OR-rule. However, these benefits are obtained at the cost of a larger bandwidth for the R-channel. The hard decision fusion rules occur with less complexity, but also with a lower detection performance than soft combination schemes. In particular, for $\bar{Q}_f = 0.0001$, $\bar{Q}_d$ is above 0.91, 0.77, 0.59, 0.51, 0.66, 0.02, and 0.22 for MRC, SLC, SLS, SC, OR-rule, AND-rule, and majority-rule, respectively. Thus MRC fusion yields the best performance among all the fusion rules.

IV. Conclusion

The performance of CSS have been evaluated with a proposed analytical framework under several soft data fusion schemes (SLS, MRC, SLC, and SC) using energy detection in Rician faded sensing channel. Missed detection performance based on our developed framework is presented under several numbers of CRs, time-bandwidth products and fading severity parameters. The CSS with soft data fusion schemes have shown excellent performance improvement as compared to CSS with hard decision fusion rules. The MRC fusion scheme has been shown to outperform other schemes such as SLS, SLC, and SC in AWGN as well as Rician fading in S-channel. To achieve better detection performance with lower number of CRs in worse S-channel fading condition, MRC can be used. The performance of CSS with any type of fusion scheme outperforms single CR based spectrum sensing (no-fusion case). Results based on derived expressions in the paper match with the results based on Monte Carlo simulations.

Abstract— The performance of Quasi-orthogonal space time block codes (QO-STBC) are generally verified by assuming that the channels remain static over the entire code word length. However, in time selective channel, this assumption does not hold good and causes severe interferences. Therefore, the simple pairwise maximum likelihood decoding scheme is not sufficient to recover original transmitted signals perfectly. Hence, in this paper, we have analyzed several detection schemes namely zero forcing (ZF), two-step zero forcing (TS-ZF), minimum mean square error (MMSE), zero forcing-interference cancellation-decision feedback equalizer (ZF-IC-DFE)and minimum mean square error-interference cancellation-decision feedback equalizer (MMSE-IC-DFE). We have also proposed two iterative detection schemes namely zero forcing iterative zero forcing successive interference cancellation (ZI-ZF-SIC) and minimum mean square error iterative zero forcing successive interference cancellation (MI-ZF-SIC). The simulation results show that the proposed detection method outperform the conventional methods for QO-STBC over time selective channel.

Keywords—QO-STBC; Detection;Time Selective; ZI-ZF-SIC; MI-ZF-SIC

I. INTRODUCTION

In recent years, the transmit diversity schemes have attracted much more attention after Alamouti [1] proposed an elegant orthogonal space-time block codes (OSTBCs) for two transmit antenna and one receive antenna because they give full diversity with low complexity ML decoding. However, it is seen that, OSTBC cannot achieve full rate and full diversity at the same time for more than two transmit antennas [2]. Hence, a full rate with partial diversity Quasi-Orthogonal Space-Time Code (QOSTBC) was introduced in [3] for flat fading channel. However, the time selective channel does exit in practice. Most research on QO-STBC assumes that the channel is quasi-static over the entire channel matrix. However, in a fast fading scenario, this assumption does not hold good and causes two interferences namely inter symbol interference (ISI) and inter antenna interferences (IAI) [4]. The ISI and IAI effect occurs due to quasi orthogonal code matrix and time selective nature of the channel respectively. Hence, a simple pairwise ML detection method is not sufficient to recover the original transmitted signal at the receiver side. In [5], a two-step ZF (TS-ZF) detector was proposed to eliminate the interferences for QOSTBC for time selective channel. This method is composed of two steps. In the first step a transform matrix is multiplied with the channel matrix to get a diagonal matrix and then a simple least square detection is performed to detect the transmitted signals. In [4], the authors propose two detection schemes ZF-IC-DFE and MMSE-IC-DFE. These detection techniques consist of three steps. In the first two steps ZF–IC or MMSE-IC is performed followed by DFE at the last step to recover the original transmitted signal.

In this paper, we propose two detection schemes to cancel the interferences based on iterative zero forcing-successive interference cancellation (I-ZF-SIC) for QO-STBC over time selective channel. Initially, either ZF or MMSE method is used to estimate the transmitted signal. Then, by using the estimated signal coming from ZF/MMSE method, the interferences are cancelled iterative followed by ZF-SIC method and soft decision. We call the proposed scheme as zero forcing iterative zero forcing successive interference cancellation (ZI-ZF-SIC) or minimum mean square error iterative zero forcing successive interference cancellation (MI-ZF-SIC) depending upon whether the initial signal is estimated by using either ZF or MMSE method.

The rest of the paper is organized as follows. In Section II, the system model for the QO-STBC is discussed. The conventional various detection methods are presented in Section III. Section IV describes the proposed detection methods. In Section V, the performance of these detection methods are compared on the basis of SER. Finally, Section VI concludes the paper.

II. SYSTEM MODEL

Consider the QO-STBC proposed in [3] with 4 transmit antennas (4Tx) and 1 receive antenna (1Rx). Four complex signals x_1, x_2, x_3 and x_4 are first grouped together and then passed through a QO-STBC encoder. The encoded output can be written as

$$X = [x_{il}] = \begin{bmatrix} x_1 & x_2 & x_3 & x_4 \\ -x_2^* & x_1^* & -x_4^* & x_3^* \\ -x_3^* & -x_4^* & x_1^* & x_2^* \\ x_4 & -x_3 & -x_2 & x_1 \end{bmatrix} \quad (1)$$

where x_{il} denotes the signal transmitted from the ith transmitted antenna at lth time slot.

After passing the encoded signal through the channel, the received signal can be expressed as

$$r = Hx + n \quad (2)$$

where $x = [x_1 \quad x_2 \quad x_3 \quad x_4]^T$ $r = [r_1 \quad r_2^* \quad r_3^* \quad r_4]^T$ and $n = [n_1 \quad n_2^* \quad n_3^* \quad n_4]^T$.

n_i is a complex additive white Gaussian noise (AWGN) with zero mean and a variance of σ_n^2. The channel matrix (*H*) can be written as

$$H = \begin{bmatrix} h_1(1) & h_2(1) & h_3(1) & h_4(1) \\ h_2(2)^* & -h_1(2)^* & h_4(2)^* & -h_3(2)^* \\ h_3(3)^* & -h_4(3)^* & -h_1(3)^* & -h_2(3)^* \\ h_4(4) & -h_3(4) & -h_2(4) & h_1(4) \end{bmatrix} \tag{3}$$

where $h_i(l)$ denotes the channel gain for the *i*th transmit antenna at the *l*th time slot. Here, we assume that all the channels undergo frequency flat and time selective channel generated from modified Jakes Sum-of-Sinusoidal (SOS) [8] model with zero mean and autocorrelation $E[h_i(l)h_i(l+m)^*] = \sigma_h^2 R_h(m)$ where σ_h^2 denotes the power of path gain and we normalize the power of path gain to unit. According to Jakes Model [10]

$$R_h(m) = J_0(2\pi f_d T_S m) \tag{4}$$

$J_0(.)$ is the zero order Bessel functions of the first kind, f_d is the Doppler frequency and T_s is the symbol period.

At first, the channel is assumed to be time invariant flat fading i.e. $h_i = h_i(l) = h_i(l+m)$ for *m* = 1,2 3. In such scenario, the pairwise maximum likelihood (ML) method proposed in [3] is applied to separate the transmitted signals. This can be performed in two steps. In the first step, matched filter operation is performed followed by a joint decoding of two symbol pair using ML method. The matched filter operation can be performed by multiplying H^H on both sides of (2) and is given by

$$\begin{aligned} r' &= H^H H x + H^H n \\ &= \Theta x + n' \end{aligned} \tag{5}$$

where Θ is the Gram matrix and is given by

$$\Theta = H^H H = \begin{bmatrix} a & 0 & 0 & b \\ 0 & a & -b & 0 \\ 0 & -b & a & 0 \\ b & 0 & 0 & a \end{bmatrix} \tag{6}$$

$$a = \sum_{i=1}^{4} |h_i|^2$$

$$b = 2\,\mathrm{Re}\left(h_1 h_4^* - h_2 h_3^*\right)$$

where Re(.) denotes the real parts of the complex. Then Pairwise ML method separates the transmitted signal into the sum of two independent terms $f(x_1,x_4) + f(x_2,x_3)$ and can be written as

$$\hat{x} = \arg\min_{x \subset \Omega} \left\| r' - \Theta x \right\| \tag{7}$$

Hence, by using pairwise ML method the transmitted signal can be perfectly recovered from the mixer of transmitted signals at the receiver side.

But, when the channel is time selective, the quasi-static assumptions does not hold well as $h_i(l) \neq h_i(l+m)$. Hence, $H^H H$ is no longer an quasi-orthogonal matrix and is given by

$$\begin{aligned} \Theta = H^H H &= \underbrace{\begin{bmatrix} a_1 & \Lambda_1 & \Lambda_2 & \beta \\ \Lambda_1^* & a_2 & \partial & \Lambda_3 \\ \Lambda_2^* & \partial^* & a_3 & \Lambda_4 \\ \beta^* & \Lambda_3^* & \Lambda_4^* & a_4 \end{bmatrix}}_{\Theta} \\ &= \underbrace{\begin{bmatrix} a_1 & 0 & 0 & \beta \\ 0 & a_2 & \partial & 0 \\ 0 & \partial^* & a_3 & 0 \\ \beta^* & 0 & 0 & a_4 \end{bmatrix}}_{\Theta_D + \Theta_{AD} = \Theta_S} + \underbrace{\begin{bmatrix} 0 & \Lambda_1 & \Lambda_2 & 0 \\ \Lambda_1^* & 0 & 0 & \Lambda_3 \\ \Lambda_2^* & 0 & 0 & \Lambda_4 \\ 0 & \Lambda_3^* & \Lambda_4^* & 0 \end{bmatrix}}_{\Theta_{ND}} \end{aligned} \tag{8}$$

where a_i denotes the desired diversity gain terms and are the diagonal entry of the Gram matrix given as Θ_D. β, ∂ and their corresponding conjugate denotes the ISI effect and are located on the anti- diagonal Gram matrix Θ_{AD}. Λ_i and their corresponding conjugate are the IAI effect occurs due to the time selective nature of the channel and are presented on the non-diagonal entry of the matrix i.e. Θ_{ND}. As the off diagonal matrix are not zeros, the pairwise ML method cannot be sufficient to recover the original transmitted signal as the likelihood function can no longer be decomposed into the sum of two pair-wise functions. Hence, in this paper, we have analyzed various detection methods and also proposed two detection methods to improve the system performance by cancelling these interferences.

III. COVENTIONAL DETECTION METHODS

In this section, we describe different conventional detection methods namely TS-ZF, ZF-IC-DFE and MMSE-IC-DFE for QO-STBC system over time selective flat fading channel.

A. TS-ZF Method

The TS-ZF method is proposed in [5] to detect the QOSTBC signal. As $H^H H$ does not give a quasi-orthogonal matrix, a transform matrix Ω is multiplied instead of H^H and then a simple least square algorithm has been performed.

[Step1] Multiply Ω matrix on both side of (2) and is given by

$$\Omega r = \Omega H x + \Omega n = D x + n' \tag{9}$$

$D = diag(\chi_1, \chi_2, \chi_3, \chi_4)$ and χ_i are the diagonal entry of ΩH.

[Step2] Apply simple LS detection scheme to estimate the transmitted signal and can be written as

$$\hat{x}_i = \arg\min_{x \in \Gamma} \left\| [\Omega]_i r - \chi_i x \right\|^2 \tag{10}$$

where $[\Omega]_i$ denotes the *i*th row of Ω. The TS-ZF performs better than pairwise ML method as it forces the two interference signals i.e. IBI and ICI to zero.

B. ZF-IC-DFE

The ZF-IC-DFE was proposed in [4]. It involves three steps in order to detect the transmitted signal. The algorithm is given below

[Step1] The ZF detection scheme [9] is used to obtain the initial estimated signal and is given by

$$\hat{x} = [H^H H]^{-1} H^H r \tag{11}$$

where $H \in C^{N_T \times N_T}$ is the channel matrix and $r \in C^{N_T \times 1}$ is the received signal.

[Step2] Use the estimated signal coming from the ZF output detector to cancel the off diagonal Gram matrix and can be written as

$$r_{IZ} = r' - \Theta_{ND}\hat{x} = \Theta_s \hat{x} + n' \tag{12}$$

where $r' = H^H r$ is the matched filter output of the received signal. Θ_{ND} denotes IAI occurs due to time selective channel and can be obtained by subtracting the diagonal and anti-diagonal of the Gram matrix given as given in (8)

$$\Theta_{ND} = \Theta - (\Theta_D + \Theta_{AD}) \tag{13}$$

[Step 3] Decompose the Θ_s using Cholesky decomposition and then apply DFE to obtain the transmitted signal

Applying Cholesky decomposition to Θ_s can be written as

$$\Theta_s = \Theta_D + \Theta_{AD} = L^H D L \tag{14}$$

where $L \in C^{N_T \times N_T}$ is an upper triangular matrix with diagonal matrix having the value one and $D \in C^{N_T \times N_T}$ is a diagonal matrix. Then DFE is performed by premultiplying the matrix $D^{-1}L^{-H}$ and is given by

$$r_D = D^{-1}L^{-H} r_{IZ} = Lx + D^{-1}L^{-H} n' \tag{15}$$

where r_{IZ} is the output of DFE and *L* is an upper triangular matrix and is given by

$$L = \begin{bmatrix} 1 & 0 & 0 & \Delta_1 \\ 0 & 1 & \Delta_2 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \tag{16}$$

where Δ_1 and Δ_2 are the coeffiecnt of feedback filter. Thus, x_3 and x_4 are detected separately and then this information is used to help make a decision about x_1 and x_2.

C. MMSE-IC-DFE

The MMSE-IC-DFE works very similar to previously mentioned ZF-IC-DFE. It employs the MMSE method [9] in the first step instead of ZF method to estimate the initial transmitted signal and is given by

$$\hat{x} = [H^H H + \sigma_n^{\ 2} I]^{-1} H^H r \tag{17}$$

where $\sigma_n^{\ 2}$ is the noise variance and *I* is the identity matrix.

The rest two steps i.e. Interference cancellation and Cholesky decomposition based DFE are same as previously mentioned ZF-IC-DFE detection method.

Both the ZI-ZF-SIC and MMSE-ZF-SIC outperform their corresponding linear detection parts i.e. ZF and MMSE, because they apply interference cancellation and DFE to further improves the system performance. However, the performances of these detection methods are not satisfactory due to the propagation of less reliable transmitted signal to estimate the other transmitted signals. Hence we have proposed two detection methods which provide more reliable information signals and are presented in the next section.

IV. Proposed Detection Method

We have proposed two detection schemes namely ZI-ZF-SIC and MI-ZF-SIC to cancel the ISI and IAI effects. In the first step either ZF or MMSE method is used to estimate the initial signal and then by using these estimated signal IAI effect are cancelled iteratively. Then by applying the IAI free received signal, the ISI effects are cancelled by adopting ZF-SIC method. Finally, the ZF-SIC output signal are soft decoded by using log likelihood ratio (LLR) and then feedback to the IAI canceller unit for the next iteration.

A. ZI-ZF-SIC

The ZI-ZF-SIC method uses ZF method to estimate the initial data symbol. Then by using the estimated signal coming from ZF output, the IAI signal are generated and then subtracted from received signal iteratively with the help of soft ZF-SIC method to get the IAI free signal. The algorithm for ZI-ZF-SIC are given below

[Step1] Set iteration number k=0 and obtain $x_i^{(0)}$ from ZF method as given in (11) and can be written as

$$x_i^{(0)} = \hat{x}_i \tag{18}$$

[Step2] Use the initial estimated signal coming from ZF output to cancel the IAI iteratively. For iteration *k=1, 2,...I*, the IAI free signal can be obtained as

$$\begin{aligned} r_{off_IAI}^{k}(i) &= r'(i) - \Theta_{ND}\hat{x}_i^{(k-1)} \\ &= \Theta_s \hat{x}_i^{(k-1)} + n' \end{aligned} \tag{19}$$

where $r_{off_IAI}^{k} = [r_{off_IAI}^{k}(1) r_{off_IAI}^{k}(2) r_{off_IAI}^{k}(3) r_{off_IAI}^{k}(4)]^T$ are the IAI free signal for the *k*th iteration.

[Step3] Separate $r_{off_IAI}^{k}$ into two groups that contain the symbol pair ($\hat{x}_1^{\,k-1}, \hat{x}_4^{\,k-1}$) and ($\hat{x}_2^{\,k-1}, \hat{x}_3^{\,k-1}$) and

$$\begin{bmatrix} r_{off_IAI}^{k}(1) \\ r_{off_IAI}^{k}(4) \end{bmatrix} = \begin{bmatrix} a_1 & \beta \\ \beta^* & a_4 \end{bmatrix} \begin{bmatrix} \hat{x}_1^{\,k-1} \\ \hat{x}_4^{\,k-1} \end{bmatrix} + \begin{bmatrix} n_1' \\ n_4' \end{bmatrix} \tag{20}$$

$$\begin{bmatrix} r^{k}_{off_IAI}(2) \\ r^{k}_{off_IAI}(3) \end{bmatrix} = \begin{bmatrix} a_2 & \partial \\ \partial^{*} & a_3 \end{bmatrix} \begin{bmatrix} \hat{x}_2^{\,k-1} \\ \hat{x}_3^{\,k-1} \end{bmatrix} + \begin{bmatrix} n'_2 \\ n'_3 \end{bmatrix} \quad (21)$$

Then, use ZF-SIC method in the first group to detect $\hat{x}_1^{\,k-1}$ and $\hat{x}_4^{\,k-1}$ signals.

[Step 4] Apply zero forcing method to obtain $\hat{x}_1^{\,k-1}$, $\hat{x}_4^{\,k-1}$ and is given by

$$\begin{aligned} \begin{bmatrix} \hat{x}_1^{\,k-1} \\ \hat{x}_4^{\,k-1} \end{bmatrix} &= \begin{bmatrix} a_1 & \beta \\ \beta^{*} & a_4 \end{bmatrix}^{-1} \begin{bmatrix} r^{k}_{off_IAI}(1) \\ r^{k}_{off_IAI}(4) \end{bmatrix} \\ &= \frac{1}{\phi} \begin{bmatrix} a_4 & -\beta \\ -\beta^{*} & a_1 \end{bmatrix} \begin{bmatrix} r^{k}_{off_IAI}(1) \\ r^{k}_{off_IAI}(4) \end{bmatrix} \end{aligned} \quad (22)$$

where $\phi = -(a_1 a_4 + |\beta|^2)$ is a scalar quantity.

[Step 5] Adopt SIC method [7] joint with ZF method to obtain more reliable data signal. The algorithm for ZF-SIC method is given in below

1. $r^{k}_{off_IAI}(1) = a_1 \hat{x}_1^{\,k-1} + \beta\, x_4^{\,k-1} + n'_1$ (23)
2. $r^{k}_{off_IAI}(4) = \beta^{*} \hat{x}_1^{\,k-1} + \alpha_4 \hat{x}_4^{\,k-1} + n'_4$ (24)
3. *if* $\alpha_1 > \alpha_4$

$$\bar{x}_1^{\,k-1} = Q(\hat{x}_1^{\,k-1}) \quad (25)$$

$$\tilde{x}_4^{\,k-1} = (r^{k}_{off_IAI}(4) - \beta^{*} \bar{x}_1^{\,k-1})/a_4 \quad (26)$$

$$\hat{x}_1^{\,k-1} = (r^{k}_{off_IAI}(1) - \beta Q(\tilde{x}_4^{\,k-1}))/a_1) \quad (27)$$

4. *else*

$$\bar{x}_4^{\,k-1} = Q(\hat{x}_4^{\,k-1}) \quad (28)$$

$$\tilde{x}_1^{\,k-1} = ((r^{k}_{off_IAI}(1) - \beta \bar{x}_4^{\,k-1})/a_1) \quad (29)$$

$$\hat{x}_4^{\,k-1} = (r^{k}_{off_IAI}(4) - \beta^{*} Q(\tilde{x}_1^{\,k-1}))/a_4) \quad (30)$$

where Q denotes the hard decision function.

[Step 6] Finally adopt the soft decision rule using the LLR method and then the soft decoded signals are feedback for next iteration.

The $\hat{x}_2^{\,k-1}$ and $\hat{x}_3^{\,k-1}$ are detected similarly by applying ZF-SIC method as given in *[Step4]-[Step6]*.

B. MI-ZF-SIC

The working principle of MI-ZF-SIC method is similar to ZI-ZF-SIC method. In MI-ZF-SIC, MMSE method is used instead of ZF method to estimate the initial signal.

V. SIMULATION RESULTS

The performance comparison of various detection methods which include Pairwise ML, ZF, TS-ZF, MMSE, ZF-IC-DFE, MMSE-IC-DFE, ZI-ZF-SIC and MI-ZF-SIC methods are carried out on the basis of symbol error rate (SER) for QO-STBC over time selective flat fading channel. Modified Jakes' model is adopted to construct the time-selective fading environment. The channel varies from symbol to symbol and perfect channel state information is assumed at the receiver side. The simulation parameters used for simulation is listed on the Table1. The simulation platform is performed using MATLAB 2010b. The SER performance of conventional and proposed detection methods for QO-STBC over mobile speed of 400km/h is shown in the figure 1. The simulation result shows that pairwise ML method suffers severe performance degradation due to time selective channel. The ZF and TS-ZF give almost similar performance and outperforms the pairwise ML method as both these method forces the interferences signals to zero. The MMSE method gives better results than ZF method as it utilizes the noise correlation properties. It has almost the same performance to ZF-IC-DFE detection method. The MMSE-IC-DFE outperforms the ZF-IC-DFE as it uses MMSE method instead of ZF method to estimate the initial data symbol. The MMSE-IC-DFE and ZF-IC-DFE give better performance than their corresponding linear detection method. However, both these methods suffer performance degradation due to error floor as less reliable data are propagated to estimate the other transmitted signal. The simulation results show that the proposed ZI-ZF-SIC method gives better result than the conventional MMSE-IC-DFE and ZF-IC-DFE method as more reliable data sequences are estimated using iterative ZF-SIC method. The MI-ZF-SIC gives better results than ZF-IC-DFE due to the implementation of MMSE rather than ZF method in order to estimate the initial data information.

Table 1 Simulation Parameters

Parameter	Value
Antenna configuration	4Tx,1Rx
Channel Model	Modified Jakes SOS
Carrier frequency	2GHz
Symbol duration	128/(3.84×10e6)
Modulation type	QPSK
Mobile velocity	400Km/h
Normalized Doppler Spread	0.025

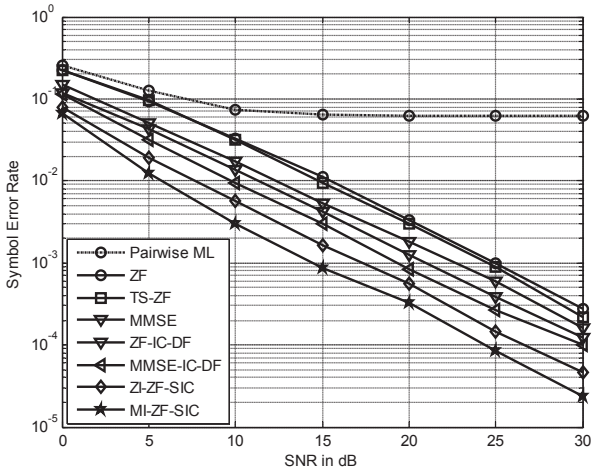

Fig.1 Performance Comparision of different detection methods for QO-STBC over mobile speed 400Km/h

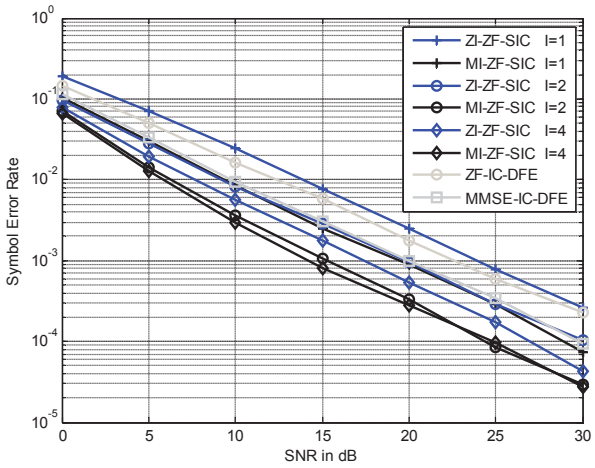

Fig.2 Performance of Proposed methods with respect to number itearion number

Figure 2 show the SER performance of the two proposed methods for different number of iteration I = 0, 2, 4. The simulation results show that as the number of iteration increases, the performance of the proposed methods improves. It is seen than, iteration I= *2* or I= *4* delivers most of the performance gain in the proposed detection schemes and thus we consider iteration I = 4 for comparison with other conventional methods as shown in Figure 1. The performance of different detection methods in the descending order are given as follows MI-ZF-SIC, ZI-ZF-SIC, MMSE-IC-DFE, MMSE, ZF-IC-DFE, TS-ZF, ZF and Pairwise ML.

VI. CONCLUSIONS

In this paper, we have analyzed various conventional detection methods and proposed two new detection methods namely ZI-ZF-SIC and MI-ZF-SIC technique methods to suppress the interferences effects for QO-STBC system over time selective channel. The various detection techniques which include TS-ZF, ZF, MMSE, ZF-IC-DFE, MMSE-IC-DFE and the proposed ZI-ZF-SIC, MI-ZF-SIC methods are compared in terms of SER. From the simulation results, it is seen that, both the proposed methods significantly outperforms the conventional detection methods.

***Abstract*—In this paper, we consider optimization of number of cognitive users (N) by minimizing global error rate of a given voting rule (k) at cognitive radio (CR) base station over erroneous reporting channel. Expressions for optimal N are derived for $k = m+1$ and $k = N-m$ voting rules. Where m is an integer ($m \geq 0$). We show that optimal N depends on m, effective probability of false alarm (P_{fe}) and effective probability of miss detection (P_{me}) of a cognitive user over erroneous reporting channel. We consider improved energy detector as an example for the analysis. Based on this analysis following observations are made;**

1) **If CR base station uses $k = m+1$ or $k = N-m$ voting rule, performance of cooperative spectrum sensing improves as m increases.**
2) **For a given m, performance of $k = m+1$ voting rule is better compared to $k = N-m$ voting rule.**

Finally, we numerically obtain the values of optimal detection threshold, optimal p of the improved energy detector and optimal N. We also compare with conventional energy detector. We show that performance using optimal values is better than conventional energy detector.

***Index Terms*—Cognitive radio, cognitive radio base station, erroneous reporting channel, optimization.**

I. Introduction

The idea of cognitive radio (CR) has evolved to overcome the spectrum shortage problem caused by the current inflexible spectrum allocation policy. A CR is an intelligent wireless communication system that monitors for the presence of the spectrum hole by changing different modulation strategies and forms the best way of communication between primary and cognitive user [1]. In many realistic environments due to multipath fading and shadowing, detection performance of a cognitive user degrades. To overcome this issue, different cognitive users may need to cooperate to enhance the performance of the cooperative spectrum sensing [2] - [3].

In cooperative CR network, each cognitive user can send the local decision to CR base station in a single time slot. As number of cognitive users increase, CR base station may take long time in deciding the decision on primary user [4]. One of the practical limitations in cooperative spectrum sensing is subject to fading and additive noise, the reporting channel between cognitive user and CR base station may also experiences errors, which results in poor performance [5]. Cooperative spectrum sensing over erroneous reporting channel is presented in [6] and it is shown that OR and AND rule are never optimal for practical cases. Optimization of number of cognitive users using OR rule at CR base station is addressed in [7].

In this paper, in lieu of OR, AND rules, in general we consider $k = m+1$ and $k = N-m$ voting rules at CR base station. Note that if $m = 0$ implies $k = 1$ (OR Rule) and $k = N$ (AND Rule). Optimal N can be obtained by minimizing the global error rate of $k = m+1$ and $k = N-m$ voting rules. We show that optimal N depends on P_{fe}, P_{me} and m. As more the number of cognitive users in the CR network does not guarantee to improve the performance of cooperative spectrum sensing. Hence, it is important to find the optimal N. Following [7], we numerically obtain values of optimal detection threshold, optimal p of improved energy detector and optimal N for $k = m+1$ and $k = N-m$ voting rules. We show performance using optimal algorithm is better compared to conventional energy detector.

The remaining part of the paper is organized as follows. In Section II we present the system model of cooperative spectrum sensing. In Section III, we obtain the expressions for optimal N by minimizing the global error rate of $k = m+1$ and $k = N-m$ voting rules at CR base station. We also discuss numerical analysis with improved energy detector. Finally, in Section IV, we draw our conclusions.

II. System Model

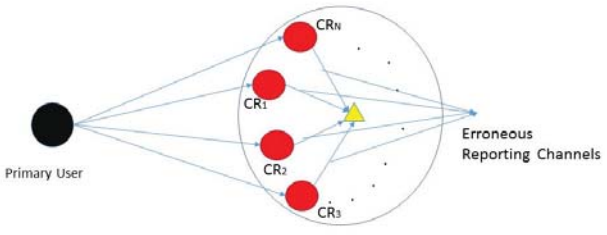

Fig. 1. Cooperative spectrum sensing model, N cognitive users communicate with CR base station over erroneous reporting channel.

We consider cooperative spectrum sensing model as shown in Fig. 1, where N CRs (cognitive users) communicate with CR base station over erroneous reporting channel. Each cognitive user identifies the primary user independently and send their local decision to CR base station over erroneous reporting channel. For the ith cognitive user with the improved energy

detector, the probability of false alarm, probability of detection and probability of missed detection are given by [8]

$$\mathrm{P}_{f,i} = \frac{\Gamma\left(n_0, \frac{T_i}{m_0}\right)}{\Gamma(n_0)}, \ \mathrm{P}_{d,i} = \frac{\Gamma\left(n_1, \frac{T_i}{m_1}\right)}{\Gamma(n_1)}, \quad (1)$$

and

$$P_{m,i} = 1 - P_{d,i}, \quad (2)$$

where

$$m_0 = \frac{2^{p/2}}{L} \frac{\sqrt{\pi}\Gamma\left(\frac{2p+1}{2}\right) - \Gamma^2\left(\frac{p+1}{2}\right)}{\Gamma\left(\frac{p+1}{2}\right)\sqrt{\pi}}, \quad (3)$$

$$n_0 = n_1 = L \frac{\Gamma^2\left(\frac{p+1}{2}\right)}{\Gamma\left(\frac{2p+1}{2}\right)\sqrt{\pi} - \Gamma^2\left(\frac{p+1}{2}\right)}, \quad (4)$$

$$m_1 = \frac{2^{p/2}(1+\gamma_i)^{p/2}}{L} \frac{\sqrt{\pi}\Gamma\left(\frac{2p+1}{2}\right) - \Gamma^2\left(\frac{p+1}{2}\right)}{\Gamma\left(\frac{p+1}{2}\right)\sqrt{\pi}}, \quad (5)$$

and where $\Gamma(.,.)$ denotes the upper incomplete gamma function, $\Gamma(.)$ denotes the gamma function, T_i is the detection threshold of the ith cognitive user, γ_i is the average *signal-to-noise ratio* (SNR) of the ith cognitive user, L be the number samples of a signal received at ith cognitive user and p is the positive power of the improved energy detector.

Following [4], we assume that distance between any two cognitive users is small, hence each cognitive user experiences identical path loss. Therefore, we can assume all cognitive users has same SNR. We also assume that all cognitive users has same thresholds i.e., $T_1 = T_2 = ... = T_N = T$. Hence they have same probabilities of detection and false alarm. Further more, we assume all reporting channels introduce identical probability of error, P_e. In summary

$$T_i = T, P_{f,i} = P_f, P_{d,i} = P_d, P_{m,i} = P_m, P_{e,i} = P_e.$$

Let P_{fe}, P_{de} and P_{me} be the effective probability of false alarm, effective probability of detection and effective probability of miss detection of a cognitive user respectively, over erroneous reporting channel as seen by the CR base station and is given by

$$P_{fe} = 1 - [(1-P_f)(1-P_e) + P_f P_e], \quad (6)$$
$$P_{de} = 1 - [(1-P_d)(1-P_e) + P_d P_e], \quad (7)$$
$$P_{me} = 1 - P_{de}. \quad (8)$$

Every cognitive user in CR network makes one bit binary decision θ_i (logic 1 denotes primary user is present, logic 0 denotes primary user is absent) and sends it to the CR base station over erroneous reporting channel. At CR base station all these one bit decisions are fused together and voting rule is applied to identify the presence or absence of primary user. i.e.,

$$Z = \sum_{i=1}^{N} \theta_i \begin{cases} \geq k, & H_1, \\ < k, & H_0, \end{cases}$$

where H_1, H_0 denotes inference drawn by CR base station that primary user is present or absent respectively. k is the voting rule. Note that we consider $k = m+1$ and $k = N-m$ voting rules.

For a, b positive integers and $0 \leq P < 1$, regularized incomplete beta function defined as

$$I_{1-P}(b-a, a+1) = \sum_{l=0}^{a} \binom{b}{l} P^l (1-P)^{b-l} \quad (9)$$

For a given voting rule (k), probability of error in the reporting channel (P_e), we define probability of false alarm and probability of miss detection at CR base station as

$$P_{F,k} = \sum_{i=k}^{N} \binom{N}{i} {P_{fe}}^i (1-P_{fe})^{N-i}$$
$$= 1 - \sum_{i=0}^{k-1} \binom{N}{i} {P_{fe}}^i (1-P_{fe})^{N-i}$$
$$= 1 - I_{1-P_{fe}}(N-k+1, k), \quad (10)$$

$$P_{M,k} = 1 - \sum_{i=k}^{N} \binom{N}{i} {P_{de}}^i (1-P_{de})^{N-i}$$
$$= I_{1-P_{de}}(N-k+1, k), \quad (11)$$

Global error rate of $k = m+1$ voting rule at CR base station can be expressed as

$$P_{GE,m+1} = P_{F,m+1} + P_{M,m+1}$$
$$= 1 - I_{1-P_{fe}}(N-m, m+1) + I_{1-P_{de}}(N-m, m+1) \quad (12)$$

Similarly, global error rate of $k = N-m$ voting rule at CR base station can be expressed as

$$P_{GE,N-m} = P_{F,N-m} + P_{M,N-m}$$
$$= 1 - I_{1-P_{fe}}(m+1, N-m) + I_{1-P_{de}}(m+1, N-m) \quad (13)$$

III. Optimization of Number of Cognitive Users in Cooperative Spectrum Sensing Over Erroneous Reporting Channels

In this section we derive the expression for optimal number of cognitive users by minimizing the global error rate of $k = m+1$ and k = $N-m$ voting rules at CR base station.

A. Optimal Number of Cognitive Users for $k = m+1$ Voting Rule

Fig. 2 shows variation of error rate with respect to detection threshold for six values of N for $k = 3$ ($k = m+1$; for $m = 2$) voting rule at CR base station. It is observed that for $N \geq 3$ there exists an optimal N for a given detection threshold. Clearly, the value of N plays an important role in describing the performance of cooperative spectrum sensing. In the following proposition we give exact solution for optimal N by minimizing the global error rate of $k = m+1$ voting rule at CR base station.

Proposition 1: Given $k = m+1$ voting rule at CR base station, the optimal number of cognitive users in CR network,

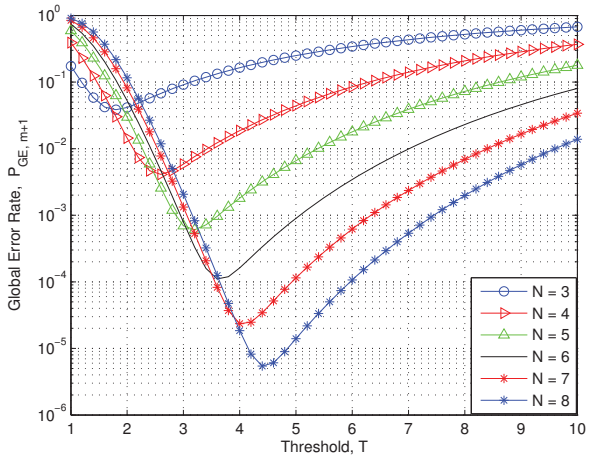

Fig. 2. Global error rate versus detection threshold, for $k = 3$ ($k = m+1$; for $m = 2$) voting rule at CR base station for p = 2, L = 5, P_e = 0, SNR = 10 dB, N = 3, 4, . . . , 8, for improved energy detector.

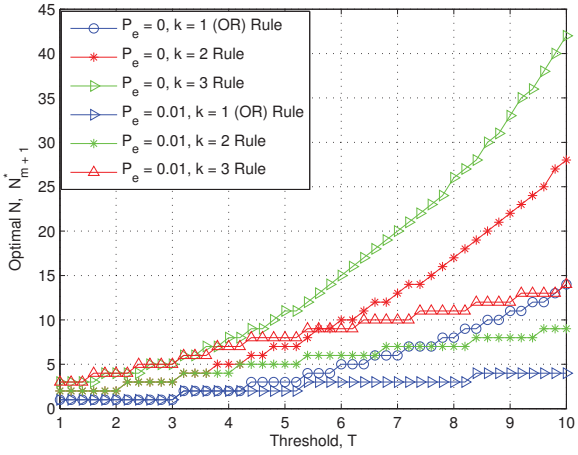

Fig. 3. Effect of reporting channel error: Optimal N versus detection threshold, T for $k = m+1$ ($m = 0, 1, 2$) voting rules at CR base station for P_e = 0, 0.01, SNR = 10 dB and p = 2, for improved energy detector.

denoted as N^*_{m+1}, that minimizes the $P_{F,m+1} + P_{M,m+1}$ is given by

$$N^*_{m+1} = \lceil (m+1)\alpha + m \rceil, \quad \alpha = \frac{\ln \frac{1-P_{me}}{P_{fe}}}{\ln \frac{1-P_{fe}}{P_{me}}}, \tag{14}$$

where $\lceil . \rceil$ indicates ceiling function.

Proof: Appendix I. ■

From proposition 1, we can make the following observations which apply to any detector (though the example plots are given for improved energy detector).

- Substituting $m = 0$ in (14), we get optimal N for OR rule ($k = 1$) and is given by $N^*_{OR} = \lceil \alpha \rceil$.
- From (14), we have

$$(m+1)\alpha + m \leq N^*_{m+1} < (m+1)\alpha + m + 1,$$

$$\Rightarrow \frac{N^*_{m+1}}{m+1} - 1 < \alpha \leq \frac{N^*_{m+1} - 1}{m+1}. \tag{15}$$

Note that $P_{fe} + P_{me} < 1$, which implies $\alpha > 0$. From (15), we draw inference as $N^*_{m+1} \geq m+1$. This means that there exists an optimal N if there exist at least $m+1$ cognitive users in the CR network.

Fig. 3 plots the of optimal N versus detection threshold of $k = m+1$ ($m = 0, 1, 2$) voting rule for various values of P_e. It is observed that for given probability of error in the reporting channel, optimal N increases as voting rule increases. However, for a given voting rule at CR base station, optimal N decreases as P_e increases. This means that error in the reporting channel deteriorates the reliability of decisions received at CR base station.

The observations we have made above are corroborated from Fig. 2 and Fig. 3

B. Optimal Number of Cognitive Users for $k = N-m$ Voting Rule

Fig. 4 plots the global error rate of $k = N-2$ ($k = N-m$; for $m = 2$) voting rule with respect to detection threshold for six values of N. It is observed that for $N \geq 3$ there exists an optimal N for a given detection threshold. Clearly, the value of N plays an important role in describing the performance of cooperative spectrum sensing. In the following proposition we give exact solution for optimal N by minimizing the global error rate of $k = N - m$ voting rule at CR base station.

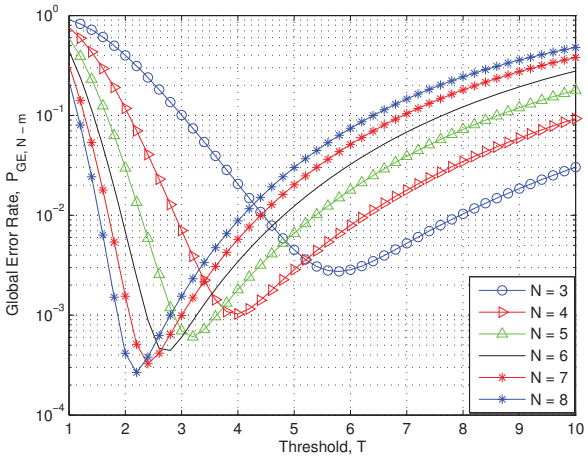

Fig. 4. Global error rate versus detection threshold, for $k = N-2$ ($k = N-m$; for $m = 2$) voting rule at CR base station for p = 2, L = 5, P_e = 0, SNR = 10 dB, N = 3, 4, . . . , 8, for improved energy detector.

Proposition 2: Given $k = N - m$ voting rule at CR base station, the optimal number of cognitive users in CR network, denoted as N^*_{N-m}, that minimizes the $P_{F,N-m} + P_{M,N-m}$ is given by

$$N^*_{N-m} = \left\lceil \frac{(m+1)}{\alpha} + m \right\rceil, \tag{16}$$

where α is given by (14).

Proof: Appendix II. ■

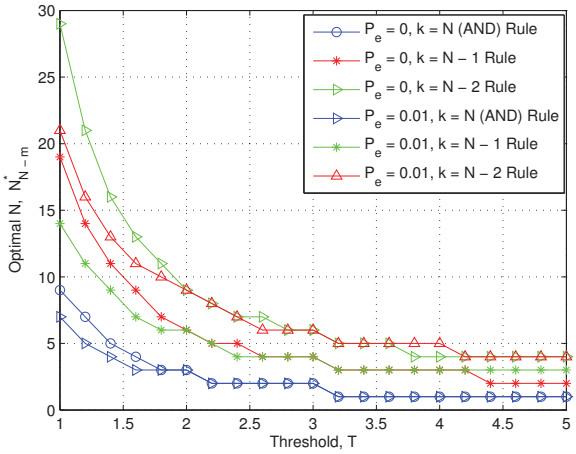

Fig. 5. Effect of reporting channel error: Optimal N versus detection threshold, T for $k = N - m$ ($m = 0, 1, 2$) voting rules at CR base station for P_e = 0, 0.01, SNR = 10 dB and p = 2, for improved energy detector.

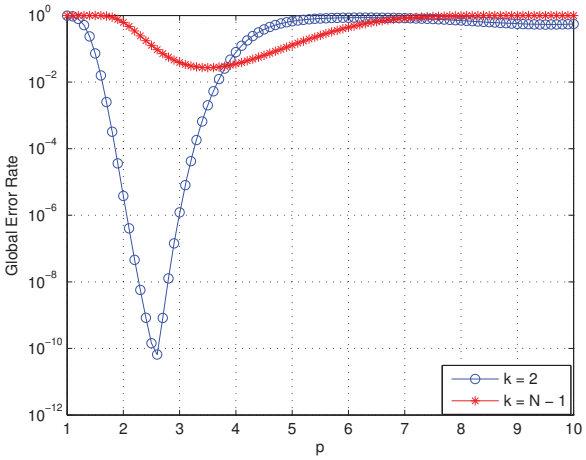

Fig. 6. Global error rate versus p, for $k = m + 1$ and $k = N - m$ (for $m = 1$) voting rules at CR base station for N = 10, L = 10, T = 10, SNR = 10 dB, for improved energy detector.

From proposition 2, we can make the following observations which apply to any detector (though the example plots are given for improved energy detector).

- Substituting $m = 0$ in (16), we get optimal N for AND rule ($k = N$) and is given by $N^*_{AND} = \lceil 1/\alpha \rceil$.
- From (16), we have

$$N^*_{N-m} - 1 < m + \frac{m+1}{\alpha} \leq N^*_{N-m},$$

$$\frac{m+1}{N^*_{N-m} - m} \leq \alpha < \frac{m+1}{N^*_{N-m} - (m+1)}. \qquad (17)$$

Since $\alpha > 0$, from (17) we conclude that $N^*_{N-m} \geq m + 1$. This means that there exist minimum $m + 1$ cognitive users in the CR network to obtain the value of optimal N.

Fig. 5 plots the of optimal N versus detection threshold of $k = N - m$ ($m = 0, 1, 2$) voting rule for various values of P_e. It is observed that for given probability of error in the reporting channel, optimal N increases as voting rule decreases. However, for a given voting rule at CR base station, optimal N decreases as P_e increases. This means that error in the reporting channel deteriorates the reliability of decisions received at CR base station.

The observations we have made above are corroborated from Fig. 4 and Fig. 5

Fig. 6 plots the global error rate with respect to p for $k = m + 1$ and $k = N - m$ voting rules. It is observed that for a given N, there exists an optimal p for each voting rule.

C. Comparison and Optimization of Improved Energy Detector for $k = m + 1$, $k = N - m$ Voting Rules

Fig. 7 shows the performance comparison of $k = m + 1$ and $k = N - m$ (for m = 0, 1, 2, 3) voting rules with respect to SNR. It is observed that for a fixed m, $k = m + 1$ rule performs better compared to $k = N - m$ voting rule. It is also observed that for a given voting rule at CR base station, as m increases global error rate decreases.

Following [7], we use optimal algorithm, i.e., we numerically obtain the values of optimal p, optimal detection threshold, optimal N with respect to SNR. Using this optimal algorithm we have plotted the error performance of $k = m+1$ and $k = N-m$ voting rules for $m = 1$. We also compare with performance of conventional energy detector (p = 2). From Fig. 8 we conclude that performance using optimal algorithm is better compare to conventional energy detector.

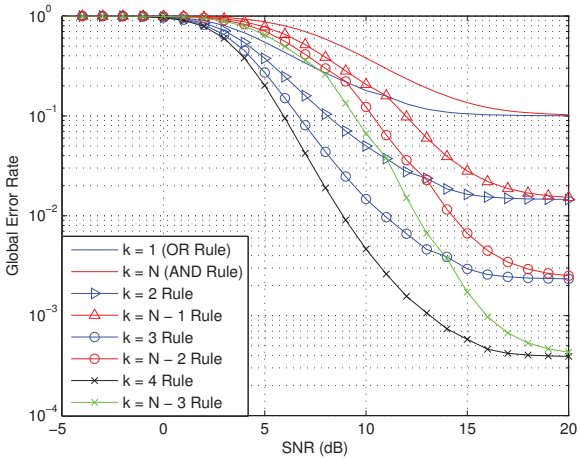

Fig. 7. Comparison of $k = m + 1$ and $k = N - m$ (for m = 0, 1, 2, 3) voting rules at CR base station for P_e = 0.05, L = 5, $p = 2$, $T = 10$, using optimal N for improved energy detector.

IV. CONCLUSION

We have derived the expressions for optimal N by minimizing the global error rate of $k = m + 1$ and $k = N - m$ voting rules at CR base station. We show that for a given m, performance of $k = m + 1$ voting rule is better compared to

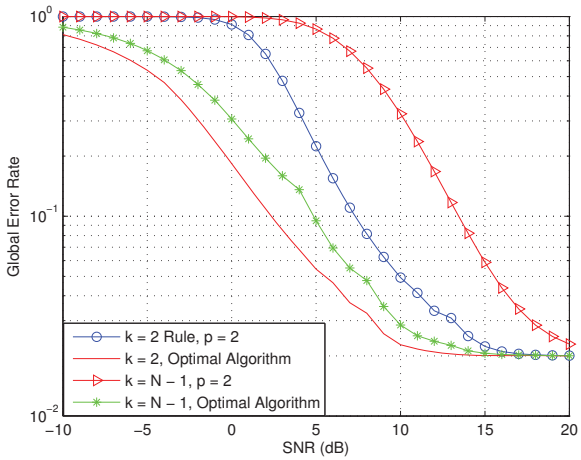

Fig. 8. Global error rate versus SNR, for $k = m + 1$ and $k = N - m$ ($m = 1$) voting rules at CR base station for P_e = 0.01, L = 5, using optimal p, optimal N, for improved energy detector.

$k = N-m$ voting rule. Finally, we use optimal algorithm, i.e., we numerically obtain the jointly optimized values of detection threshold, p of the improved energy detector and optimal N. We also compare with conventional energy detector. We show that performance using optimal algorithm is better than conventional energy detector.

Appendix I: Proof of Proposition 1

Proof: To prove proposition 1, we consider (12)

$$P_{GE,m+1} = 1 - I_{1-P_{fe}}(N-m, m+1) + I_{1-P_{de}}(N-m, m+1) = f(N)$$

Optimal value of N can be obtained when difference equation $\Delta f(N) = f(N+1) - f(N)$ equal to zero. i.e., when

$$I_{1-P_{fe}}(N-m, m+1) - I_{1-P_{fe}}(N-m+1, m+1) = I_{1-P_{de}}(N-m, m+1) - I_{1-P_{de}}(N-m+1, m+1) \quad (18)$$

For x, y are positives integers, regularized incomplete beta function can also expressed as

$$I_P(x,y) = (1-P)^y \sum_{i=x}^{\infty} \binom{y+i-1}{i} P^i \quad (19)$$

Using (19), we show that

$$I_P(x,y) - I_P(x+1,y) = \binom{x+y-1}{x} P^x (1-P)^y \quad (20)$$

Simplifying (18), using (20) and rearranging, we get

$$\left(\frac{1-P_{fe}}{P_{me}}\right)^{N-m} = \left(\frac{1-P_{me}}{P_{fe}}\right)^{m+1}$$

$$\Rightarrow N^*_{m+1} = \lceil (m+1)\alpha + m \rceil$$

where α is given by (14). ■

Appendix II: Proof of Proposition 2

Proof: To prove proposition 2, we consider (13)

$$P_{GE,N-m} = 1 - I_{1-P_{fe}}(m+1, N-m) + I_{1-P_{de}}(m+1, N-m) = g(N)$$

Optimal value of N can be obtained when difference equation $\Delta g(N) = g(N+1) - g(N)$ equal to zero. i.e., when

$$I_{1-P_{fe}}(m+1, N-m) - I_{1-P_{fe}}(m+1, N-m+1) = I_{1-P_{de}}(m+1, N-m) - I_{1-P_{de}}(m+1, N-m+1) \quad (21)$$

Using (9), we show that

$$I_{1-P}(x,y) = 1 - I_P(y,x) \quad (22)$$

Simplifying (21) by using (22) and rearranging, we have

$$I_{P_{fe}}(N-m, m+1) - I_{P_{fe}}(N-m+1, m+1) = I_{P_{de}}(N-m, m+1) - I_{P_{de}}(N-m+1, m+1)$$

Further simplifying above equation using (20) and rearranging, we get

$$\left(\frac{1-P_{me}}{P_{fe}}\right)^{N-m} = \left(\frac{1-P_{fe}}{P_{me}}\right)^{m+1}$$

$$\Rightarrow N^*_{N-m} = \left\lceil \frac{(m+1)}{\alpha} + m \right\rceil$$

■

where α is given by (14).

Abstract—**The new paradigm of Machine-to-Machine (M2M) communications poses problems in regard to the spectrum usage, arising the need to share radio resources. Downlink with low-fixed-rate Device-to-Device (D2D) underlay and Successive Interference Cancellation (SIC) are emergent solutions. The considered scenario can be described by two links: Infrastructure-to-Device (I2D) and D2D links. In this work, Long Term Evolution (LTE) physical layer, Single-Input Single-Output (SISO) mode and block flat Rayleigh fading are assumed for both links, where Link Adaptation (LA) is only performed by the Base Station (BS). In this context, this paper seeks to validate that it is possible to guarantee a certain Quality of Service (QoS) requirement, despite not being able to determine the D2D CSI in the LA process, while simultaneously addressing technical implementation problems that arise.**

Keywords—M2M, D2D Underlay, SIC, Link Adaptation, LTE

I. INTRODUCTION

Currently, the design of future 5th generation (5G) cellular networks is in the works and, within this framework, several technologies are being investigated. In [1], it is argued that a significantly better performance cannot be accomplished by simply adding new features to the existing standards and that such goal requires instead the introduction of disruptive technologies that force the deep-rooted cellular principles to be reformulated. Among those technologies, there are two that fall into the scope of this work: Device-to-Device (D2D) and Machine-to-Machine (M2M) communications.

D2D communication refers to the ability of one wireless device to communicate, via direct link, with another using the spectrum that is available for regular cellular communications. It is noteworthy that existing technologies, such as Wi-Fi and Bluetooth, already allow devices to directly communicate with each other, but the usage of unlicensed radio resources leads to several limitations given that interference levels cannot be properly controlled. On the other hand, M2M consists of a multitude of Machine-Type communications Devices (MTDs) connected to the network. These devices are often described in the context of Wireless Sensor Networks (WSNs) which are able to offer numerous applications related to data collection, ranging from environmental to health-care monitoring.

One problem that arises is related to the spectrum usage. In a situation where there is a need for a massive number of devices to communicate, efficient Radio Resource Management (RRM) algorithms are of extreme importance, reinforcing also the emergence of Interference Cancellation (IC) techniques. Indeed, if one is to interpret the interferers as yet other sources of useful information (from other devices), one can readily understand that IC techniques permit the coexistence of multiple links. Moreover, in Orthogonal Frequency-Division Multiplexing (OFDM) systems, of which LTE is part of, extracting the signal of an interferer by means of channel decoding is generally the only processing gain available [2]. It is precisely in this circumstance that the concept of Successive Interference Cancelation (SIC) arises.

The basic principle of SIC is to decode different devices sequentially, such that the interference due to the decoded devices is subtracted before decoding the others. Allied to SIC, there is also the need to adapt the transmission parameters to the channel conditions. This is referred to as Link Adaptation (LA).

Additionally, in [3], the concept of cellular downlink with low-fixed-rate D2D underlay is explored, providing insight into its relationship with SIC. In fact, it is shown analytically that "SIC is an important enabler of underlay D2D communication". In [4], this synergy is further investigated and it considers the possibility of partial Channel State Information at the Transmitter (CSIT). The noteworthy conclusion is that, in theory, there is "a positive downlink rate that can always be decoded" which leads to "zero-outage of the downlink signal".

That said, this paper seeks not only to validate, but also to evaluate in a new scenario the concept originally presented in [4] by considering a low-fixed-rate D2D underlay, the usage of SIC and partial CSIT in a LTE setting. The aim is not to achieve a zero-outage situation, but to prove that a certain QoS can be guaranteed. It is also worth emphasizing the relevance of the constraint that is associated to the knowledge of the D2D CSI in the LA process, i.e. partial CSIT. This constraint arises from the fact that, in the context of M2M communications, MTDs might exhibit intermittent activity, rather than continuous. However, the receiver is only able to report the CSI estimate if transmission occurs, given that this estimate is computed from reference signals. Thus, in such scenarios, the receiver can report an accurate Infrastructure-to-Device (I2D) CSI due to continuous transmission, but, since the D2D communication occurs intermittently, the reported D2D CSI can be fairly outdated, reporting an estimate that might be highly inaccurate.

The rest of the paper is organized as follows: Section II describes the system model; Section III focuses on the LA strategies; numerical results are given in Section IV and conclusions are drawn in Section V.

II. SYSTEM MODEL

A. Link Level Overview

Consider the topology depicted in Fig. 1 which consists of two Single-Input Single-Output (SISO) links. The link denoted by D2D refers to the transmission of the MTD data to a given UE, whereas the I2D targets the same UE but has the Base Station (BS) as the transmit entity. The D2D is considered to be a low-rate link when compared to the I2D. It is also assumed that the BS is able to dynamically adjust its rate as opposed to the MTD whose rate is fixed, i.e. fixed Modulation and Coding Scheme (MCS). Another assumption is that the system operates under non-line-of-sight conditions such that these links are characterized by two independent block flat Rayleigh fading channels whose gains remain constant over each Transmission Time Interval (TTI) and over all the assigned subcarriers. Furthermore, it is assumed that the UE has always perfect CSI knowledge during the decoding process so much so that no estimation error arises when determining both channel gain estimates and the noise power. For LA purposes, the UE computes the MCS to be reported to the BS according to a given rule (see Section III). In turn, this report is assumed to occur in an instantaneous fashion so that the BS can apply the most appropriate MCS for each instantaneous channel realization. It should be noted that, in a real scenario, rather than instantaneous, the report has a delay, but if one considers that the fading is sufficiently slow, the reports are still accurate enough, validating the simplification. That said, let the post-detection received signal on a given subcarrier be defined as

$$Y = H_M X_M + H_B X_B + w, \tag{1}$$

where X_M and X_B are the Quadrature Amplitude Modulation (QAM) symbols transmitted by the MTD and the BS respectively; H_M and H_B are the complex coefficients of the two independent channels and w represents the white Gaussian noise with variance σ_w^2. The Signal-to-Noise Ratio (SNR) of each link can then be written as

$$\gamma_i = \frac{|H_i|^2 P_i}{\sigma_w^2}, \qquad i \in \{M, B\}, \tag{2}$$

where $P_i = E[|X_i|^2]$ is the average transmitted power of the respective entity (MTD or BS). Furthermore, the corresponding Signal-to-Interference-plus-Noise Ratio (SINR) is given by

$$\eta_i = \frac{|H_i|^2 P_i}{\sigma_w^2 + |H_j|^2 P_j} = \frac{\gamma_i}{1 + \gamma_j}, \qquad (i, j) \in \{M, B\}^2, i \neq j. \tag{3}$$

B. Transmitter Model

The transmit entities are the MTD and the BS, both of which are modelled as two separate LTE downlink transmitters [5] and whose model is shown in Fig. 2.

The processing chain begins by grouping the data into chunks of variable length known as Transport Blocks (TBs),

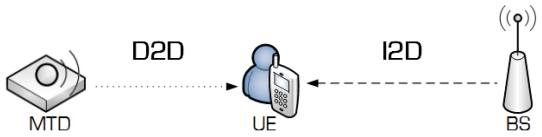

Fig. 1. Link Level Topology

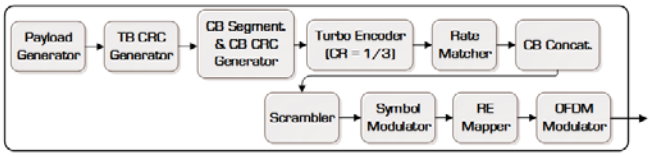

Fig. 2. LTE Downlink Transmitter Model

followed by the calculation and attachment of a 24-bit Cyclic Redundancy Check (CRC) to each TB as a means to detect errors at the receiver side. The CRC-attached TB may be split into several Code Blocks (CBs) since the turbo coder interleaver has a maximum size of 6144 bits. In such case, each CB is attached with its own 24-bit CRC (CB-CRC). Subsequently, each CRC-attached CB is rate-1/3-turbo-code encoded followed by a rate matching procedure which includes additional interleaving and produces CB Code Words (CWs) with the target code rate. The CB-CWs are then concatenated to form a TB-CW and scrambled with a unique Gold sequence based on the physical level identity of the respective transmitter. The resulting sequence passes through a symbol mapper whose modulation can be 4-, 16- or 64-QAM depending on the MCS index. Finally, the symbols are mapped to Resource Elements (REs) that form the resource grid which, in turn, serves as input to the OFDM modulator, producing the baseband time-domain signal to be transmitted. Overheads and retransmissions are not modeled.

C. Receiver Model

The considered receiver is a Hard SIC receiver based on TB CRC [6] whose model is depicted in Fig. 3. In the literature, namely where SIC is applied to LTE systems, the focus is on cancelling transmissions from multiple antennas pertaining to the same transmit entity, e.g. [6]. In such case, all the signals are encoded with the same MCS. It thus follows that the optimal order of decoding is to sort the signals according to their SINR such that the signal experiencing the highest SINR is decoded first. In the present case, this does not apply, seeing that MTD and BS generally encode their messages with different MCSs. Consequently, the rule to determine the order of decoding is not based on which link experiences the highest SINR, but rather on how great the margin between the SINR and the operation threshold associated to the given MCS is. This operation threshold is, in turn, the SINR value at which the receiver is able to decode the signal with a given target Block Error Rate Probability (BLEP).

D. Modulation and Coding Schemes

The MCSs considered in this work are the same as those in [7] and are listed in Table 1. The MTD uses the most robust MCS, i.e. MCS 1, while the BS has the ability to encode its messages with any of the listed MCSs. Additionally, in a standardized LTE system, the receiver reports a 4-bit index, Channel Quality Indicator (CQI), limited to 15 different MCSs. Therefore, in said system, the BS uses the CQI report allied to other factors, such as positive/negative acknowledgement rate, to determine the

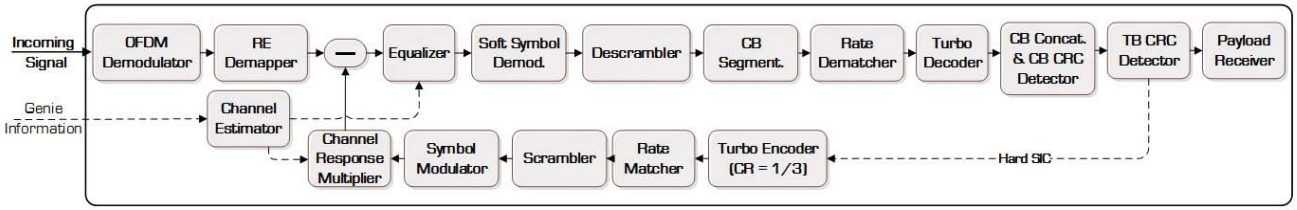

Fig. 3. LTE Receiver Model

MCS. In this work, it is assumed that the CQI is not restricted to 4 bits such that the receiver is able to report any of the available schemes, existing thus a one-to-one relationship between the CQI and the chosen MCS. In practice, this means that the MCS choice has been delegated to the receiver. Note, however, that since the CQI report is assumed instantaneous, it is analogous to the case where the BS (transmitter) is aware of the instantaneous CSI, i.e. CSIT, and chooses the MCS.

E. Operation Modes

Four operation modes are considered:

1. Orthogonal mode (Ortho): D2D and I2D links occur simultaneously, but different resources are assigned to each link. There is thus no interference, at the expense of having to allocate twice the resources.
2. Legacy mode (Legacy): D2D and I2D links occur simultaneously and share the same resources which leads to interference. The receiver (UE) does not perform SIC.
3. SIC with full CSIT (SICF): Similar to the previous mode in the sense that both links operate at the same time and share the same resources, but the UE is now a SIC-capable device. For LA purposes, both CSIs are known.
4. SIC with partial CSIT (SICP): Same conditions as the previous mode, except that the D2D CSI cannot be determined when performing LA.

Recall that the last mode is the primary focus of this work, while the other three are included for benchmarking purposes.

III. LINK ADAPTATION STRATEGIES

A. Single Link without Interference

First consider the orthogonal mode. From a LA stance, this is equivalent to the case where there is only a single link without any interference. Let k denote the index of a given MCS, $\mathcal{K}$ the set of available MCSs such that $k \in \mathcal{K} := \{1, \dots, K\}$ and that a higher MCS index corresponds to a more efficient (and less robust) MCS. Each MCS has thus its own spectral efficiency, denoted by $\mathcal{E}(k)$, and operation threshold Γ_k that corresponds to the point at which the kth MCS experiences a BLEP equal to the target Block Error Rate (BLER) given by ξ, i.e., $BLEP(k) = \xi$. Recalling that γ denotes the received instantaneous SNR, the focus is to maximize the expected instantaneous efficiency (equivalent to throughput) under the constraint that the estimated BLEP is smaller or equal than the target BLER. It is, thus, obvious that this problem can only be solved if $\gamma \geq \Gamma_1$. Provided that this condition is generally met by means of an appropriate power control scheme, the optimization problem for this scenario can be written as:

Table 1. Modulation and Coding Schemes

Index	Modulation	Code Rate	Index	Modulation	Code Rate
1	4-QAM	1/9	14	16-QAM	0.54
2	4-QAM	1/6	15	16-QAM	0.58
3	4-QAM	0.21	16	16-QAM	0.61
4	4-QAM	1/4	17	16-QAM	2/3
5	4-QAM	1/3	18	16-QAM	0.73
6	4-QAM	0.42	19	16-QAM	4/5
7	4-QAM	1/2	20	64-QAM	0.58
8	4-QAM	0.58	21	64-QAM	0.62
9	4-QAM	2/3	22	64-QAM	2/3
10	4-QAM	0.73	23	64-QAM	0.70
11	16-QAM	0.43	24	64-QAM	0.74
12	16-QAM	0.46	25	64-QAM	4/5
13	16-QAM	1/2	26	64-QAM	0.85
			27	64-QAM	0.90

$$\begin{aligned} \max_{k \in \mathcal{K}} \quad & \mathcal{E}(k).\big(1 - BLEP(\gamma, k)\big). \\ s.t. \quad & BLEP(\gamma, k) \leq \xi \end{aligned} \tag{4}$$

Assuming optimal coding and recalling that the MCS indices are sorted in terms of increased efficiency, the cost function simplifies into $f(k) = k$. Based on this approach, the only values that need to be stored are the operation thresholds Γ_k, determined from a prior calibration step [8]. The algorithm then consists in finding the highest MCS whose threshold is smaller or equal than the received SNR, i.e. SNR-MCS mapping. Lastly, it is worth pointing that the optimal coding simplification is justified by the near optimality exhibited by real coding [9] in which the BLEP decreases rapidly once the target BLER is met.

B. Single Link with Interference

Consider now the scenario where the link is also affected by interference (Legacy). In this case and assuming that the interference can be treated as Gaussian noise, the optimization problem can still be written as in (4), noting that the metric to measure the link quality becomes SINR, η, instead of SNR, γ. Following the same optimal coding simplification, the MCS is obtained by using the algorithm described in the previous subsection, but using the SINR as the metric. Also note that the problem is only solvable if $\eta \geq \Gamma_1$, which means that the system can be in outage not only due to a deep fade, but also if the interference is strong.

C. SIC with full CSIT

In this case, the goal is still to maximize the expected instantaneous efficiency of the I2D link, but under the constraint that the BLEPs of each link are smaller or equal than ξ:

$$\begin{aligned} \max_{k \in \mathcal{K}} \quad & \mathcal{E}(k).(1 - BLEP_B), \\ s.t. \quad & BLEP_M \leq \xi \\ & BLEP_B \leq \xi \end{aligned} \tag{5}$$

where the indices M and B specify the transmit entity and consequently the link, i.e. D2D and I2D links respectively.

Recalling that the D2D MCS is fixed (MCS_M), the BLEPs are given by:

$$BLEP_M = BLEP(\eta_M, MCS_M) - BLEP(\eta_M, MCS_M) \times \left(1 - BLEP(\eta_B, k)\right) \times \left(1 - BLEP(\gamma_M, MCS_M)\right), \quad (6)$$

$$BLEP_B = BLEP(\eta_B, k) - BLEP(\eta_B, k) \times \left(1 - BLEP(\eta_M, MCS_M)\right) \times \left(1 - BLEP(\gamma_B, k)\right), \quad (7)$$

where the second term results from the ideal SIC principle [2] in which the interference can be perfectly cancelled.

Assuming again the optimal coding simplification, there are only two cases to be evaluated. If $\eta_M \geq \Gamma_M$, the first constraint in (5) is automatically satisfied and the second degenerates into $BLEP(\gamma_B, k) \leq \xi$, being analogous to the single link without interference case. On the other hand, if $\eta_M < \Gamma_M$, the second constraint becomes $BLEP(\eta_B, k) < \xi$, forcing the I2D MCS to be chosen such that $\Gamma_B \leq \eta_B$. The first constraint then simplifies into $BLEP(\gamma_M, MCS_M) < \xi$ which is independent of the choice of I2D MCS, but provided that the system is well-dimensioned is satisfied for most cases, unless a deep fade occurs. Consequently, this rule can be described as follows:

Algorithm 1: SICF

```
Γ_M = get_threshold(MCS_M)
for each TTI do                    // new channel conditions
    if η_M ≥ Γ_M then              //effective I2D channel quality metric
        SINR_eff = γ_B
    else
        SINR_eff = η_B
    end if
    MCS_B = get_max_MCS(SINR_eff)  //SINR-MCS mapping
    report(MCS_B)
end for
```

D. SIC with partial CSIT

As above, the problem is expressed by (5), but now the D2D CSI is not known. Thus, the approach is to design the LA for the worst scenario. Considering again the use of optimal coding, this occurs when the MTD signal cannot be decoded without IC, i.e. $\eta_M < \Gamma_M$, which, as first derived in [4], means that

$$\eta_M = \frac{\gamma_M}{1+\gamma_B} < \Gamma_M \Leftrightarrow \gamma_M < \Gamma_M (1+\gamma_B) \quad (8)$$

and, consequently,

$$\left(\eta_B = \frac{\gamma_B}{1+\gamma_M}\right) > \left(\frac{\gamma_B}{1+\Gamma_M(1+\gamma_B)} := \widetilde{\eta_B}\right), \quad (9)$$

where $\widetilde{\eta_B}$ corresponds to the infimum and is the I2D channel quality metric ($SINR_{eff}$) used to determine the I2D MCS. It should be stressed that it is again required that $\gamma_M \geq \Gamma_M$, else the first constraint cannot be met.

Finally, note the importance of using a robust MCS_M such that Γ_M is low; otherwise, the I2D throughput is severely limited even when $\eta_B \to \infty$:

$$\lim_{\eta_B \to \infty} (\widetilde{\eta_B}) = \lim_{\gamma_B \to \infty} \left(\frac{\gamma_B}{1+\Gamma_M(1+\gamma_B)}\right) = \frac{1}{\Gamma_M}. \quad (10)$$

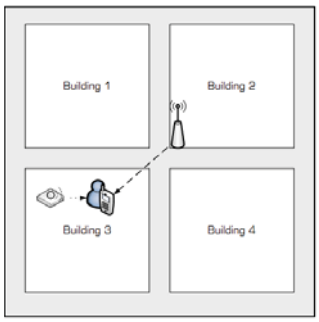

Fig. 4. Indoor on-body MTD Scenario

IV. SIMULATIONS

A. Link Level Simulator Setup

An indoor on-body MTD scenario is considered. The layout is shown in Fig. 4 and is based on "Test Case 2" of [10]: a 2x2 grid with wrap-around constituted by 120x120m 8-floor buildings whose floor height is 3.5 m and spaced apart by 18 m. The 3.5 m-tall BS is located in the southwest corner of the roof of the northeast building and it communicates with the 1.5 m-tall UE that is inside the southwest building. For each floor, the user randomly picks 500 different positions that are uniformly distributed and the I2D path losses follow the "Urban Macro Outdoor-to-Indoor" propagation model.

Additionally, this user has an on-body sensor (MTD) which directly communicates with the corresponding UE. The path loss for the D2D link is fixed and is 60 dB [11]. Each stationary measurement, in turn, has a duration of 10^5 TTIs. Other parameters include: 1.4 MHz bandwidth (6 Resource Blocks) for each link; 800 MHz carrier frequency; 9 dB UE noise figure; 0 dBi UE and MTD antenna gains; 15 dBi BS antenna gain; 0 dBm and 46 dBm transmit powers for the MTD and BS respectively [12].

Furthermore, the implemented simulator is based on a publicly available LTE link level simulator and therefore no calibration procedure had to be conducted [13]. Normal cyclic prefix, zero forcing equalization, an 8-iteration max-log-Maximum-a-Posteriori algorithm and $\xi = 10\%$ [8] are used. A full-buffer traffic model is also assumed.

B. Simulation Results

Simulations analyze the four operation modes in regard to BLER and throughput (R) per Resource Block (RB) for the D2D and I2D links, Fig. 5 and Fig. 6 respectively. Begin by noticing that only the Legacy and SICF BLER curves are shown in Fig. 5. This is due to Ortho and SICP exhibiting BLERs so low that all fall below the minimum resolution, i.e. $BLER < 10^{-5}$. Regardless, the primary goal is to evaluate if the modes meet the 10% BLER which is satisfied for all modes except Legacy, emphasizing not only that SIC is a necessity if resources need to be shared, but also attesting that SICP can indeed meet a certain QoS without full CSI knowledge during LA.

Regarding the throughput per RB, in the D2D link, the throughput is proportional to the block success rate which is given by $1 - BLER_M$. Naturally, in Legacy, a wide range of throughput rates is experienced by the user, while in the other modes the absolute throughput is practically always the

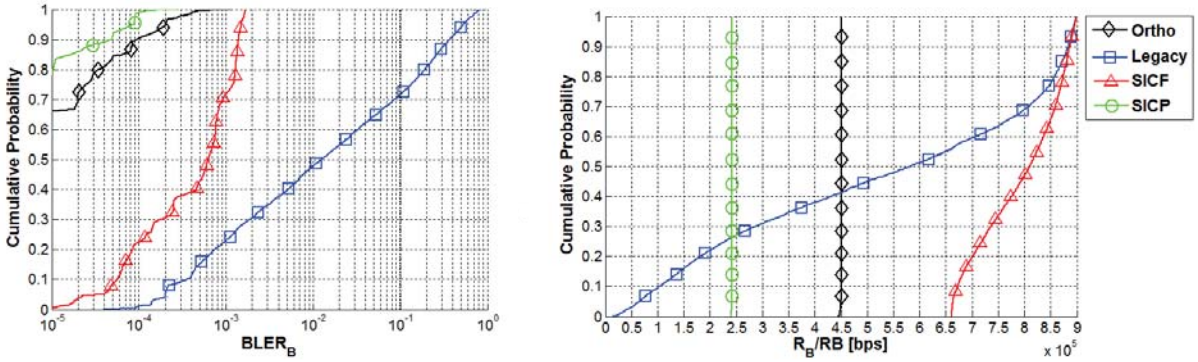

Fig. 5. BLER and Throughput per RB CDFs - D2D link

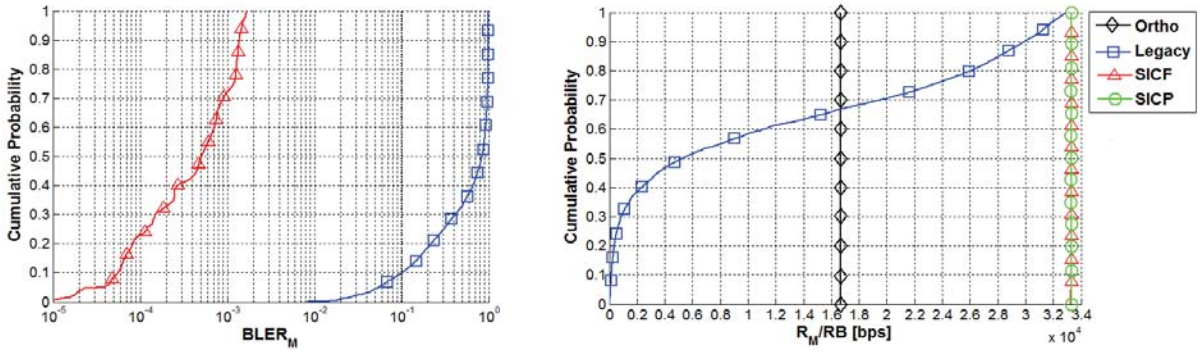

Fig. 6. BLER and Throughput per RB CDFs - I2D link

maximum. Although achieving the same absolute throughput, twice the resources are allocated in Ortho, thus the throughput per RB is halved. In the I2D link, despite using twice the resources, Ortho reaches a throughput per RB that is almost twice than that of SICP. On the other hand, Legacy experiences again a range of throughputs that covers nearly all the possible throughputs, while SICF can always guarantee a throughput per RB that is roughly 50% higher than that of Ortho and can go up to 100%.

V. CONCLUSION

This paper began by addressing technical implementation problems that arise when applying SIC LA strategies to cellular downlink with low-fixed-rate D2D underlay and whose physical layer is based on OFDM. It also validated that SICP can guarantee a certain QoS without knowledge of the D2D CSI in a LTE setting. Results show that its performance is roughly half than that of Ortho in the I2D link. To decrease this gap an even more robust D2D MCS such as Binary Phase-Shift Keying or lower coding rates, currently not standardized by LTE, ought to be used. Note that its usage should not compromise most M2M services since they are to operate at very low throughput rates.

ACKNOWLEDGEMENT

The authors would like to thank FCT for the support by the project UID/EEA/50008/2013. In addition, a word of gratitude to Nuno Pratas and Petar Popovski (Aalborg University) for their helpful and valuable contribution.

Sinhgad Academy of Engineering, Pune, India
pranotibalki1@gmail.com,kppatil.sae@sinhgad.edu

Abstract— **In cognitive radio networks most of the routing protocols uses either dedicated unlicensed Common Control Channels (CCC) at 2.4 GHz or free Primary User (PU) licensed CCC for routing. In case of licensed CCC, the path selection and coordination among cognitive radio nodes takes more time. But, the problem of congestion occur at larger level in case of 2.4 GHz CCC due to interference from other wireless services and saturation which further leads to rise in link failure and routing control overhead that degrades the performance of system. In our proposed work, we have used lower unlicensed frequency as a low rate CCC since it is underutilized. Cognitive radio network routing necessitates a cross-layering approach due to close coupling and interaction between protocol layers. In this paper we presents comparative study for low (902-928 MHz) and high frequency (2.4GHz) CCC based AODV protocol with distributed optimization in cross layering via Genetic Algorithm. Assuming each node, with wireless links employing non-congestion Orthogonal Frequency Division Multiplexing (OFDM) to enable Dynamic Spectrum Access (DSA). Simulation (NS-2.32) results show that the low rate Common Control Channel performs better in terms of throughput, BER, hop count and end to end delay.**

I. INTRODUCTION

Spectrum scarcity is the major issue currently faced by the world due to rigid spectrum management policies. Unlicensed radio spectrum is the most heavily used and is occupied by a wide range of application in unlicensed Industrial, Scientific and Medical (ISM) fields that results in spectrum overcrowding. National regulatory bodies like Federal Communication Commission (FCC) [1] states that most of the allocated static licensed spectral bands is of similar type and geographical variation. Its usage is ranging from 15% to 85% in the band below 3 GHz. According to [2] Cognitive Radio (CR), is a new paradigm that provides the solution to the problem of spectrum scarcity and is capable of automatically choosing device parameters based on the prevailing operating conditions.

Many existing CR routing protocol uses 2.4 GHz band in collaboration with IEEE 802.11x for channel path selection and node coordination message transfer [3][4]. But the higher frequency band (2.4 GHz) has lower transmission range than lower frequency band. This is because of reflection, refraction, vegetation path loss, diffractions, attenuation, scattering and free space path [5]. The lower frequencies which are present at lower spectrum band (902-928 MHz) have relatively higher transmission range because of less space path loss compared with higher frequencies.

Cross-layer optimization is one of the key features of CR which enable simultaneous optimization of several operating parameters across different OSI layers of the device [6]. In addition, cognitive radio provides new proficient technology to improve the spectrum scarcity problem and increases the spectrum utilization i.e. Dynamic Spectrum Access (DSA) [7]. CR has ability to find the spectrum hole and transmit by using it without interference to the legitimate users. Genetic algorithm (GA) in combination with CR is employed in many works to achieve adoption automation and optimization in wireless networks. In [8], a population adaptation technique is presented for a GA that takes benefit of the information from prior cognition cycle, with an objective to diminish the time required to accomplish an optimal decision. According to J. F. Hauris [9] GA is used to solve the optimization of RF parameter for a wireless network to implement the adaptive process for CR on an autonomous vehicle, with chromosome structure for optimal radio communication in the varying RF environment. Distributed optimization has recently become the most active area of investigation in the wireless network. In [10], Y. Shi and Y. Hou verified that how distributed algorithm is designed for future multi hop CR network where conservative approach and aggressive approach are integrated to maximize the data rate for a set of user communication session. According to [11] it is given that a distributed channel assignment mechanism is used to plan a multiracial multi hop network where each node is outfitted with numerous IEEE 802.11 wireless transmitters and receivers.

In this paper, we proposed two Common Control Channels performing cross layer optimization via Genetic Algorithm and DSA using Cognitive Radio. Out of them, one is 2.4 GHz of CCC, and other is Low rate (902-928 MHz) CCC. The proposed approach is based on the previous work [12] where they have used low unlicensed spectrum band

(902-928 MHz) as a low rate AODV CCC for broadcasting route control messages and CR coordination message. The proposed system shows that the GA is used to route control messages by Low rate CCC and 2.4 GHz of CCC. Our simulation results show that the overall throughput of the system increases while BER, hop count and the end-to-end delay of the system decreases for low rate CCC.

The rest of the paper is organized as follows: Section II provides overview of the cross-layer design. Section III presents a brief description to our proposed scheme including multi-objective fitness function. Section IV shows the simulation results. Section V gives some concluding remark and observation.

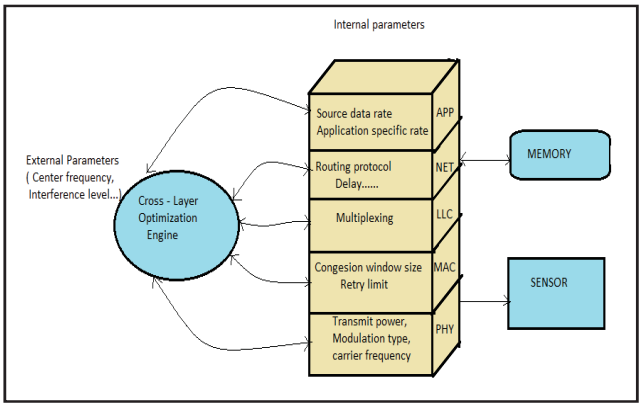

Figure 1. Framework of a generic cross-layer optimization framework

II. Cross Layer Optimization Overview

Fig.1 shows the general layout of the Cross-layer optimization architecture. The cross-layer optimization engine is provided to each node that takes the set of internal and external parameter as input by well-organized sensing methodology or via the control channel. All the sets of an internal operating parameter that are distributed across the different layer of a wireless device are decided by the optimization engine to achieve maximum performance and to coexist with another wireless device.

Some important parameter adjustments are 1) to adjust the center frequency and subcarrier number according to available spectrum. 2) to choose modulation type based on the trade-off between BER and data rate. 3) to adjust congestion window size based on data rate, 4) to set routing protocol parameter according to network stability and density. We have used Genetic Algorithm to implement optimization engine.

III. Proposed System

A. System Model

In the proposed work it is considered that all the wireless node employing non-contagious Orthogonal Frequency Division Multiplexing. This is widely considered as suitable contender for spectrally agile wireless transmission because of the advantage of subcarrier scalability and robustness to frequency fading [13]. Fig 2 shows an example of the distributed network architecture with 902 MHz and 2.4 GHz control channels. The information among different secondary nodes is exchanged by the control channels to perform distributed optimization.

In our work, we are working on four different parameters: center frequency f, normalized transmission power p, modulation index b and bandwidth w. As we are using NC-OFDM, each subcarrier has set off these four variables. Our optimization engine is used to optimize them together.

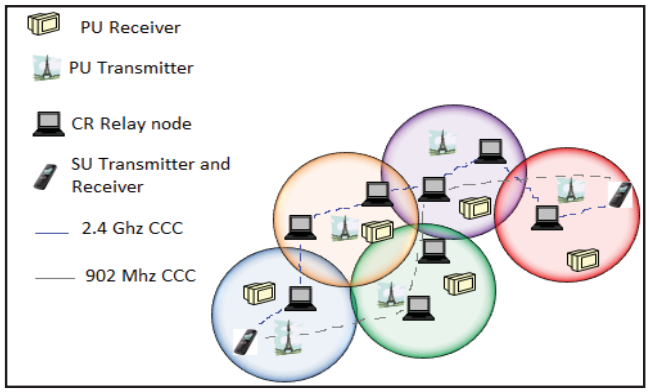

Figure 2. Schematic of distributed network architecture with 902 MHz CCC and 2.4 GHz CCC

When we consider a center frequency as 2.4 GHz, the overall bandwidth becomes high which results in the lower modulating index. Moreover, the performance of CR routing protocol has a direct effect on end-to-end network transit delay [12]. As QoS is dependent on minimal transit delay, it is essential to reduce hop count for delay sensitive application. Equation (1) explains about the possible network transit delay (D_{NT}) in between CR source and destination which include sensing delay, queuing delay, propagation delay, processing delay and medium access delay. The overall network transit delay increases as the total number of hops in between CR source and destination increases. Due to short range transmission the hop count in 2.4 GHz is higher, which results in longer end-to-end data transmission delay and additional network resource overhead [12].

$$D_{NT} = \sum_{i=1}^{p} W_i * D_i(\mathrm{c}) + \sum_{i=1}^{k} T_s(\mathrm{i}) * T_{inter-spec} \qquad (1)$$

With the fact that lower frequency gives longer transmission range, hence there is scope to reduce the total hop count and select best suitable shortest channel-path in CR sender and receiver nodes. For example in figure 2, it is clearly shown that 902 MHz CCC takes three hops to reach destination CR nodes whereas 2.4 GHz CCC takes almost seven hops to reach towards the same destination. Also with the increase in operating frequency the CR node transmission power is increases. Hence, 2.4 GHz control channels requires higher input transmission power as compared to 902 MHz Moreover, with higher input transmission power, there may be chances of interference with PU receiver signal.

B. *Fitness Function*

Following subsection presents fitness function required for cross layer optimization:

1. Overall Multi-objective Function:- Enhancing the performance of cognitive radio network using a multi-objective function for a node includes minimizing the BER, maximizing the throughput, minimizing power usage, minimizing interference with another node. The multi-objective optimization problem is solved by forcing the sum of these objectives to the optimum level. One of the disadvantages of this method is the optimum level of these objectives depends on the requirement of specific application and hence it needs to be adjust carefully. To define these function initially two thresholds has to describe i.e. lower threshold and the upper threshold.

2. Bit Error Rate Fitness Function:- If the source node needs to communicate with its destination, the average BER of all the subcarrier should be less than lower threshold for successful optimization of this function. If its value is greater than upper threshold communication is not possible. If its value is in between two thresholds it has to adjust by using these two thresholds.

3. Throughput Fitness Function:- To satisfy this function modulating index of subcarrier link between source to destination node should be maximum. If it is higher than upper threshold fitness criteria satisfies successfully. The fitness criterion is not satisfied, if its value is less than lower threshold. If it is in between the two thresholds, it has to adjust carefully with lower threshold and both the thresholds of average BER of subcarrier link between source and destination.

4. Interference Fitness Function:- Interference caused by source node to the other nodes in the network should be as minimum as possible. These values can be obtained either by estimating the environmental parameter or by control channels. Hence its value should be less than lower threshold. Otherwise it has to adjust with the receiving signal power level.

***5. Transmission Power Fitness Function*:-** When taking into consideration portable devices, whose energy supply is limited, this function is a necessary component in optimization. Its value depends upon the maximum attainable transmitting power for one subcarrier of source node and the transmitting power of subcarrier.

C. *Genetic Algorithm*

In the proposed work, we are using genetic algorithm optimization approach. Genetic algorithm is used to reflect the interplay property among all the layers by evaluating the fitness function for individual layers. Hence an effective cross layer optimization frame work is obtained which is used to find optimized power control, channel allocation and route selection in polynomial time. In this algorithm, all the input variables of the node are given to its optimization engine. Internally, it searches for an overall solution that gives the high fitness score using a fitness function. A flow chart shown in figure 3 describes the standard GA technique.

Initially, GA searches for all the channel information from the environment and selects the appropriate node. In standard GA fitness function across an entire node is calculated. After inputting all the variables of node to optimization engine, initialization of Genetic Engine takes place. Further, the fitness function for that node is evaluated, and check against the stopping criteria to check whether it satisfy the required fitness for individual layer or not.

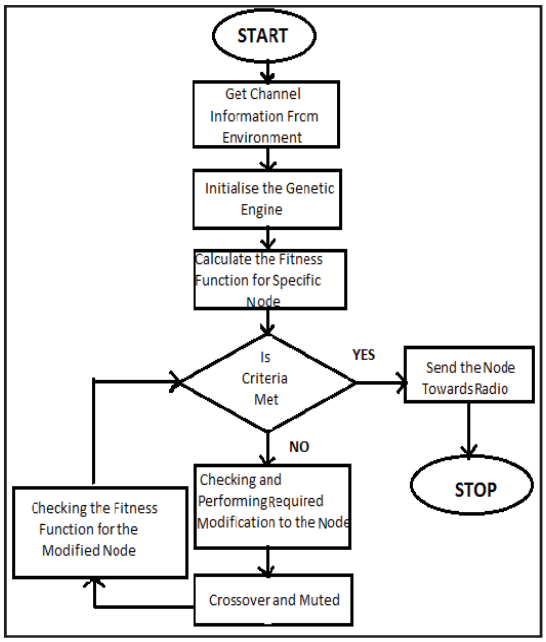

Figure 3. Flow chart of genetic algorithm

If it is found that required stopping criteria (Fitness Function) is achieved, that specific node moves towards further routing process, and the task for Genetic engine ends for that particular node. If the adequate fitness is not achieved by that node, the required modifications are performed with the help of external parameters. Moreover the fitness for the modified node is calculated and is again checks for the stopping criteria and the process repeated. When the required fitness is achieved by that node, it starts routing process and the variables of new node inputs to the engine.

IV. Result Analysis

In this section, the performance of low rate control channel is evaluated in terms of throughput achieved, Bit Error Rate, End-to-End delay of network and hop count and is compared with the performance of 2.4 GHz control channel. Experimental results are carried out using NS 2.31 simulator. The simulation results show that Low rate control channels have higher performance, and it works better in cross layering with lower central frequency. Simulation runs with the parameters shown in the following Table 1.

Fig 4 shows the graph of throughput of the network. The graph shows that initially because of higher center frequency the efficiency of 2.4 GHz CCC tends to rise and reach up to maximum value but suddenly because of higher drop-tail it

starts to go down. On another hand because of lower center frequency graph for Low rate (902 MHz) CCC takes a longer

TABLE 1.SIMULATION PARAMETER

Simulator	NS2 (ns 2.32)
Channel	Wireless channel
Propagation	Two Ray Ground
MAC	Mac/ 802_11
Ifqueue	Queue/DropTail/ProQueue
Link Layer	LL
Antenna	Omni Antenna
Ifqueue length	50
Routing	AODV
Number of nodes	34
Frequencies	902 MHz- 2.4 GHz
Flow rate	1024 Bytes
Traffic	TCP
Simulation time	2s-60s

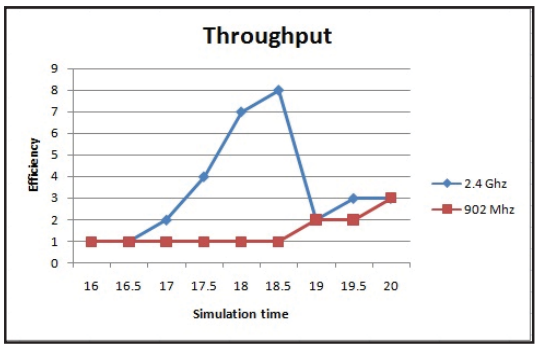

Figure 4. Graph of Throughput

time to rise but once it starts raising it provides a stable output response.

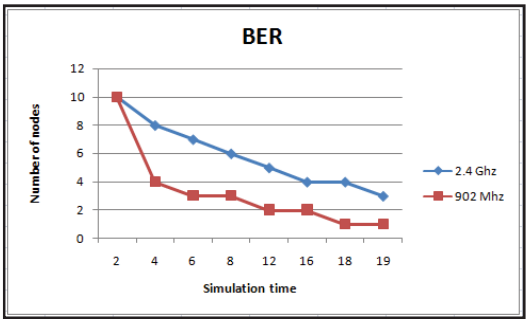

Figure 5. Graph of BER

Fig 5 shows graph for bit error rate (BER) variation. In digital transmission bit error is the number of received bits over the communication channel that is altered due to noise, interference, distortion, attenuation. Because of higher frequency such problem occurs at greater extend in 2.4 GHz of CCC. Graph shows that the BER is higher for 2.4 GHz CCC than that of low rate CCC (902 MHz).

Fig 6 Shows graph for one of the performance parameters i.e. hop count. In cognitive radio network goal is to search for the shortest path towards the destination node and this can be achieved through longer transmission range. As 2.4GHz CCC have shortest transmission range, the hop count of 2.4 GHz CCC is high while 902 MHz provides longer transmission range because of lower frequency range its hop count is low.

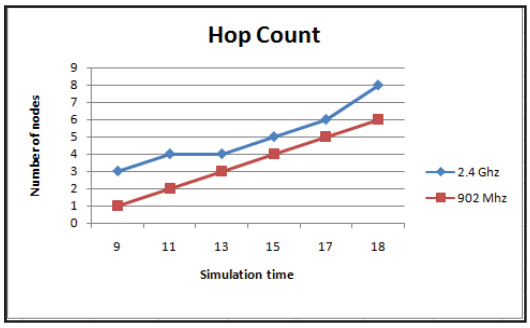

Figure 6. Graph of hop count

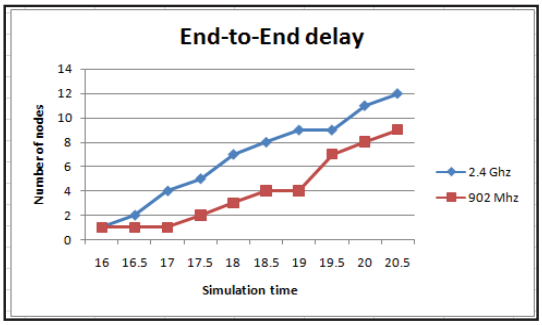

Figure 7. Graph of End-to-End Delay

End-to-End delay is the average time taken by the data packet to arrive at the destination node. It is a delay produced due to route maintenance process. Lower the value of End-to-End delay better the performance of the system. Fig 7 shows the low rate control channel has a lower end to end delay because of lower hop count.

V. CONCLUSION

This paper proposes a comparison of low rate CCC and 2.4 GHz CCC performing cross layer optimization via. GA. We have demonstrated that cross layer optimization performed with the help of GA by satisfying all the fitness criteria. Fitness function can be used to guide the wireless user to optimize coexistence with others through several tests. Our proposed work uses low rate CCC to overcome the drawback of 2.4 GHz of CCC occurs due lower transmission range. Low rate CCC with distributed optimization to gives stable throughput, low BER, hop count and the end-to-end delay. Those kind of distributed optimization passes significant potential to solve the problem of global spectrum usage in

both commercial and military application. . In future the proposed work can be implemented by using block wise Genetic Algorithm to perform cross layer optimization.

***Abstract*—Cognitive Radio Wireless Mesh Networks (CR-WMNs) are reliable and promising technology to access opportunistically spectrum holes from the licensed bands with intelligible Software Defined Radio (SDR). It has the capability to revolutionize the way next generation applications having available spectrum. Multi-radio and multichannel CRWMNs are dynamic networks, which creates routing protocol design as a complex. It has a capability of assessing the spectrum availability during routing, which enhance the efficiency of the network. The proposed algorithm is a novel multipath algorithm. The path selected in this algorithm based the minimal interference information, which is useful to make this routing approach as more reliable. Channel selection has the capability to identify more suitable links for data transmission in the network. It uses a channel load metric to calculate the load throughput of available channels. The proposed algorithm has simulated in NS2. The simulation results demonstrate the efficiency of proposed channel selection and path aware routing algorithm.**

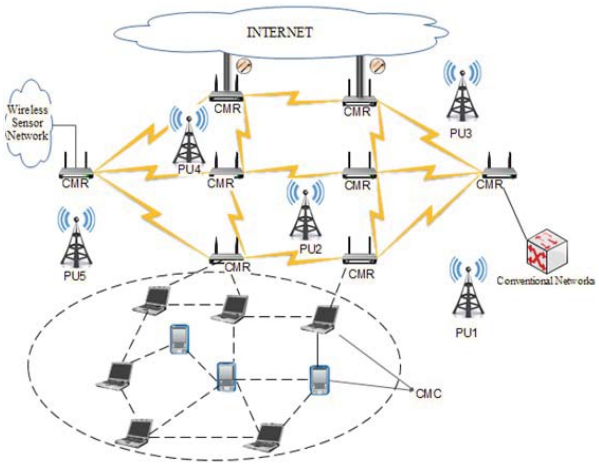

Fig. 1. Routing overhead and Number of nodes

I. Introduction

Wireless mesh networks (WMN) are highly used low cost networks. Now a days wireless mesh networks are mostly employed in local area networks (LAN), wide area networks (WAN) and metropolitan area networks (MAN). Due to their high connectivity and better performance people prefer these types of networks everywhere like broadband home networking, community and neighborhood networks, enterprise networks and building automation [1] [2]. Today entire world try to access different kinds of wireless networks, most of the wireless networks using unlicensed bands to transmit the data. The assigned wireless bands 2.4 Ghz and 5 Ghz are limited and number of users in this area are increasing day to day. It causes lot of spectrum scarcity at the unlicensed spectrum bands. To overcome this problem Federal Communication Commission (FCC) introduced the cognitive radio concept for utilizing underutilized spectrum at TV spectrum [1][2][3]. Cognitive enabled wireless mesh networks (CWMN) provide solution to spectrum scarcity for accessing broadband services. Cognitive radio enabled mesh routers (MR) or mesh clients (MC) are called as secondary users (SU). SUs are needed to identify the spectrum holes in the wireless environment and access the available spectrum without any interference with the primary user (PU). Cognitive Radio Wireless Mesh Networks architecture is showing in Fig. 1.

Most of the research has been focused on sensing, accessing, sharing and mobility of the spectrum. There are standards for direct access based medium access control (MAC) and physical (PHY) standards like IEEE 802.22. In CWMN, PU Spectrum holes behavior is in stochastic manner, this will affect the network performance of the network. During PU presence, SU quit form the occupied PU spectrum. In multi-hop cognitive wireless mesh networks, routing is a complex and distinctive problem. Establishing routes and its maintenance requires lot of information from the network [10]. Cognitive radio enabled wireless mesh network is a heterogeneous network and it has lot of problems during routing, if spectrum availability information is not considered. Multi-hop cognitive radio networks require spectrum allocation information to design better routing for the networks [8]. Routing algorithm provides information related to PU presence or absence with the help of spectrum sensing and accessing mechanisms. It will help to make network more efficient. In this paper, channel selection from the available PU spectrum and path selection has to be done with the minimum interference and maximum throughput information [18].

II. Related Work

Network performance depends on the design of routing protocol, mainly CWMN kind of networks has lot of dynamism in the network, hence it requires spectrum information from the MAC and PHY layers [10]. Licensed users has lot of spectrum under utilization, make them as use it solves the spectrum scarcity problem. Sensing a wide spectrum range, dynamically identifying currently unused spectrum

blocks for data communications, and intelligently accessing the unoccupied spectrum called Spectrum Opportunities (SOP) [8] [10]. WMN devices are enabled with cognitive radios can be networked smart wireless mesh networks called it as Cognitive Wireless Mesh Networks (CRWMN), recently gained lot of scope to improve the performance of wireless broadband services and provides a solution to limited spectrum allocations and utilization of the available spectrum at licensed users [12] [10].

In mesh networks, Routing is an extremely challenged research area and the network efficiency depends on its routing characteristics. In cognitive wireless mesh networks, routing is more complex issue than the wireless/wired mesh networks. It has lots of dynamism at spectrum identification and channel assignment. SEARCH is a distributed routing protocol; it works based on the PU activity, route optimization and awareness of the dynamic channel environment. Route optimization is purely based on the latency in the selected path. Channel assignment is defined by the mobility of the CR user [7]. End-to-End throughput for communication and optimal routing calculations based on the PU activity and path selection without any self loop paths are discussed [17]. In the presence of PU activity some of the CRs are unable to sense the available channel, so available channel identification in the presence of PU is a challenged task [16]. The available resources are identified based on the distributed routing and it has more capability to identify the end-to-end bandwidth on the available path [15]. In routing, adaptability based resource allocations and findings are useful for accurate routing solutions [14]. Primary Users are the ones who use traditional wireless communication systems with static spectrum allocation. Secondary Users are equipped with CRs and exploit Spectrum Opportunities (SOPs) to sustain their communication activities without interfering with PU transmissions. Indeed, the cognitive paradigm can be applied to different scenarios of multi-hop wireless networks including,

1) Cognitive Wireless Mesh Networks featuring a semistatic network infrastructure,
2) Cognitive radio Ad Hoc Networks (CRAHNs) characterized by a completely self-configuring architecture, composed of CR users which communicate with each other in a peer to peer fashion through ad-hoc connections [10].

Cognitive radio enabled wireless mesh networks is a heterogeneous network and it has lot of problems during routing, if spectrum availability information is not considered. Multi-hop cognitive radio networks are required spectrum allocation information to design better routing for the networks [10] [8].

Cognitive radio technology gives system the ability to operate around any interference, including any licensed traffic. This technology allows the detection of the communication channels or frequency bands which are vacant or not in use, while avoiding any occupied ones, hence improving the spectrum efficiency. This technology allows the detection of the frequency bands which are vacant or not in use, while avoiding occupied ones, resulting in spectrum efficiency [10]. There are various design challenges

1) *Channel Saturation*: The saturation problem basically occurs when the variety of nodes that are try to gain access of the control channel resulting in a high rate of packet collisions. Hence overall performance degradation.As more data channels are included in the network, the networks performance decreases gradually. The increased traffic load creates a negative impact on the overall throughput of the network that is the performance of the network worsens when more data channels are added and gradually reaches its saturation point [10].
2) *Robust PU Activity*: Unless a channel has been allocated in a primary user free frequency band, it is prone to primary user activity and interference at any time. Hence, this is another design issue that has to be taken care of.
3) *Channel Coverage*: It is not possible for all cognitive radio users to listen to the same channel; hence the coverage of a common control channel is limited to a certain area where a particular group of users are tuned in to the same channel for control message exchange. Large common control channel coverage leads to less overhead of control signaling but doing so is quite typical.

III. Path and Load Aware Routing Algorithm for Cognitive Radio Wireless Mesh Networks

In this work, all mesh routers are equipped with Cognitive Radios(CR) and Mesh Clients(MCs) also have this capability and cooperatively share the spectrum availability information without any interference.

A. Protocol Overview

Wireless mesh networks with cognitive radio capability have more scope to improve performance of wireless services. In this work, a novel approach has been introduced to find maximum throughput with minimal interference path among multiple paths. Path selection depends on the availability of PU spectrum bands in the path and its bandwidth. This algorithm considered both MAC and routing layer for implementation. Hence, it is a cross layer protocol. It has two major modules, and one provides the maximum throughput channel selection and its load from multiple channels and other module identify the minimum interference path. This approach leads to find the better path to the source and destination.

B. Working Procedure of PLRP

The proposed routing protocol using by mainly three stages, which are spectrum excerption, channel selection and load identification. In this PLRP,

C. Network Model and Assumptions

In this paper, the network consists of a set PU of primary users, set SU of secondary users, S is a set of spectrum information, set P includes all possible paths between any two or more nodes. Each primary user $(pu_1, pu_2, pu_3, ..., pu_n)$ has some fixed spectrum allocations. Spectrum holes create the opportunity for accessing spectrum, which mobile nodes equipped with cognitive radios they can access without any interference.

$$p^m_{u,v}(t) = \begin{Bmatrix} 1 & \exists m \in [1,2,.....,N] \\ 0 & Otherwise \end{Bmatrix} \quad (1)$$

Let $p_{uv}^{m}(t)$ denotes the communication channel m used to transmit data from CR enabled user u to CR enabled user v at a time t. Each channel characterized by the link throughput $\Psi_{u,v}^{m}(t)$, which calculates the number of packets conveyed in a unit time. The transmission from u to v through channel m. In this throughput calculation, several components are needed to use like bandwidth, channel spectral efficiency and the radio propagation. Let $\Psi_{u,v}^{m}$ has been worked out in this paper like in the following.

$$\Psi_{u,v}^{m} = \frac{\Psi_{A_u}\Phi_m Z_m(1-Pr_m)}{\sum_{k=0}^{n}\Phi_k Z_k(1-Pr_k)} \tag{2}$$

Ψ_{A_u} aggregated throughput at u (assumed based on IEEE 802.11).

$$\Phi_m = \frac{\omega_m \xi_m}{\sum_{m=0}^{n}\omega_m \xi_m)} \tag{3}$$

$\Psi_{u,v}^{m}(t)$ denotes the throughput at the channel m, and it uses between the CR nodes u and v at time t. In this, Φ_m represents the service probability of channel i. ω_m provides the window size at the back-off time t and ξ_m calculates channel capacity for channel m and ω_m is for maximum channel capacity, which has defined for nodes in the network [12].

$$\omega_m = \beta_m log_2\left[1 + \frac{R_{u,v}^{m}}{AW_0 + p_{I,v}^{m}}\right] \tag{4}$$

PU nodes $\in P$ such that each node has m orthogonal bandwidth frequencies, $\beta_0, \beta_1, ..., \beta_m$, R_{uv}^{m}, means received the power of the licensed channel m used for CR nodes u and v. $P_{I,v}^{m}$ is provided the interference information at node u for channel m, AW_0 is having white Gaussian noise power value. Pr_m represents the channel loss probability in the network. $\Psi_{u,v}^{m}(t)$ has the capability for calculating the maximum throughput of a channel in a particular spectrum S.

In this multipath algorithm, it has identified less interference and high throughput path among available paths with the help of a channel selection algorithm and interference aware metric. κ has to provide minimum interference with better packet delivery information and useful to select a better suitable path from available paths in the networks [3].

$$Min\lambda(p_{u,\vartheta}^{\delta}) = \frac{1}{N_l \times \varphi_{u,\vartheta}}\sum_{\delta\in p}\eta_\delta + \sum_{\delta\in p}\chi_\delta \tag{5}$$

$\lambda(p_{u,\vartheta}^{\delta})$ with this minimum interference path selection is being done in this work. If it has a value close to zero means, it has minimum interference to channel δ. N_p represents a neighbor set, which is useful to find the interfere nodes with node u during transmission with channel δ. φ has information about the expected transmission time (ETT), η has to be calculated the resource available without any interference with the channel δ.

$$\varphi_{u,\vartheta} = \frac{1}{(d_f \times d_r)} \times \frac{S}{B} \tag{6}$$

$$\eta_\delta = \varphi_{u,\vartheta} \times N_l \tag{7}$$

$$\chi_\delta = \begin{Bmatrix} W_1 & if p_u^{\delta} \neq p_u^{\delta-next} \\ W_2 & if p_u^{\delta} = p_u^{\delta-next} \end{Bmatrix} \tag{8}$$

Algorithm 1: Path Aware Routing with Channel Selection Algorithm

Input: u,v ∈ N and δ ∈ C, ϑ ∈ N p ∈ P
Output: max,p,c

PathAware(p,c)
- $\vartheta \leftarrow u_next_hop$; **while** $\vartheta \neq v$ **do**
  - $\delta \leftarrow Channel_Selection(p_{u,\vartheta})$
  - **if** $\kappa(p_{u,\vartheta}^{\delta} == 0)$ **then**
    - **if** $\vartheta = v$ **then**
      - $p_{uv}^{\delta} \leftarrow 1$;
    - **else**
      - $p_{u,\vartheta}^{\delta} \leftarrow 1$;
      - $u \leftarrow \vartheta$;
      - $\vartheta \leftarrow \vartheta_next_hop$;
  - **else**
    - $\vartheta \leftarrow \vartheta_next$;

ChannelAware(p,c)
- **Input**: m is number of channels c ∈ C, and p ∈ P ;
- $c \leftarrow 1$ **while** $c < m$ **do**
  - $\eta_1 \leftarrow \Psi(p_u^c)$;
  - $\eta_2 \leftarrow \Psi(p_u^{c_next})$;
  - **if** $\eta_1 < \eta_2$ **then**
    - $max \leftarrow \eta_2$;
    - $c = c_next$;
  - **else**
    - $max \leftarrow \eta_1$;
  - $c = c + 1$;
- **return** max, p, c;

S and B are prob packet size and bandwidth measured from the channel δ, d_f and d_r are denoted for number of successful packets delivered and receive. This protocol identifies the minimum interference path with help of path aware algorithm and channel selection algorithm identifies the maximum throughput channel.

IV. Simulations and Results

The proposed algorithm implementation performed with the help of Network Simulator(ns-2) simulator. The simulation completed with ns-2 having cognitive radio module. The simulation parameters are chosen such that they can resemble a real environment. The performance of any routing mechanism measured in terms of average throughput, Packet delivery ratio and Routing Overhead. The number of nodes used for this simulation is 10, 20,40,80 and 125. The number of CBR sources and destinations are increased based on the number of nodes and simulation area.

A. Performance parameters

1) *Routing Overhead*: The total number of control packets sent or forward to route the data packets. The ratio of control packets and data packets is called routing overhead for a protocol.

Description	Value
Total Data Channels	4
Total Simulation Area	1000 × 1000 m
Routing Protocol	PLAR, SEARCH, CRP, AODV
Number of SUs	10/20/40/80/100
Number of PUs	2/4/8/16/20
Channel Bandwidth	100, 250, 500, 650 Mbps
Packet Size	1200 Bytes
Channel Switching Delay	200μs
Mesh Routers	3/6/12/24/30μs

TABLE I. SIMULATION PARAMETERS

2) *Average Throughput* : The total data delivered at nodes in a given time unit. The average throughput measured in this simulation in kilobytes per seconds(kBps).
3) *Packet Delivery Ratio*: The number of packets that were delivered successfully in total simulation.

Performance parameters compare with number of nodes. Simulation results prove the performance of this Routing Protocol and compared with traditional routing protocols in wireless mesh networks.

B. Simulation Results

In this section, results are compared with existing protocols like Ad-hoc On-demand Modified Distance vector(AODV) [20], Cognitive Radio Ad-hoc Routing Protocol (CRP) [13] and SEARCH: A routing protocol for mobile cognitive radio ad-Hoc networks [19]. Performance parameters are here, packet loss ratio, average throughput, and average throughput throughput. Performance parameters compare with number of nodes and number of PU nodes in the simulation.

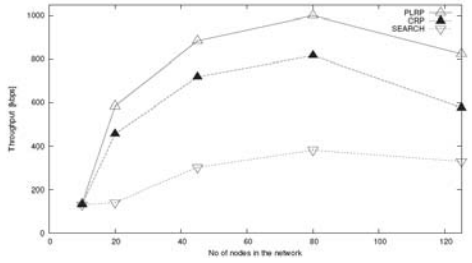

Fig. 2. Throughput and Number of nodes

In the Fig. 2 and Fig. 3, this result shows proposed algorithm dominating other two routing approaches. In the proposed approach, the channel selection method is useful to obtain the maximum throughput channel. But both SEARCH and CRP protocols are failing to reach the proposed routing approach performance related to average throughput. There is no specific approach to identify the channel selection method neither in SEARCH nor in CRP.

In the Fig. 4 and Fig. 5, the Normalized Routing Load(NRL) is very less because it uses a limited number of paths to perform routing in the network, at the same time SEARCH uses its control message more for finding routes from the available routes in the network. A mesh

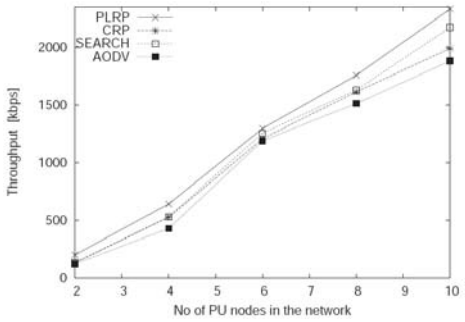

Fig. 3. Throughput and Number of PU nodes

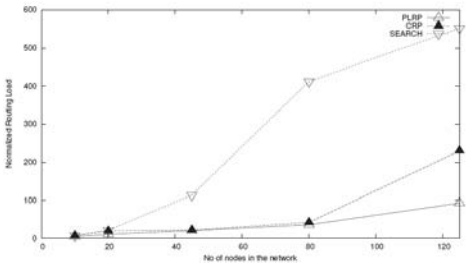

Fig. 4. Routing overhead and Number of nodes

network with multiple channels so that SEARCH required more control packets to identify the shortest path from the available paths with the help of its control packets. An error occurred during the transmission, identification path from the available spectrum it is needed many route request packets. The CRP routing protocol is better compared to SEARCH at this point, why it is doing routing based on the metric, which is helping to find the most reliable paths in the network. So that it needs very less number of control packets. In the same scenario, our proposed approach has been performed far better than the both these protocols, because of its channel and path aware concept.

In the Fig. 6 and Fig. 7, routing performance will be defined by the packet delivery ratio, as per the results proposed approach has been performed slightly better then the remaining two protocols. With the help of multi-path routing it has achieved this.

V. CONCLUSION

Now a days Cognitive Wireless Mesh Nsetworks is an emerging technology. In this paper, a new channel selection

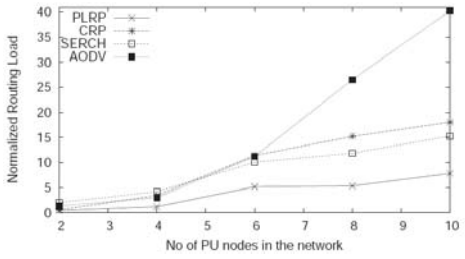

Fig. 5. Routing overhead and Number of PU nodes

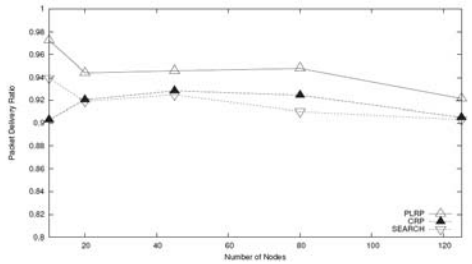

Fig. 6. Packet delivery ratio and Number of nodes

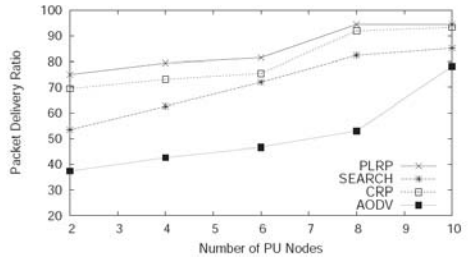

Fig. 7. Packet delivery ratio and Number of PU nodes

algorithm is designed to find the maximum throughput channel from the available spectrum. Generally in the presence of PU's, SUs are unable to identify the unused spectrum from the wireless environment. But the proposed algorithm has the capability to identify the available channels from the spectrum in the presence of PU's. It also discovers minimal interference channels in a path, so that it avoids interference with PU's. The efficiency of the proposed algorithm has been analyzed via its implementation on NS2 and it outperforms the existing routing algorithms in terms of the packet delivery ratio, normalized routing load and throughput. In future the enhancement of proposed algorithm can be performed to reduce end-to-end delay.

***Abstract*—Future space exploration demands inter-satellite links (ISL) that allow high speed communication between two or more satellites. This paper is concerned with the antenna system capable of establishing and maintaining ISL at 60 GHz. A high gain corrugated antipodal linear tapered slot antenna (ALTSA) based on Substrate integrated waveguide (SIW) technology for inter-satellite communications at 60 GHz is proposed. SIW technology has opened-up interesting avenues in millimeter wave planar antenna and circuit development which can be fabricated with low cost printed circuit board technology. A gain of 16.2 dBi achieved with SIW based corrugated ALTSA and the 1 x 2 antenna array with dimension of 69.36 mm x 21.11 mm has a gain of 18.5 dBi with return loss below -10 dB at 60 GHz band.**

Keywords—ALTSA, intersatellite networks; millimeter wave; satellite communications; substrate integrated waveguide.

I. INTRODUCTION

The scope of specialized space communication network has increased in recent years with more space exploration scheduled in the near future. The main objective of space communication is to provide direct connectivity between two or more satellites via inter-satellite links (ISL) or cross links. Using ISL the constellation formed from clusters of several satellites can communicate with each other when necessary. To some extent this can eliminate the ground stations as the information is routed through satellites in different orbits. Several communication technologies and architectures for space networks are proposed in [1] which discusses about the international space station standard (ISS). Further in recent days low cost and small satellites have seen emerging market in earth observation application which assists in improving environmental management [2]. In these applications apart from communication with the earth station the satellite in low earth orbit (LEO) and medium earth orbit (MEO) also have to route data among themselves for fast information delivery mechanism. Therefore, a high speed ISL is necessary to interconnect the satellites in LEO, MEO and geostationary earth orbit (GEO) as well. Generally two type of ISL will be required for each satellite. They are inter-orbit ISL and intra-orbit ISL [3]. In the past 30 years ISL have been seen in large platforms [4] like TDRSS and Iridium etc. Some of them are listed in Table I.

The 60 GHz band with almost 7 GHz of bandwidth [5] is an attractive option for high speed ISL. At millimeter wave frequency band the losses in the planar microstrip circuit is high. Therefore this requires more efficient technology like the substrate integrated waveguide (SIW) to be used. It provides advantages of the traditional rectangular waveguide such as low loss, high quality factor, complete shielding and a high power handling capability [6] along with the combined advantage of planar circuit designs [7]. These have proved to be a good choice for the construction of millimeter-wave circuits. Fig. 1 shows the inter-satellite link.

TABLE I. INTER-SATELLITE LINKING SYSTEM [4]

Satellite Launch Year	Satellite Name	Frequency used for ISL
1972-1978	OSCAR 6,7,8	146 MHz
1976	LES-8 and 9	36, 38 GHz
1983-2013	TDRSS	C, Ku, Ka
1997	Iridium	23 GHz
1998	Spot-4	Optical
1994-2003	MilSTaR I/II	60 GHz
2010	AEHF SV-1	60 GHz

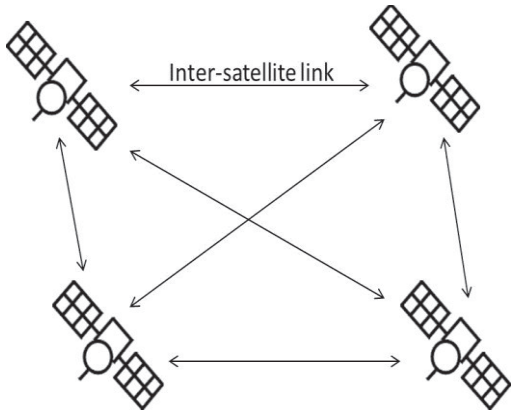

Fig. 1. Inter-satellite link.

Antenna is a vital part of any communication system. Many papers have given attention to Antipodal linear tapered slot antenna (ALTSA) for its good performance which includes high element gain and wide bandwidth. TSA antennas with corrugation structure have been used to reduce TSA width without any significant degradation in the radiation pattern [8]-[9] which helps in making the antenna array more compact. It is seen that rarely any development has been reported for the 60 GHz ISL utilizing SIW fed ALTSA array. In this paper a SIW fed ALTSA and 2-element array for inter-satellite networks at 60 GHz is proposed.

II. DESIGN AND SIMULATIONS

The ALTSA performance is sensitive to the thickness t and the dielectric constant ε_r .

$$f_{substrate} = \frac{t(\sqrt{\varepsilon_r}-1)}{\lambda_0} \quad (1)$$

where $0.005 \leq f_{substrate} \leq 0.03$. For SIW the diameter of the via is given by equation (2) and the pitch of the vias is given by equation (3).

$$D < \frac{\lambda_g}{P} \quad (2)$$

$$P \leq 2D \quad (3)$$

where λ_g is the guided wavelength. Effective width W is calculated using

$$W = W_s - 1.08\frac{D^2}{P} + 0.1\frac{D^2}{W_s} \quad (4)$$

In [10] authors have designed plain and corrugated ALTSA. The corrugated ALTSA has a gain of 16.2 dBi. The ALTSA design and fabricated antennas are shown in Fig. 2 and 3 respectively.

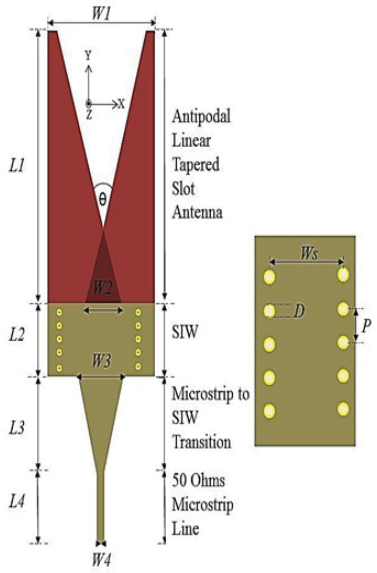

Fig. 2. ALTSA design [10].

Further the design and simulation of 1×2 planar array of the corrugated ALTSA is performed. Ansys HFSS is adopted as the main simulator for simulation of the antenna array design. Rogers RT/duroid 5880 with relative permittivity of 2.2 and thickness of 0.381 mm is used for ALTSA array design. In this design a Y-junction SIW power divider is used to feed the array. To obtain maximum gain, two antennas are fed with same phase and amplitude. Fig. 4 shows the SIW Y- junction power divider. The SIW power divider has 3 ports. Port 1 is the input port and the antennas are connected to port 2 and port 3.

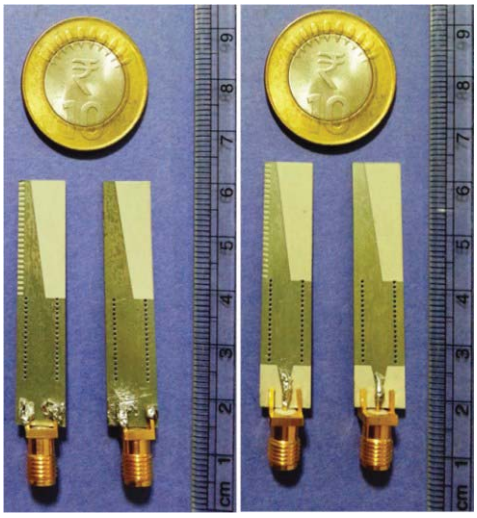

Fig. 3. Fabricated ALTSA [10].

TABLE II. DIMENSION OF ANTENNA ELEMENT [10]

Parameter	**DielectricSubstrate:RT/duriod (εr=2.20, h=0.381mm)**	
	Symbol	Value mm
ALTSA Length	L1	44.61
SIW Length	L2	22.36
Taper Length	L3	4.93
Microstrip Line Length	L4	1.5
ALTSA Width	W1	9.93
Overlapping Area Width	W2	1.8
Taper Width	W3	3.12
Microstrip Line Width	W4	0.5
SIW Effective Width	Ws	6.2
Diameter of Vias	D	0.6
Pitch of Vias	P	0.90
Corrugation Width	RCw	0.5
Space between Corrugation	RCs	0.5
Corrugation Length	RCl	1.25

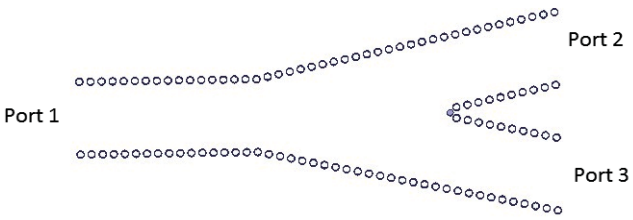

Fig. 4. SIW power divider.

Fig. 5 shows the E-field in the antenna. It shows the interaction of fields between the antipodal flares of both ALTSAs. Most E-field is observed in the linearly tapered structure. Simulated s-parameters of the power divider are shown in Fig.6. From Fig. 6 it is observed that the return loss for the power divider is below -10 dB in the entire 60 GHz band. Also, S21 and S31 are observed to have similar magnitude. Fig. 7 shows the ALTSA array design. The design consists of the SIW power divider, two corrugated ALTSA

and microstrip to SIW transition. The total dimension of the ALTSA array is 69.36 mm x 21.11 mm.

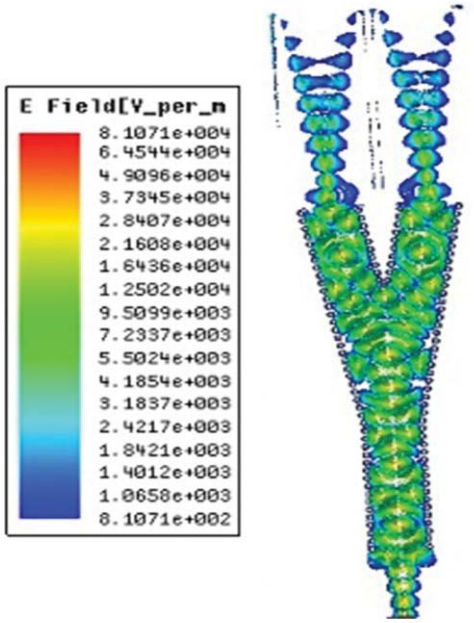

Fig. 5. E-field in the ALTSA array.

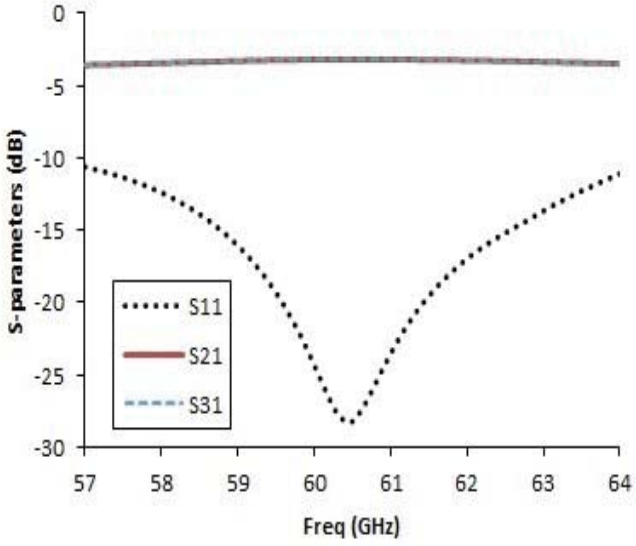

Fig. 6. S-parameters of SIW power divider.

Fig. 8 shows the return loss for the antenna array. The return loss is observed to be less than -23 dB at 59 GHz and less than -11 dB from 59-64 GHz. Fig. 9 shows the 3D radiation pattern of the antenna array. The gain of the antenna is observed to be 18.5 dBi. Fig. 10 shows the E-plane and H-plane radiation pattern of the ALTSA array. It is observed that the side lobe level in E-plane is below -18 dB. Similarly the side lobe level in the H-plane is below -10dB.

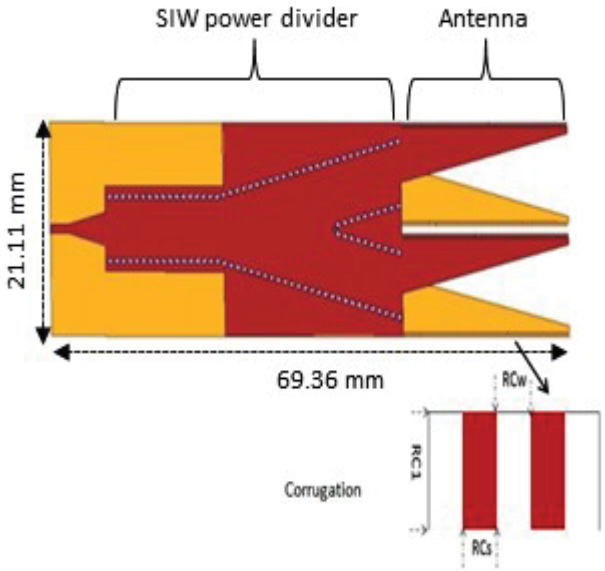

Fig. 7. Corrugated ALTSA array.

Further the 3 dB beam-width in E-plane is observed to be 34° and the 3 dB beam width in H-plane is observed to be 11°. The cross polarization level is observed to be below -17 dB. Thus, it is noted that with a compact size, high gain and large bandwidth the simulated antenna array is a good choice for the ISL network at 60 GHz. Table III lists the comparison table of the performance parameters of ALTSA array.

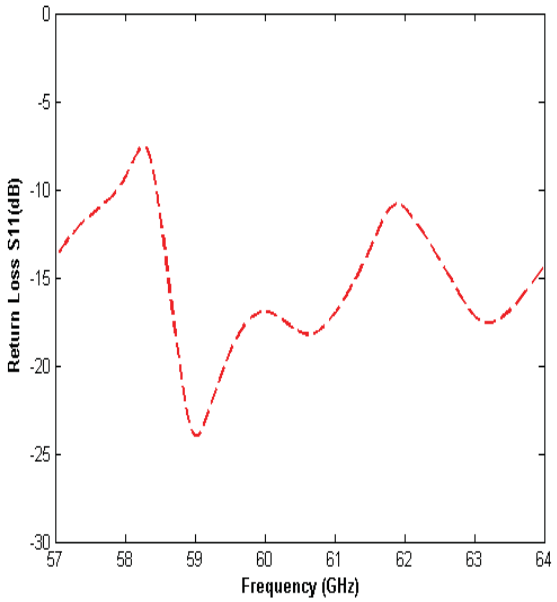

Fig. 8. Return loss of ALTSA array.

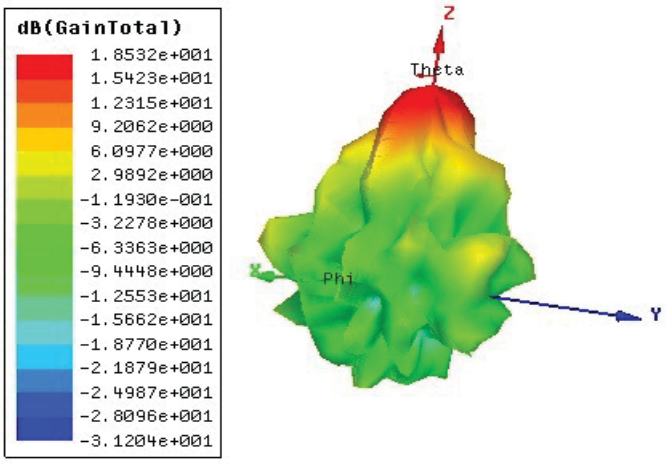

Fig. 9. 3D radiation pattern of ALTSA array.

TABLE III. COMPARISON OF ALTSA ARRAY PERFORMANCE PARAMETERS

Antenna Performance	[9]	[11]	This work
Array size	1 x 12	1 x 4	1 x 2
Gain (dBi)	19.25	19	18.5
Beamwidth (Degree)	10	-	34
Return loss(dB)	-23	-35	-17
Bandwidth(GHz)	22-30	70-100	59-64

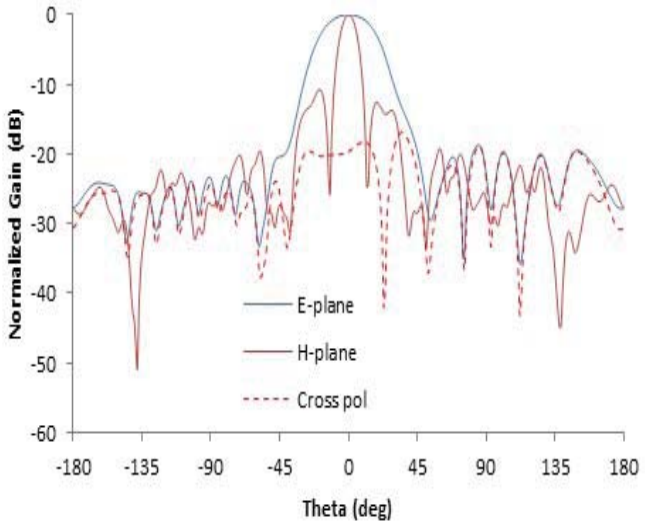

Fig. 10. E-plane and H-plane radiation pattern.

III. LINK ANALYSIS

Further link analysis is performed with the proposed antenna for ISL at 60 GHz. There are several factors that may impact the overall system performance in the inter-satellite wireless networks. Available and permitted output power, available bandwidth, receiver sensitivity, antenna gains, radio technology and environmental conditions are some of the major factors that may impact system performance. These parameters are analyzed through the RF Link budget. Table IV shows the link budget analysis. The first parameter to be discussed in an ISL is distance [12]. The distance or range between the two satellites is a function of angular separation of satellites.

$$R = 2(R_0 + H_0)\sin\left({}^{A_s}/_{2}\right) \tag{5}$$

where R is the distance, R_0 is the radius of earth, H_0 is the altitude and A_s is the angular separation. In any communication system the major issue is the transmission power. In order to transmit over a great distance sufficient transmission power is required. Further power considerations also have an impact on interference and the gain required etc. The satellite system has to be designed in such a way that it will feed the required power to the antenna. Depending on the altitude and range different power levels are used in various inter-satellite missions. ISL are operated above the earth atmosphere where the medium is vacuum. In vacuum signal propagation is faster when compared to ground based communication. In this link budget analysis it is assumed that the medium is a vacuum. No losses are considered due to fading. The path loss is given by [13],

$$PL(dB) = -10log\left[\frac{G_t G_r \lambda^2}{(4\pi)^2 d^2}\right] \tag{6}$$

Received power (P_r) is calculated as

$$P_r = P_t G_t G_r \left(\frac{\lambda}{4\pi d}\right)^2 \tag{7}$$

where, λ is the wavelength in meters and d is the distance in meters. P_t is the transmitter power, P_r is the received power, G_t is the transmitter antenna gain, G_r is the receiver antenna gain. Fig. 11 shows the received power vs distance and path loss vs. distance; reflecting the trend of increasing path loss and decreasing received power with distance respectively. Further, noise power at the input in a receiver ignoring the implementation loss is given by [13],

$$P_{noise} = 10log\left(KT_{sys}\right) + 10\log(B) + NF_{rx} \tag{8}$$

where P_{noise} is the noise power in dBm, K is the Boltzman's constant, T_{sys} is the system temperature, NF_{rx} is the noise figure of the receiver in dB and B is the bandwidth of the signal in Hz. NF_{rx} is assumed to be 6 dB. The signal to noise ratio can be calculated by the equation [13],

$$SNR(dB) = P_r - P_{noise} \tag{9}$$

where, $SNR(dB)$ is the signal to noise ratio in dB, P_r is the received power and P_{noise} is the noise power.

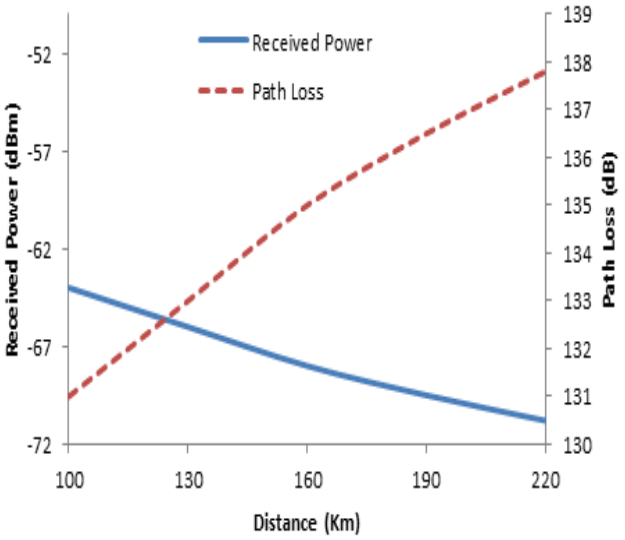

Fig. 11. Received power and path loss Vs. Distance.

TABLE IV. LINK BUDGET

Parameter	Specification
Satellite Orbit	LEO
Orbit Altitude	600 km
Satellite link Band	V-band
Carrier frequency	60 GHz
Transponder output	1W
Intersatellite Distance	220 km
Angular separation (A_s)	17 Deg
Transmitter antenna gain	18.5 dB
Receiver antenna gain	18.5 dB
Transmitted power	1 W
Path loss	137.8 dB
SNR	20.5 dB

TABLE V. SUMMARY OF LINK BUDGET ANALYSIS

Antenna performance	Single element ALTSA	ALTSA array
Transmitter and receiver antenna gain (dBi)	16.2	18.5
Received power (dBm)	-61	-64
Path loss (dB)	133.4	137.8
Estimated distance (Km)	150	220

IV. CONCLUSION

SIW based high gain corrugated ALTSA array with Y-junction power divider is designed and simulated for 60 GHz based inter-satellite wireless communications. Link budget analysis using the parameters from the designed antenna array is performed. The ALTSA array is compact in size with high gain and is suitable for the ISL at 60 GHz for high speed data transfer between the satellite communication networks.

ACKNOWLEDGMENT

Authors are very much obliged to ISRO, Government of India, for the support provided for the execution of this research work.

Scalable and Adaptable Modeling & Simulation framework key to expedited Radar System design, trade-off analysis, and verification

Uma S. Jha, Ph.D.
Space & Airborne Systems, Raytheon Co
El Segundo, California

Jon Wada
Space & Airborne Systems, Raytheon Co
El Segundo, California

***Abstract*— Modeling and Simulation (M&S) has been a key contributor to the validation of key system concepts, trade-off analysis, and dimensioning of the system performance before it could be realized in cost effective and timely manner. Leading system developers harness M&S capabilities for competitive advantage and operational/business efficiency by leveraging advances in VLSI technologies (processing horse power, memory, storage, high throughput buses), graphics, display, and networking technologies and its utility spans not only across concept development, and trade-off analysis but also in system design and development, test and evaluation, failure analysis, and, to some extent, identifying production issues.**

Keywords—Modeling, Simulation, Trade-off analysis, CONOPS, Design & development, Performance evaluation, Testing & Verification, Prototyping, Failure Analysis, Algorithm Development

INTRODUCTION

The main objective of the M&S is to make informed decisions based on use cases, systems analysis, and trade-off studies to minimize developmental glitches and to facilitate prudent programmatic decisions making. The novel goal of M&S is to support the entire product life cycle from initial concept development to design, integration, test, validation, verification, cannibalization, and follow-on products. The purpose, type, fidelity and complexity of analyses performed across the program life cycle of concept development through product realization requires an scalable M&S model, which can add value at each stages of the development process and in addition provide a collaborative and open framework to take advantage of state-of-the-art tools, technology, and process improvements.

In modeling and simulation realm all functional and behavior models of a system attributes and characteristics are represented in digital domain and can be manipulated digitally. Thus physical and behavioral models based system can be tested in a computer generated virtual, digital world in the same manner as the real systems are tested in the real world. An additional benefit of this approach is the ability to integrate multiple simulations into high-fidelity system of systems test beds. Additionally, the advancements in VLSI technology and software tools to support high-fidelity target and environment simulations as well as immersive visualization environments can be leveraged to facilitate wide variety of concept of operations (CONOPS) development and trade-off analysis.

The simulation fidelity typically grows as the system progresses towards the maturity and end-to-end system performances and interactions are validated. While initial studies often rely on analytical tools, real-time simulations are necessary for assessing complex interactions (such as the scheduling and resource loading of multimode airborne radar). These simulations will rely on lower-fidelity representations of the system since the detailed design may not be fully understood or completely developed. In addition the simulation fidelity (both all-digital and Hardware in the Loop (HWIL)) is only as good as the simulated threats and operating environments being modeled.

Due to advancements in VLSI technology, the ability to model key aspects of a system design before it is built, and to simulate that design's performance over time, has made it possible to significantly improve system performance while alleviating the need to build expensive hardware for test purposes. The enhanced offerings and capabilities of computing, networking, graphics, and storage technologies should be leveraged in architecting a simulation, which can link multiple simulations and operate them collectively towards achieving a common goal. The genesis of a Modeling & Simulation framework at large system integration house is to achieve physically distributed simulation nodes to interact in an all-inclusive simulation with human interfaces. This effort has allowed for effective utilization of the corporate wide company resources providing a very tolerant and highly available system with adequate redundancy at each level of simulation for stake holders. Today, we apply a more integrated approach that is based on rapidly configurable simulations that can grow in fidelity as a system design matures from its initial trade studies through SIL/HWIL testing. These simulation and modeling effort has reduced the risk of design and test errors, alleviated cost overruns, and improved the quality of analysis in the development of complex systems.

BACKGROUND (HISTORICAL PERSPECTIVE)

During early 80's in a complex system development environment, the constituent stake holders brought

Copyright © 2015 Raytheon Company. All rights reserved

their own favorite tools and processes, while systematic but due to the lack of the processing horse power and integrated software development environment did not allow for scalability and seamless integration. Sub-systems developed in silo did not integrate well and scale adequately to manage evolving requirements as well as lacked the capabilities to take advantage of the technological advancements to churn out the best possible solution. Requirements in general came in form of a worksheet; systems team developed their algorithm and performance compliance using mathematical tools (e.g. Matlab, Mathematica …); software team used their own code development processes and tools, and hardware team integrated, tested and sold off to the ultimate customer. The whole process was not sufficiently integrated resulting in loss of traceability and accountability through the development cycle

The cost overrun and project delay variation depended on the development stage, where the issue surfaced and whether a patch could be stitched together or not. The Figure-1 depicts the cost overrun impact [1] as a function of the project stage and its severity as it trudges towards the completion.

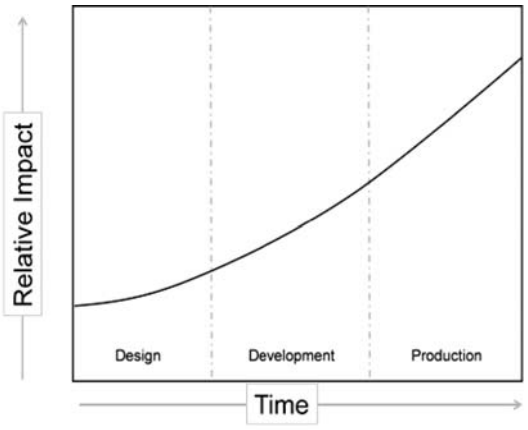

Figure – 1: Impact of system issues on cost and timeline

To overcome this, various processes and tools were considered and experimented to manage traceability from requirements to product design, testing, and sell-off phases utilizing DOORS, Ada programming language including water fall as well as agile processes. Although these showed improvements in execution of the projects from the ground up but did not solve the issues of integrating the heterogeneous complex system prevalent in most of the Department of Defense (DoD) contracts in which some subsystems lasted across the multiple generations of system of systems platform while others keep evolving to counter new threats and improved foe capabilities in the battlefield.

MODELING & SIMULATION FRAMEWORK

Modeling and Simulation capabilities are developed to benefit all stakeholders comprising of systems, test, verification, and sell-off personnel. In a complex radar system development scenario a simulation framework must accommodate and add value across its user base and be able to scale and adapt based on stakeholder's emerging requirements. Special attention is also given to the heterogeneity of the SW development processes, disparate HW capabilities and plethora of interfaces so that it is able to reuse legacy modules and HW pieces to minimize the cost and resource requirements.

MSF provides module and session management, messaging and configuration services. Modules may model processors, sensors, actuators, targets, clutters, atmospheric background, and/or environmental effects, serve as interfaces to other simulation systems.

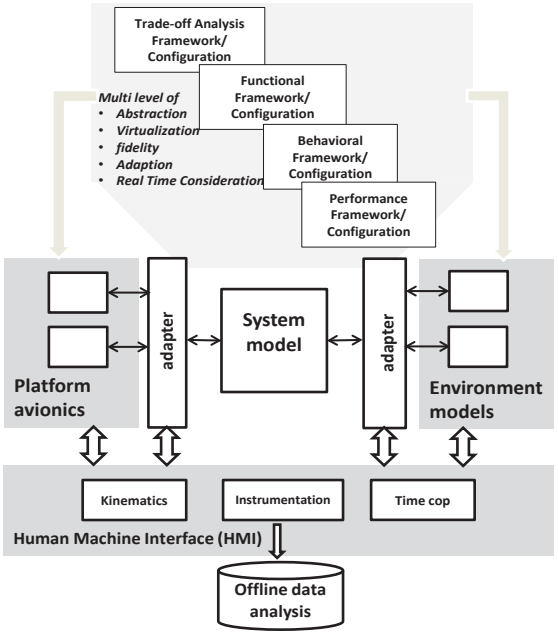

Figure – 2: M&S Architecture Framework

MSF manages session and module configuration, initialization, launch and shutdown, and provides a messaging framework for inter-module communication.

Configuration

Configuration files are an extended form of JSON [4], with extensions for file inclusion, variable substitution, and object inheritance. MSF parses configuration files into a tree, with a subtree for each module to be included in a simulation session. Each module-specific

Copyright © 2015 Raytheon Company. All rights reserved

configuration tree is used to launch its respective module, and is passed to the module's initialization function.

Modules and Messaging

MSF modules may be implemented in C++, Python or Matlab. In C++ and Python, MSF provides a Module abstract base class that's inherited by all simulation modules written in those languages; in Matlab, the framework provides a Module class that can contain function handles to implement the functionality of a Matlab simulation module.

MSF modules communicate with each other via messaging. A Message class is implemented in each of the three module languages. ZeroMQ [5] is used as the underlying messaging library. We've implemented a Messager class in Python and C++ as a wrapper around ZeroMQ, both to provide an abstraction layer and to provide some higher-level services for dispatching and handling messages. Messages are sent point-to-point; there's no central broker, to minimize network traffic and avoid bottlenecks.

Each message has:

- One "sender" (the module that sent it) and zero or more "receivers" (the modules to which it was sent).
- A string "topic"; which is used by the Messager instances in the receiving modules to dispatch message handlers. A message handler is a function, usually a method on the concrete Module subclass.
- Zero or more "payload" parts. Each payload part may have a distinct encoding; currently supported encodings are HDF5 [6] , best suited for binary and numerical data; JSON, for small-to-moderate amounts of mixed-type data, and RAW, a collection of bytes to be interpreted by the receiver.

Each message topic is associated with one "type": PUBLISH, REQUEST or ACCEPT

- PUBLISH messages are sent to any module that subscribes to that topic; no reply is returned. PUBLISH messages have no explicit receivers.
- REQUEST messages are sent to one or more explicit receivers; the sender will block until a reply is received from each receiver, and the collection of replies is returned to the caller.
- ACCEPT messages are sent to one or more explicit receivers; no acknowledgement or reply is returned.

MSF compiles a *Phonebook*, which contains a "white pages" section listing all modules running in this simulation session and the message topics they support, and a "yellow pages" section listing the union of all message topics supported by modules in this session, and which module support them. The Phonebook is distributed to all modules at session initialization.

Each MSF module runs in its own process; it may be configured to run on any host or cluster of hosts on the network or in distributed environment. Modules may be implemented in C++, Python or Matlab to accommodate a variety of needs for execution performance, use cases, ease of implementation and maintenance.

Time Management

Simulation time is maintained as a double-precision floating-point scalar, managed by a standard module called the Timecop. Simulation time moves monotonically forward, in discrete steps; the value of each time step is variable, depending on the needs of the simulation modules. The Timecop manages the process of negotiating the next time step, determines when all modules are ready for the time step to occur, then notifies modules that the time step is occurring.

MSF Modules may be Time Aware, Time Managing, or Time Agnostic. The framework provides a TimeAwareModule class derived from Module, and a TimeManagingModule class derived from TimeAwareModule.

- Time Aware Modules are notified of all time advance events. They may receive, but not send, Time-Stamped Messages.
- Time Managing Modules additionally are required to notify the Timecop when they're ready for simulation time to advance, and to specify a *lookahead*. A module's lookahead is the largest time step it can tolerate (or zero if it doesn't care); the Timecop will ensure that the next time advance is to a value less than or equal to the minimum of the lookahead values of all Time Managing Modules in the simulation. Time Managing Modules are allowed to send and receive Time-Stamped Messages.
- Time Agnostic Modules may query for the current simulation time, but are not notified of time advances. They may not send or receive Time-Stamped Messages

Before issuing a time advance, the Timecop will query all Time Aware Modules for counts of messages sent and received, and determines whether there are any messages in flight. It will wait until all in-flight messages are received before issuing a Time Advance.

Logging and Instrumentation

All simulation output for a given session is organized in a *session folder*: a single directory hierarchy in a network-mounted filesystem. This includes:

- A copy of the configuration tree;

Copyright © 2015 Raytheon Company. All rights reserved

- A copy of the environment for the session process and for each module process;
- Hashes of the executables for each module process, as well as any additional files identified by the module (so that we can ascertain whether two simulation sessions were run with identical software or not)
- Log and error messages from each process in the simulation
- Intermediate data files written by each module for debugging and analysis purposes
- Instrumentation data produced by any embedded software being exercised in the simulation

Adapters

Adapters are the system's principal mechanism for federating simulations; an Adapter is an MSF module that provides a bridge between MSF and an external system, stimuli or simulation. An Adapter to an external system is responsible for translating messages and message protocols from one system to another, and for negotiating time advances between systems.

An Adapter's Translators are responsible for translating message formats between MSF Messaging and the external system's data formats. They can also serve as abstraction layer, to isolate the two systems from local changes in data formats.

An Adapter's Scheduler and TimeSynchronizer negotiate time advances between systems. MSF was not designed to federate with real-time simulations, but was designed to allow an MSF session to be a federate in an HLA [6] simulation.

Adapters have been used, for example, to link the M&S system with Raytheon's existing Desktop Tactical Simulator (DTS), which executes embedded software in a desktop environment. Adapters are used to bridge DTS's internal messaging protocol with M&S messaging, and to keep the Timecop in sync with the DTS simulation's internal simulation clock.

Operators

Operators are MSF modules that simulate operator-in-the-loop behavior. They receive messages from other simulation modules that inform them of simulated system outputs and environmental conditions, and send messages to other simulation modules to simulate human input to simulated systems. Operators have been implemented as custom Python scripts, as well as rule-based systems using pyCLIPS [8].

Scalability

The M&S system was designed to run in a clustered environment, with multiple computers and network storage connected by a fast local-area network (LAN) [9].

This architecture was chosen to allow for load scalability, where compute or storage nodes can be added to or removed from the cluster as demand changes, or redeployed from one program to another as business needs change. Nodes within the cluster can also be updated incrementally over time, providing flexibility in (maintenance/refresh) costs. And ZeroMQ's brokerless architecture minimizes messaging bottlenecks and allows for flexibility of deployment – e.g., localizing simulation sessions to subnets without having to worry about broker placement.

Applicability Across the Product Development Cycle

The system's modular design facilitates its use throughout the product development cycle, from early conceptual studies through final Validation and Verification (V&V).

Early in the product development phase, concept studies and design tradeoffs can be performed, and system performance can be predicted using mature environment model from previous simulation efforts using MSF, augmented with new and/or specific models. Behavioral models of system behavior in Matlab or Python; as the design solidifies, models can be refined and coded in C++ for better runtime performance. As embedded software is developed, it can be introduced into the simulation via instruction-set simulators or other embedded-processor simulations, and it's expected that Adapters can be employed to introduce hardware components for Hardware in the Loop (HWIL) simulation in some applications where the hardware may not require real world operation. Finally, once the system is implemented and high-fidelity simulation models are complete, the M&S system can be used to exercise the system in situations that are difficult to realize in an actual flight test: environments requiring complex orchestration of a large number of range assets, for example, or where range assets are difficult to acquire, or tests that exhaustively cover the performance envelope, or that require a large number of Monte Carlo trials.

Federating Simulations

MSF's modular architecture was designed to facilitate the integration of external simulation systems, both legacy and evolving. We've demonstrated this by integrating Raytheon's Desktop Tactical Simulator (DTS), a system that executes airborne radar embedded software in a Microsoft Windows desktop environment. We've successfully integrated multiple instances of DTS, simulating the operation of multiple airborne radar systems, in a single target/clutter environment.

Kinematics

Six (6) Degree of Freedom (DoF) kinematics model are provided by a single MSF module in each session; this module is implemented as a wrapper around one or more kinematics sources, which can be autonomous kinematics simulations or alternatively, can be supplied by a federated simulation. The kinematics module also allows for mixed kinematics sources, so that kinematics data for different bodies can be drawn from different sources:

For example, synthetic targets can be used to

- *Augment the playback of TSPI data collected during flight test*
- *Expedite requirements development and*
- *Requirements sell-off – validate against real platform*

Operator Input(Human Machine Interface)

Operator input can be generated in a number of ways:

- MSF modules can be implemented to accept interactive input, via GUI or by presenting a command-line console. These modules can then generate messages to be sent to other simulation modules to command the desired behavior.
- Federated simulations may have operator interfaces, which directly or indirectly command MSF modules
- MSF modules can be implemented to accept messages from other modules, and to be programmed to respond to those messages. For example, a module has been implemented that accepts messages output by a DTS-simulated airborne radar system to its mission computer, correlate any reported targets to "truth" kinematics obtained from the MSF kinematics module, and command the simulated radar to initiate a high-quality track on desired targets. Other "operator" modules have been implemented using pyCLIPS [10] , to demonstrate a capability for rule-based decision-making.

CONCLUSIONS

Modeling and Simulation is one of the most versatile tools in the arsenal of the system developers, especially for complex system development. This allows for stakeholders to perform a comprehensive evaluation of system before it can be built in cost effective and timely manner. This also facilitates the customers and systems integrator to carry out the trade-off analysis, performance dimensioning, alternate design considerations, and future improvements considerations at very early stage of the program to minimize unnecessary risks and late stage surprises. The advances in technology, tools, and process have consistently enhanced the capabilities to model complex real time physical systems employing high performance distributed computers and broadband network with high fidelity input signal models and real life engagement scenario. The signal processing algorithms developed in quasi real time scenario allows system developer to design a system with right mix of cost, time, and performance offerings. These capabilities keep on improving as the digital and broadband technology continue to evolve following the Moore's law. System upgrades and performance enhancements can be established and demonstrated to key stake holders in a controlled and deterministic way without building a system. It is not farfetched that a system could be sold off solely on the basis of simulation results avoiding costly flight and real assets.

ACKNOWLEDGMENT

Authors would like to recognize the support from the Raytheon's Systems and Software group as well as their valuable suggestions during the preparation of this manuscript.

***Abstract*—In this paper, we proposed a novel algorithm for identifying the modulation scheme of an unknown incoming signal in order to mitigate the interference with primary user in Cognitive Radio systems, which is facilitated by using Automatic Modulation Classification (AMC) at the front end of Software Defined Radio (SDR). In this study, we used computer simulations of analog and digital modulations belonging to eleven classes. Spectral based features have been used as input features for Sequential Minimal Optimization (SMO). These features of primary users are stored in the database, then it matches the unknown signal's features with those in the database. Built upon recently proposed AMC, our new database approach inherits the benefits of SMO based approach and makes it much more time efficient in classifying an unknown signal, especially in the case of multiple modulation schemes to overcome the issue of intense computations in constructing features. In various applications, primary users own frequent wireless transmissions having limited their feature size and save few computations. The SMO based classification methodology proves to be over 99 % accurate for SNR of 15 dB and accuracy of classification is over 95 % for low SNRs around 5dB.**

Keywords- Automatic modulation classification, cognitive radio, Database, sequential minimal optimization, unknown signal detection, primary user, spectral based features.

I. INTRODUCTION

Cognitive Radio (CR) is a cutting edge technology on which rigorous research and Development (R&D) is occurring recently. CR enables efficient usage of radio frequency spectrum. Empty spaces in both licensed and unlicensed spectrum commonly known as white spaces are used by CR to achieve its set of objectives. The idea here is to sense for a spectrum hole and use it until its rightful owner appears. The CR then modifies its frequency to match another white space and possibly another class of modulation scheme and coding. This phenomenon supposedly may occur every now and then, imposing a heavy feedback to the receiver every time the modulation scheme and the coding changes. One possible solution to this problem is to use Digital Signal processing (DSP) analysis called automatic modulation classification. These calculations can determine the type of modulation effectively using particular feature set. But most of the work in this direction is applied to High Frequency (HF) noise and cannot be applied to Additive White Gaussian Noise (AWGN) channels. [1]

The goal of this study is to implement an automatic modulation classifier in an AWGN environment. So, we designed the database assisted AMC, analysed the need for fast classification and proposed a solution. This paper proposes Sequential Minimal Optimization (SMO) to train the Support vector machines (SVMs) to do classification by segregating a mixture of both digital and analog modulation schemes into different classes. Consequently, our contribution to Cognitive Radio research lies in classifying an unknown signal in a time efficient manner, through integration of database.

The paper is organized as follows: Section II explains sequential minimal optimization and related work. Simulation of modulated signals, feature extraction and modulation classification are presented in Section III. Section IV is about proposed database assisted design and algorithm. Results and discussions of proposed approach are presented in Section V. Conclusion is drawn in VI.

II. SEQUENTIAL MINIMAL OPTIMIZATION

Support Vector machines are built using linear kernels for classification. We make use of Sequential minimal optimization algorithm to train the SVMs. An SMO model is a representation of the data sets as points in space; they are mapped so that the data sets of the separate categories are divided by a clear gap, which is as wide as possible. New data sets are then mapped into that same space and predicted to belong to a category based on which side of the gap they fall into. It trains a support vector classifier using kernel functions such as Gaussian and Polynomial kernels. It takes minimal time in doing so [2].

The $K(x, x_i)$ are the support vectors used by SMO. α is the weight or lagrange multiplier. The output equation is given as,

$$y = f(x);\ f(x) = \sum_{k=1}^{m} \alpha_k.K(x, x_k) + b \quad (1)$$

SMO is widely used in training support vector machines (SVMs). The amount of memory required for this algorithm is linear in the training set size, due to which large training sets

are handled with very less complexity and also matrix computation is avoided. So, SMO spans somewhere between linear and quadratic in the training set size for various test problems, while the standard SVM algorithm spans somewhere between linear and cubic in the training set size. SMO's computation time is took over by SVM evaluation, hence SMO is the best algorithm for linear SVMs. On real world sparse data sets, SMO can be approximately more than 1000 times faster than the normal algorithm [2].

A. Related works

Azzouz and Nandi [3] have proposed spectral based features and algorithms to classify both analog and digital modulated signals. Popoola and Olst have extracted same set of features and proposed ANN based classification system [4]. The key features proposed by Nandi are later used in [5] [6] and many more. But in practicality, accuracy of these features depends upon noise, carrier offset error, symbol rate estimation error that affect the probability of identification. Arulampalam et al., [13] have used only digital modulation schemes using ANN and features proposed by Nandi and Azzouz, validated over non-weak segment of the incepted signal and also used maximum power spectral density of normalized instantaneous frequency of intercepted signal. When we compare our work with the study, we have obtained better results by using SMO Algorithm [8] [15] for classificaion of both analog and digital modulations at low SNRs. Our contribution is in building upon this existing work on AMC, via a database approach and classifying the unknown signal in a time efficient manner.

III. STUDY METHODOLOGY

The study flow involved three steps. The first step was extraction of the statistical features keys used as inputs to the developed classifier. The second step was development of automatic modulation classifier system. Third step was to integrate the system with the database. Satisfactory accuracy was achieved in the final step.

A. Simulation of modulated signals

Signals are generated for eleven modulation schemes, both analog and digital modulations. Modulated signals are generated using the formulae. For example, the AM modulated signal is generated using the formula,

$$Y_{am}(t) = [1 + K_a.F_t](\cos(2\pi f_c t)) \tag{2}$$

The FM modulated signal is generated using the formula,

$$Y_{fm}(t) = \cos(2\pi f_c t + k_f \sin(2\pi f_m t)) \tag{3}$$

Similarly, DSB, SSB, ASK, FSK and PSK modulated signals were generated by using their respective formulas. AWGN(Additive White Gaussian Noise) is added to the modulated signals.

B. Feature extraction

Feature extraction is a prerequisite for recognition. The motive here is to identify a pattern by using minimum number of features or attributes which are important for determining the pattern class identification. The employed classification technique was derived from the amplitude, phase and frequency instantaneous values of signal simulations. These values are obtained from the discrete time analytic signal. Hilbert transform is used for calculating the instantaneous values of a signal. The feature keys are spectral based features and had earlier been used by Nandi [3] [7].

(i) γ_{max} : This feature corresponds to maximum value of the PSD (Power spectral density) . It measures the variance in signal amplitude.

$$\gamma_{max} = \frac{max|DFT(a_{cn}[n]|^2}{N} \tag{4}$$

i.e. taking a discrete Fourier transform of the signal samples. Here $a_{cn}(n)$ is centered instantaneous amplitude at time, $t = \frac{n}{f_s}(n = 1, 2, 3...N)$ and a sampling frequency, f_s. $a_{cn}(n)$ is defined as

$$a_{cn}(n) = a_n[n] - 1 \ , \ a_n(n) = \frac{a[n]}{m_a} \tag{5}$$

Here m_a is the mean value of samples.

$$m_a = \frac{1}{N}\sum_{n=1}^{N} a[n] \tag{6}$$

All centered values refer to normalized instantaneous values.

(ii) σ_{dp} : This feature measures the variance in direct instantaneous phase. It discriminated 2PSK from other modulation schemes. This is given as σ_{dp}

$$\sigma_{dp} = \sqrt{\frac{1}{N_c}\left(\sum_{A_n > A_t} \Phi_{NL}^2[n]\right) - \left(\frac{1}{N_c}\sum_{A_n > A_t} \Phi_{NL}[n]\right)^2} \tag{7}$$

(iii) σ_{ap} : This feature corresponds to the standard deviation of the centered non-linear component of the instantaneous phase. Here we take absolute values. This is given as

$$\sigma_{ap} = \sqrt{\frac{1}{N_c}\left(\sum_{A_n > A_t} \Phi_{NL}^2[n]\right) - \left(\frac{1}{N_c}\sum_{A_n > A_t} |\Phi_{NL}[n]|\right)^2} \tag{8}$$

This is very useful in finding PSK modulation order.

(iv) P : This feature is the calculation of spectrum symmetry around the carrier frequency. This quantity is a decision factor to classify amplitude-based modulations with different properties in the frequency domain.

$$P = \frac{P_l - P_u}{P_l + P_u} \tag{9}$$

$P_l$is the spectral power of sideband (lower) and $P_u$is the spectral power of the other sideband (upper).

$$P_l = \sum_{n=1}^{f_{cn}} |F(n)|^2, \ P_u = \sum_{n=1}^{f_{cn}} |F\left[n + f_{cn} + 1\right]|^2 \tag{10}$$

Here $F(n)$ is the Fourier transform of the received signal. $(f_{cn} + 1)$ is the sample number for carrier frequency f_c . f_{cn} is defined as

$$f_{cn} = \frac{f_c N}{f_s} - 1 \tag{11}$$

(v) σ_{aa} : This feature corresponds to the standard deviation of the centered instantaneous amplitude of signal samples. N is the total number of signal samples. We take absolute and normalized values. Though this feature is similar to γ_{max}, it has the ability to discriminate 2ASK from other modulation schemes.

$$\sigma_{aa} = \sqrt{\frac{1}{N}\left(\sum_{n=1}^{N} A_{cn}^2(n)\right) - \left(\frac{1}{N}\sum_{n=1}^{N}|A_{cn}(n)|\right)^2} \quad (12)$$

(vi) σ_{af} : This feature corresponds to standard deviation of the centered instantaneous frequency. We take absolute and normalized values. It has the ability to discriminate 2ASK from 4ASK. N_c is the number of samples that meet the condition: $A_n[n] > A_t$. A_t is the threshold value.

$$\sigma_{af} = \sqrt{\frac{1}{N_c}\left(\sum_{A_n[n]>A_t} f_N^2(n)\right) - \left(\frac{1}{N_c}\sum_{A_n[n]>A_t}|f(n)|\right)^2} \quad (13)$$

(vii) σ_a: This feature corresponds to the standard deviation of the centered frequency. We take normalized values here. It has the ability to differentiate 2ASK and 4ASK.

$$\sigma_a = \sqrt{\frac{1}{N_c}\left(\sum_{A_n[n]>A_t} a_{cn}^2[n]\right) - \left(\frac{1}{N_c}\sum_{A_n[n]>A_t} a_{cn}[n]\right)^2} \quad (14)$$

(viii) μ_{42}^a: This feature is the kurtosis of normalized and centered instantaneous amplitude. It differentiates AM signal from the rest.

$$\mu_{42}^a = \frac{E\{A_{cn}^4[n]\}}{\{E\{A_{cn}^2[n]\}\}^2} \quad (15)$$

(ix) μ_{42}^f: This feature is the kurtosis of normalized and centered instantaneous frequency. It differentiates FM signal from the rest.

$$\mu_{42}^f = \frac{E\{f_N^4[n]\}}{\{E\{f_N^2[n]\}\}^2} \quad (16)$$

C. Modulation classification

Modulation can be defined as varying amplitude, frequency and phase of a carrier wave with frequency f_c with respect to modulating signal with frequency f_m[6].

While training the SVM, nominal attributes in the arff format are converted into two class (binary) ones. Coefficients in the output are based on the normalized data. The SMO algorithm will use pair wise classification considering the fact that the problem here is a multi-class one. We choose to make use of Poly Kernel i.e. polynomial kernels. Here since we have 11 classes the 11 binary SMO models have been output with one hyperplane each to support each of the possible pair of class values. In such Kernel based methods, similarity must be a kernel function satisfying some mathematical properties [11] [12].

IV. DESIGN AND ALGORITHM

The steps in design of the database assisted AMC are presented in Fig. 1.

The steps for implementing the Database assisted AMC system are divided into two phases.

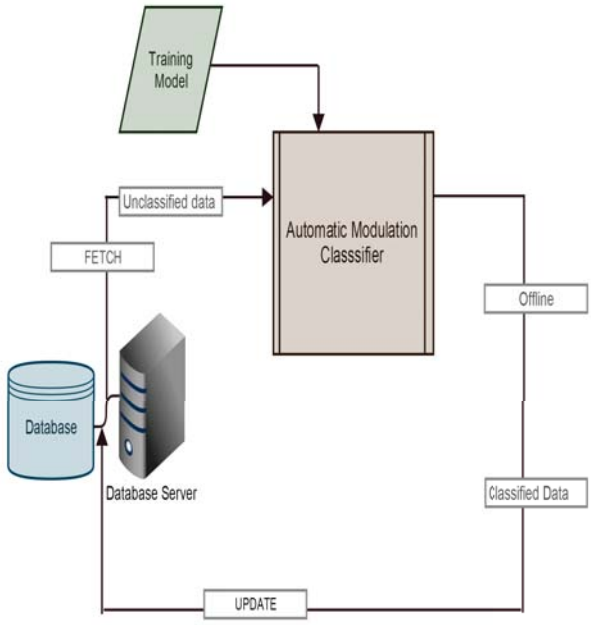

Fig. 1. Database assisted Automatic modulation classifier

1) Offline Phase:

- Firstly we had realized computer simulated signals of different modulation schemes using MATLAB codes reproducing the work of A.K. Nandi and E.E. Azzouz [3].
- Then, stored the simulated and labeled signal data into the database server.
- Thereafter we have generated reference sample data, to train the SMO model offline.
- Further saved the trained model into the file system.
- Finally evaluated by giving an unlabeled data as input to the database server (this will be used as test data that will be classified by AMC).

2) Classification Phase:

- Secondly we have connected to the database using JDBC MySQL connector/J.
- Accordingly fetched all the unlabeled data into the program.
- Next we attached arff (attribute relation file header) header format to this data in order to transform it into an arff test file.
- Then read the testing file into the program and loaded the trained SMO model.
- Afterwards we have applied the model's configuration on the test file. With this step, modulation classification is completed. In the end, updated the database server with the classified signal data.

V. RESULTS AND DISCUSSIONS

Here we have input test data (unknown signal) of 25dB SNR and applied an SMO trained model over it. The model uses

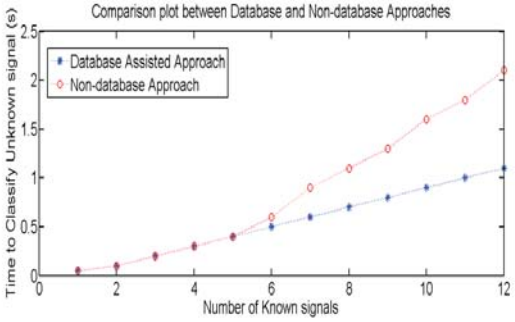

Fig. 2. Time for classification of unknown signal vs. number of known signals.

some hyper planes to divide the space to form 11 regions, each representing one modulation scheme. This has been explained in section II of this paper.

In database assisted approach, when an unknown signal's features are among the training data stored in database, an existing record in the database is selected and its modulation scheme is returned. We have first trained the SMO classifier and stored the trained model in WEKA [9] and database. Finally, we are classifying unknown signal with an assumption that it should belong to one of the known modulation schemes mentioned in section III of this paper.

In our database assisted approach, we record the features of known signals in the database system. Then, AMC monitors each incoming signal's transmitting sequence. For example, let us suppose that initially only one known signal, such as AM is present in an environment and detect the unknown signal. Then, in the next input sequence consider only two known signals such as AM, FM and compare the unknown signal's feature vectors with those in the database. In various applications, known signals have routine wireless transmissions, hence they own a limited number of feature vectors, meaning that the subsequent database is stable and limited in size. Whenever an unknown signal's feature vector does not have a match entity in the database, our approach will detect it's action as unusual by taking the stability of known signals into account and identifies it as a malicious signal, hence save some computations compared to the previous approaches in the literature. This way we realized that our proposed idea on database assisted approach for AMC is a novel work. So, we ran computer simulations and in future would like to implement this idea on a system model similar to cognitive radio scenario of known signals. Known signals are analogous to primary users' signals and an unknown signal referred as primary user is to be detected so that interference can be avoided with neighboring primary users. Therefore, we assumed all basic modulation schemes possible as the only modulation types used by authentic primary users' signals, referred as known signals. Here our research contribution is to evaluate the performance of database approach over non database in terms of efficiency, thereby solving the problem of severe computations in constructing features.

Our limitations are as follows:

1) At any instance of time, only one signal is transmitted by users' either primary, unknown or secondary.
2) Secondary users transmit at very low powers not interfering with primary and unknown users.
3) Secondary users, unknown users and primary users are utilizing the area within the same frequency band.
4) Secondary users' modulation scheme is different from primary and unknown users.
5) We cannot detect intelligent unknown users' who pretend to be primary users.
6) We have not considered other modulation schemes for transmission of unknown signal, instead used only those modulation schemes mentioned in section III of this paper.

In non database approach, we have assumed that the test signal's feature is among the training data. To match this test signal to a record in the arff format, we need to search for the record. But running a search query is not preferred in flat files (File that doesn't have any internal hierarchy). The reason is that database is a structured way of storing data, whereas flat file is unstructured way of storing data.

It is very clear from Fig. 2 that for both database and non database methods the time taken for classifying an unknown signal is surely dependent on number of known signals. When there are more known signals in the system, it consumes more time for conclusion. However, it is observed that with a larger number of known signals, the classification time increases more drastically in the case of non database approach. The database assisted approach takes linear growth, because time taken for classification is dominated only by searching time of database. Whereas, non database approach follows approximately exponential rise, due to increase in classification time with number of known signals.

At low SNRs like 5 dB, as signals are transmitted with low power, it is a challenge to classify 11 different modulation schemes, as sometimes there is confusion to classify the similar modulation schemes. Generally, we get accuracy of 80-90% at low SNRs by recent methods. But by these features we are getting around 95%.

A. *Probability of correct detection*

In multi-class prediction, the result on a test set is often displayed as a two dimensional confusion matrix with a row and column for each class. It is defined by this formula, $P = (TP+TN)/(TP+TN+FP+FN)$. Here TP means True Positives, TN means True negatives FP means False positive and FN means False negative. The error rate is one minus this [10].

TABLE I. CORRECT DETECTION RATE

Modulation Scheme	Accuracy	
	SNR = 15 dB	
	Present Work	Popoola Work [4]
2ASK	100	99.99
4ASK	100	99.98
2FSK	100	99.92
2PSK	100	99.75
4PSK	100	99.98
AM	100	99.95
DSB	99.97	99.98
FM	100	99.91
LSB	100	99.97
USB	99.97	-

TABLE II. CONFUSION MATRIX

	Confusion matrix for SNR = 15 dB					
	AM	DSB	LSB	USB	FM	2ASK
AM	1	0	0	0	0	0
DSB	0	1	0	0	0	0
LSB	0	0	1	0	0	0
USB	0	0	0.01	0.99	0	0
FM	0	0	0	0	1	0
2ASK	0	0	0	0	0	1

TABLE III. CONFUSION MATRIX

	Confusion matrix for SNR = 15 dB				
	4ASK	2FSK	4FSK	2PSK	4PSK
4ASK	1	0	0	0	0
2FSK	0	1	0	0	0
4FSK	0	0	1	0	0
2PSK	0	0	0	1	0
4PSK	0	0	0	0	1

Table I illustrates the improvement of present work with reference work by Popoola's [4] [16] feed forward neural networks [14]. Table II and III illustrate the confusion matrix for different modulation schemes at an SNR = 15 dB.

VI. CONCLUSION

In this paper, we have developed and implemented an AMC with database acting as an abettor in automating the whole process of classification. The database assisted approach gave us better results than the non database approach in terms of time taken. We have applied SMO model configuration on both labeled and unlabeled data. Firstly, SMO based classification alone gave better performance when trained and evaluated with labeled signals. The results proved to be over 98% accurate for 15 dB data. The future work of this paper includes validation of our approach through hardware implementation to show its feasibility in real life conditions.

In future, consider same modulation type during classification. Till now we are assuming that the unknown signal's modulation should belong to any one of the 11 modulation schemes generated in simulations. But, in real life we need to detect an unknown signal, which may be different from modulations stored in database. Then we consider such an unknown signal as malicious. Now as malicious users (unknown users) are intelligent they pretend modulations of primary users. So, in this case, if both primary and unknown users use same modulation type, then during the detection of unknown signals if no match is found in database, one should use methods which detect unknown signals.

***Abstract*—Orthogonal multiple access (OMA) is widely employed in traditional cellular wireless communication systems due to a low-complexity receiver is needed. However, multiple access scheme with higher spectral efficiency and the ability of access more users than OMA scheme is preferred for future wireless communication system. In this work, a non-orthogonal transmission scheme called pattern division multiple access (PDMA) is proposed for the fifth generation (5G) wireless communication system. Two pattern matric are designed for 150% and 200% overloaded PDMA systems. Both of extrinsic information transfer (EXIT) chart analysis and simulation results show that the proposed PDMA scheme outperforms the traditional OMA system significantly. Thus PDMA scheme is a good choice for future multiple access scheme for 5G wireless communication systems.**

***Index Terms*—Pattern division multiple access (PDMA), overload, symbol-wise belief propagation, fifth generation**

I. Introduction

Orthogonal multiple access (OMA) is widely adopted in current wireless communication system due to that a low complexity detection algorithm can be employed at the receiver. In recent years, communication networks are facing the challenges of the rapid increase of mobile data growth and huge amount of access users. Overloaded non-orthogonal transmission by squeezing more users to limited number of time-frequency resource can provide both of higher spectral efficiency and large numbers of access than those of OMA scheme [1-2]. However, a new issue that we must cope with is multiple user interference (MUI) which leading to significant performance degradation. Maximum a posteriori (MAP) or maximum likelihood algorithm is known as optimal with the computational complexity increase exponential with the number of users and the order of modulation, which make it impossible for practical applications. The decorrelator and MMSE detector provide acceptable performance with much lower complexity compare to their optimum counterpart in underloaded systems. Unfortunately, they fail to achieve satisfactory performance under an overloaded condition as the desired signal sub-spaces becomes rank-deficient [3].

Belief propagation (BP) algorithm has attracted great attention due to its success in decoding theory, multiple input multiple output (MIMO) detection and other signal processing problems. In [4], degree distribution optimized low density parity check (LDPC) code with BP decoding can approach the binary input additive white Gaussian noise (BIAWGN) channel capacity with only a gap of 0.0045dB. An important feature of BP algorithm is that it can be depicted by the message passing on factor graph [5]. The extrinsic information is transferred from the leaf node to its parent node and ultimately to root node and the estimate of the transmitted symbol converge to its real value for cycle free graph. However, for full connected graph, e.g. MIMO system, the convergence cannot be guaranteed due to the error propagation [6].

Inspired by the idea of the irregularity of LDPC code and the diversity gain of multicarrier code division multiple access (CDMA) system [1,7], we propose an orthogonal frequency division multiplexing (OFDM) based non-orthogonal multiple access scheme called pattern division multiple access (PDMA) for future wireless communication systems. The features of PDMA can be summarized as: 1) For multicarrier CDMA system, every subcarrier is shared by all users, while PDMA allows every subcarrier to be used by a subset of data symbols that belongs to different users. As we will see later, the computational complexity of the BP based MUD can be reduced significantly by this way especially for high order modulation or high overloaded systems; 2) For multicarrier system, user symbols will be spread over all interested subcarriers, while a subset of subcarriers instead for PDMA system. Furthermore, the effective processing gain of each user can be different; 3) Symbol-wise BP is employed as MUD algorithm to achieve complexity and performance tradeoffs.

This paper is organized as follows: Section II presents the system model of the proposed PDMA system architecture and proposed two pattern matric with different overload factor respectively. Section III depicts the symbol-wise BP MUD algorithm of PDMA system. Numerical results and analysis are provided in Section IV. Conclusions are drawn in section V.

II. System Model and PDMA

A. System model

Consider the uplink PDMA system with N_t users with indices $k = 1, \ldots, N_t$ transmitting to the same base station where the base station and each user are equipped with a single antenna. The block diagram of an uplink PDMA system is shown in Fig. 1. Assume that each user take their symbols from the same constellation alphabet and all users have the same number of data symbols N_s which equal

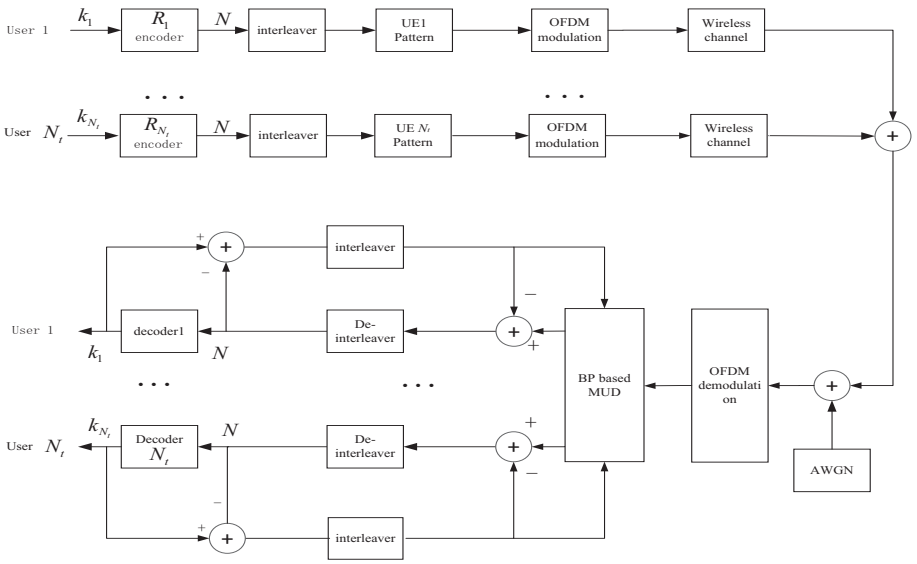

Fig. 1. The structure of the proposed transceiver

to the length of turbo code used. In the PDMA technique, the original data streams are first multiplied with their user-specific pattern sequences and then modulated on different sub-carriers. Assume that a user-specific pattern has d_v non-zero elements, we define d_v as the effective spreading factor of the specific user as in [8]. Similarly, we define d_c as the number of symbols that are allowed to interfere to each other at a specific chip. In PDMA system, d_v of each user can be different, thus d_c of all interest subcarriers can also be different. At the receiver side, after performing OFDM demodulation operations the signal is passed to a belief propagation based MUD [9], there exist two iterative processes: inner and outer iterative processing for MUD and the turbo-style processing, respectively. Considering now that two iterative processes are involved, the message update algorithm should be addressed accordingly. Define two types of supporting sets, one is row supporting set $N_c(j)$ and the other is column supporting set $N_v(i)$. Let row supporting set $N_c(j) = \{i|\mathbf{S}_{j,i} \neq 0, 1 \leq i \leq N_t\}$ denotes the subset of users that share subcarrier j, and let column supporting set $N_v(i) = \{j|\mathbf{S}_{j,i} \neq 0, 1 \leq j \leq N_r\}$ denotes the subset of subcarriers where user symbol x_i is spread. The received signal y_j at subcarrier j can be expressed as:

$$y_j = \sum_{i \in N_c(j)} h_{ji} x_i + n_j \tag{1}$$

Where $h_{j,i}$ denotes the channel fading coefficient from i-th user to j-th subcarrier, x_i is the data symbol of i-th user , n_j is the AWGN with mean zero and variance σ_n^2. The single user average bit signal-to-noise E_b/N_0 is define as in [10]

$$\left(\frac{E_b}{N_0}\right)_{dB} = \left(\frac{E_S}{N_0}\right)_{dB} + 10\log_{10}\left(\frac{1}{R_c m}\right) \tag{2}$$

where E_s denotes the symbol energy of each user, $N_0 = 2\sigma_n^2$ denotes the single side power spectral density, R_c denotes the channel coding rate, and m denotes the number of bits that mapping to a constellation point.

$$\mathbf{S}_{2,3} = \begin{bmatrix} 1 & 1 & 0 \\ 1 & 0 & 1 \end{bmatrix} \Rightarrow \begin{array}{c} \\ \text{RE1} \\ \text{RE2} \end{array} \begin{array}{c} \text{UE1} \quad \text{UE2} \quad \text{UE3} \\ \begin{bmatrix} x_1 & x_2 & 0 \\ x_1 & 0 & x_3 \end{bmatrix} \end{array}$$

Fig. 2. Proposed $\mathbf{S}_{2,3}$ pattern matrix for 150% overload

B. Proposed pattern matric for PDMA system

For example, we have design two pattern matric $\mathbf{S}_{2,3}$ and $\mathbf{S}_{3,6}$for 150% and 200% overload PDMA systems, as shown in Fig. 2 and Fig.3 respectively. The overload factor is defined as $\rho = N_t/N_r$ [11]. For $\mathbf{S}_{2,3}$, user 1 spread its symbol x_1 over RE1 and RE2 for transmission, while user 2 and user 3 spread its symbols x_2 and x_3 over RE1 and RE2 respectively. Consequently, the diversity order (effective processing gain) of user1, user2 and user3 is 2, 1,1 respectively. In addition, it is obviously that the d_c of both of RE1 and RE2 are 2. The first column of matrix $\mathbf{S}_{2,3}$ is the pattern sequence of user 1, the second and last column of matrix $\mathbf{S}_{2,3}$ are the pattern sequences of user 2 and user 3 respectively and so on.

III. Proposed symbol-wise Belief propagation based MUD

An PDMA system with N_t users and N_r chips can be described by a factor graph $\mathcal{G}(\mathcal{V}, \mathcal{C}, \mathcal{E})$ where variable nodes $x_i (1 \leq i \leq N_t)$ and function nodes $y_j (1 \leq j \leq N_r)$ representing the symbol and chip respectively and the relationship between the received chip and its constrained users are represented by edges. Fig.4 shows the factor graph of $\mathbf{S}_{2,3}$.

As shown in [6,8], the *a posteriori* LLR of i-th symbol , denoted by $\mathcal{L}_{MUD}^{D}(x_i = \chi(\alpha))$, can be written as

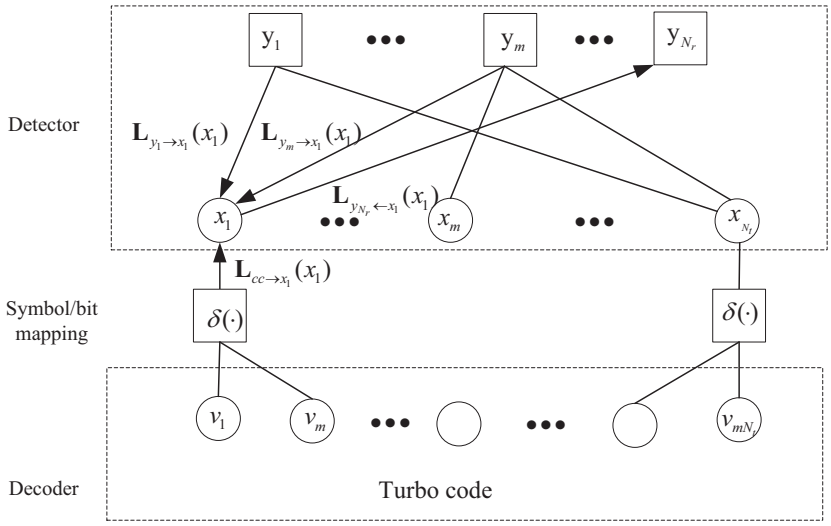

Fig. 6. Joint factor graph of the receiver

$$\mathbf{S}_{3,6}=\begin{bmatrix}1&1&1&0&1&0\\1&1&0&1&0&1\\1&0&1&1&0&0\end{bmatrix}\Rightarrow\begin{array}{c}\\RE1\\RE2\\RE3\end{array}\begin{array}{c}UE1\ UE2\ UE3\ UE4\ UE5\ UE6\\\begin{bmatrix}x_1&x_2&x_3&0&x_5&0\\x_1&x_2&0&x_4&0&x_6\\x_1&0&x_3&x_4&0&0\end{bmatrix}\end{array}$$

$$L^D_{MUD}\left(x_i=\chi(\alpha)\right))$$
$$\cong \ln\frac{\prod_{j'\in N_v(i)}\sum_{x_{N_c(j)\setminus i}}p\left(y_j|x_{N_c(j)\setminus i},x_i=(\alpha)),H\right)\prod_{\ell\in N_c(j)}p(x_\ell)}{\prod_{j'\in N_v(i)}\sum_{x_{N_c(j)\setminus i}}p\left(y_j|x_{N_c(j)\setminus i},x_i=\chi(0)),H\right)\prod_{\ell\in N_c(j)}p(x_\ell)}$$
$$=\ln\prod_{j'\in N_v(i)}\frac{\sum_{x_{N_c(j)\setminus i}}p\left(y_j|x_{N_c(j)\setminus i},x_i=\chi(\alpha)),H\right)\prod_{\ell\in N_c(j)}p(x_\ell)}{\sum_{x_{N_c(j)\setminus i}}p\left(y_j|x_{N_c(j)\setminus i},x_i=\chi(0)),H\right)\prod_{\ell\in N_c(j)}p(x_\ell)}$$
$$=\sum_{j'\in N_v(i)}\ln\frac{\sum_{x_{N_c(j)\setminus i}}p\left(y_j|x_{N_c(j)\setminus i},x_i=\chi(\alpha)),H\right)\prod_{\ell\in N_c(j)}p(x_\ell)}{\sum_{x_{N_c(j)\setminus i}}p\left(y_j|x_{N_c(j)\setminus i},x_i=\chi(0)),H\right)\prod_{\ell\in N_c(j)}p(x_\ell)} \tag{3}$$

where $0\le\alpha\le|\mathcal{A}|-1$, $\chi(\cdot)$ denotes the constellation mapping, χ^{-1} denotes the inverse mapping, $N_v(i)\backslash j$ denotes the column supporting set $N_v(i)$ except function node j. The channel transition probability function in (3) can be expressed as

$$p\left(y_j|x_{N_c(j)\setminus i},x_i=\chi(\alpha)),\cdots,x_{N_t},\mathbf{H}\right)=\frac{1}{\pi N_0}e^{-\frac{\left|y_j-\mathbf{h}^{[j]}\mathbf{x}\right|^2}{N_0}} \tag{4}$$

Where $\mathbf{h}^{[j]}$ denotes the j-th row of matrix $\mathbf{H}$, $\mathbf{x}=[x_1,\cdots,x_{N_t}]^T$, $N_0=2\sigma_n^2$. Combining (4) into (3), $\mathcal{L}^D_{MUD}(x_i=\chi(\alpha))$ can be rewritten as

$$\mathcal{L}^{D}_{MUD}\left(x_i=\chi(\alpha)\right) = \sum_{j'\in N_v(i)} \ln \frac{\sum_{x_{N_c(j)\backslash i, x_i=\chi(\alpha)}} e^{-\frac{\left|y_j-\mathbf{h}^{[j]}\mathbf{x}\right|^2}{N_0}} e^{\sum_{\ell\in N_c(j), x_\ell\neq\chi(0)} L^a(x_\ell)}}{\sum_{x_{N_c(j)\backslash i, x_i=\chi(0)}} e^{-\frac{\left|y_j-\mathbf{h}^{[j]}\mathbf{x}\right|^2}{N_0}} e^{\sum_{\ell\in N_c(j), x_\ell\neq\chi(0)} L^a(x_\ell)}} \tag{5}$$

As can be seen in (5), the $ln(\cdot)$ function following the first sum in (5) can be interpreted as chip-level Log-domain maximum *a posteriori* (MAP) detection. To calculate $\mathcal{L}^{D}_{MUD}(x_i=\chi(\alpha))$ in an iterative manner, after subtracting the *apriori* LLR $\mathcal{L}^{a}(x_i)$ from $\mathcal{L}^{D}_{MUD}(x_i=\chi(\alpha))$, the extrinsic information $\mathcal{L}_{y_j\to x_i}(x_i=\chi(\alpha))$ transferred from the function node y_j to variable node x_i, as shown in Fig. 5 (a), can be written as

$$\mathcal{L}_{y_j\to x_i}\left(x_i=\chi(\alpha)\right) = \ln \frac{\sum_{N_c(j)\backslash i, x_i=\chi(\alpha)} e^{-\frac{\left|y_j-\mathbf{h}^{[j]}x\right|^2}{N_0}} \cdot e^{\sum_{\ell\in N_c(j)\backslash k, x_\ell\neq\chi(0)} \mathcal{L}^a(x_\ell)}}{\sum_{N_c(j)\backslash i, x_i=\chi(0)} e^{-\frac{\left|y_j-\mathbf{h}^{[j]}x\right|^2}{N_0}} \cdot e^{\sum_{\ell\in N_c(j)\backslash k, x_\ell\neq\chi(0)} \mathcal{L}^a(x_\ell)}} \tag{6}$$

Similarly, the extrinsic information sent from variable node i to function node j can be divided into two cases. For the first case, i.e. symbol-wise BP without iterative decoding, as shown in Fig.5 (b), $\mathcal{L}_{y_j\to x_i}(x_i=\chi(\alpha))$ can be written as

$$\mathcal{L}_{y_j\leftarrow x_i}\left(x_i=\chi(\alpha)\right) = \sum\nolimits_{j'\in\{N_v(i)\backslash j\}} \mathcal{L}_{y_{j'}\to x_i}\left(x_i=\chi(\alpha)\right) \tag{7}$$

For the second case, i.e. symbol-wise BP with iterative decoding, $\mathcal{L}_{y_j\to x_i}(x_i=\chi(\alpha))$ can be written as

$$\mathcal{L}_{y_j\leftarrow x_i}\left(x_i=\chi(\alpha)\right) = \sum\nolimits_{j'\in\{N_v(i)\backslash j\}} \mathcal{L}_{y_{j'}\to x_i}\left(x_i=\alpha\right) + \mathcal{L}_{cc\to x_i}(x_i=\chi(\alpha)) \tag{8}$$

The basic form of chip level iterated MUD can be explained as follows. Using MPA, messages containing the reliability values of adjacent variable node are exchanged between the function nodes and the variable nodes iteratively. After appropriate number of iterations the soft output which is the calculated log likelihood ratio at each variable node, i.e. for variable node i, the *a posteriori* LLR $\mathcal{L}^{D}_{MUD}(x_i=\chi(\alpha))$ can be rewritten as

$$\mathcal{L}^{D}_{MUD}\left(x_i=\chi(\alpha)\right) = \sum\nolimits_{j'\in N_v(j)} \mathcal{L}_{y_{j'}\to x_i}\left(x_i=\chi(\alpha)\right) \tag{9}$$

After symbol/bit LLR conversion, the extrinsic LLRs of BP based MUD will be sent to the channel decoders. More details regarding the symbol/bit LLR conversion can be found in appendix. The iterative receiver of PDMA is based on iterative detection/decoding between PDMA symbol-wise MUD and users' FEC decoders. This is realized by iterative exchange of extrinsic information between detection and FEC decoding stages. The block diagram of PDMA's iterative MUD is illustrated in Fig. 6 and the BP based MUD algorithm is summarized as algorithm 1.

IV. Simulation Results

In this section, the performance of the proposed PMs are compared with that of the ones proposed in [2]. Both schemes employ turbo code of length 480 bits and rate 5/12 according to 3GPP's LTE-standard [12]. Under BPSK modulation and AWGN channel, as shown in Fig. 7, the coded BLER performance is compared between the proposed scheme the scheme proposed in [2] . The performance of the proposed $\mathbf{S}_{2,3}$ PM is superior to the $\mathbf{S}_{6,9}$ PM about 1.1dB, and the performance of the proposed $\mathbf{S}_{3,6}$ PM with about the same the performance as the $\mathbf{S}_{12,24}$. Under QPSK modulation and independent identical distribution (IID) rayleigh fading channel, simulation results are shown in Fig.8. It is need to say that the decoding complexity of both the proposed pattern matric is lower than that of the corresponding ones in [2]. For the PDMA systems employing QPSK modulation and BP-IDD algorithm, as shown in Fig. 9 and Fig. 10, the coded BLER performance of all the proposed schemes of 150% and 200% overload, outperform the OMA scheme about 2.1dB and 0.5dB respectively.

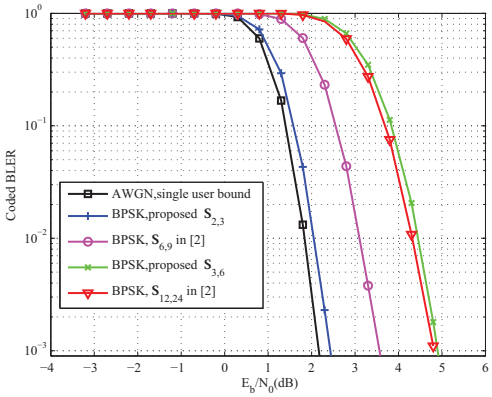

Fig. 7. Coded BLER performance comparison, AWGN channel, BPSK

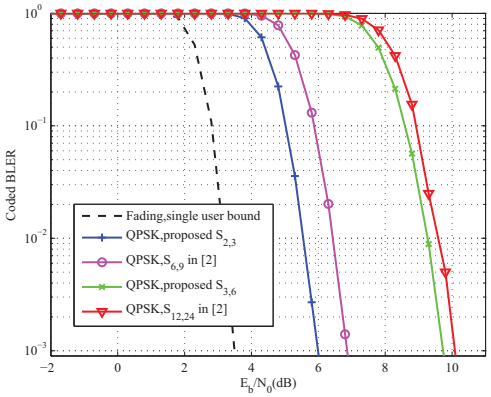

Fig. 8. BLER performance comparison, fading channel, QPSK

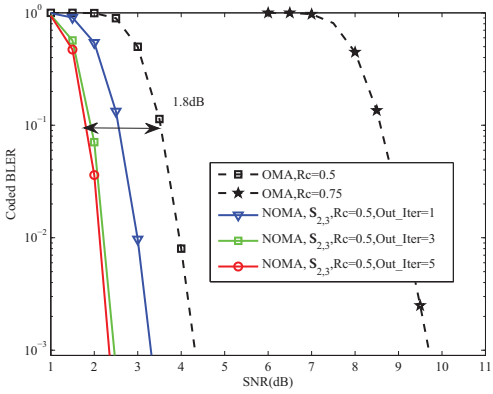

Fig. 9. BLER performance comparison between $\mathbf{S}_{2,3}$ and OMA

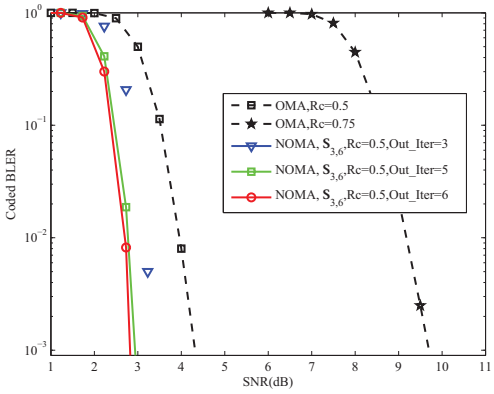

Fig. 10. BLER performance comparison between $\mathbf{S}_{3,6}$ and OMA

V. CONCLUSION

In this work, a PDMA scheme is proposed for future 5G cellular wireless communication system for the purpose of high spectral efficiency and high overload system. The proposed PMs for PDMA system achieves better performance than the existing scheme and significant performance gains than OMA scheme. It is a attractive multiple access scheme for 5G communication system.

Email: {resmi, sonali}@iitg.ernet.in

***Abstract*—Reliable data transmission is the first and foremost goal of any communication system. However, for energy constrained wireless sensor networks, the critical design constraint is energy conservation. A novel method of error control is proposed in this paper keeping reliability and energy efficiency as the prime goals. The method yields an enhanced coding gain (CG) compared to stronger codes, without any redundancy or even with savings in number of bits transmitted. Further, the upper and lower bounds on the bit error rate (BER) performance are also presented. The reliability and transmitted data savings provided are interdependent on each other and hence the name, interdependent source channel coding. Simulation results show that the proposed scheme achieves a CG of 4.093 dB in AWGN channel at BER of 10^{-5}, when there are 50 symbols in a codeword.**

***Index Terms*—WSNs, energy efficiency, coding gain, compression**

I. Introduction

A wireless sensor network (WSN) is a set of connected nodes deployed for observing a physical phenomenon and is widely used in a variety of applications. The design constraints of WSNs are very different from other traditional wireless networks because of its unique features like dense network, limited processing capability, and limited power supply. In most of the applications, sensor nodes are deployed in remote or secluded locations and are supposed to run for long time. Hence, energy conservation becomes the most important design issue of a WSN [1]. Any protocol or technique developed for WSN should be energy efficient.

Reliable information exchange is the prime motive of any communication system. Reliability is provided generally in two ways. i) Automatic Repeat Request (ARQ) and ii) Forward Error Correction (FEC). ARQ scheme is based on error detection techniques and retransmissions, while FEC on error correction at the receiver. ARQ is simpler compared to FEC schemes, and hence seems to be more suitable for WSNs, since complexity adds to energy expenditure. The authors in [2], [3] found ARQ energy inefficient for WSNs, due to the retransmissions of erroneous packets.

FEC is a good alternative to ARQ for adverse channel conditions. FEC corrects errors with help of added redundancy, and hence reduces the transmit energy required for achieving the same bit error rate (BER) of uncoded transmission. This saving is termed as coding gain (CG). This comes with the cost of additional transmit energy for parity bits and computation energy for encoding/decoding operation. If the additional energy expenditure underweighs the gain in transmit energy, FEC is energy efficient. Unlike traditional wireless networks, in a dense network, nodes are very close to each other and difference between computation energy and transmitting energy cannot be high [4]. The authors in [5] have found that FEC is an energy efficient solution for WSNs considering all the energy components of sensor nodes and encoding-, transmission-, and modulation-parameters.

There has been an extensive research in finding the optimal FEC scheme for WSNs, though none is standardized. To find an optimal scheme, both BER performance and energy consumption have to be considered. Basically, there are two types of error control codes, block codes and Convolutional codes. The block codes have been observed to be energy efficient compared to Convolutional codes. In [4], the authors have observed that to achieve the same CG, Convolutional code needs higher redundancy and complexity than Reed-Solomon (RS) code. The authors of [6] show that, even the best Convolutional codes are not energy efficient compared to BCH codes. In [7], it has been shown that the Convolutional coded channel with Viterbi decoder consumes more energy than uncoded channel and hence not suitable for WSN. The authors have also compared Hamming code, Golay code, Convolutional code, and RS codes and concluded that Hamming code is the simplest code, but has the lowest performance. Various Hamming, Convolutional, and RS codes with QPSK modulation are compared in [8] with all the energy components of a node and found an optimal code for WSNs. LDPC and turbo codes were claimed to perform well by the authors in [9]. However, these codes were incompetent in satisfying memory and timing requirement pertaining to industrial WSNs as cited in [9]. In furtherance, these codes exhibit an intense computational burden when implemented for WSNs.

Further, numerous joint source channel coding (JSCC) schemes were proposed in the literature for conventional systems. Nevertheless, these techniques are not specific for WSNs and are generally energy inefficient in WSN scenario. The existing JSCC techniques specific to WSNs, exploit the redundancy in

the measured data due to data correlation from nearby nodes for error correction [10]. This leaves scope for further research on the design of energy efficient coding technique which relaxes the strict requirement of data correlation in JSCC based methodologies.

In view of the works cited in literature, it is clear that stronger codes give better protection, but consume more computational energy, while simpler codes consume less energy. The only issue that limits the usage of existing simple codes, for example, Hamming and Repetition codes, is their poor BER performance. Therefore, the main objective of our work lies in the design of an energy efficient coding scheme for WSNs, yielding an appreciable CG.

In this paper, we propose a novel scheme for error correction as well as compression. Relative to the reported works on JSCC techniques in literature, the proposed coding scheme is prolific in the sense that it is computationally simple and neither requires source characteristics nor any data correlation information. Moreover, the methodology presented yields a coding scheme which achieves an enhanced CG exhibiting lesser computational complexity vis-à-vis existing FEC techniques. The CG and the compression ratio can be varied by varying the code parameters used.

The paper is organized as follows. In Section II, the methodology of proposed scheme is discussed. The BER performance is given in Section III. The simulation parameters and results are presented and illustrated in Sections IV and V, respectively. Finally, conclusions are drawn in Section VI.

II. Methodology

We propose a novel error control technique which gives better CG as compared to stronger error control codes. It also comes with an added advantage of compression, i.e., our method gives protection without added redundancy, or even with saving in number of bits transmitted. The basic idea is to divide the input data into some groups such that in each group the data is separated from each other by a minimum Hamming distance d_{min}. Then, the data from the same group is concatenated together, in addition to a label to identify their group, to form a codeword. For this method to apply, we need a group of data which is typical in WSN applications, e.g., temperature-, pressure-monitoring, etc.

The proposed methodology has been explained in a stepwise manner below:

Step 0: *Defining groups*

- Consider the input message of k_m bits. We split this message into k_1 and k_2 bits, where $k_m = k_1 + k_2$.
- We keep aside k_1 most significant bits from the input message.
- The remaining k_2 bits are named the SYMBOL.
- To achieve a minimum Hamming distance d_{min}, $k_2 \geq d_{min}$. In this paper, we have considered $d_{min} = 3$ for 1-bit error correction capability.
- There are 2^{k_2} possible SYMBOLs. These are divided into groups of 2^{k_1} members with $d_{min} = 3$. So we get $2^{k_2-k_1}$ such groups.
- We label these groups in order to distinguish among them. We need at least $\log_2(2^{k_2-k_1})$ bits for this Group label.

Step 1: *Coding the input data*

- For each input message, last k_2 bits belong to one of the groups defined in Step 0 and named SYMBOL, as shown in the upper branch of Fig. 1.
- The first k_1 bits of the input message, and the Group label of the SYMBOL together named as LABEL as shown in the lower branch of Fig. 1. Each LABEL has $k_L = (k_1 + log_2(2^{k_2-k_1}))$ number of bits.
- There are $L = 2^{(k_1+log_2(2^{k_2-k_1}))}$ number of LABELs in total.
- Thus each k_m bit input message is represented now as [LABEL : SYMBOL]. This consists of $\log_2(2^{k_2-k_1}) + k$ number of bits.

Step 2: *Concatenation of data*

- Since more than one SYMBOL can have the same LABEL, we can append all such SYMBOLs together, with LABEL appearing only once. This saves the number of bits transmitted. The concatenation is shown in Fig. 2.

Step 3: *Protection of LABEL*

- Each SYMBOL belongs to a group with $d_{min} = 3$. So, once the LABEL is identified correctly, each SYMBOL with the LABEL is robust to one-bit error.
- To achieve this, LABEL has to be identified correctly. Hence, the LABEL part is protected with a simple linear block code. Depending on the required error correction capability, a suitable code can be selected.
- The concatenated SYMBOLs with their corresponding protected LABEL forms a codeword.

Beyond a certain number of SYMBOLs appended with a protected LABEL, the codeword length is lesser than the total information bits. This minimum number of SYMBOLs in a codeword for achieving compression is not very large. For example, if there are minimum 6 SYMBOLs in a codeword for the case, $k_m = 7$ and $k_1 = 2$, we can achieve compression. As we append more SYMBOLs in a codeword, the compression is increased.

The definition of groups, encoding of data as SYMBOL and LABEL, and protection of LABEL by linear block code can be executed a prior and list the possible input messages and corresponding protected LABEL plus SYMBOL representation in a table. On receiving data, only comparison and concatenation need to be done. Hence, our scheme is much simpler and energy efficient compared to other schemes.

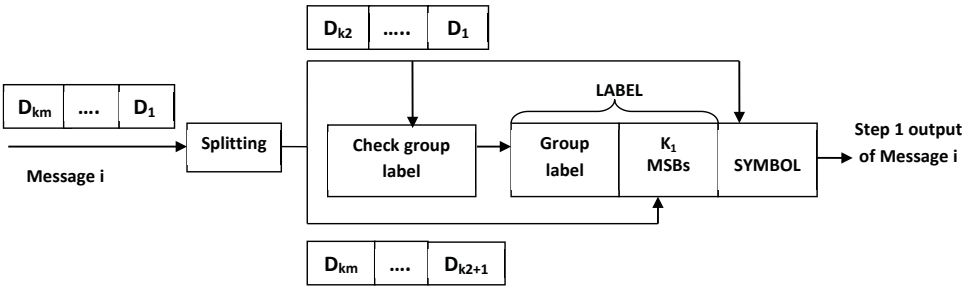

Fig. 1. Encoding of the input data as SYMBOL and LABEL (Step 1).

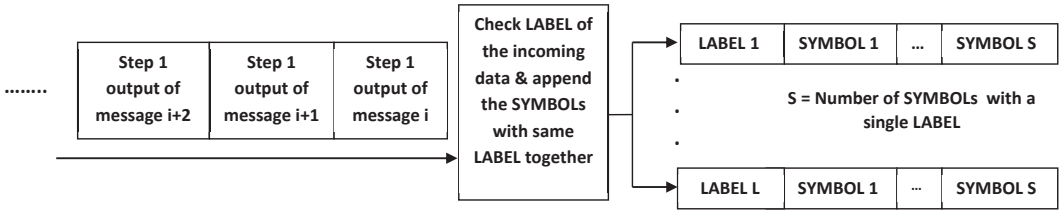

Fig. 2. Concatenation of SYMBOLs with LABEL (Step 2).

III. Bit Error Rate Performance

In this section, we present the BER performance of the proposed scheme as well as the lower and upper bounds of the BER. Probability of m errors in a block of n bits for a binary symmetric channel is upper bounded by [11]

$$P_M \leq \sum_{m=t+1}^{n} \binom{n}{m} p^m (1-p)^{n-m} \tag{1}$$

where t is the error correction capability and p is the channel transition probability given by

$$p = \frac{1}{2}\text{erfc}\left(\sqrt{R\frac{E_b}{N_0}}\right) \tag{2}$$

for binary phase shift keying (BPSK) modulation in additive white Gaussian noise (AWGN) channel, R is the rate of the code and E_b/N_0 is the signal to noise ratio per bit.

Using (1) and (2) and assigning $n = n_1$ and $t = t_1$, we can calculate the block error probability of the LABEL (P_{LABEL}), where n_1 is the length of protected LABEL and t_1 is the error correction capability of the linear block code used to protect LABEL.

When the LABEL is decoded correctly, each of the SYMBOLs have t_2 bit error correction capability. The block error probability of a SYMBOL (P_{SYMBOL}) can be calculated using (1) and (2), assigning $n = k_2$ and $t = t_2$. If the LABEL is decoded incorrectly, then entire codeword is decoded incorrectly. Hence, the error probability of the entire codeword can be calculated using,

$$P_e = (1 - P_{LABEL})P_{SYMBOL}^S + P_{LABEL} \tag{3}$$

where S is the number of symbols in a codeword. Bit error probability of a SYMBOL is calculated using the following equation from [12] as,

$$P_{bit} = \frac{1}{n}\sum_{m=t+1}^{n} (m+t)\binom{n}{m} p^m (1-p)^{n-m}. \tag{4}$$

Bit error probability of the codeword is upper bounded by the block error probability and lower bounded by block error probability divided by the number of information bits contained in the codeword [13]

$$P_{bit-upperbound} = P_e, \tag{5}$$

$$P_{bit-lowerbound} = \frac{P_e}{k_1 + Sk_2}. \tag{6}$$

IV. Simulation Parameters

For simulation, we consider an AWGN channel and BPSK modulation scheme. BPSK modulation is chosen here, because it is one of the modulation schemes defined in the standard used for specifications of WSN, IEEE 802.15.4 and the simplest. At this point, a notation for our proposed coding scheme is introduced as follows. The code is characterized mathematically by $\{S,\ k_m,\ k_1,\ k_2\}$, where, S denotes the number of SYMBOLs in a codeword, k_m defines the length of each message block, k_2 gives the number of bits in a SYMBOL and $k_1 = k_m - k_2$. Simulations have been performed using the presented coding methodology for different characterizations given by $\{S,\ k_m,\ k_1,\ k_2\}$. For instance, simulation results have been demonstrated for $\{5,\ 7,\ 2,\ 5\}$, $\{10,\ 7,\ 2,\ 5\}$, and $\{50,\ 7,\ 2,\ 5\}$, respectively. These results will help us in learning the effect of changing values of S on CG and compression. To give 1-bit error protection to LABEL (5 bits), we select the nearest possible simple linear block code, that is, rectangular (11, 6) code [14]. Since our LABEL length is 5, we add one 0-bit to the LABEL and perform rectangular (11, 6) encoding,

wherein the notation $(n,\ k)$ denotes the code length by n and the block length by k, respectively. But, while transmitting, the first bit is removed since it is known at the receiver. Finally the rectangular (11, 6) code ends up in a (10, 5) code. At the receiver the 0-bit is appended again and decoding is performed. The resulting LABEL will be one bit error corrected. Hence, the group is identified from the group label part of the LABEL. Once the group is known, each of the SYMBOLs can be corrected against 1-bit error, as there is a minimum distance restriction of 3 within the group.

The code is further simulated under various conditions with constant $S = 10$, as characterized by the following sets as given below,

$$\mathscr{R}_{k_2} := [\{10,6,1,5\},\ \{10,7,2,5\},\{10,8,3,5\}]$$
$$\mathscr{R}_{k_m} := [\{10,8,1,7\},\ \{10,8,2,6\},\{10,8,3,5\}]$$
$$\mathscr{R}_{k_1} := [\{10,6,1,5\},\ \{10,7,1,6\},\{10,8,1,7\}]$$

where, $\mathscr{R}_{k_2}$, $\mathscr{R}_{k_m}$ and $\mathscr{R}_{k_1}$ denote the cases considered for simulation purposes with k_2, k_m and k_1 held constant, respectively. Further, theoretical and simulation results are presented for $\{10,\ 7,\ 2,\ 5\}$ alongwith the upper and lower bounds on the BER.

V. Results and Discussions

In this section, the results obtained by simulating our scheme with various values of S, k_m, k_1, and k_2 are presented.

Fig. 3 plots the performance of our scheme for $\{5,\ 7,\ 2,\ 5\}$, $\{10,\ 7,\ 2,\ 5\}$, and $\{50,\ 7,\ 2,\ 5\}$; Hamming (7, 4) code; RS (31, 29) code, and uncoded transmission. We can observe that our proposed coding scheme gives significant improvement in CG compared to the simple Hamming (7, 4) code, and stronger RS (31, 29) code. It can also be observed that as the number of SYMBOLs in a codeword increases, CG also increases. The CG achieved at BER=10^{-5} is 2.833 dB for $S = 5$; 3.46 dB for $S = 10$; and 4.093 dB for $S = 50$.

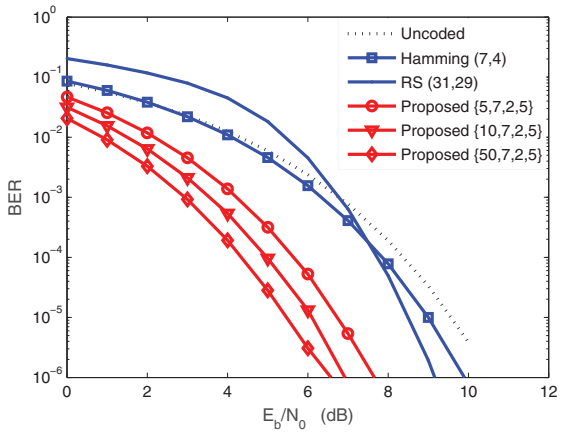

Fig. 3. BER vs. E_b/N_0 performance of the uncoded, Hamming, RS and Proposed code for $\{S,\ 7,\ 2,\ 5\}$ with $S = 5,\ 10$ and 50.

Compression can be calculated by taking the ratio of the difference in the number of input and coded bits to the number of input bits. It is found that, compression increases as S increases. Although the compression achieved for $S = 5$ is zero yet a significant CG is attained. Both CG and compression are achieved simultaneously from $S > 5$. For $S = 10$, compression achieved is 14.2857% and that for $S = 50$, is 25.7143%.

The theoretical and simulation results of the case $S = 10$, along with upper and lower bounds are plotted in Fig. 4. Using (4), BER of a SYMBOL can be calculated. This SYMBOL BER is used in (3) in the place of P_{SYMBOL}, to find the BER of the entire codeword. The upper and lower bounds of BER are calculated using (5) and (6), respectively. Theoretical and simulation BER performance fall well within the upper and lower bound curves.

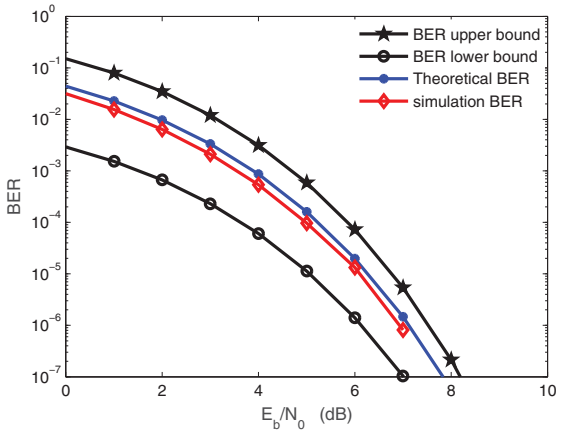

Fig. 4. Theoretical, simulation, upper bound and lower bound BER performance for $\{10,\ 7,\ 2,\ 5\}$.

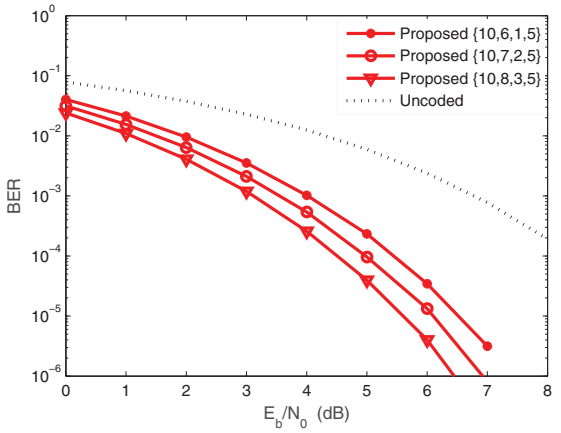

Fig. 5. BER vs. E_b/N_0 performance of the proposed code for cases contained in $\mathscr{R}_{k_2}$.

Fig. 5 shows the comparison of results for the cases contained in $\mathscr{R}_{k_2}$. An increment in the value of k_m and k_1 increases CG and compression. In each of the cases contained in $\mathscr{R}_{k_2}$, the achieved CG and compression are found as (3.045 dB, 3.33%), (3.46 dB,

14.2857%), and (3.962 dB, 23.75%). Further, results are illustrated for the cases in $\mathscr{R}_{k_m}$ in Fig. 6. As the value of k_1 increases, better CG is achieved in addition to compression, as depicted in Fig. 6. This is because as k_1 increases, our grouping improves with more members in a group with minimum distance restriction. Similarly for $\mathscr{R}_{k_m}$, the CG and compression are found as (2.796 dB, 0%), (3.393 dB, 12.5%), and (3.962 dB, 23.75%).

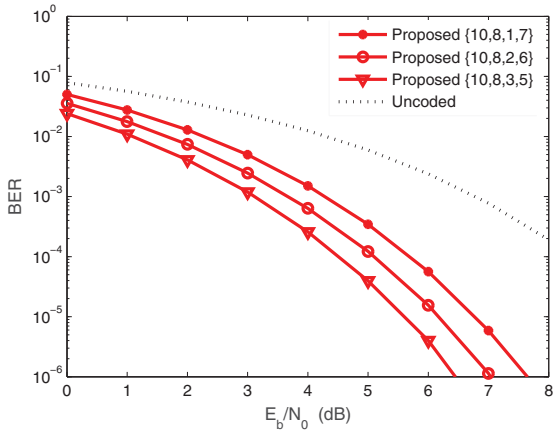

Fig. 6. BER vs. E_b/N_0 performance of the proposed code for cases encompassed in $\mathscr{R}_{k_m}$.

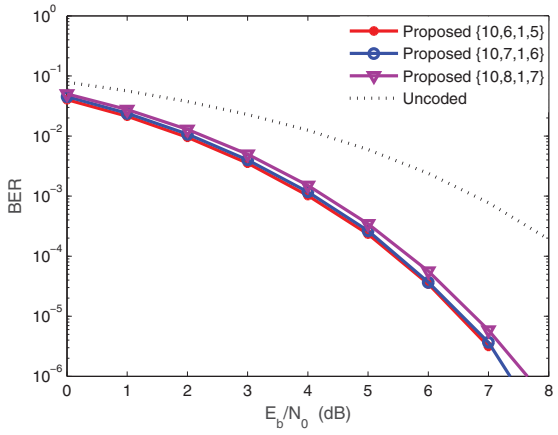

Fig. 7. BER vs. E_b/N_0 performance of the proposed code for cases contained in $\mathscr{R}_{k_1}$.

Withal, results for the cases encompassed in $\mathscr{R}_{k_1}$ are demonstrated in Fig. 7. It can be easily inferred that an increasing value of k_m leads to a marginal decrease in both CG and compression. The performance degradation with increasing message length is due to the reducing effect of grouping. In the limiting case of $k_1 = 0$, there is no grouping at all. Therefore, for $\mathscr{R}_{k_1}$, CG and compression are evaluated as (3.045 dB, 3.33%), (2.996 dB, 2.8571%), and (2.796 dB, 0%).

VI. Conclusions

In this paper, a novel technique for error correction in energy constrained WSNs is presented. The bounds of BER performance have also been derived. As evident from the theoretical and simulation results, the proposed methodology provides considerable amount of compression in addition to good coding gain. Our scheme achieves an enhanced CG with a relative enhancement factor of 3.024 dB for {50, 7, 2, 5} as compared to RS (31, 29). If the application is delay tolerant, more number of SYMBOLs can be attached in a codeword, thereby attaining a better CG and compression. Utilizing stronger codes for LABEL protection can improve the BER performance further. In addition, the proposed technique is computationally less complex relative to the existing near performance codes intuitively. Quantification of the computational complexity for the proposed coding scheme would prove to be a value addition to the presented work which is under development.

***Abstract*— The demand for spectrum resource has been raising significantly all over the world with the development of the wireless communication technologies. However, spectrum resources are increasingly becoming insufficient and it is strongly required to use this limited resources wisely. Among the technologies that allow efficient use of spectrum, TV white spaces (TVWS) has been promoted as a feasible solution to address this demand in many countries. Singapore is one of those countries that have been very active in promoting the TVWS technology. This paper presents Singapore regulations regarding TVWS as well as results of the first IEEE 802.11af indoor experiment in Singapore. The prototyped IEEE 802.11af-based system and its experiment results demonstrate the promising capability and practicality of the TVWS communication system.**

Keywords— TV white-spaces (TVWS); IEEE 802.11af; field experiment; Dynamic Spectrum Access

I. INTRODUCTION

The demand for spectrum resource has been raising significantly all over the world with the development of the wireless communication technologies. The spectrum resources are limited and becoming increasingly insufficient. However, many frequencies are not fully utilized and it is strongly required to use this limited resources wisely.

White spaces (WS) refer to parts of the spectrum not used by primary users spatially or temporarily, and can be accessed by secondary users with measures in place to protect the primary users. TVWS refers to the WS in the TV bands such as the VHF and UHF bands that are unused from time to time by broadcasters or other licensees. As many countries have shifted their TV broadcasting systems from analogue TV to digital TV, frequencies in the UHF and VHF bands will be freed up. This presents huge chunk of frequencies that could be used for different scenarios and applications. Regulators will have an opportunity to examine these spectrums for full utilization.

For these reasons, regulators are carefully and actively opening TVWS for secondary usage on unlicensed basis. The FCC (Federal Communications Commission) in the U.S.A. established rules and approved the use of White Space Devices (WSD) in Nov. 2008 [8], Sep. 2010 [9] and Apr. 2012[1]. In June 2009 and Nov. 2010, the Ofcom in the U.K. (Office of Communications) permitted the use of TVWS as license-exempt access for WSDs [2]. In Japan 2013, discussions for the transmission in TVWS were finished and the standard documentation was completed by the ARIB (Association of Radio Industries and Businesses) [3]. In June 2014, IDA (Infocomm Development Authority of Singapore) in Singapore finalized the regulatory framework for WSD's accesses of TVWS [4].

Among these pioneering countries, Singapore has been very active in promoting the TVWS technology. The history of TVWS in Singapore started from 2009, when the IDA released a roadmap for innovation and adoption of TVWS and established a supporting regulatory framework. The IDA facilitated a key step by conducting proof of concept trial in the CRAVE (Cognitive RAdio VEnue) zones in 2010 with participation of five organisations. The trial showed that WSDs and traditional broadcasters could share the same spectrum band. In 2013, IDA had sent the TVWS public consultation paper to all stake holders in Singapore to get feedbacks and suggestions regarding regulation of TVWS in Singapore, then IDA finalized the TVWS regulation in 2014 [4].

This paper presents Singapore TVWS regulations in details as well as results of the first IEEE 802.11af [5] experiment in Singapore. The trial indoor experiment was successfully carried out in TeleTech Park Building located in Singapore Science Park II, in May 2015. The prototyped IEEE 802.11af-based system and its experimental results demonstrate the capability and practicality of the TVWS communication system.

This paper is organized as follows. TVWS Regulations in Singapore are presented in Section II. Section III presents the IEEE 802.11af experiment setup. Indoor experiment results are presented in Section IV. Finally, Section V concludes the paper.

II. SINGAPORE REGULATION REGARDING TVWS

With a careful but open approach, the IDA issued a consultation paper to seek comments and feedback from the industry in June, 2013 [7]. One year later on June 16, 2014, the IDA published its response to the submissions made during the consultation period on how to regulate TVWS in Singapore. These regulations [4], which came into effect on November 1, 2014, set Singapore alongside the US and the

UK as global leaders in the development and usage of TVWS on a licence-exempt basis.

These regulations allow the secondary usage of the TVWS services in the future with certainty, especially in the amount of spectrum set aside for WSDs. The regulations also specify the licensing and regulatory requirement, as well as the operating parameters of WSDs, Geo-location database, etc.

IDA's regulations specify measures to protect TV broadcasters by limiting the use of adjacent channels and placing limits on the WSD's power emissions. Existing users of wireless microphones and public mobile services are also protected through a dedicated channel and a registration process for special events.

Following is a brief overview of the regulatory framework.

A. General Regulations

- Usage of TVWS channels will be licence-exempt and not subject to spectrum usage fees, but this does not apply if public telecommunications services are offered. The use of spectrum will be on a non-exclusive and unprotected basis, and subjected to technical parameter requirements set by the IDA, such as transmission power levels, OOB (Out of Band) emission limits.
- From now until 2020, WSDs can use up to 189 MHz of spectrum when digital TV broadcasting is steadily replaced analogue TV broadcasting. This spectrum consists of 3 VHF channels and 21 UHF channels. After 2020, WSDs can use 183 MHz when some of the frequencies will be used for other services.
- Geo-location database service providers will be in charge of spectrum sensing. WSDs may also use their own spectrum sensing technologies where they do not cause interference but WSDs still need to send query to the geo-location database for available TVWS channels every 6 hours.

B. Device Regulations:

- All TVWS equipment need to comply with the general equipment registration (GER) requirements to avoid potential interference. There are 3 modes of WSD devices: *Fixed* WSDs with 4W EIRP maximum transmission power; *Mode 1* and *Mode 2* WSDs with 100mW EIRP maximum transmission power. Mode 1 devices can only operate in conjunction with Fixed or Mode 2 devices. Only Fixed and Mode 2 WSDs are required to query geo-location databases for available TVWS channels and maximum power level before operation.
- Required mobile WSDs need to query geo-location database every time before starting the TVWS communication, or when they move more than 100 metres away from their original location during the communication.
- To further protect the TV analogue broadcasting, IDA only allows low-power WSDs (Mode 1 and 2) to use adjacent channels of analogue broadcasting transmissions. In addition, WSDs are not allowed to operate on two adjacent channels of digital broadcast services. Therefore, Channels 25 and 26 will not be permitted for secondary usage by WSDs.
- Each WSD will have a unique device identifier (UDI), either ETSI/FCC authorised or regulator defined format. Geo-location database providers have to accept different UDI formats. Every WSD (portable/personal) must have antenna permanently attached. Antenna height of WSDs will be used by the geo-location database in calculation of available TVWS channels.
- Co-existence of WSDs will be left for the industry to decide. However WSD operators are expected to implement collision avoidance protocols to minimize the chances of interference arising when WSDs are in close proximity of each other.
- To protect the licence-exempt wireless microphones and not to cause excessive reduction in the number of channels available for WSDs, the two designated safe Channel 25 (502 – 510 MHz) and Channel 47 (678 – 686 MHz) will be set aside for licence-exempt wireless microphones.

C. TVWS DB - WSDB Regulations

- Geo-location database provider should use the Hata-Urban propagation model for interference computations.
- Geo-location databases can offer more services such as advance queries at multiple locations as an competitive advantage that could benefit WSD's users. These advanced services, however, are allowed for mode 2 WSDs only.
- Fixed and Mode 2 WSDs are required to obtain the position with the accuracy of at least ±50 m. They can use different kind of location technologies (GPS, etc).

D. High Priority Channels regulation

- Singapore is the first and only country until now which has the regulation for the high priority channels (HPCs). The IDA will set aside two HPCs which can be offered as a premium service by geo-location database providers to WSD users who require a higher-level of reliability and real-time transmission basis. The number of HPCs may be increased or decreased by the IDA according to the market demand.

IDA's regulations open the path to not only the commercialization of TVWS services in Singapore but also the new services in overseas markets. With this open, proactive but careful approach in TVWS regulation, Singapore has managed to groom its local TVWS market and attracted international attentions.

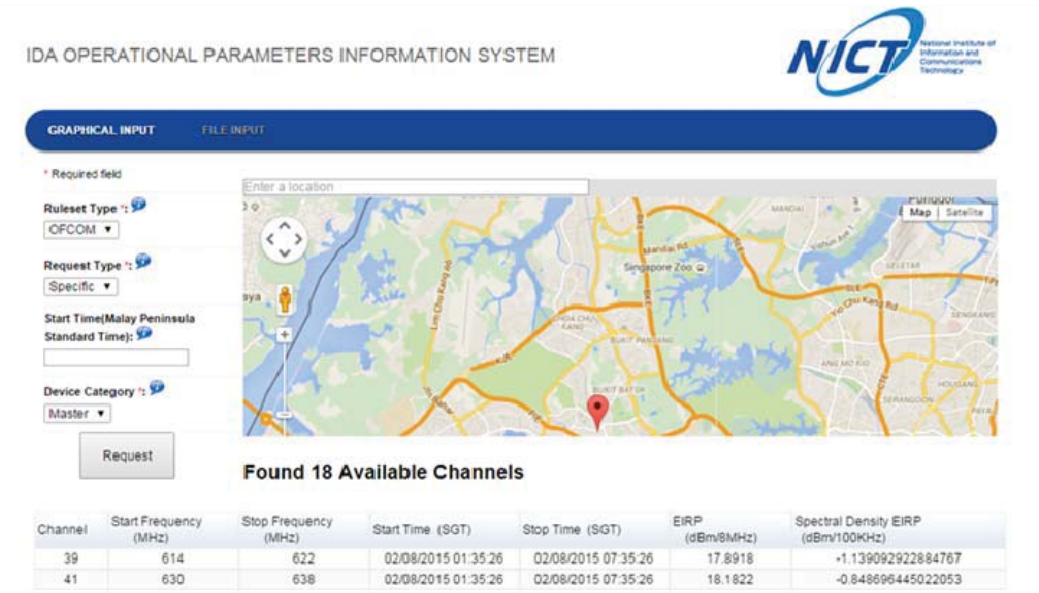

Fig. 1: The trial WSDB web page interface

III. IEEE 802.11af EXPERIMENT SETUP

IEEE 802.11af extends the IEEE 802.11 standard to allow IEEE 802.11af-based devices to operate in TVWS spectrum. It provides a framework that allows IEEE 802.11af-based WSDs to operate around the world without causing interference to primary users by using the geo-location-based white-space database (WSDB) and registered location secure server (RLSS). The WSDB will allow an IEEE 802.11af WSD to operate according to regulation requirement at its current location. The RLSS acts as a local database to distribute operation parameters to Access Points (APs) and Stations (STAs) under its control.

The IEEE 802.11af prototyped hardware used in Singapore experiment supports a high transmission power of up to +30 dBm in conformance with IDA regulations [6]. This IEEE 802.11af-based system consists of a WSD station (STA), an access point (AP), a TVWS database (WSDB) and a registered location secure server (RLSS), as shown in Fig. 2. The WSDB used in the experiment is developed by NICT and granted trial license by the IDA in Jan, 2015.

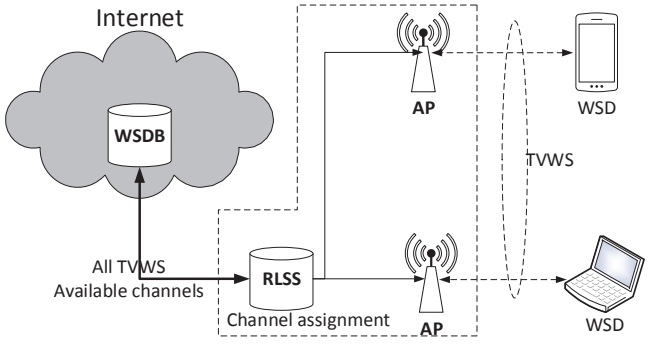

Fig. 2: IEEE 802.11af system architecture overview

A. TVWS Database WSDB

To protect the primary users, Singapore regulation requires that all WSDs need to query the WSDB for available channels and permitted transmission powers before operation. A WSDB for Singapore has been designed and developed based on the IDA regulation described in Section II. This WSDB has been granted with a trial license by the IDA in Jan, 2015. The graphical interface of the WSDB is shown in Fig. 1 On the left-hand side, users can choose different WSD types (OFCOM/FCC - fixed or mobile), and set the parameters such as antenna height. On the right-hand side is the Google map of Singapore where users can select location of the WSD and submit query to the WSDB. All the available channels in the selected location with permitted EIRP power level will be returned by the WSDB.

In addition, the RLSS is also used to avoid inter-system interference in the TVWS operating channels in the case that multiple IEEE 802.11af APs are operated in the same area. The RLSS will assign different channel to each AP from all the available channels provided by the WSDB.

B. STA and AP IEEE 802.11af system used in Singapore

The IEEE 802.11af prototyped hardware used in Singapore experiment supports a high transmission power of up to +30 dBm in conformance with IDA regulations [6]. Parameters of the prototyped devices used in Singapore experiment are shown in Table 1.

TABLE I. PHY PARAMETER

Air interface	OFDM
Operating frequency	Channel 46 (674MHz)
Operating channel bandwidth	8MHz
Modulation	MCS0 (BPSK)
Channel coding	Block convolution coding

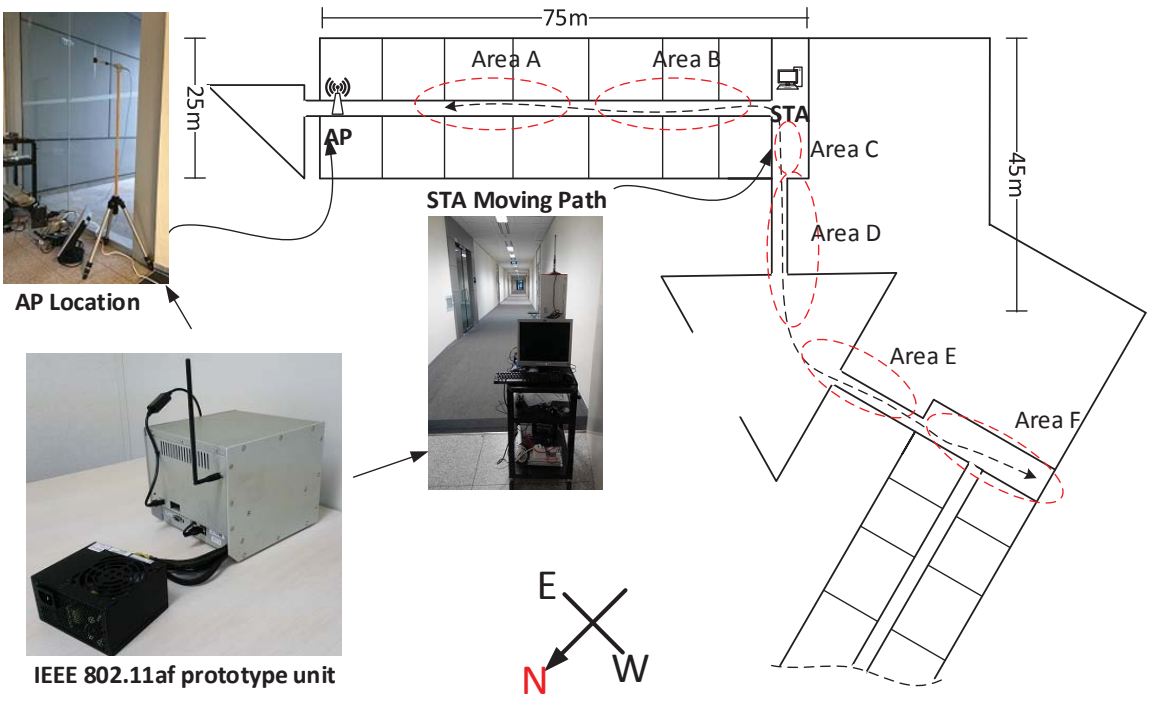

Fig.3: The indoor trial setup

The AP that was connected to the Internet was set up and fixed at the end of east wing corridor of TeleTech Park building as shown in Fig. 3.

The STA was put on the trolley with a power source that consists of a DC 12 V battery, a DC/AC inverter, and moving from Area A to Area F with a 150m distance to measure the received signal strength indicator (RSSI) and throughput around the experiment environment. The whip antenna with height of 1.5 m was connected to the STA using co-axial cable and a 10dB attenuator. The AP used dipole antenna with a 2.2 dBi antenna gain at a height of 1.7 m. TVWS channel 46 (670 −678MHz) was used for the experiment.

IEEE 802.11af TVWS_MODE_0 with MCS 0 (Max throughput of about 1.45 Mbit/s) was applied as the communication mode. Average output power was set to 20 dBm for both STA and AP.

C. *Experiment setup*

The experiment was done in the first floor of TeleTech Park Building in Singapore Science Park II. TeleTech Park Building is in the V shape with west and east wing as shown in Fig. 3. The main dimensions are summarized in Table 2. The AP was fixed at the end of east wing corridor.

TABLE II. EXPERIMENT ENVIRONMENT

West/East wing's corridor	Length: 75m, width: 2.1m
Ceiling height	2.7m
STA Moving Path	150m
AP Antenna height	1.7m
STA Antenna height	1.5m

The STA was moving around along to the 150 m moving path from east wing to west wing as shown in Fig. 3. AP was connected to the Internet for WSDB enquiry.

When the STA and AP are turned on, the RF hardware parts will do the calibration to clear the interference. Three mode of calibration was used and the throughput measurement was taken along the moving path:

- **With 50 ohm mode**: STA and AP use 50 ohm during calibration at start-up to clear the interference.
- **With Band Pass Filter (BPF) mode**: STA and AP use the BPF during calibration at start-up to suppress the interference outside the using channel.
- **Normal mode**: STA and AP use neither 50 ohm nor BPF during calibration at start-up.

IV. INDOOR EXPERIMENT RESULTS

The UDP throughput is measured by the popular iperf tool. The RSSI was measured and stored in a log file with timestamp. Throughput and RSSI were then extracted and matched together based on the timestamp. The measurement result is shown in Fig. 4.

1) RSSI: Received signal power of the STA was measured as RSSI, and is generally proportional to the distance between the AP and the STA in both cases of Line-of-Sight (LoS) and Non-Line-of-Sight (NLoS) situation along the STA 150 m moving path.

When STA moved from Area A to Area F, the RSSI level reduced from −30 dBm (Area A) to −50 dBm (Area B), −60 dBm (Area C), −65 dBm (Area D), −75 dBm (Area E) and −85 dBm (Area F). The connection was lost when STA moved

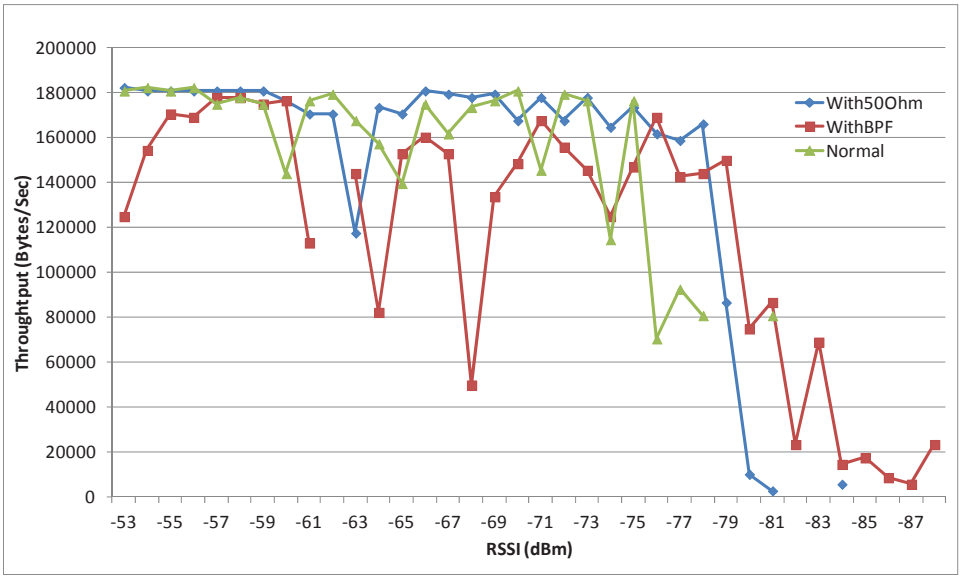

Fig. 4: Throughput vs RSSI

from LoS (Area A, B) to NLoS at the beginning of Area C. However, because the shadowing effect in the corridor, the connection was re-established at the Area D. Deflection effect was the main factor for this. In this area, the throughput was still quite high.

When STA moved to area E, the connection was lost again, because the penetration loss was higher in this area. The connection was re-established at Area F, even though the received signal power was lower than −80 dBm due to the shadowing effect. However, the throughput was severely low in this location.

2) Throughput: The measured throughput basically depends on the RSSI level. However the throughput deteriorated at Area C, Area E. The throughput was improved slightly, when 50 ohm was used during the calibration at startup as shown in Fig. 4. In addition, using BPF did not improve any throughput at all. These results indicates that the deterioration of the throughput is not mainly caused by the interference but the multi-path fading.

Based on the throughput measurement both in LoS Area A, B and NLoS Area D, F, it can be observed that in typical indoor environment, an IEEE 802.11 af AP with an output power of +20 dBm can cover a sufficiently large area (in this case 150 m) compared with normal 802.11 [10], however the prototyped WSDs need some more improvements in NLoS areas for full commercial deployment.

V. Conclusion

TVWS has been promoted as an efficient way to address the demand for spectrum resource shortage all over the world and regulators are proactively rolling out regulation for operations in TVWS spectrum. Singapore TVWS regulations has been carefully rolled out with small market share of Singapore in mind as well as the specific feature only Singapore has such as HPC channels.

Under Singapore regulation, the first IEEE 802.11af experiment had been successfully carried out in Singapore Science Park II. The IEEE 802.11af prototype system experiment results demonstrate the promising future TVWS could achieve for various practical applications.

***Abstract*—Orthogonal frequency division multiplexing (OFDM) systems are now a part of all major wireless standards, because of its potential to offer high data rate. Cyclic prefix (CP) in OFDM system converts a multipath channel to a flat fading channel, thus simplifies the design of equalizer. However, there is a lot of ambiguity in choosing the length of CP. In this paper, we propose a new method for calculation of length of CP using cumulant features. The merits of proposed method are verified by computer simulation.**

***Keywords*—Orthogonal frequency division multiplexing (OFDM), Cyclic prefix (CP), Blind channel length estimation.**

I. Introduction

Increasing in the number of wireless applications and users demands for reliable, high data rate communication. High data rate can be achieved by effective utilization of the spectrum. Over the past decade, dynamic spectrum access (DSA) has been seen as a potential solution for utilizing the spectrum effectively. The research efforts in DSA are further fueled by the advent of cognitive radio (CR) [1], due to its potential platform for implementing DSA. High data rates can also be achieved by employing multiple input multiple output (MIMO) and orthogonal frequency division multiplexing (OFDM) based systems. CR combined with MIMO and OFDM has the potential to achieve reliability and high data rate. In fact, utilization of CR along with MIMO and OFDM is included in the 4G standards.

OFDM provides high data rate by exploiting the orthogonality in the frequency domain. One of the key issue in OFDM is to choose the length of cyclic prefix (CP). CP enables OFDM to convert multipath channel to flat fading channel and hence simplifies the design of equalizer. In general, the length of CP is decided greater than delay spread of the channel. For practical implementation, generally we consider CP length as one fourth of the OFDM symbol [2]. The way of choosing the fixed CP length by this traditional method leads to the wastage of transmission bandwidth. As CP does not carry any extra information, it is required to optimize the length of CP without disturbing the original data. The length of CP should be longer than the length of the channel impulse response (CIR). However, the length of the CIR is not known at the transmitter. Hence, it has to be estimated at the receiver end and then conveyed to the transmitter through some control channel (Refer Fig. 1).

Some of the existed work on calculation of channel length and CP length for OFDM system is summarized as follows: In [3], Jong Bu Lim *et al.* proposed iterative CP reconstruction procedure based on residual inter symbol interference cancellation (RISIC). In [4], D. Salvatore *et al.* introduced bit loading algorithms for an adaptive CP length to enhance the performance of system. In [5], Bin Sheng *et al.* presented blind algorithm to estimate the channel length based on minimum description length (MDL) for OFDM system.

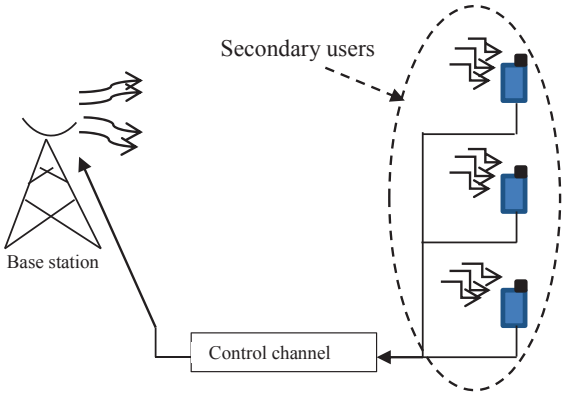

Fig. 1: Proposed system representation for OFDM transmission

In this paper, we propose a novel method to choose the CP length. The proposed approach is blind, that is no pilot or training sequence is required and hence further saves bandwidth. The proposed method is well suited for a DSA setup as illustrated in Fig. 1. In Fig. 1, the secondary users estimate the ideal CP length, and communicate it to the base station via control channel. The base station then adjusts the CP length for the future transmission. Therefore, by estimating the channel length, CP length can be adjusted. Moreover, the bandwidth can be utilized effectively by avoiding the pilot sequence transmission. In the proposed method, we first estimate the channel length and then use this information to choose the CP length. For estimating the channel length, we used the algorithm presented in our previous published work [6]. The method is based on cumulant features. Cumulant features have been widely used in the field of blind signal processing [7]–[11]. In this paper, we exploit some unique properties of cumulant features that make it suitable for channel length estimation.

The rest of this paper is structured as follows: Section II presents the problem statement. Section III introduces mathematical background on cumulant features whereas Section

IV describes the proposed method. Section V presents the simulation results followed by conclusion in Section VI.

II. Problem statement

In this paper, we consider an OFDM system with N subcarriers. The m^{th} OFDM block or symbol is denoted as $\bar{X}_m = \{X_m(0), X_m(1), X_m(2), \ldots X_m(N-1)\}$, where $X_m(k)$ is a complex valued alphabet drawn from a QAM constellation. The inverse discrete Fourier transform (IDFT) $\mathscr{F}^{-1}$ of the m^{th} block is denoted as $\bar{x}_m = \{x_m(0), x_m(1), x_m(2), \ldots x_m(N-1)\}$, i.e.,

$$\bar{x}_m = \mathscr{F}^{-1}\left\{\bar{X}_m\right\} \tag{1}$$

The transmitted symbol is subjected to multi-path fading. The multi-path channel can be modeled as a finite impulse response (FIR) filter

$$h(z^{-1}) = h(0) + h(1)z^{-1} + \ldots + h(M)z^{-M} \tag{2}$$

where M is the length of the multipath channel and $h(i)($ for $i = 0, 1 \ldots M)$ is the multi-path gains vector. CP is added before transmitting the time domain block $\bar{x}_m$. As mentioned earlier, CP is added to avoid intersymbol interference (ISI). Let, the length of CP is denoted as P, and hence the total length of the m^{th} block is $(N+P)$. The m^{th} received OFDM block after removing CP is denoted as $\bar{y}_m = \{y_m(0), y_m(1), y_m(2), \ldots, y_m(N-1)\}$. The corresponding frequency domain block is given by $\bar{Y}_m = \{Y_m(0), Y_m(1), Y_m(2), \ldots Y_m(N-1)\}$ where

$$\bar{Y}_m = \mathscr{F}\left\{\bar{y}_m\right\}, \tag{3}$$

where $\mathscr{F}$ denotes the DFT.

The relationship between the transmitted and received symbols of m^{th} block is given by

$$Y_m(K) = H(K)X_m(K), \quad K = 0, 1, \ldots N-1 \tag{4}$$

where $H(K) = H(0), H(1), \ldots, H(N-1)$ is the N point DFT of the channel impulse response in (3).

Selection of the length of CP is a challenging problem. The CP length must be greater than the length of the channel impulse response (let M) in order to avoid ISI. However, length of the channel impulse response is not known. In this paper, we propose a novel blind algorithm to estimate the CP length P at the receiver. The block diagram of the proposed method is shown in Fig. 2. In the proposed algorithm, we first estimate the channel length and then use this information to choose the CP length. The algorithm for estimating the channel length is based on exploiting the properties of n^{th} order cumulant features.

III. Background Theory on Cumulant Features

In this paper, n^{th} order cumulants features are used. For a complex random process $v(n)$, the n^{th} order moment is defined as [7], [8], [11], [12]

$$R_{v(n,m)}(\tau) = E[\prod_{j=1}^{n} v^{*_j}(\tau_j)] \tag{5}$$

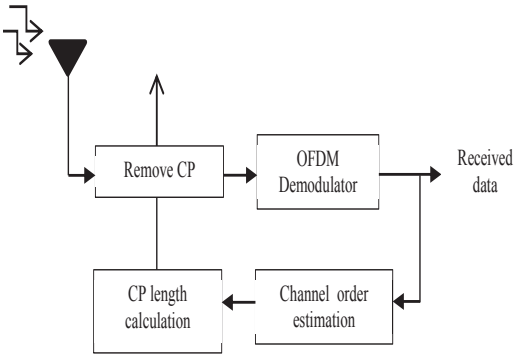

Fig. 2: Block diagram of proposed system at the receiver

where n is the order, m is the number of conjugate factors and $\tau = [\tau_1, \tau_2, \ldots, \tau_n]$ is the delay vector. The n^{th} order cumulant function is defined as [7], [8], [11], [12].

$$C_{v(n,m)}(\tau) = \sum_{pn} F(p) \prod_{j=1}^{p} R_{v(n_j,m_j)}(\tau) \tag{6}$$

where the sum is over distinct partition of indexed set $1, 2, \ldots, n$ and $F(p) = (-1)^{p-1}(p-1)!$. The normalized n^{th} order cumulant values are defined as

$$\tilde{C}_{v(n,m)}(\tau) = \frac{|C_{v(n,m)}(\tau)|}{[C^2_{v(2,1)}(0)]} \quad \text{for} \quad n = 4, 6 \tag{7}$$

The rationale behind choosing cumulant features, is the following two properties of cumulants:
Additive property: Let $x(k)$ and $y(k)$ be two independent random processes. If $z(k) = x(k) + y(k)$ then the n^{th} order cumulant value of $z(k)$ is the sum of those of $x(k)$ and $y(k)$. That is,

$$C_{z(n,m)}(\tau) = C_{x(n,m)}(\tau) + C_{y(n,m)}(\tau) \tag{8}$$

Scaling property: Let $x = ay$. Then the n^{th} order cumulant value of $x(k)$ is $|a|^n$ times the cumulant value of y(k).

IV. Proposed Method

Before illustrating the proposed approach, we first study the effect of multipath channel over n^{th} order cumulant values of the received OFDM symbols. The relationship between the transmitted and received symbols of the m^{th} block is given by $Y_m(K) = H(K)X_m(K) \quad \text{for} \quad k = 0, 1, \ldots, N-1$ where

$$H(K) = \sum_{i=0}^{M-1} h(i)e^{-}\frac{(i2\Pi k)}{N} \tag{9}$$

Using the scaling property of the cumulant features, it can be easily shown that

$$\tilde{C}_{Y_m(K)(n,m)}(\tau, M) = \beta(M)\tilde{C}_{X_m(K)(n,m)} \tag{10}$$

where $\tilde{C}_{Y_m(K)(n,m)}$ is the normalized cumulant value of k^{th} OFDM symbol in m^{th} block and

$$\beta(M) = \frac{\sum_{K=0}^{M-1} |H(K)|^n}{(\sum_{K=0}^{M-1} |H(K)|^2)^{n/2}} \quad (11)$$

where M is the order or length of channel. By observing (9) and (11), and by using the fact that $|e^{-\frac{(i2\Pi k)}{N}}| = 1$, it can be easily shown that $\beta(M) < 1$. Hence, it is clear that the length of channel is inversely proportional to the magnitude of cumulant values of the received OFDM symbols. The magnitude of the cumulant values of the received OFDM symbols shrinks by increasing the length of channel. Also, the magnitude of shrinkage depends on the value of M, i.e.,

$$\beta(M) < \beta(M') \quad \text{for} \quad M > M' \quad (12)$$

and hence

$$\tilde{C}_{Y_m(K)(n,m)}(\tau, M) < \tilde{C}_{Y_m(K)(n,m)}(\tau, M') \quad \text{for} \quad M > M' \quad (13)$$

The pseudocode of the proposed algorithm is shown as below:

Algorithm 1 Pseudocode of the proposed algorithm

Input: Received data $Y_m(K)$ with N subcarriers
Estimate the received cumulant $\tilde{C}_{Y_m(K)}$ values of the received data using the method in [7], [8], [11], [12]
for *i*=1,2, ...*M* **do**
  if $\frac{\tilde{C}_{Y_m(K)}(i+1)+\tilde{C}_{Y_m(K)}(i)}{2} < \tilde{C}_{Y_m(K)} < \frac{\tilde{C}_{Y_m(K)}(i-1)+\tilde{C}_{Y_m(K)}(i)}{2}$ **then**
    if *M*=*M'* **then**
      Terminate loop
    endif
  else
    i=*i*+1;
  endif
endfor
EndProcedure

The estimated channel length M', is used to calculate the ideal CP length. Typically, CP length P is chosen such that $P \geq M$. In this work, we choose CP length P to be

$$P = k \times M' \quad (14)$$

where k is an integer greater than two (here, k is selected as the double that of the estimated channel length). The value of P is chosen in such a way that it is at least double of the estimated channel length.

V. Simulation Results

MATLAB simulations are performed to test the proposed algorithm and the results are summarized. In this case, probability of correctness (P_c) is taken as performance metric and can be defined as P_c= prob(detection says M' is true $\mid$ M is M'). In other words, P_c = $P(M'/M')$ is the probability that the channel length is estimated as M', given the channel length is M'. Cumulant values are calculated at the output of the OFDM demodulator. For the simulations, 4^{th} and 6^{th} order cumulants $|C_{Y_m(4,0)}|$ and $|C_{Y_m(6,0)}|$ features are considered, as they are robust to phase rotation. The following experiments are performed with BPSK constellation.

Experiment-1: In this experiment, we considered fourth order cumulant features. Channel order considered as 1,2. That is the proposed algorithm has to estimate whether the tap of the channel is 1 or 2. Here, we have used $N = 1024$ bits per OFDM symbol to estimate the cumulants. The results are summarized in Fig. 3. In Fig. 3, $M = 1$ denotes the probability of correctly estimating the 1 tap channel and $M = 2$ for 2 tap channel. From Fig. 3, it can be observed that the probability of correctly estimating the channel (P_c) is more than 75% even at negative SNR (in dB scale).

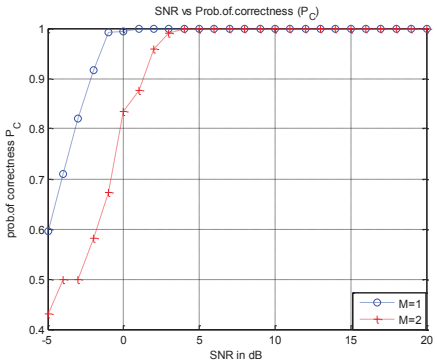

Fig. 3: SNR vs P_c with $N = 1024$

Experiment-2: This experiment is similar to previous one, except that four possible conditions are considered. That is the algorithm need to identify whether the channel is a 1 tap, 2 taps, 3 taps or 4 taps. The results are summarized in Fig. 4. In Fig. 4, $M = i$ (for $i = 1, 2, 3, 4$), has the same meaning as previous experiment. It can be seen that the algorithm performs well in estimating 1, 2 and 3 tap channel. However, in the case of 4 tap channel the performance of the method is poor. This is because, the shrinkage in the cumulant values is high and more number of bits or samples are required to estimate it. We repeat the experiment with more number of samples ($N = 4096$) and the results are summarized in Fig. 5. From the Fig. 5, it can be seen that the performance of estimating 4 tap channel is improved (70% at 0 dB) when N is increased.

Experiment-3: In this experiment, we consider the same case as experiment 1, here we considered sixth order cumulants instead of fourth order and channel length is indicated with L. From Fig. 6, it can be seen that the robustness of correct detection. The reason is sixth order cumulants are more robust than fourth order cumulants.

From the experiments, it can be seen that our proposed algorithm estimates the channel length even at low SNR, compared to MDL method [5], whose performance degrades at low SNR. In the proposed method, once the channel length is estimated the CP length is chosen to be twice the channel length. This results in a significant reduction in bandwidth as illustrated in Table I. Here, we consider $N = 1024$ subcarriers per OFDM symbol. In the traditional method, CP length is

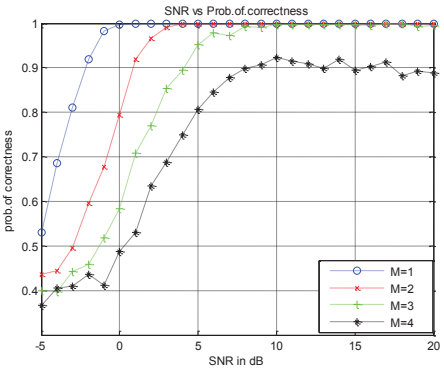

Fig. 4: SNR vs P_c with $N = 1024$

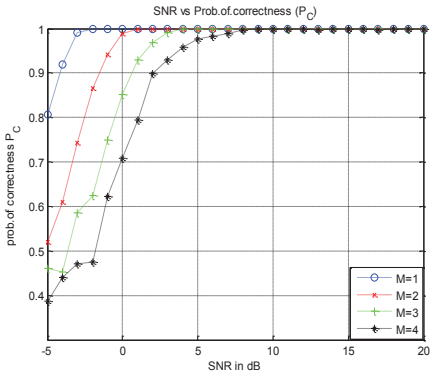

Fig. 5: SNR vs P_c with $N = 4096$

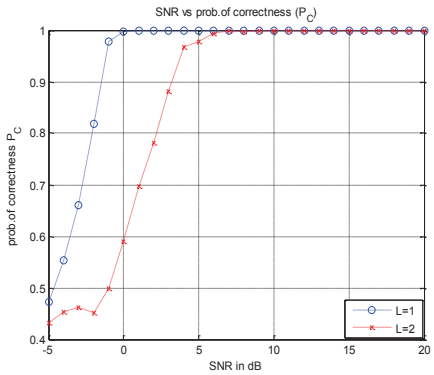

Fig. 6: SNR vs P_c by sixth order cumulants with $N = 1024$

TABLE I: CP Length Comparison

Channel order	CP length by traditional method [2] (bits per OFDM symbol)	CP length by proposed method (bits per OFDM symbol)
1	256	2
2	256	4
3	256	6
4	256	8

chosen as one fourth of the OFDM symbol length, i.e., 256 bits per OFDM symbol. However, in our proposed method CP length is chosen according to channel length.

VI. CONCLUSION

In this paper, a new method is introduced for calculating the ideal CP length in OFDM system. The significant reduction in CP length leads to bandwidth efficient OFDM system. As a part of work a novel algorithm for estimating the channel length has been proposed. The proposed algorithm is blind and does not require any training sequence to estimate channel length. Using simulation results, it was shown that the proposed algorithm outperforms other algorithms even at low SNR.

***Abstract* -- Social services make the most use of the user profile matching to help the users to discover friends with similar social attributes (e.g. interests, location, age). However, there are many privacy concerns that prevent to enable this functionality. Privacy preserving encryption is not suitable for use in social networks due to its data sharing problems and information leakage. In this paper, we propose a novel framework for privacy–preserving profile matching. We implement both the client and server portion of the secure match and evaluate its performance network dataset. The results show that a secure match can achieve at least one order of accuracy and better computational performance than the techniques that use homomorphic encryption.It can handle and tackle new characteristics and an environment for a particular application in a mobile social network.**

Keywords: Cloud Computing, Privacy Preserving, Friend Discovery, CRM.

I.INTRODUCTION

Mobile services have become a popular method for users to build their social relationship and share interests. The most popular mobile social networks services available allow the user to share the location, information, interests and even chat with friends. During the profile matching process, the 'users' social profiles are compared in a server owned by the social network application to find other similar social users with the same attributes (e.g. interest, location, age) in the social network. An effective profile matching process would benefit the user and the social network services. The user would enjoy more experience, while the social network providers see increased users activities in their social networks. Even through the simple public interest attributes, considered harmless by users, such as an 'interest' (or 'like'), users can reveal some basic 'private' social attributes (e.g. age, condition, interests) [1]. In social services, the user can mostly face the problem of unwanted advertisement [2] or easily crack a weak user password [3]. Hence, the privacy concerns must be addressed when developing profile matching techniques for mobile social networks [4], [5]. In social networking, through the antivirus we provide security to the network usage but to preserve the privacy on a mobile network, a more power efficient profile matching scheme is needed. To provide the privacy preserving profile matching process or techniques, homomorphic encryption [6], [7] is mostly implemented [8]. In the homomorphic encryption, certain types of computations are allowed on a plaintext and ciphertext. Here, the ciphertext preserves the information of the plaintext. Ciphertext and plaintext are encrypted by the same key. In this paper, we propose a secure match for a privacy preserving profile matching techniques for mobile network services. We identify the key sharing problems regarding the information leakage and propose verification techniques for the user to verify the profile matching result without obtaining any extra information about the other user's profile attribute. 'Friend Discovery' describes the Customer Relationship Management (CRM) database in an organization with social networks. All 'Friend Discovery' services are connected to the CRM [1] [5]. 'Friend Discovery' represents the interaction because it helps the user to find friends who also care about a particular organization and its product and services [2]. When we are developing an application according to "Friend Discovery" we have to consider/several rules, as follows:

A. Do not share any default setting.

To reduce the probability of mistakes by the user, the "do not share" rule is used to protect all information about the customer's interactions with the company.

B. Trust some selective friends more than strangers.

When sharing some information or updates on Facebook or tweet on Tweeter, some users do not wish to have visibility to the whole friend network. The second rule states that the customers need to be able to control, which friends in their social graph get access to which type of information.

C. My Relationship data is my relationship own data.

This rule enables that the 'Friends Discovery' to temporarily store the user data in the CRM database without compromising any condition in it.

D. Friend Discovery follows different formats.

Popular mobile social applications are Facebook, Twitter, Google, and LinkedIn. A few common chat-only applications are

GTalk, Whatsapp, Wechat, Hike and many more [3], [6]. Communication is mainly done between the client and the server. A different point mechanism is used for the client-server communication (e.g. client-server, centralized, decentralized, distributed, and multi-tier). The "Friend Discovery" concept has been created not only to find a friend, exchange profile, select, add and chat, but can be used in various areas such as social networking sites, and help call centers, such as a healthcare center, where secure information will get communicated.

In this paper we propose a blind transformation algorithm to protect the personal information and user privacy. The attackers of mobile social networks can directly associate the personal profiles with real persons nearby and then launch more advanced attacks. Existing research shows that the loss of privacy can expose the users to unwanted advertisement and spams/scams, cause social reputation or economic damage, and make the users victims of blackmail or even physical violence [6].

II. Related Work

The existing mobile social network systems pay little heed to the security and privacy concerns associated with revealing one's personal social networking preferences and friendship information to the ubiquitous computing environment.

[4] explored the concept of secure localization, authentication and building (SLAB) scheme for the wireless network. SLAB provides both security guarantee and performance in terms of system compromise receiving capability, and workload of the receiving broker (RB). This friend discovery SLAB scheme has been proposed for service oriented metropolitan area wireless mobile networks [4], [12].

[3] proposed a secure multilayer delay tolerant network (SMART) [3]. SMART provides low cost Internet service, e.g. to open email and send data form a source to a destination address [12].

[1] proposed 'Finding U in Privacy' preserving profile matching to use in mobile social networks. In this environment, 'friend discovery' shows various boundaries and issues. Proximity based user discovery and key establishment are two important issues for the usability of our profile matching protocols, towards designing light weight protocols [1], [12].

[2] explored a secure and privacy preserving opportunistic computing framework for mobile healthcare emergency (SPOC). The system introduced the flourish of mobile healthcare but still faces many challenges including information security and privacy preservation [2], [12].

[5] proposed topic a privacy preserving profile matching for proximity based mobile social networks. Here, a fine grained private matching protocol is used with a wide range of matching metrics at different privacy levels [5]. In this case, the private matching between two users is possible, allowing for comparison of the personal profiles without disclosing them to each other. It supports a variety of private matching metrics at different privacy levels [5], [12].

[6] Proposed a fine-grained privacy preserving friend matching protocol, used to improve the navigation effectiveness of the website, while minimizing two current structures. Further, transformation and personalization approaches are integrated. [6] [12].

III. Proposed System

With the existing mobile social networks, privacy preserving is very sensitive to whether a person is login with their secured ID or not. The 'Friend Matching' technology is unique in the sense that every person has its unique identity on a mobile social networking application. It is different even in the case of identical twins ID. Adding authentication to this will enable additional security.

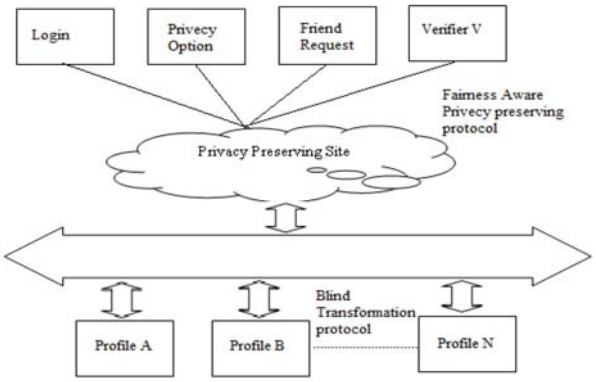

Fig. 1. System Architecture

In Figure 1, Profile A and B are two profiles one is a personal profile, composed of the fields *name*, *date of birth* (DOB), *address* and the other is an interest profile containing the fields *hobbies*, *movies*, *books*. To match the two profile fields, the process will configure the blind transformation and the fairness aware steps will add/delete requests. Here, the module contains the IF (Interest Field). The NIF (Non Interest Fields) are mandatory to fill in both profiles, i.e., the personal and the interest at the time of registration. For comparing, adding and deleting the profile, the system architecture uses the blind transformation and fairness aware protocol. From login to adding a friend in the user's friend list, each process will pass through the privacy options to be verified by the verifier *V*. Here only, the friend matching condition would decide on the user's interest profile. The personal profile is restricted to the user only. When the maximum fields (more than 60%) are matched, then the user would be able to view the other users in the finding friend list. The user has the authority to send requests, add or delete a friend. Here, the software/application controlled by file sharing, controls the access to each.

A.Blind And Fair Transformation Algorithm

The algorithm separates the personal profile and the interest profile, encrypts each user's profile with his/her public key by using the Paillier cryptosystem. It performs vector addition and shuffling, and comparison of the blind profiles. Each user's encrypted profile would be prepared for the matching phase and more matching fields to the interest profile will be added if necessary.

The proposed algorithm is based on the Paillier homomorphic Encryption.

The entity's Paillier public and private keys are $< N, g >$ and λ, where $< N, g >$ are public parameters, and λ is used to calculate a multiple of a prime integer. Here, mainly two encryption and decryption steps are used to encrypt and decrypt data, where g is public parameter, c is cipher text, d denotes the derived parameters, r is the string and n is the number of messages.

For the encryption, the cipher text could be given by,

$$E\ (m\ mod\ N, r\ mod\ N) = gm\ , rn\ mod\ N2 \quad (1)$$

E is the encryption applied on the parameters m, r, and all the public parameters combined together.

For the decryption the cipher text can be given by

$$D(c) = L\left[\frac{c\ \lambda\ mod\ N2}{L}(g\ \lambda\ mod\ N2)\right] mod\ N \quad (2)$$

Where D is the decryption.

To access and calculate the encryption key, we use the homomorphic property as below.

Given that $\{m1, m2, r1, r2\} \epsilon\ Zn$, the following homomorphic property can be satisfied:

$$E\ (m1).E\ (m2) = E\ (m1\ +\ m2), \quad (1)$$

Where, the two encryption functions are :

$$M\ \rightarrow\ gm, rn\ mod\ N2,$$

$$M\ \rightarrow\ gm\ +\ rn\ mod\ N2$$

$$D\ (E\ (m1)\ E\ (m2)\ mod\ N2)\ \ =\ km\ mod\ n, \quad (2)$$

In (4), the encrypted messages are decrypted one by one and added through the particular profile record. K is a constant. If:

$$D\ (E\ (m1)\ gm2\ mod\ n2 =\ m1 + m2\ m$$

by using the blind transformation over any cipher text, we have:

$$\forall m\ \in Zn\quad and\quad r \in N$$

$$D\ (E\ (m1)gm2)mod\ n2 =\ m \quad (3)$$

The above equations define the set of all content, which we combine through the messages. In the considered cryptosystem, the homomorphic added elements are $m = m1, m2$. Here, we use the Paillier homomorphic property for the key generation method. It works on plaintext and the ciphertext. It allows for the hash function to access large and different form of data [11], [12]. Figure 2 and Figure 3, show the accuracy and the performance obtainable through the algorithm.

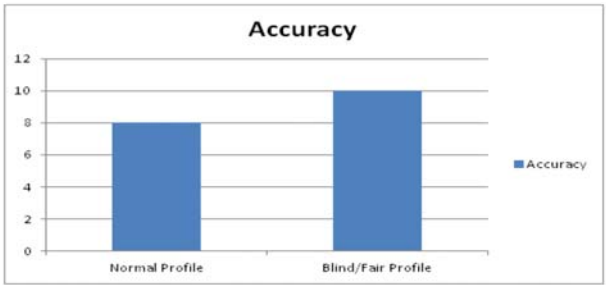

Fig. 2. Accuracy for the model

Figure 2 shows the accuracy for the profile matching for the normal profile and the blind/fairness aware profile. Here, the accuracy defines the accurate profile match. The blind/fairness aware profile is higher than the accuracy obtained than normal profile. The y-axis defines the matching level and the x-axis defines the profile methods.

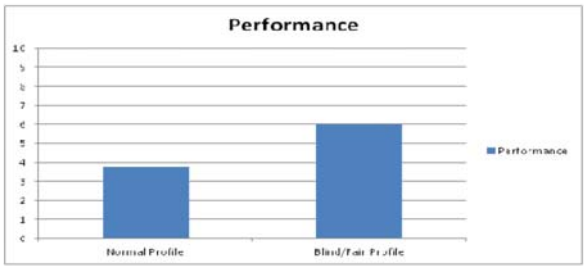

Fig. 3. Performance for the model

Figure 3 shows the performance for the profile searching and matching for a normal profile and for the blind/fair aware profile. Here, the Y-axis shows the number of profiles that were created and that performed well during the execution. The blind/fairness aware profile shows better performance for the searching. The x-axis shows profile created by different method.

Figure 4 and 5 show the time and security needed for a particular input to the model. Here, the x-axis contains the Paillier homomorphic Encrypted input and the random security access (RSA) elements. The y-axis contains the time and the calculated security factors. Figure 4 shows the key generation. It shows how the profile is searching for a particular match for the Paillier homomorphic Encryption model and the RSA. The time (in milliseconds) indicates how many matches have been generated for the combination.

As shown in Figure 4, the x-axis shows the counting of the result fetch in ms, and per process, i.e., for the existing system and for the proposed system. The y-axis shows the counting time in milliseconds per process for both systems. The result shows how the profile searches for a particular match .The Paillier homomorphic Encryption model and the RSA points are used for the cryptosystem for the key encryption and the decryption for Ciphertext and the Plaintext. The results show how many matches would be generated for the combination.

Figure 5 shows how security is provided to the Paillier homomorphic Encryption. The existing system takes more time for each process in the system and the proposed system is faster when combining the two processes. It also provides better security for each process in the system. Even the fetching time for the existing system is longer than for the proposed system.

Result Fetch in Time

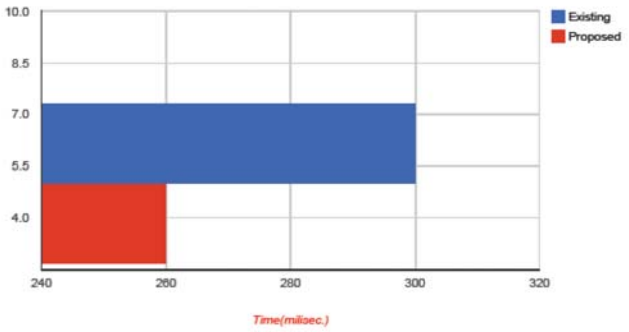

Fig. 4. Key Generation Time Graph

Figure 5 shows the use of the security parameters for the Paillier homomorphic encryption to ensure the fairness and the privacy of the privacy-preserving network. In Figure 5, the x-axis defines the security parameter for the existing and the proposed systems and the y-axis shows the provided level of security in percentage for the system and for each profile. The security for the proposed model results in more fetch per unit of time from the start to the end and it does not skip processes in between when the process is running. The security for the existing model is low through the whole process.

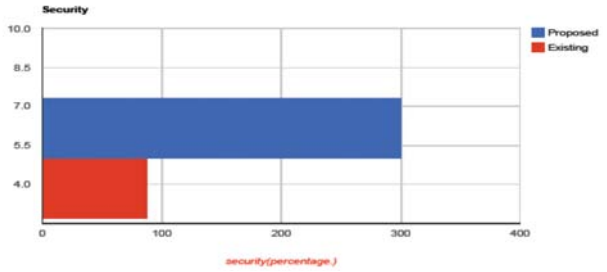

Fig. 5. Security Graph

IV. CONCLUSIONS

This paper proposed a blind transformation profile to increase security levels for the process of profile matching in in mobile social networks. The lack of sufficient security may result in the leaking of personal information. The issues to be addressed in existing mobile social networks are the slow start and the security issue. In existing systems the created profile is filtered separately by use of two separate algorithms, which leads to weakened security and confusion in between the profile matching process or in friend discovery processes. The proposed here algorithm can provide fine grained interest profile matching and can be used as a basis to investigate more security and privacy issues in mobile social networks, which can improve the negative impact of slow start of the process and the security for each profile.

Here, we combined the blind transformation and the fairness-aware algorithms. This combination allows for the filtering of each profile from the key generation technique and the fair matching process gives more secured fields to the profile. This results that only the interest profile would be visible to another user. The total security is provided to the personal profile i.e.,it is invisible for the friend and visible for the profile holder. Our future work includes how to provide fine-grained interest profile matching and investigate more security and privacy issues in mobile social networks.

Abstract — **In Radar Intelligence, Surveillance and Reconnaissance (ISR) applications maximizing range and resolution are key objectives for the system developers. The predicament of having long range requires higher transmit power (wider pulse), which affects the range resolution adversely. This issue of range and range resolution compromise has been resolved using the pulse compression techniques such as Linear Frequency Modulation (LFM) and Coded Binary Sequences (e.g. Barker code). These techniques have served the radar community well, but with the advancements in VLSI technologies (e.g. processing power, memory, process nodes etc…) other complex techniques should be explored, especially the ones which have been tried in the commercial world with great success and differentiated offerings. Some algorithmically enhanced Pseudo Random Noise (PRN) sequences in cellular applications exhibit both good autocorrelation and low sidelobe characteristics, which are desirable for Radar ISR applications. The LFM waveform is a very common radar waveform, and has been used for the ISR application for many years. However, the pulse compressed output of the LFM signal produces an unacceptable level of sidelobes, typically only 13 dB below the mainlobe. The mainlobe to sidelobe ratio improvement is typically accomplished by applying a weighting function in conjunction with the matched filter. This results in Signal-to-Noise Ratio (SNR) reduction of 1-2 dB (depending on the weighting function), which degrades the detection range performance. The proposed PRN binary sequence codes in conjunction with the LFM waveform exhibits promising results in air-to-air and air-to-ground applications and achieve excellent range and range resolution performance at a substantially reduced sidelobe level.**

Keywords— Radar, Range, Resolution, Pulse Compression, Autocorrelation, LFM, Barker Code, Side lobes, Pulse Shaping, Pseudo Random Noise (PRN) Code, anti-jamming, antidetection, Processing Gain, 3 dB Bandwidth

I. INTRODUCTION

Typically radar systems in ISR applications transmit a pulsed electromagnetic wave and measure the returned time of the reflected echo from a distant object as shown in Figure – 1 and are used to determine the range using Eq. 1. The fundamental relationship between the radar parameters, target and received signal, is known as the radar range equation.

In general, a pulsed radar system transmits and receives a train of pulses, as illustrated in Figure – 2.

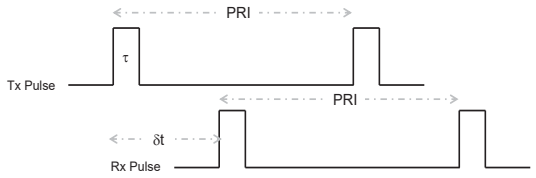

Figure -1

$$R = \frac{C * \delta t}{2} \qquad (1)$$

C - Speed of the light

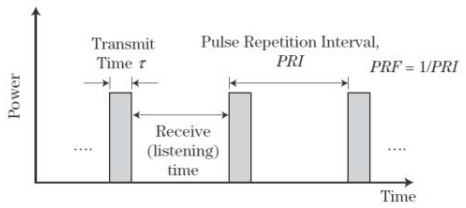

Figure -2

In a pulsed radar system, detectable range is limited by the transmit power and the range resolution by the pulse width. The design of any radar system always involves a trade-off between these two competing constraints. Pulse compression techniques have been employed extensively to achieve improved range resolution while maintaining an acceptable range capability. One of the basic types of pulse compression technique in use today is binary phase coding, which encodes the transmitted pulse with information that is known a priori to the receiver. The receiver processes the waveform of the received signals using a matched filter and depending on the length of the binary coded sequence achieves pulse compression (or processing gain) and subsequently imp roves range resolution.

By definition, range resolution is the ability of a radar system to detect targets in close proximity to each other as distinct objects. The range resolution, δR, is inversely proportional to the pulse width, i.e. the narrower the pulse width, the better the range resolution. Without pulse compression, the

Copyright © 2015 Raytheon Company. All rights reserved

instantaneous bandwidth of a radar receiver, B, is equal to pulse bandwidth. By incorporating narrower pulses of duration τ/N, the range resolution could be improved N times. Eq. 2 describes the essence of pulse compression. Resolution in the range domain, δR, corresponds to the time domain resolution, τ.

$$\delta R = \frac{C * \tau}{2} = \frac{C}{2 * B} \qquad (2)$$

Other key characteristics of a desirable radar waveform development could require a binary coded sequence to provide higher sidelobe rejection and superior autocorrelation properties. The radar community has developed many such sequences such as the Barker code which demonstrates good autocorrelation and better than average sidelobe rejection characteristics.

Autocorrelation

The cross-correlation function is the degree of likeness of one signal to another. For two identical signals the cross-correlation operation is known as autocorrelation. Mathematically, the autocorrelation function of a discrete time sequence $x[n]$, (n =1, 2..., N) is given by Eq. 3.

$$R_x(k) = \sum_{i=1}^{N-1} x[i]x^*[i+k] \qquad (3)$$

where k = 0,1,...,N -1 is the discrete time-index, the asterisk on the second term in the product of the right side of Eq. 3 denotes the complex conjugate.

Peak Sidelobe

The autocorrelation operation produces a main lobe surrounded by several sidelobes with time lags in both positive and negative sides. The autocorrelation function of a uniform Power Spectral Density (PSD) pulse is shown in Figure–3. The absolute maximum value of the secondary peaks in the sidelobes is defined as the peak sidelobe level (*PSL*) [1], which is expressed as

$$PSL = \max_{k \neq 0} \{R_x(k)\} \qquad (4)$$

This quantity is more often expressed as a value relative to the mainlobe level in decibels and defined as the peak sidelobe level ratio (*PSLR*). The *PSLR* in decibels is represented in Eq. 5 and is annotated in Figure – 3.

$$PSLR_{dB} = 20 \log_{10}\left[\frac{PSL}{R_x(0)}\right] \qquad (5)$$

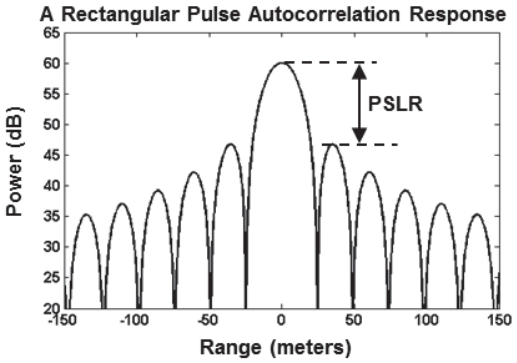

Figure -3

II. Background (Historical Perspective)

The matched filter and pulse compression concepts are the key constituents of radar pulsed signal processing. Since radar return includes noise, ground clutter and background interference in addition to the target, the receiver must be capable of differentiating a real target from accompanying noise and interference. The matched filter is widely used to decipher the signal from the noise, ground clutter and background interference.

Pulse compression is a classic radar signal processing technique used to increase range resolution without increasing the transmit power. Instead of a fixed frequency waveform, the transmitted pulse is modulated by a linearly varying frequency waveform, which broadens the bandwidth of the transmitted pulse. The receiver uses a matched filter to process returned echoes and matches the transmitted waveform at the same time to reject noise, interference and clutters. The transfer function of a matched filter is designed to maximize the attainable Signal to Noise Ratio (SNR) at the receiver output.

Linear Frequency Modulation

The Linear Frequency Modulation (LFM) waveform is the most commonly and extensively used pulse compression technique in radar systems. The bandwidth of an LFM waveform is widened using a quadratic phase coefficient (α), which varies the frequency linearly over the duration of the pulse. The LFM waveform is defined as Re{s(t)} in Eq. 6.

$$s(t) = \exp\left\{j2\pi\left(f_c t + \frac{1}{2}\alpha t^2\right)\right\}, \ -\frac{T}{2} \le t \le \frac{T}{2} \qquad (6)$$
$$= 0, \qquad elsewhere$$

Where f_c is the carrier frequency of the transmitted waveform and α is the chirp rate of the waveform and defined as

$$\alpha = \frac{B}{T} \qquad (7)$$

Copyright © 2015 Raytheon Company. All rights reserved

Where, B and T are the waveform bandwidth and the pulse width respectively of the LFM waveform. The instantaneous phase of the LFM waveform across the pulse width T is illustrated in Figure– 4.

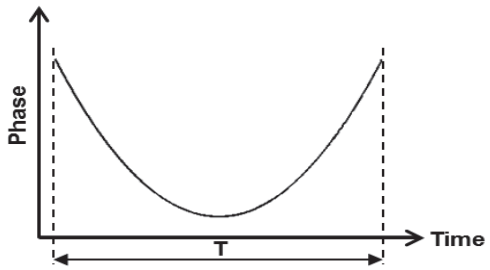

Figure -4

The instantaneous frequency *f(t)* can be obtained by differentiating the phase portion of the Eq. 6 ,

$$f(t) = \frac{d(f_c t + \frac{1}{2}\alpha t^2)}{dt} = f_c + \alpha t \qquad (8)$$

The autocorrelation function for this waveform is depicted in Figure–5. As expected it achieves a 3 meter range resolution (Eq. 2) but it has a peak sidelobe of only 13.4 dB below the mainlobe. The peak sidelobe of this level is not ideal and a weighting function may be used to reduce the sidelobes without compromising the range resolution or range performance of the system.

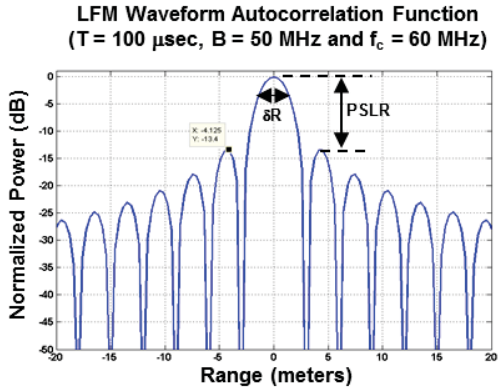

Figure -5

A commonly used Taylor [3] weighting function reduces the PSLR by 30dB as shown in Figure–6. The weighting function reduces the sidelobe peak at the expense of marginalizing the effectiveness of the matched filter as it is no longer matched precisely causing loss of SNR.

Binary Coded Barker Code

Pulse compression is also realized using binary coded sequences with good autocorrelation and sidelobe properties. The Barker code [2] is one of the most widely used binary coded sequences in radar applications, as it exhibits excellent autocorrelation characteristics as well as favorable sidelobe suppression.

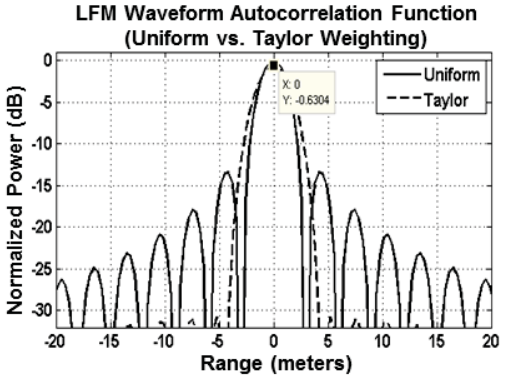

Figure -6

In order to achieve pulse compression, a binary coded wideband sequence is transmitted and the return signal is processed through matched filtering. This process results in enhancing the signal power due to the processing gain and thus improving the range resolution due to widening of the pulse bandwidth. The transmitted pulse carries the binary coded sequence of smaller chip duration, which is used to phase modulate the carrier frequency. An example of a 7-chip Barker code is shown in Figure-7. This waveform represents a carrier frequency being modulated in phase every chip between 0 and π according to the code [-1 -1 -1 1 1 -1 1] sequence, where -1 represents a phase of 0 degree and +1 represents a phase reversal of π. The amount of compression possible is equivalent to the time-bandwidth product (BT) of the code, which is the product of the signal bandwidth and the pulse duration. Bandwidth of a phase-coded signal is $B=1/\tau_c$ where τ_c is the chip duration. The returned signal power increase is proportional to the code length while the range resolution (δR) is inversely related to the bandwidth as described in Eq. 2.

The weakness of a binary coded system is the growth of sidelobe spurs, which are an artifact of the pulse compression. Figure–7 shows the matched filter output of a 7 chip Barker code. Barker codes have the property of producing mainlobe that is higher than the sidelobes by a factor of the code length. For a code length of 7 chips, the mainlobe is 7 times higher than the sidelobes.

Typically Integrated Sidelobe Level (ISL) and Peak Sidelobe Level (PSL) are used to characterize the performance of the ISL. ISL represents total power in sidelobes with respect to the main lobe, while PSL represents the peak sidelobe amplitude with respect to the mainlobe as defined in Eq. 9 & 10. In both of

Copyright © 2015 Raytheon Company. All rights reserved

these equations, x_0 refers to the mainlobe magnitude while x_i refers to all other output range sidelobes except the mainlobe.

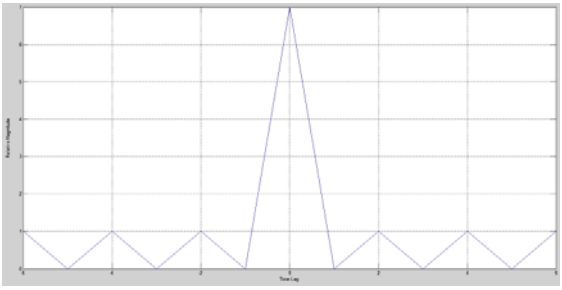

Figure -7

$$ISL = 10\log_{10}\sum_{i\neq 0}\frac{x_i^2}{x_0^2} \quad (9)$$

$$PSL = 10\log_{10}\frac{\max_{i\neq 0}(x_i^2)}{x_0^2} \quad (10)$$

III. Proposed PRN Code Framework

This section documents the detailed framework of the proposed Pseudo Random Noise (PRN) coded LFM waveform, which exhibits excellent pulse compression characteristics and subsequently better range and range resolution performance for ISR applications.

The ease of generating an LFM waveform and subsequent processing by a Matched Filter lends into an efficient hardware implementation. However, an LFM waveform is susceptible to jamming in an electronic warfare (EW) environment due to its distinguishable waveform features.

Figure–8 shows a simplified time domain design architecture which utilizes a Commercially Off-The-Shelf (COTS) LFM Direct Digital Synthesis (DDS) to incorporate a PRN phase modulated LFM waveform generator. The quadratic phase portion of LFM in φ(n) from Figure–8 can be represented by

$$\varphi_q(n) = an^2 + bn + c \quad (11)$$

Where,

n = sample number from 0, 1, 2…N,

N = number of samples generated within a transmit pulse width at the Digital to Analog Convertor (DAC) sampling rate f_s,

a = LFM chirp rate which is defined by the waveform bandwidth to pulse width ratio,

b = Intermediate Frequency (IF), and

c = a constant phase offset.

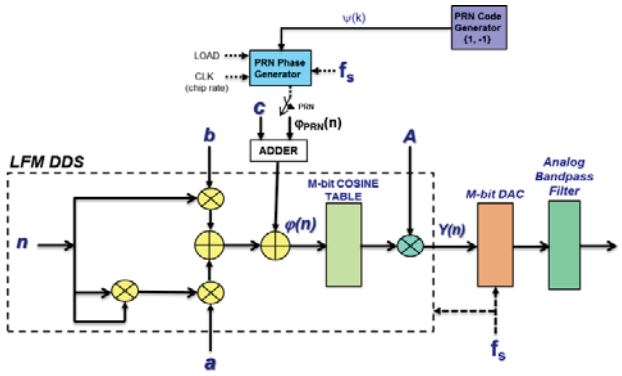

Figure -8

The modulated LFM phase φ(n) in Figure–8 is then defined as

$$\varphi(n) = \varphi_q(n) + \varphi_{PRN}(n) \quad (12)$$

Each phase sample φ(n) is then indexed into the cosine lookup table to generate the waveform samples. Each waveform sample is scaled by the control parameter (A), as shown in Figure-9, prior to the input of a Digital to Analog Convertor (DAC).

The PRN code generator in Figure–8 is a uniformly distributed binary code generator from a set $\Lambda \in \{+1, -1\}$. The code length is defined by the number of chips within a transmit pulse. Time duration of a single chip can be defined by the pulse duration divided by the length of the code. For example, a 2.5 μsec pulse with a code length of 125 has a chip time duration of 20 nanoseconds. The output PRN phase samples from the PRN Phase Generator in Figure–8 are continuous by design for any set of binary PRN codes across the transmit pulse.

The LFM quadratic samples are phase modulated by the PRN phase generator samples, as defined by Equation 12. The performance results of the proposed PRN phase modulated LFM waveform was evaluated based on a simulation developed in MATLAB. The performance of the PRN phase modulated LFM waveform generated from Monte Carlo run was compared to the same PRN phase coded waveform without the presence of LFM waveform. Figure–9 shows a comparison between the frequency spectra of the two separate waveforms generated from one of the test runs. Note that the PRN phase modulated LFM waveform exhibits a flat white noise like Power Spectral Density (PSD). On the other hand, the PRN phase coded waveform spectrum in Figure–9, without the presence of LFM waveform shows distinct spectral characteristics desirable for many other applications.

Copyright © 2015 Raytheon Company. All rights reserved

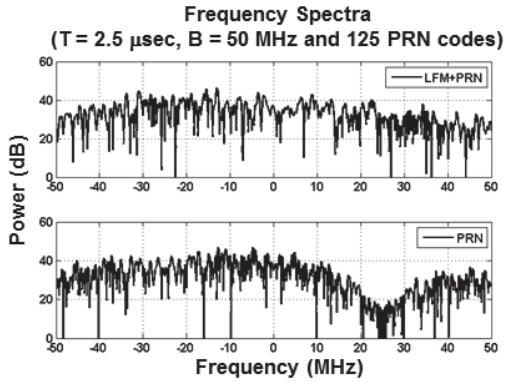

Figure -9

In addition, the target detection probability of the PRN phase modulated LFM waveform shows better performance than the PRN coded binary waveform as shown in Figure–10.

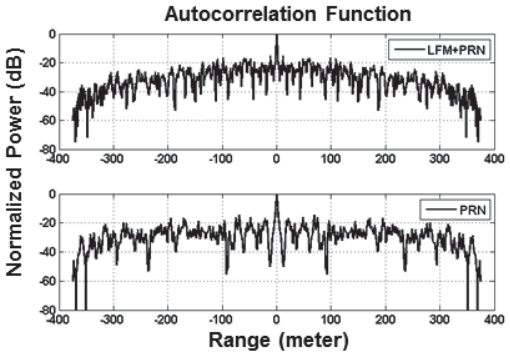

Figure -10

A comparison of the PRN phase modulated LFM waveform (solid line) shows better range resolution performance as well with respect to the PRN coded waveform as shown in Figure–11.

The autocorrelation functions (Figure–12) between LFM and PRN phase modulated LFM waveforms are also compared for a 100 μsec pulse width case. The autocorrelation results show that the PRN phase modulated LFM waveform also performed better in comparison to that LFM waveform.

IV. CONCLUSIONS

In this paper we have presented the framework of the PRN coded LFM waveform and shown that the performance of the proposed waveform matches the range performance and far exceeds the sidelobe reduction compared to widely employed LFM and Barker coded binary sequence waveforms. The simulation results also show a better range resolution in addition to having superior range and sidelobe suppression performance for ISR applications.

***Abstract*—Geometry-based stochastic channel model (GBSM) is an important approach for standard channel modeling, and will be a part of future 5G channel models. In this paper, we present a generic and compatible implementation for two-dimensional (2D) and three-dimensional (3D) GBSMs for both link level and system level simulations. Our approach enables a simple, flexible and scalable method for developing and simulating different GBSMs. It mainly consists of three related parts, i.e. the antenna configuration, the network layout and the channel parameters generation. We calibrate and verify our implementation by comparing several given channel parameters with reference results from other organizations, and it's in good agreement with the references. Furthermore, resulting in MIMO outage capacities are shown. The proposed implementation can be applied to simulate different GBSMs in a consistent way and to evaluate various wireless systems.**

I. Introduction

Channel models are important tools for the development of new radio systems and technologies. They allow estimation and validation of new concepts in mobile communication systems. At the same time, these concepts also motivate the development of channel models. Multiple-input multiple-output (MIMO) and 3D beamforming have been identified as key technologies for performance enhancement in communication systems, as well as in future 5G systems [1], [2]. So directional channel models that take the direction of arrival and departure in consideration are required for simulating and testing such systems [3].

There have already been several suggestions for directional channel models. Molisch *et al.* [3] have compared some of them, and selected geometry-based stochastic approach for most parts of COST-259 channel model. Since geometry-based stochastic channel model (GBSM) can keep a good balance between accuracy and complexity for simulating directional channels, it has been widely used in standard channel models, such as the 3GPP spatial channel model (SCM) [4], SCM extension (SCME) [5], WINNER model [6], [7] and IMT-Advanced model [8]. However, most of these models are based on 2D modelling approach, and not appropriate for evaluating technologies like massive MIMO and 3D beamforming which take the elevation dimension into account. This was taken up partly in WINNER II model [7] and 3GPP 3D model [9]. Recently, METIS has developed its GBSM from WINNER and IMT-Advanced channel models for future 5G communiation systems, which suppots full 3D channel simulation, spatial consistency and wide range of propagation scenarios [10].

Along with the standardization process, commercially and academic available channel simulators have been developed. The MATLAB implementations of SCM/SCME, WINNER and WINNER+ channel models developed by WINNER project partners [11] have been widely used in many systems. Ellenbeck *et. al* [12], [13] presented an efficient and fully calibrated C++ implementation of ITU-R channel model suitable for system level simulations of IMT-Advanced systems. However, to the best of our knowledge, none of these implementations is compatible with 3D channel models.

The main contribution of this paper is the generic and compatible implementation for 2D and 3D channel models. Its module-based structure results in a much more organized, understandable and maintainable implementation in which new antenna arrays filed pattern, new network layout topologies and new generation algorithms are easily added and tested. Furthermore, the proposed implementation is verified and calibrated with reference results from other organizations.

The remainder of this paper is outlined as follows. Sec. II gives an overview of 2D and 3D GBSMs. Sec. III presents our proposed implementation. Sec. IV discusses different calibration and validation approaches and presents calibration results. Finally, conclusions are drawn in Sec. V.

II. Overview of 2D and 3D GBSMs

A. MIMO Channel Realisations

Geometry-based modeling of the radio channel enables separation of propagation parameters and antennas. The channel parameters for individual snapshots are determined stochastically based on statistical distribution extracted from channel measurements. Channel realisations are generated through the application of the geometrical principle by summing contributions of rays (plane waves) with specific small-scale parameters like delay, power, angle-of-arrival (AoA) and angle-of-departure (AoD).

Considering an $U \times S$ MIMO channel, we denote the channel impulse response (CIR) of cluster n at time t to delay τ as [9]

$$\begin{aligned} h_{u,s,n}(t;\tau) = \sum_{m=1}^{M} & \mathbf{F}_{rx,u}^{T} \cdot \mathbf{X}_{n,m} \cdot \mathbf{F}_{tx,s} \\ & \times \exp\left(jk\left(\bar{r}_{rx,n,m} \cdot \bar{d}_{rx,u}\right)\right) \exp\left(jk\left(\bar{r}_{tx,n,m} \cdot \bar{d}_{tx,s}\right)\right) \\ & \times \exp\left(j2\pi\nu_{n,m}t\right) \delta\left(\tau - \tau_{n,m}\right) \end{aligned} \quad (1)$$

where $\mathbf{F}_{rx,u}$ and $\mathbf{F}_{tx,s}$ are the antenna array response matrices for the receiver (Rx) and the transmitter (Tx) respectively, $\mathbf{X}_{n,m}$ is the complex gain matrix of cross-polarisations, where n denotes a cluster and m denotes a ray within cluster n, $(\cdot)^T$ denotes the matrix transposition. Furthermore, j is the square

root of -1, k is the wave number $2\pi/\lambda$ where λ is the carrier wavelength in meters, $\bar{r}_{rx,n,m}$ is AoD unit vector, $\bar{r}_{tx,n,m}$ is AoA unit vector, $\bar{d}_{rx,u}$ and $\bar{d}_{tx,s}$ are the location vectors of element s and u respectively, and $\nu_{n,m}$ is the Doppler frequency component.

By taking a discrete Fourier transform (DFT) in the delay domain, the channel response at frequency f is given by [13]

$$H_{u,s}(f;t) = \sum_{n=1}^{N} h_{u,s}(n,t) \cdot \exp(-j2\pi\tau_n f) \qquad (2)$$

According to the existing standardized 2D fading channel models, including IMT-Advanced model and 3GPP SCM, the characteristics of the spatial domain mainly focus on the horizontal direction. Based on the elevation angles, the 2D channel model based on the IMT-Advanced channel model can be transformed into a 3D model [14].

B. Correlated Large Scale Parameters (LSPs)

At system level, all large scale fading parameters (LSPs) are fully correlated between MSs being connected to the same BS (but not between different BSs) as well as among each other for the same link. These correlations are mostly caused by some scatters contributing to different links (similarity of the environment) [7].

The procedure to achieve this stems from [6], [7] which uses a grid of locations based on MSs and a two dimensional finite impulse response (FIR) filter to generate separately the influence of LSP cross-correlations and exponential auto-correlation. Furthermore, the correlated LSPs of 2D channel models include shadow fading term, the delay spread and azimuth angular spreads and the Ricean K factor. Besides the above-mentioned LSPs, other correlated LSPs of 3D channel models include elevation angular spreads. These LSPs are used to parametrize the random distributions of the actual small scale parameters used by the spatial channel model [13].

However, correlations of LSPs between different MSs is not supported in SCM/SCME. In 3GPP SCM, shadowing fading for links from one MS to different BSs exhibits constant correlation coefficient equal to 0.5. And this correlation does not depend on distances between BSs or their relative angular positions as seen from MS [7].

C. Small Scale Parameters (SSPs)

Firstly, correlated LSPs are drawn randomly from tabulated distribution functions, then actual small scale parameters (like delay of each cluster and associated power, arrival and departure angle of each ray of each cluster) can be drawn randomly according to tabulated distribution functions and random LSPs. In order to characterize the spatial fading channel, power angle spectrum (PAS) and angular spread (AS) of the azimuth angle have been introduced. In the existing 2D channel models, PAS of the azimuth angle is well fitted by Gaussian distribution or Laplacian distribution at the BS. At the MS, it is usually assumed to be uniform distribution [14]. Similar to the horizontal domain, the basic parameters of the vertical domain, such as PAS and AS, should be studied and modelled. For scenarios defined in 3GPP 3D channel model [9], the elevation PAS at both MS and BS can be well fitted by Laplacian distribution. Furthermore, the height dependence of elevation offset angle, which is defined as the difference between the line-of-sight (LoS) direction and the mean angle of the elevation PAS, at BS observed from the ray-tracing data, is not showing a common and strong trend.

III. Compatible Implementation for 2D and 3D GBSMs

A. Implementation Framework

The block diagram of proposed compatible channel model implementation is shown in Fig. 1. Similar to other implementations [11], [13], the core part consists of: (i) the antenna configuration, (ii) the network layout and (iii) the parameters generation.

The antenna configuration part specifies separately the

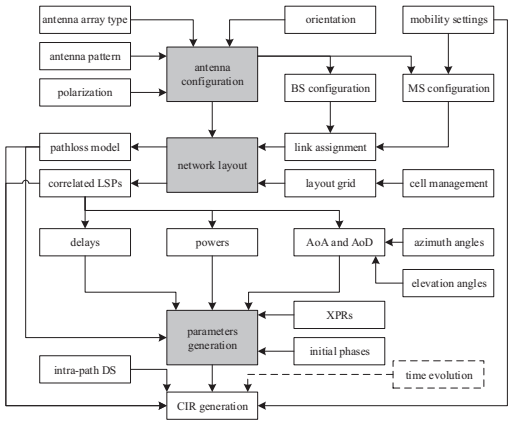

Fig. 1. Block diagram of the compatible implementation for 2D and 3D GBSMs

antenna characteristics used for generating the channel impulse responses (CIR). On the other hand, the network layout part defines the scenario layout grid type, cell management, mobility settings and locations and configurations of each BS and MS. Furthermore, the channel parameters generation part generates randomly correlated LSPs and actual SSPs of the simulated link according to tabulated distribution functions. As a mean to support bandwidth extension, intra-cluster delay spread is introduced in SCME [5]. And the dashed time evolution component depicted in Fig. 1 means that the dynamic channel simulation is not fully supported in existing channel models.

B. Implementation Workflow

The workflow of the implementation framework is shown in Fig. 2. The procedure of the proposed implementation is as follows:

Step 1: Select an appropriate channel model (2D or 3D GBSM) to start one simulation according to radio systems or technologies to be evaluated;

Step 2: Choose one deployment scenario which defined in the channel model for the evaluation, this must be done as the followed network layout configuration depend on it;

Step 3-A: Give the antenna array type (linear array or 2D planar array), polarization, position of each element and also

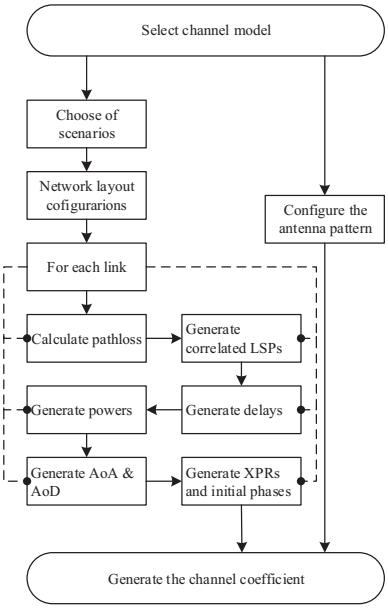

Fig. 2. Workflow of the proposed implementation

field pattern $\mathbf{F}_{tx}$ and $\mathbf{F}_{rx}$ of each BS and MS;

Step 3-B: Give the location, orientation and mobility of each BS and MS in the layout grid, assign each link with line-of-sight (LoS), non-line-of-sight (NLoS), outdoor-to-indoor (O2I) or indoor-to-outdoor (I2O) propagation condition, and calculate the line-of-sight angles of departure and arrival of each link.

Step 4: For each link which was assigned in the layout, generate the following parameters:

1) The pathloss PL;
2) Correlated LSPs include the shadow fading term σ_{SF} and the line-of-sight Rice factor K_R *et. al.*;
3) Initial delay τ_n and power P_n of each cluster n;
4) AoA and AoD of azimuth and/or elevation of each ray;
5) XPRs and initial random phases of each different polarisation combinations of each ray.

Step 5: Generate time-delay domain channel coefficients using (1), then compute the channel frequency response by discrete Fourier transform (DFT) using (2).

Generally speaking, the generation of channel parameters in *Step 4* can be done only once, because all these values stay constant during one simulation drop and independent between different simulation drops. However, on dynamic/non-stationary channel models which are channel models with time-varying channel parameters, time-evolution of channel parameters between different simulation drops should be taken.

By utilizing the framework which support both link level and system level simulations, we can simulate a number of existing channel models with a compatible implementation. It can also be applied to evaluate the performance of radio systems or technologies under different channel models. Consequently, we can simplify the channel model simulation by keeping these dominate parameters as random variables while fixing others as constants.

IV. Calibration and Simulation Results

Calibrating different simulation tools is an important requirement for obtaining comparable and reliable simulation results [13]. In this section, we calibrate the 3GPP 3D channel model implementation with reference values from other organizations. Furthermore, the outage capacities of 2D and 3D channel models are shown.

A. Standardized Calibration Phases

The phased calibration work has been agreed in RAN1 for 3D channel model [15]. The phase-1 calibration covers large scale channel characteristics including coupling loss, geometry, and LoS angle distributions with several antenna configurations. The phase-2 calibration includes fast fading channel characteristics such as distribution of elevation angular spread and singular value distribution. Further details of phase-1 and phase-2 simulation assumptions and calibration metrics are described in [16].

Phase-1 calibration: Phase-1 calibration relies on the large-scale fading parameters. The objective of this phase is to calibrate the correct scenario layout, antenna characterises, pathloss models, assignment of LoS or NLoS propagation conditions and shadow fading. The main calibration metrics of this phase are referred to as coupling loss, geometry factor and LoS elevation angles of departure (EoD).

The coupling loss measures the difference between the received signal and the transmitted signal along the LoS direction, and its computation for MS m based on reference signal received power (RSRP) is given by [17]

$$CL_m = RSRP_{k_m} - P_{TX} \tag{3}$$

where k_m is the best serving site k which maximizes the RSRP; P_{TX} is the transmitted power in dB, and the RSRP is given by

$$\begin{aligned} RSRP_{k_m} = P_{TX} &+ G_T\left(\phi_{k,m}^{LoS}, \theta_{k,m}^{LoS}\right) \\ &+ G_R\left(\varphi_{k,m}^{LoS}, \vartheta_{k,m}^{LoS}\right) \\ &+ PL_{k,m}^{LoS}(dB) - \sigma_{SF,k,m}(dB) \end{aligned} \tag{4}$$

where $\left(\phi_{k,m}^{LoS}, \theta_{k,m}^{LoS}\right)$ and $\left(\varphi_{k,m}^{LoS}, \vartheta_{k,m}^{LoS}\right)$ are the LoS direction of departure and arrival with respect to the k-th site respectively; $G_T(\cdot)$ is the antenna gain at the transmitter in dB, and $G_R(\cdot)$ is the antenna gain at the receiver in dB; $PL_{k,m}^{LoS}$ is the LoS pathloss in dB and $\sigma_{SF,k,m}$ is the shadow fading term in dB.

In Fig. 3 and Fig. 5, we present the obtained results of the coupling loss and LoS EoD for the urban macro (UMa) scenario respectively when antenna config 1 is assumed [16]. These results comply with those obtained by majority of the companies participating in the calibration process [16].

Phase-2 calibration: For phase-2 calibration, the cumulative distribution function (CDF) of small scale channel characteristics, like the azimuth and elevation angular spreads as well as the delay spread, should be given [18]. Moreover, to calibrate the channel generation procedure, CDF of the first and second largest eigenvalues of the channel should also be presented. The fact is that when the channel is known to the transmitter, spatial diversity is related to the dominant eigenmode of channel matrix [19].

Fig. 4 shows the calibration metric curves for the elevation

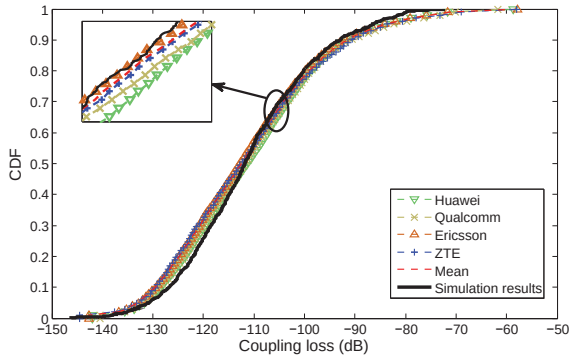

Fig. 3. Calibration of coupling loss for the UMa scenario

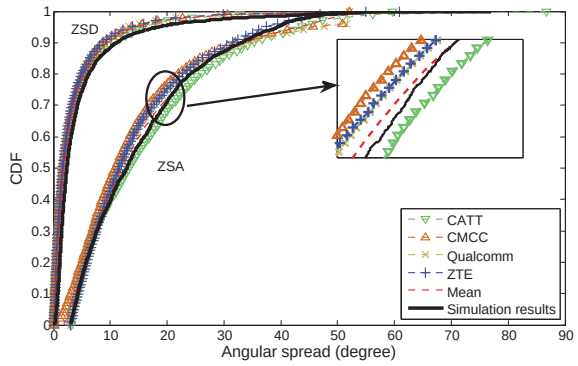

Fig. 4. Calibration of Elevation Angular Spread of Departure for the UMa scenario

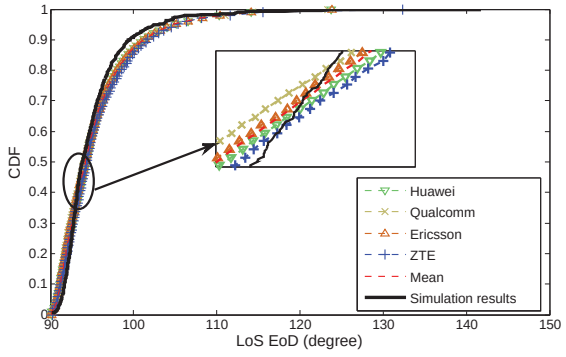

Fig. 5. Calibration of LOS ZoD for the UMa scenario

angular spread of departure and arrival which derived from the implementation of 3GPP 3D channel model for the UMa scenario in comparison with reference results from other organizations [16]. The curves closely match with the majority of reference curves thus underlining the correct implementation of our framework.

TABLE I. ASSUMPTIONS OF OUTAGE CAPACITY SIMULATION

Parameters	**Description**
Scenarios	UMa and UMi
Carrier Frequency	2.0 GHz
BS antenna configurations	2 Tx, ULA, 10.0λ H spacing
MS antenna configurations	2 Rx, ULA, 0.5λ H spacing
Polarisation	X-pol at both BS and MS
MS velocity	30.0 km/h and 3.0 km/h
Sample density	8 samples per half wavelength
No. of frequency bins	600
SNR	$\rho = 14.0$ dB

B. Further Calibration

A common way to characterize the time-frequency domain channel matrices $\mathbf{H}$ given in (2) that a channel model produces, is to consider the distribution of the resulting MIMO capacity [13]. The outage capacity, i.e. the CDF of the channel capacity, when the channel is unknown to the transmitter is preferred instead of the ergodic capacity which can be derived from the CDF. The approximation of capacity C of each channel realization t can be given by [19]

$$\tilde{C}_t(\rho) = \frac{1}{F}\sum_{f=1}^{F} \log_2 \det\left(\mathbf{I}_U + \frac{\rho}{\beta^2 S}\mathbf{H}_{ft}\mathbf{H}_{ft}^H\right) \quad (5)$$

where f and F are the discrete sample point and total sample points of the channel frequency response respectively. U is the number of receive antennas and S is the number of transmitter antennas. $\mathbf{I}$ denotes the identity matrix, ρ denotes the signal-to-noise ratio (SNR) and $(\cdot)^H$ denotes the Hermitian transpose operation. β is a common normalization factor for all channel realizations such that the average channel power gain is unitary [19], i.e.,

$$E_H\left\{\frac{1}{\beta}\|\mathbf{H}_{ft}\|_F^2\right\} = U \times S \quad (6)$$

where $E_H\{\cdot\}$ denotes the expectation operator over H; $\|\cdot\|_F$ denotes the Frobenius norm.

Fig. 6 and Fig. 7 show the outage capacity complementary cumulative distribution function (CCDF) comparing with 3GPP 3D channel model, the IMT-Advanced channel model as well as the SCM channel model against the capacity purely random Gaussian i.i.d. distributed channel matrices would yield. For all models, the values were generated assuming a configuration as Table I shows.

Obviously, the correlations considered by the different channel models yield lower than Gaussian capacities, especially for LoS conditions. From the result, we can see that the outage capacity of 3GPP 3D channel model is close or even lower than the outage capacity of IMT-Advanced channel model and SCM when linear antenna array been deployed at BS. It seems that the modelling of elevation dimension trends to increase the channel correlation and cause the loss of MIMO channel rank. However, when we consider the planar antenna arrays, Fig. 8 shows that the outage capacity of the 3D channel model is higher than 2D channel models.

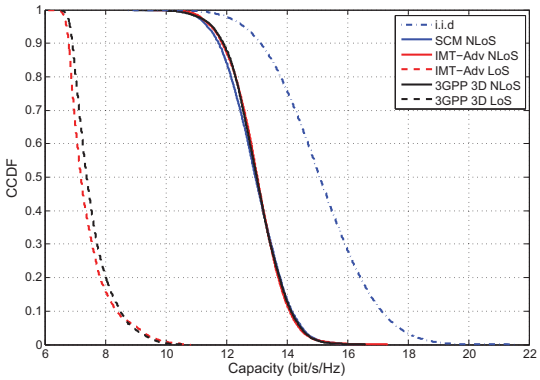

Fig. 6. The CCDF of the 2×2 MIMO wideband outage capacity in urban macro environment with fixed $\rho = 14$ dB

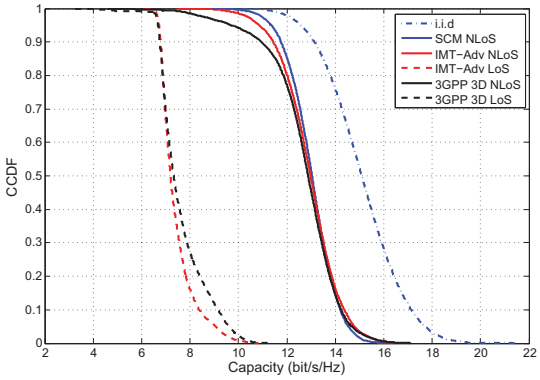

Fig. 7. The CCDF of the 2×2 MIMO wideband outage capacity in urban micro environment with fixed $\rho = 14$ dB

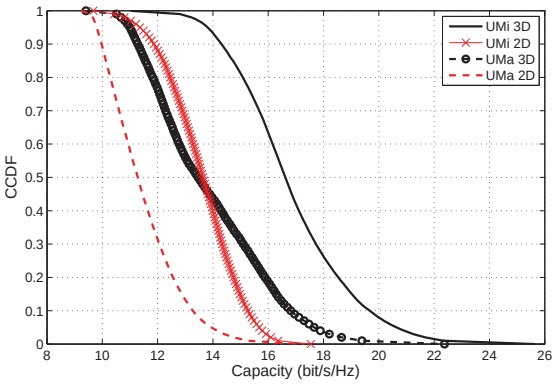

Fig. 8. The CCDF of the 32×32 MIMO wideband outage capacities with fixed $\rho = 14$ dB

V. Conclusion

In this paper we present a generic and compatible implementation for 2D and 3D GBSMs based on existing 2D channel model implementations. We discuss numerous calibration approaches from the standardization and present calibration results underlining the correctness of our implementation. It's obvious that our proposed implementation supplies a much more compatible and scalable simulation for different GBSMs.
